**Warning:** You can **not pass** a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the .values attribute of the Series. The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```python
apply_integrate_f(df['a'], df['b'], df['N'])
```

But rather, use .values to get the underlying ndarray:

```python
apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
```
Note: Loops like this would be extremely slow in Python, but in Cython looping over NumPy arrays is fast.

In [4]: %timeit apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
1000 loops, best of 3: 1.25 ms per loop

We’ve gotten another big improvement. Let’s check again where the time is spent:

In [11]: %prun -l 4 apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
215 function calls in 0.001 seconds

Ordered by: internal time
List reduced from 55 to 4 due to restriction <4>

<table>
<thead>
<tr>
<th>ncalls</th>
<th>tottime</th>
<th>percall</th>
<th>cumtime</th>
<th>percall</th>
<th>filename:lineno(function)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.001</td>
<td>0.001</td>
<td>0.001</td>
<td>0.001</td>
<td>{built-in method <em>cython_magic</em> 039cb0af339d11610fbd07bd4033a1cf.apply_integrate_f}</td>
</tr>
<tr>
<td>3</td>
<td>0.000</td>
<td>0.000</td>
<td>0.000</td>
<td>0.000</td>
<td>internals.py:4137(iget)</td>
</tr>
<tr>
<td>1</td>
<td>0.000</td>
<td>0.000</td>
<td>0.001</td>

<td>0.000</td>
<td>0.000</td>
<td>0.000</td>
<td>generic.py:4378(<strong>setattr</strong>)</td>
</tr>
</tbody>
</table>

As one might expect, the majority of the time is now spent in apply_integrate_f, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

25.1.5 More advanced techniques

There is still hope for improvement. Here’s an example of using some more advanced Cython techniques:

In [12]: %%cython
.....: cimport cython
.....: cimport numpy as np
.....: import numpy as np
.....: cdef double f_typed(double x) except? -2:
.....:     return x * (x - 1)
.....: cpdef double integrate_f_typed(double a, double b, int N):
.....:     cdef int i
.....:     cdef double s, dx
.....:     s = 0
.....:     dx = (b - a) / N
.....:     for i in range(N):
.....:         s += f_typed(a + i * dx)
.....:     return s * dx
.....: @cython.boundscheck(False)
.....: @cython.wraparound(False)
.....:     cdef int i, n = len(col_N)
.....:     assert len(col_a) == len(col_b) == n
.....:     cdef np.ndarray[double] res = np.empty(n)
.....:     for i in range(n):
.....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
.....:     return res

25.1. Cython (Writing C extensions for pandas) 1245
Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn’t checked. For more about boundscheck and wraparound, see the Cython docs on compiler directives.

### 25.2 Using Numba

A recent alternative to statically compiling Cython code, is to use a *dynamic jit-compiler*, Numba.

Numba gives you the power to speed up your applications with high performance functions written directly in Python. With a few annotations, array-oriented and math-heavy Python code can be just-in-time compiled to native machine instructions, similar in performance to C, C++ and Fortran, without having to switch languages or Python interpreters.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycc tool). Numba supports compilation of Python to run on either CPU or GPU hardware, and is designed to integrate with the Python scientific software stack.

**Note:** You will need to install Numba. This is easy with *conda*, by using: `conda install numba`, see [installing using miniconda](https://conda.io/docs/user-guide/install/miniconda.html).

**Note:** As of Numba version 0.20, pandas objects cannot be passed directly to Numba-compiled functions. Instead, one must pass the NumPy array underlying the pandas object to the Numba-compiled function as demonstrated below.

#### 25.2.1 Jit

We demonstrate how to use Numba to just-in-time compile our code. We simply take the plain Python code from above and annotate with the `@jit` decorator.

```python
import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype='float64')
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        # (continues on next page)
```
Note that we directly pass NumPy arrays to the Numba function. `compute_numba` is just a wrapper that provides a nicer interface by passing/returning pandas objects.

```python
In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop
```

In this example, using Numba was faster than Cython.

### 25.2.2 Vectorize

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following toy example of doubling each observation:

```python
import numba
def double_every_value_nonumba(x):
    return x*2

@numba.vectorize
def double_every_value_withnumba(x):
    return x*2

# Custom function without numba
In [5]: %timeit df['col1_doubled'] = df.a.apply(double_every_value_nonumba)
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df['col1_doubled'] = df.a*2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit df['col1_doubled'] = double_every_value_withnumba(df.a.values)
1000 loops, best of 3: 145 us per loop
```

### 25.2.3 Caveats

**Note:** Numba will execute on any function, but can only accelerate certain classes of functions.

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. When passed a function that only uses operations it knows how to accelerate, it will execute in `nopython` mode.

If Numba is passed a function that includes something it doesn’t know how to work with – a category that currently includes sets, lists, dictionaries, or string functions – it will revert to `object` mode. In `object` mode, Numba
will execute but your code will not speed up significantly. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument `nopython=True` (e.g. `@numba.jit(nopython=True)`). For more on troubleshooting Numba modes, see the Numba troubleshooting page.

Read more in the Numba docs.

### 25.3 Expression Evaluation via `eval()`

The top-level function `pandas.eval()` implements expression evaluation of `Series` and `DataFrame` objects.

**Note:** To benefit from using `eval()` you need to install `numexpr`. See the [recommended dependencies section](#) for more details.

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large `DataFrame` objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default `numexpr` is used for evaluation).

**Note:** You should not use `eval()` for simple expressions or for expressions involving small DataFrames. In fact, `eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol’ Python. A good rule of thumb is to only use `eval()` when you have a `DataFrame` with more than 10,000 rows.

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

**Note:** The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

#### 25.3.1 Supported Syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (<<) and right shift (>>) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4 or not df_bool`
- `list` and `tuple` literals, e.g., `[1, 2] or (1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval('df')` (this is not very useful)
- Math functions: `sin`, `cos`, `exp`, `log`, `expm1`, `log1p`, `sqrt`, `sinh`, `cosh`, `tanh`, `arcsin`, `arccos`, `arctan`, `arccosh`, `arcsinh`, `arctanh`, `abs` and `arctan2`.

This Python syntax is **not** allowed:

- Expressions
  - Function calls other than math functions.
- `is/is not` operations
- `if` expressions
- `lambda` expressions
- `list/set/dict` comprehensions
- `Literal dict and set` expressions
- `yield` expressions
- `Generator` expressions
- `Boolean expressions` consisting of only scalar values

**Statements**
- Neither `simple` nor `compound` statements are allowed. This includes things like `for`, `while`, and `if`.

### 25.3.2 eval() Examples

`pandas.eval()` works well with expressions containing large arrays.

First let’s create a few decent-sized arrays to play with:

```python
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in range(4)]
```

Now let’s compare adding them together using plain ol’ Python versus `eval()`:

```python
In [15]: %timeit df1 + df2 + df3 + df4
11.4 ms +- 829 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
In [16]: %timeit pd.eval('df1 + df2 + df3 + df4')
8.35 ms +- 508 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let’s do the same thing but with comparisons:

```python
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
27.5 ms +- 329 us per loop (mean +- std. dev. of 7 runs, 10 loops each)
In [18]: %timeit pd.eval('(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)')
10.2 ms +- 332 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

eval() also works with unaligned pandas objects:

```python
In [19]: s = pd.Series(np.random.randn(50))
In [20]: %timeit df1 + df2 + df3 + df4 + s
20.6 ms +- 788 us per loop (mean +- std. dev. of 7 runs, 10 loops each)
In [21]: %timeit pd.eval('df1 + df2 + df3 + df4 + s')
9.59 ms +- 810 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**Note:** Operations such as

### 25.3. Expression Evaluation via eval()
should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type `bool` or `np.bool_`. Again, you should perform these kinds of operations in plain Python.

### 25.3.3 The `DataFrame.eval` method

In addition to the top level `pandas.eval()` function you can also evaluate an expression in the “context” of a `DataFrame`.

```python
In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=['a', 'b'])

In [23]: df.eval('a + b')
Out[23]:
   0   1   2
0 -0.25 5.0 -0.246747
1  0.87 6.1  0.867786
2 -1.63 7.2 -1.626063
3 -1.13 8.3 -1.134978
4 -1.03 9.4 -1.027798
dtype: float64
```

Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don’t have to prefix the name of the `DataFrame` to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for *formulaic evaluation*. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

New in version 0.18.0.

The `inplace` keyword determines whether this assignment will performed on the original `DataFrame` or return a copy with the new column.

**Warning:** For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas - if your code depends on an inplace assignment you should update to explicitly set `inplace=True`.

```python
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [25]: df.eval('c = a + b', inplace=True)
In [26]: df.eval('d = a + b + c', inplace=True)
In [27]: df.eval('a = 1', inplace=True)

In [28]: df
Out[28]:
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
```

(continues on next page)
When `inplace` is set to `False`, a copy of the DataFrame with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
Out[29]:
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26

In [30]: df.eval('e = a - c', inplace=False)
   →
   a  b  c  d  e
0  1  5  5 10 -4
1  1  6  7 14 -6
2  1  7  9 18 -8
3  1  8 11 22 -10
4  1  9 13 26 -12

In [31]: df
   →
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26
```

New in version 0.18.0.

As a convenience, multiple assignments can be performed by using a multi-line string.

```
In [32]: df.eval(""
      ......: c = a + b
      ......: d = a + b + c
      ......: a = 1""", inplace=False)
      .....:
Out[32]:
   a  b  c  d
0  1  5  6 12
1  1  6  7 14
2  1  7  8 16
3  1  8  9 18
4  1  9 10 20
```

The equivalent in standard Python would be

```
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

25.3. Expression Evaluation via `eval()`
In [34]: df['c'] = df.a + df.b
In [35]: df['d'] = df.a + df.b + df.c
In [36]: df['a'] = 1
In [37]: df
Out[37]:
   a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  9  18
3  1  8 11  22
4  1  9 13  26

New in version 0.18.0.
The `query` method gained the `inplace` keyword which determines whether the query modifies the original frame.

In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [39]: df.query('a > 2')
Out[39]:
   a  b
3  3  8
4  4  9
In [40]: df.query('a > 2', inplace=True)
In [41]: df
Out[41]:
   a  b
3  3  8
4  4  9

**Warning:** Unlike with `eval`, the default value for `inplace` for `query` is `False`. This is consistent with prior versions of pandas.

25.3.4 Local Variables

You must explicitly reference any local variable that you want to use in an expression by placing the `@` character in front of the name. For example,

In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list('ab'))
In [43]: newcol = np.random.randn(len(df))
In [44]: df.eval('b + @newcol')
Out[44]:
   0 -0.173926
   1  2.493083
   2 -0.881831
   3 -0.691045
If you don’t prefix the local variable with @, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```python
In [46]: a = np.random.randn()
In [47]: df.query('@a < a')
Out[47]:
   a    b
0 0.863987 -0.115998
```

With `pandas.eval()` you cannot use the @ prefix at all, because it isn’t defined in that context. pandas will let you know this if you try to use @ in a top-level call to `pandas.eval()`. For example,

```python
In [49]: a, b = 1, 2
In [50]: pd.eval('@a + b')
Traceback (most recent call last):
    exec(code_obj, self.user_global_ns, self.user_ns)
  File "<ipython-input-50-af17947a194f>", line 1, in <module>
    pd.eval('@a + b')
  File "/Users/taugspurger/sandbox/pandas-release/pandas-docs/pandas/core/computation/eval.py", line 283, in eval
    _check_for_locals(expr, level, parser)
  File "/Users/taugspurger/sandbox/pandas-release/pandas-docs/pandas/core/computation/eval.py", line 150, in _check_for_locals
    raise SyntaxError(msg)
SyntaxError: The '@' prefix is not allowed in top-level eval calls, please refer to your variables by name without the '@' prefix
```

In this case, you should simply refer to the variables like you would in standard Python.

25.3. Expression Evaluation via eval()
25.3.5 pandas.eval() Parsers

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

```python
In [52]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'
In [53]: x = pd.eval(expr, parser='python')
In [54]: expr_no_parens = 'df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0'
In [55]: y = pd.eval(expr_no_parens, parser='pandas')
In [56]: np.all(x == y)
Out[56]: True
```

The same expression can be “anded” together with the word and as well:

```python
In [57]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'
In [58]: x = pd.eval(expr, parser='python')
In [59]: expr_with_ands = 'df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0'
In [60]: y = pd.eval(expr_with_ands, parser='pandas')
In [61]: np.all(x == y)
Out[61]: True
```

The and and or operators here have the same precedence that they would in vanilla Python.

25.3.6 pandas.eval() Backends

There’s also the option to make eval() operate identical to plain ol’ Python.

**Note:** Using the 'python' engine is generally not useful, except for testing other evaluation engines against it. You will achieve no performance benefits using eval() with engine='python' and in fact may incur a performance hit.

You can see this by using pandas.eval() with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python.

```python
In [62]: %timeit df1 + df2 + df3 + df4
   11.8 ms +- 1.24 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```
25.3.7 pandas.eval() Performance

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame`/`Series` objects should see a significant performance benefit. Here is a plot showing the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

![DataFrame.eval() plot](image)

**Note:** Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

![DataFrame.eval() plot](image)

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.
25.3.8 Technical Minutia Regarding Expression Evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to `ndarray.astype(str)` will truncate any strings that are more than 60 characters in length. Second, we can’t pass object arrays to `numexpr` thus string comparisons must be evaluated in Python space.

The upshot is that this only applies to object-dtype’d expressions. So, if you have an expression—for example

```python
In [64]: df = pd.DataFrame({'strings': np.repeat(list('cba'), 3),
                      'nums': np.repeat(range(3), 3)})
```

```python
In [65]: df
Out[65]:
    strings  nums
   0      c     0
   1      c     0
   2      c     0
   3      b     1
   4      b     1
   5      b     1
   6      a     2
   7      a     2
   8      a     2
```

```python
In [66]: df.query('strings == "a" and nums == 1')
```

→ Empty DataFrame
Columns: [strings, nums]
Index: []

the numeric part of the comparison (`nums == 1`) will be evaluated by `numexpr`.

In general, `DataFrame.query()`/`pandas.eval()` will evaluate the subexpressions that can be evaluated by `numexpr` and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.
Note: The \texttt{SparsePanel} class has been removed in 0.19.0

We have implemented “sparse” versions of \texttt{Series} and \texttt{DataFrame}. These are not sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (\texttt{NaN} / missing value, though any value can be chosen) is omitted. A special \texttt{SparseIndex} object tracks where data has been “sparsified”. This will make much more sense with an example. All of the standard pandas data structures have a \texttt{to_sparse} method:

```
In [1]: ts = pd.Series(randn(10))
In [2]: ts[2:-2] = np.nan
In [3]: sts = ts.to_sparse()
In [4]: sts
Out[4]:
   0   0.469112
   1  -0.282863
   2  NaN
   3  NaN
   4  NaN
   5  NaN
   6  NaN
   7  NaN
   8  -0.861849
   9  -2.104569
   
BlockIndex
Block locations: array([0, 8], dtype=int32)
Block lengths: array([2, 2], dtype=int32)
```

The \texttt{to_sparse} method takes a \texttt{kind} argument (for the sparse index, see below) and a \texttt{fill_value}. So if we had a mostly zero \texttt{Series}, we could convert it to sparse with \texttt{fill_value=0}:

```
In [5]: ts.fillna(0).to_sparse(fill_value=0)
Out[5]:
   0   0.469112
   1  -0.282863
   2   0.000000
   3   0.000000
   4   0.000000
   5   0.000000
   
(continues on next page)
The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```python
In [6]: df = pd.DataFrame(randn(10000, 4))
In [7]: df.iloc[:9998] = np.nan
In [8]: sdf = df.to_sparse()
In [9]: sdf
Out[9]:
        0     1     2     3  
0     NaN   NaN   NaN   NaN  
1     NaN   NaN   NaN   NaN  
2     NaN   NaN   NaN   NaN  
3     NaN   NaN   NaN   NaN  
4     NaN   NaN   NaN   NaN  
5     NaN   NaN   NaN   NaN  
...    ...    ...    ...  
9993  NaN   NaN   NaN   NaN  
9994  NaN   NaN   NaN   NaN  
9995  NaN   NaN   NaN   NaN  
9996  NaN   NaN   NaN   NaN  
9997  NaN   NaN   NaN   NaN  
9998  0.509184 -0.774928 -1.369894 -0.382141  
9999  0.280249 -1.648493  1.490865 -0.890819  
[10000 rows x 4 columns]
```

```python
In [10]: sdf.density

Out[10]:
\rightarrow 0.0002
```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter. Functionally, their behavior should be nearly identical to their dense counterparts.

Any sparse object can be converted back to the standard dense form by calling `to_dense`:

```python
In [11]: sts.to_dense()
Out[11]:
        0  
0  0.469112  
1 -0.282863  
2   NaN  
3   NaN  
4   NaN  
5   NaN  
6   NaN  
```

(continues on next page)
26.1 SparseArray

SparseArray is the base layer for all of the sparse indexed data structures. It is a 1-dimensional ndarray-like object storing only values distinct from the fill_value:

```python
In [12]: arr = np.random.randn(10)
In [14]: sparr = pd.SparseArray(arr)
In [15]: sparr
Out[15]:
[-1.9556635297215477, -1.6588664275960427, nan, nan, nan, 1.1589328886422277, 0.
 -14529711373305043, nan, 0.6060271905134522, 1.3342113401317768]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

Like the indexed objects (SparseSeries, SparseDataFrame), a SparseArray can be converted back to a regular ndarray by calling `to_dense`:

```python
In [16]: sparr.to_dense()
Out[16]:
array([-1.9557, -1.6589, nan, nan, nan, 1.1589, 0.1453,
          nan, 0.606 , 1.3342])
```

26.2 SparseIndex objects

Two kinds of SparseIndex are implemented, block and integer. We recommend using block as it’s more memory efficient. The integer format keeps an arrays of all of the locations where the data are not equal to the fill value. The block format tracks only the locations and sizes of blocks of data.

26.3 Sparse Dtypes

Sparse data should have the same dtype as its dense representation. Currently, `float64`, `int64` and `bool` dtypes are supported. Depending on the original dtype, `fill_value` default changes:

- `float64`: `np.nan`
- `int64`: 0
- `bool`: False
You can change the dtype using `.astype()`, the result is also sparse. Note that `.astype()` also affects to the
fill_value to keep its dense representation.

```python
In [26]: s = pd.Series([1, 0, 0, 0, 0])

In [27]: s
Out[27]:
0   1
1   0
2   0
3   0
4   0
dtype: int64

In [28]: ss = s.to_sparse()

In [29]: ss
Out[29]:
0   1
1   0
2   0
3   0
4   0
dtype: int64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([1], dtype=int32)

In [30]: ss.astype(np.float64)
Out[30]:
0   1.0
1   0.0
2   0.0
3   0.0
4   0.0
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([1], dtype=int32)
```

It raises if any value cannot be coerced to specified dtype.

```python
In [1]: ss = pd.Series([1, np.nan, np.nan]).to_sparse()

In [2]: ss.astype(np.int64)
ValueError: unable to coerce current fill_value nan to int64 dtype
```

26.3. Sparse Dtypes
26.4 Sparse Calculation

You can apply NumPy ufunc to SparseArray and get a SparseArray as a result.

```python
In [31]: arr = pd.SparseArray([1., np.nan, np.nan, -2., np.nan])
In [32]: np.abs(arr)
Out[32]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)
```

The ufunc is also applied to fill_value. This is needed to get the correct dense result.

```python
In [33]: arr = pd.SparseArray([1., -1, -1, -2., -1], fill_value=-1)
In [34]: np.abs(arr)
Out[34]:
[1.0, 1.0, 1.0, 2.0, 1.0]
Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)
```

In [35]: np.abs(arr).to_dense()
```
Out[35]:
\[ 1., 1., 1., 2., 1.\]
```

26.5 Interaction with scipy.sparse

26.5.1 SparseDataFrame

New in version 0.20.0.

Pandas supports creating sparse dataframes directly from scipy.sparse matrices.

```python
In [36]: from scipy.sparse import csr_matrix
In [37]: arr = np.random.random(size=(1000, 5))
In [38]: arr[arr < .9] = 0
In [39]: sp_arr = csr_matrix(arr)
In [40]: sp_arr
Out[40]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
with 517 stored elements in Compressed Sparse Row format>
In [41]: sdf = pd.SparseDataFrame(sp_arr)
In [42]: sdf
Out[42]:
   0  1  2  3  4
(continues on next page)
All sparse formats are supported, but matrices that are not in COOrdinate format will be converted, copying data as needed. To convert a SparseDataFrame back to sparse SciPy matrix in COO format, you can use the `SparseDataFrame.to_coo()` method:

```
In [43]: sdf.to_coo()
Out[43]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
    with 517 stored elements in COOrdinate format>
```

### 26.5.2 SparseSeries

A `SparseSeries.to_coo()` method is implemented for transforming a SparseSeries indexed by a MultiIndex to a scipy.sparse.coo_matrix.

The method requires a MultiIndex with two or more levels.

```
In [44]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
In [45]: s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                             ...........
                             (1, 1, 'b', 0),
                             ...........
                             (2, 1, 'b', 0),
                             ...........
                             (2, 1, 'b', 1)],
                             ...........
                             names=['A', 'B', 'C', 'D'])
In [46]: s
Out[46]:
A  B  C  D
1  2  a  0  3.0
    1  NaN
1  1  b  0  1.0
    1  3.0
2  1  b  0  NaN
    1  NaN
dtype: float64
```
# SparseSeries

In [47]: ss = s.to_sparse()

In [48]: ss

Out[48]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>a</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>0</td>
<td>1.0</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>3.0</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>b</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>NaN</td>
<td></td>
</tr>
</tbody>
</table>

dtype: float64

BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 2], dtype=int32)

In the example below, we transform the SparseSeries to a sparse representation of a 2-d array by specifying that the first and second MultiIndex levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

In [49]: A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                 column_levels=['C', 'D'],
                                 sort_labels=True)

In [50]: A

Out[50]:

<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [51]: A.todense()

\[\begin{bmatrix}
0.0, & 0.0, & 1.0, & 3.0 \\
3.0, & 0.0, & 0.0, & 0.0 \\
0.0, & 0.0, & 0.0, & 0.0
\end{bmatrix}\]

In [52]: rows

\[\{(1, 1), (1, 2), (2, 1)\}\]

In [53]: columns

\[\{('a', 0), ('a', 1), ('b', 0), ('b', 1)\}\]

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

In [54]: A, rows, columns = ss.to_coo(row_levels=['A', 'B', 'C'],
                                 column_levels=['D'],
                                 sort_labels=False)

In [55]: A

Out[55]:

(continues on next page)
<3x2 sparse matrix of type 'class 'numpy.float64''
   with 3 stored elements in COOrdinate format>

In [56]: A.todense()
   →
      matrix([[ 3.,  0.],
              [ 1.,  3.],
              [ 0.,  0.]])

In [57]: rows
   →[(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]

In [58]: columns
   →[0, 1]

A convenience method SparseSeries.from_coo() is implemented for creating a SparseSeries from a
scipy.sparse.coo_matrix.

In [59]: from scipy import sparse

In [60]: A = sparse.coo_matrix([[3.0, 1.0, 2.0],
                    ([1, 0, 0], [0, 2, 3]),
               shape=(3, 4))

In [61]: A
Out[61]:
<3x4 sparse matrix of type 'class 'numpy.float64''
   with 3 stored elements in COOrdinate format>

In [62]: A.todense()
   →
      matrix([[ 0.,  0.,  1.,  2.],
              [ 3.,  0.,  0.,  0.],
              [ 0.,  0.,  0.,  0.]])

The default behaviour (with dense_index=False) simply returns a SparseSeries containing only the non-
null entries.

In [63]: ss = pd.SparseSeries.from_coo(A)

In [64]: ss
Out[64]:
  0   2   1.0
  3   2.0
  1   0   3.0
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)

Specifying dense_index=True will result in an index that is the Cartesian product of the row and columns coor-
dinates of the matrix. Note that this will consume a significant amount of memory (relative to dense_index=False)
if the sparse matrix is large (and sparse) enough.

26.5. Interaction with scipy.sparse
In [65]: ss_dense = pd.SparseSeries.from_coo(A, dense_index=True)

In [66]: ss_dense
Out[66]:
0 0   NaN
  1   NaN
  2   1.0
  3   2.0
1 0   3.0
  1   NaN
  2   NaN
  3   NaN
2 0   NaN
  1   NaN
  2   NaN
  3   NaN
dtype: float64
BlockIndex
Block locations: array([2], dtype=int32)
Block lengths: array([3], dtype=int32)
27.1 DataFrame memory usage

The memory usage of a DataFrame (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see the list of options), specifies if the DataFrame’s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the DataFrame below is shown when calling `info()`:

```
In [1]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
   ...:     'complex128', 'object', 'bool']
   ...

In [2]: n = 5000

In [3]: data = dict([(t, np.random.randint(100, size=n).astype(t))
   ...:     for t in dtypes])
   ...

In [4]: df = pd.DataFrame(data)

In [5]: df['categorical'] = df['object'].astype('category')

In [6]: df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64 5000 non-null int64
float64 5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128 5000 non-null complex128
object 5000 non-null object
bool 5000 non-null bool
categorical 5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
timedelta64[ns](1)
memory usage: 289.1+ KB
```

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.
In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64      5000 non-null int64
float64   5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128 5000 non-null complex128
object 5000 non-null object
bool 5000 non-null bool
categorical 5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1)
                   timedelta64[ns](1)
memory usage: 425.6 KB

By default the display option is set to True but can be explicitly overridden by passing the memory_usage argument when invoking df.info().

The memory usage of each column can be found by calling the memory_usage() method. This returns a Series with an index represented by column names and memory usage of each column shown in bytes. For the DataFrame above, the memory usage of each column and the total memory usage can be found with the memory_usage method:

In [8]: df.memory_usage()
Out[8]:
Index 80
int64 40000
float64 40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128 80000
object 40000
bool 5000
 categorical 10920
dtype: int64

# total memory usage of dataframe
In [9]: df.memory_usage().sum()
       296000

By default the memory usage of the DataFrame's index is shown in the returned Series, the memory usage of the index can be suppressed by passing the index=False argument:

In [10]: df.memory_usage(index=False)
Out[10]:
int64 40000
float64 40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128 80000
object 40000
bool 5000
categorical 10920
dtype: int64

The memory usage displayed by the info() method utilizes the memory_usage() method to determine the memory usage of a DataFrame while also formatting the output in human-readable units (base-2 representation; i.e. 1KB
pandas: powerful Python data analysis toolkit, Release 0.23.3

= 1024 bytes).
See also Categorical Memory Usage.

## 27.2 Using If/Truth Statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a `bool`. This happens in an `if`-statement or when using the boolean operations: `and`, `or`, and `not`. It is not clear what the result of the following code should be:

```python
>>> if pd.Series([False, True, False]):
...     print("I was true")
```

Should it be `True` because it’s not zero-length, or `False` because there are `False` values? It is unclear, so instead, pandas raises a `ValueError`:

```python
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the DataFrame, e.g. use `any()`, `all()` or `empty()`. Alternatively, you might want to compare if the pandas object is `None`:

```python
>>> if pd.Series([False, True, False]) is not None:
...     print("I was not None")
```

Below is how to check if any of the values are `True`:

```python
>>> if pd.Series([False, True, False]).any():
...     print("I am any")
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [11]: pd.Series([True]).bool()
Out[11]: True
```

```
In [12]: pd.Series([False]).bool()
```

```
Out[12]: False
```

```
In [13]: pd.DataFrame([[True]]).bool()
```

```
Out[13]: True
```

```
In [14]: pd.DataFrame([[False]]).bool()
```

```
Out[14]: False
```

## 27.2.1 Bitwise boolean

Bitwise boolean operators like `==` and `!=` return a boolean `Series`, which is almost always what you want anyways.
```python
>>> s = pd.Series(range(5))
>>> s == 4
0  False
1  False
2  False
3  False
4   True
dtype: bool
```

See boolean comparisons for more examples.

### 27.2.2 Using the `in` operator

Using the Python `in` operator on a Series tests for membership in the index, not membership among the values.

```python
In [15]: s = pd.Series(range(5), index=list('abcde'))
In [16]: 2 in s
Out[16]: False
In [17]: 'b' in s
Out[17]: True
```

If this behavior is surprising, keep in mind that using `in` on a Python dictionary tests keys, not values, and Series are dict-like. To test for membership in the values, use the method `isin()`:

```python
In [18]: s.isin([2])
Out[18]:
a  False
b  False
c   True
d  False
e  False
dtype: bool
In [19]: s.isin([2]).any()
Out[19]: True
```

For DataFrames, likewise, `in` applies to the column axis, testing for membership in the list of column names.

### 27.3 NaN, Integer NA values and NA type promotions

#### 27.3.1 Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A masked array solution: an array of data and an array of boolean values indicating whether a value is there or is missing.

- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value `NaN` (Not-A-Number) is used
everywhere as the NA value, and there are API functions isna and notna which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

### 27.3.2 Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [20]: s = pd.Series([1, 2, 3, 4, 5], index=list('abcde'))

In [21]: s
Out[21]:
   a  1
   b  2
   c  3
   d  4
   e  5
dtype: int64

In [22]: s.dtype
Out[22]: dtype('int64')

In [23]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])

In [24]: s2
Out[24]:
   a  1.0
   b  2.0
   c  3.0
   f  NaN
   u  NaN
dtype: float64

In [25]: s2.dtype
Out[25]: dtype('float64')
```

This trade-off is made largely for memory and performance reasons, and also so that the resulting Series continues to be "numeric". One possibility is to use dtype=object arrays instead.

### 27.3.3 NA type promotions

When introducing NAs into an existing Series or DataFrame via reindex() or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Promotion dtype for storing NAs</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating</td>
<td>no change</td>
</tr>
<tr>
<td>object</td>
<td>no change</td>
</tr>
<tr>
<td>integer</td>
<td>cast to float64</td>
</tr>
<tr>
<td>boolean</td>
<td>cast to object</td>
</tr>
</tbody>
</table>

### 27.3. NaN, Integer NA values and NA type promotions

1271
While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than $2^{**}53$. Some explanation for the motivation is in the next section.

### 27.3.4 Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy.floating</td>
<td>float16, float32, float64, float128</td>
</tr>
<tr>
<td>numpy.integer</td>
<td>int8, int16, int32, int64</td>
</tr>
<tr>
<td>numpy.unsignedinteger</td>
<td>uint8, uint16, uint32, uint64</td>
</tr>
<tr>
<td>numpy.object_</td>
<td>object_</td>
</tr>
<tr>
<td>numpy.bool_</td>
<td>bool_</td>
</tr>
<tr>
<td>numpy.character</td>
<td>string_, unicode_</td>
</tr>
</tbody>
</table>

The R language, by contrast, only has a handful of built-in data types: integer, numeric (floating-point), character, and boolean. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean mask denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using NaN. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.

### 27.4 Differences with NumPy

For Series and DataFrame objects, \( \text{var}() \) normalizes by \( N-1 \) to produce unbiased estimates of the sample variance, while NumPy’s \( \text{var} \) normalizes by \( N \), which measures the variance of the sample. Note that \( \text{cov}() \) normalizes by \( N-1 \) in both pandas and NumPy.

### 27.5 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the \( \text{copy}() \) method. If you are doing a lot of copying of DataFrame objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See this link for more information.

### 27.6 Byte-Ordering Issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like:
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler

To deal with this issue you should convert the underlying NumPy array to the native system byte order before passing it to Series or DataFrame constructors using something similar to the following:

```
In [26]: x = np.array(list(range(10)), '>i4')  # big endian
In [27]: newx = x.byteswap().newbyteorder()  # force native byteorder
In [28]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details.
Warning: Up to pandas 0.19, a `pandas.rpy` module existed with functionality to convert between pandas and rpy2 objects. This functionality now lives in the rpy2 project itself. See the updating section of the previous documentation for a guide to port your code from the removed `pandas.rpy` to rpy2 functions.

rpy2 is an interface to R running embedded in a Python process, and also includes functionality to deal with pandas DataFrames. Converting data frames back and forth between rpy2 and pandas should be largely automated (no need to convert explicitly, it will be done on the fly in most rpy2 functions). To convert explicitly, the functions are `pandas2ri.py2ri()` and `pandas2ri.ri2py()`.

See also the documentation of the rpy2 project: https://rpy2.readthedocs.io.

In the remainder of this page, a few examples of explicit conversion is given. The pandas conversion of rpy2 needs first to be activated:

```
In [1]: from rpy2.robjects import r, pandas2ri
In [2]: pandas2ri.activate()
```

28.1 Transferring R data sets into Python

Once the pandas conversion is activated (`pandas2ri.activate()`) many conversions of R to pandas objects will be done automatically. For example, to obtain the ‘iris’ dataset as a pandas DataFrame:

```
In [3]: r.data('iris')
Out [3]:
R object with classes: {‘character’,} mapped to:
<StrVector - Python:0x1c35fc4a88 / R:0x7fabf01646e8> ['iris']

In [4]: r['iris'].head()
```

<table>
<thead>
<tr>
<th></th>
<th>Sepal.Length</th>
<th>Sepal.Width</th>
<th>Petal.Length</th>
<th>Petal.Width</th>
<th>Species</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>setosa</td>
</tr>
<tr>
<td>1</td>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>setosa</td>
</tr>
<tr>
<td>2</td>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>setosa</td>
</tr>
<tr>
<td>3</td>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>setosa</td>
</tr>
<tr>
<td>4</td>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>setosa</td>
</tr>
</tbody>
</table>
If the pandas conversion was not activated, the above could also be accomplished by explicitly converting it with the pandas2ri.ri2py function (pandas2ri.ri2py(r['iris'])).

28.2 Converting DataFrames into R objects

The pandas2ri.py2ri function support the reverse operation to convert DataFrames into the equivalent R object (that is, data.frame):

In [5]: df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C':[7,8,9]},
                         index=['one', 'two', 'three'])

In [6]: r_dataframe = pandas2ri.py2ri(df)

In [7]: print(type(r_dataframe))
<class 'rpy2.robjects.vectors.DataFrame'>

In [8]: print(r_dataframe)

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>1</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>two</td>
<td>2</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>three</td>
<td>3</td>
<td>6</td>
<td>9</td>
</tr>
</tbody>
</table>

The DataFrame’s index is stored as the rownames attribute of the data.frame instance.
Increasingly, packages are being built on top of pandas to address specific needs in data preparation, analysis and visualization. This is encouraging because it means pandas is not only helping users to handle their data tasks but also that it provides a better starting point for developers to build powerful and more focused data tools. The creation of libraries that complement pandas’ functionality also allows pandas development to remain focused around it’s original requirements.

This is an in-exhaustive list of projects that build on pandas in order to provide tools in the PyData space.

We’d like to make it easier for users to find these project, if you know of other substantial projects that you feel should be on this list, please let us know.

### 29.1 Statistics and Machine Learning

#### 29.1.1 Statsmodels

Statsmodels is the prominent Python “statistics and econometrics library” and it has a long-standing special relationship with pandas. Statsmodels provides powerful statistics, econometrics, analysis and modeling functionality that is out of pandas’ scope. Statsmodels leverages pandas objects as the underlying data container for computation.

#### 29.1.2 sklearn-pandas

Use pandas DataFrames in your scikit-learn ML pipeline.

#### 29.1.3 Featuretools

Featuretools is a Python library for automated feature engineering built on top of pandas. It excels at transforming temporal and relational datasets into feature matrices for machine learning using reusable feature engineering “primitives”. Users can contribute their own primitives in Python and share them with the rest of the community.

### 29.2 Visualization

#### 29.2.1 Bokeh

Bokeh is a Python interactive visualization library for large datasets that natively uses the latest web technologies. Its goal is to provide elegant, concise construction of novel graphics in the style of Protovis/D3, while delivering high-performance interactivity over large data to thin clients.
29.2.2 seaborn

Seaborn is a Python visualization library based on matplotlib. It provides a high-level, dataset-oriented interface for creating attractive statistical graphics. The plotting functions in seaborn understand pandas objects and leverage pandas grouping operations internally to support concise specification of complex visualizations. Seaborn also goes beyond matplotlib and pandas with the option to perform statistical estimation while plotting, aggregating across observations and visualizing the fit of statistical models to emphasize patterns in a dataset.

29.2.3 yhat/ggplot

Hadley Wickham’s ggplot2 is a foundational exploratory visualization package for the R language. Based on “The Grammar of Graphics” it provides a powerful, declarative and extremely general way to generate bespoke plots of any kind of data. It’s really quite incredible. Various implementations to other languages are available, but a faithful implementation for Python users has long been missing. Although still young (as of Jan-2014), the yhat/ggplot project has been progressing quickly in that direction.

29.2.4 Vincent

The Vincent project leverages Vega (that in turn, leverages d3) to create plots. Although functional, as of Summer 2016 the Vincent project has not been updated in over two years and is unlikely to receive further updates.

29.2.5 IPython Vega

Like Vincent, the IPython Vega project leverages Vega to create plots, but primarily targets the IPython Notebook environment.

29.2.6 Plotly

Plotly’s Python API enables interactive figures and web shareability. Maps, 2D, 3D, and live-streaming graphs are rendered with WebGL and D3.js. The library supports plotting directly from a pandas DataFrame and cloud-based collaboration. Users of matplotlib, ggplot for Python, and Seaborn can convert figures into interactive web-based plots. Plots can be drawn in IPython Notebooks, edited with R or MATLAB, modified in a GUI, or embedded in apps and dashboards. Plotly is free for unlimited sharing, and has cloud, offline, or on-premise accounts for private use.

29.2.7 QtPandas

Spun off from the main pandas library, the qtpandas library enables DataFrame visualization and manipulation in PyQt4 and PySide applications.

29.3 IDE

29.3.1 IPython

IPython is an interactive command shell and distributed computing environment. IPython Notebook is a web application for creating IPython notebooks. An IPython notebook is a JSON document containing an ordered list of input/output cells which can contain code, text, mathematics, plots and rich media. IPython notebooks can be converted to a number of open standard output formats (HTML, HTML presentation slides, LaTeX, PDF, ReStructuredText, Markdown, Python) through ‘Download As’ in the web interface and ipython nbconvert in a shell.
Pandas DataFrames implement `_repr_html_` methods which are utilized by IPython Notebook for displaying (abbreviated) HTML tables. (Note: HTML tables may or may not be compatible with non-HTML IPython output formats.)

### 29.3.2 quantopian/qgrid

qgrid is “an interactive grid for sorting and filtering DataFrames in IPython Notebook” built with SlickGrid.

### 29.3.3 Spyder

Spyder is a cross-platform Qt-based open-source Python IDE with editing, testing, debugging, and introspection features. Spyder can now introspect and display Pandas DataFrames and show both “column wise min/max and global min/max coloring.”

### 29.4 API

#### 29.4.1 pandas-datareader

`pandas-datareader` is a remote data access library for pandas (PyPI:`pandas-datareader`). It is based on functionality that was located in `pandas.io.data` and `pandas.io.wb` but was split off in v0.19. See more in the `pandas-datareader` docs:

The following data feeds are available:

- Yahoo! Finance
- Google Finance
- FRED
- Fama/French
- World Bank
- OECD
- Eurostat
- EDGAR Index

#### 29.4.2 quandl/Python

Quandl API for Python wraps the Quandl REST API to return Pandas DataFrames with timeseries indexes.

#### 29.4.3 pydatastream

PyDatastream is a Python interface to the Thomson Dataworks Enterprise (DWE/Datastream) SOAP API to return indexed Pandas DataFrames or Panels with financial data. This package requires valid credentials for this API (non free).
29.4.4 **pandaSDMX**

pandaSDMX is a library to retrieve and acquire statistical data and metadata disseminated in SDMX 2.1, an ISO-standard widely used by institutions such as statistics offices, central banks, and international organisations. pandaSDMX can expose datasets and related structural metadata including dataflows, code-lists, and datastructure definitions as pandas Series or multi-indexed DataFrames.

29.4.5 **fredapi**

fredapi is a Python interface to the Federal Reserve Economic Data (FRED) provided by the Federal Reserve Bank of St. Louis. It works with both the FRED database and ALFRED database that contains point-in-time data (i.e. historic data revisions). fredapi provides a wrapper in Python to the FRED HTTP API, and also provides several convenient methods for parsing and analyzing point-in-time data from ALFRED. fredapi makes use of pandas and returns data in a Series or DataFrame. This module requires a FRED API key that you can obtain for free on the FRED website.

29.5 **Domain Specific**

29.5.1 **Geopandas**

Geopandas extends pandas data objects to include geographic information which support geometric operations. If your work entails maps and geographical coordinates, and you love pandas, you should take a close look at Geopandas.

29.5.2 **xarray**

xarray brings the labeled data power of pandas to the physical sciences by providing N-dimensional variants of the core pandas data structures. It aims to provide a pandas-like and pandas-compatible toolkit for analytics on multi-dimensional arrays, rather than the tabular data for which pandas excels.

29.6 **Out-of-core**

29.6.1 **Dask**

Dask is a flexible parallel computing library for analytics. Dask provides a familiar DataFrame interface for out-of-core, parallel and distributed computing.

29.6.2 **Dask-ML**

Dask-ML enables parallel and distributed machine learning using Dask alongside existing machine learning libraries like Scikit-Learn, XGBoost, and TensorFlow.

29.6.3 **Blaze**

Blaze provides a standard API for doing computations with various in-memory and on-disk backends: NumPy, Pandas, SQLAlchemy, MongoDB, PyTables, PySpark.
29.6.4 Odo

Odo provides a uniform API for moving data between different formats. It uses pandas own `read_csv` for CSV IO and leverages many existing packages such as PyTables, h5py, and pymongo to move data between non pandas formats. Its graph based approach is also extensible by end users for custom formats that may be too specific for the core of odo.

29.7 Data validation

29.7.1 Engarde

Engarde is a lightweight library used to explicitly state your assumptions about your datasets and check that they’re actually true.

29.8 Extension Data Types

Pandas provides an interface for defining extension types to extend NumPy’s type system. The following libraries implement that interface to provide types not found in NumPy or pandas, which work well with pandas’ data containers.

29.8.1 cyberpandas

Cyberpandas provides an extension type for storing arrays of IP Addresses. These arrays can be stored inside pandas’ Series and DataFrame.

29.9 Accessors

A directory of projects providing extension accessors. This is for users to discover new accessors and for library authors to coordinate on the namespace.

<table>
<thead>
<tr>
<th>Library</th>
<th>Accessor</th>
<th>Classes</th>
</tr>
</thead>
<tbody>
<tr>

<td>Series,DataFrame</td>
</tr>
</tbody>
</table>
COMPARISON WITH R / R LIBRARIES

Since pandas aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the R language and its many third party libraries as they relate to pandas. In comparisons with R and CRAN libraries, we care about the following things:

- **Functionality / flexibility**: what can/cannot be done with each tool
- **Performance**: how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use**: Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.

For transfer of DataFrame objects from pandas to R, one option is to use HDF5 files, see [External Compatibility](#) for an example.

### 30.1 Quick Reference

We’ll start off with a quick reference guide pairing some common R operations using dplyr with pandas equivalents.

#### 30.1.1 Querying, Filtering, Sampling

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>dim(df)</td>
<td>df.shape</td>
</tr>
<tr>
<td>head(df)</td>
<td>df.head()</td>
</tr>
<tr>
<td>slice(df, 1:10)</td>
<td>df.iloc[:9]</td>
</tr>
<tr>
<td>filter(df, coll == 1, col2 == 1)</td>
<td>df.query('coll == 1 &amp; col2 == 1')</td>
</tr>
<tr>
<td>df[df$coll == 1 &amp; df$col2 == 1]</td>
<td>df[(df.col1 == 1) &amp; (df.col2 == 1)]</td>
</tr>
<tr>
<td>select(df, coll, col2)</td>
<td>df[['coll', 'col2']]</td>
</tr>
<tr>
<td>select(df, -coll:col3)</td>
<td>df.loc[:, 'coll':'col3']</td>
</tr>
<tr>
<td>select(df, -(coll:col3))</td>
<td>df.drop(cols_to_drop, axis=1) but see¹</td>
</tr>
<tr>
<td>distinct(select(df, col1))</td>
<td>df[['coll']].drop_duplicates()</td>
</tr>
<tr>
<td>distinct(select(df, coll, col2))</td>
<td>df[['coll', 'col2']].drop_duplicates()</td>
</tr>
<tr>
<td>sample_n(df, 10)</td>
<td>df.sample(n=10)</td>
</tr>
<tr>
<td>sample_frac(df, 0.01)</td>
<td>df.sample(frac=0.01)</td>
</tr>
</tbody>
</table>

¹ R’s shorthand for a subrange of columns (select(df, coll:col3)) can be approached cleanly in pandas, if you have the list of columns, for example df[cols[1:3]] or df.drop(cols[1:3]), but doing this by column name is a bit messy.
### 30.1.2 Sorting

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>arrange(df, col1, col2)</code></td>
<td><code>df.sort_values(['col1', 'col2'])</code></td>
</tr>
<tr>
<td><code>arrange(df, desc(col1))</code></td>
<td><code>df.sort_values('col1', ascending=False)</code></td>
</tr>
</tbody>
</table>

### 30.1.3 Transforming

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select(df, col_one = col1)</code></td>
<td><code>df.rename(columns={'col1': 'col_one'})['col_one']</code></td>
</tr>
<tr>
<td><code>rename(df, col_one = col1)</code></td>
<td><code>df.rename(columns={'col1': 'col_one'})</code></td>
</tr>
<tr>
<td><code>mutate(df, c=a-b)</code></td>
<td><code>df.assign(c=df.a-df.b)</code></td>
</tr>
</tbody>
</table>

### 30.1.4 Grouping and Summarizing

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>summary(df)</code></td>
<td><code>df.describe()</code></td>
</tr>
<tr>
<td><code>gdf &lt;- group_by(df, col1)</code></td>
<td><code>gdf = df.groupby('col1')</code></td>
</tr>
<tr>
<td><code>summarise(gdf, avg=mean(col1, na.rm=TRUE))</code></td>
<td><code>df.groupby('col1').agg({'col1': 'mean'})</code></td>
</tr>
<tr>
<td><code>summarise(gdf, total=sum(col1))</code></td>
<td><code>df.groupby('col1').sum()</code></td>
</tr>
</tbody>
</table>

### 30.2 Base R

#### 30.2.1 Slicing with R's `c`

R makes it easy to access `data.frame` columns by name

```r
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```r
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```python
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list('abc'))
In [2]: df[['a', 'c']]  
Out[2]:
   a   c
0 -1.039575 -0.424972
1  0.567020 -1.087401
2 -0.673690 -1.478427
```

(continues on next page)
Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the \texttt{iloc} indexer attribute and \texttt{numpy.r_}.

\begin{verbatim}
In [4]: named = list('abcdefg')

In [5]: n = 30

In [6]: columns = named + np.arange(len(named), n).tolist()

In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)

In [8]: df.iloc[:, np.r_[10, 24:30]]
\end{verbatim}

\begin{verbatim}
Out[8]:
\end{verbatim}
2.2 aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called df and splitting it into groups by1 and by2:

```r
df <- data.frame(
  v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),
  v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)
```

The `groupby()` method is similar to base R `aggregate` function.

```python
df = pd.DataFrame(
    ...:     'v1': [1,3,5,7,8,3,5,na,4,5,7,9],
    ...:     'v2': [11,33,55,77,88,33,55,na,44,55,77,99],
    ...:     'by1': ['red', 'blue', 1, 2, na, 'big', 1, 2, 'red', 1, na, 12],
    ...:     'by2': ['wet', 'dry', 99, 95, na, 'damp', 95, 99, 'red', 99, na, na],
    ...:     np.nan]
    ...: )
```

```python
In [9]: df = pd.DataFrame({
    ...:     'v1': [1,3,5,7,8,3,5,na,4,5,7,9],
    ...:     'v2': [11,33,55,77,88,33,55,na,44,55,77,99],
    ...:     'by1': ['red', 'blue', 1, 2, na, 'big', 1, 2, 'red', 1, na, 12],
    ...:     'by2': ['wet', 'dry', 99, 95, na, 'damp', 95, 99, 'red', 99, na, na],
    ...:     np.nan]
    ...: )
In [10]: g = df.groupby(['by1','by2'])
In [11]: gl['v1','v2'].mean()
Out[11]:
by1  by2     v1     v2
1  95  5.0    55.0
2  95  5.0    55.0
99 Nan  Nan
big  damp  3.0  33.0
blue  dry  3.0  33.0
red   red  4.0  44.0
wet   wet  1.0  11.0
```

For more details and examples see the groupby documentation.
30.2.3 match / %in%

A common way to select data in R is using %in% which is defined using the function match. The operator %in% is used to return a logical vector indicating if there is a match or not:

```r
s <- 0:4
s %in% c(2,4)
```

The `isin()` method is similar to R `%in%` operator:

```r
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)
In [13]: s.isin([2, 4])
Out[13]:
0  False  
1  False  
2   True  
3  False  
4   True  
dtype: bool
```

The `match` function returns a vector of the positions of matches of its first argument in its second:

```r
s <- 0:4
match(s, c(2,4))
```

For more details and examples see the reshaping documentation.

30.2.4 tapply

tapply is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a data.frame called `baseball` and retrieving information based on the array `team`:

```r
baseball <- data.frame(
  team = gl(5, 5, 
             labels = paste("Team", LETTERS[1:5]),
  player = sample(letters, 25),
  batting.average = runif(25,.200,.400))
tapply(baseball$batting.average, baseball.example$team, max)
```

In pandas we may use `pivot_table()` method to handle this:

```r
In [14]: import random
In [15]: import string
In [16]: baseball = pd.DataFrame{
           'team': ["team %d" % (x+1) for x in range(5)]*5,
           'player': random.sample(list(string.ascii_lowercase),25),
           'batting avg': np.random.uniform(.200, .400, 25)
        }
In [17]: baseball.pivot_table(values='batting avg', columns='team', aggfunc=np.max)
```

(continues on next page)
Out[17]:

<table>
<thead>
<tr>
<th></th>
<th>team 1</th>
<th>team 2</th>
<th>team 3</th>
<th>team 4</th>
<th>team 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>batting avg</td>
<td>0.394457</td>
<td>0.39573</td>
<td>0.343015</td>
<td>0.388863</td>
<td>0.377379</td>
</tr>
</tbody>
</table>

For more details and examples see the reshaping documentation.

### 30.2.5 subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column’s values are less than another column’s values:

```r
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b,]  # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```python
In [18]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
In [19]: df.query('a <= b')
Out[19]:
   a    b
0 -1.0035 -0.9907
1  0.0835  0.5488
3 -0.5244  0.9044
4 -0.8378  0.7464
8 -0.5072  0.2455
```

```python
In [20]: df[df.a <= df.b]
```

```python
In [21]: df.loc[df.a <= df.b]
```

For more details and examples see the query documentation.

### 30.2.6 with

An expression using a data.frame called `df` in R with the columns `a` and `b` would be evaluated using `with` like so:
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b  # same as the previous expression

In pandas the equivalent expression, using the `eval()` method, would be:

```
In [22]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
In [23]: df.eval('a + b')
Out[23]:
     0  -0.920205
     1  -0.860236
     2   1.154370
     3   0.188140
     4  -1.163718
     5   0.001397
     6  -0.825694
     7  -1.138198
     8  -1.708034
     9   1.148616

dtype: float64
```

```
In [24]: df.a + df.b  # same as the previous expression
     0  -0.920205
     1  -0.860236
     2   1.154370
     3   0.188140
     4  -1.163718
     5   0.001397
     6  -0.825694
     7  -1.138198
     8  -1.708034
     9   1.148616

dtype: float64
```

In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see the `eval documentation`.  

### 30.3 plyr

`plyr` is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, `a` for arrays, `l` for lists, and `d` for `data.frame`. The table below shows how these data structures could be mapped in Python.

<table>
<thead>
<tr>
<th>R</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>lists</td>
<td>dictionary or list of objects</td>
</tr>
<tr>
<td>data.frame</td>
<td>dataframe</td>
</tr>
</tbody>
</table>
30.3.1 ddply

An expression using a data.frame called df in R where you want to summarize x by month:

```r
require(plyr)

df <- data.frame(x = runif(120, 1, 168),
                 y = runif(120, 7, 334),
                 z = runif(120, 1.7, 20.7),
                 month = rep(c(5, 6, 7, 8), 30),
                 week = sample(1:4, 120, TRUE))

ddply(df, .(month, week), summarize,
       mean = round(mean(x), 2),
       sd = round(sd(x), 2))
```

In pandas the equivalent expression, using the `groupby()` method, would be:

```python
In [25]: df = pd.DataFrame({
    ....:     'x': np.random.uniform(1., 168., 120),
    ....:     'y': np.random.uniform(7., 334., 120),
    ....:     'z': np.random.uniform(1.7, 20.7, 120),
    ....:     'month': [5, 6, 7, 8]*30,
    ....:     'week': np.random.randint(1,4, 120)
    ....: })

In [26]: grouped = df.groupby(['month','week'])

In [27]: grouped['x'].agg([np.mean, np.std])
Out[27]:

<table>
<thead>
<tr>
<th>month</th>
<th>week</th>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>1</td>
<td>71.840596</td>
<td>52.886392</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>71.904794</td>
<td>55.786805</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>89.845632</td>
<td>49.892367</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>97.730877</td>
<td>52.442172</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>93.369836</td>
<td>47.178389</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
<td>96.592088</td>
<td>58.773744</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>59.255715</td>
<td>43.442336</td>
</tr>
<tr>
<td>7</td>
<td>2</td>
<td>69.634012</td>
<td>28.607369</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>84.510992</td>
<td>59.761096</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
<td>104.787666</td>
<td>31.745437</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>69.717872</td>
<td>53.747188</td>
</tr>
<tr>
<td>8</td>
<td>3</td>
<td>79.892221</td>
<td>52.950459</td>
</tr>
</tbody>
</table>
```

For more details and examples see the groupby documentation.

30.4 reshape / reshape2

30.4.1 melt.array

An expression using a 3 dimensional array called a in R where you want to melt it into a data.frame:
In Python, since `a` is a list, you can simply use list comprehension.

```python
In [28]: a = np.array(list(range(1,24))+[np.NAN]).reshape(2,3,4)
In [29]: pd.DataFrame([tuple(list(x)+[val]) for x, val in np.ndenumerate(a)])
Out[29]:
     0 1 2 3
0  0  0  0  1.0
1  0  0  1  2.0
2  0  0  2  3.0
3  0  0  3  4.0
4  0  1  0  5.0
5  0  1  1  6.0
6  0  1  2  7.0
... ... ... ...
17 1  1  1  18.0
18 1  1  2  19.0
19 1  1  3  20.0
20 1  2  0  21.0
21 1  2  1  22.0
22 1  2  2  23.0
23 1  2  3  NaN
[24 rows x 4 columns]
```

### 30.4.2 melt.list

An expression using a list called `a` in R where you want to melt it into a data.frame:

```r
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```python
In [30]: a = list(enumerate(list(range(1,5))+[np.NAN]))
In [31]: pd.DataFrame(a)
Out[31]:
     0 1
0  0  1.0
1  1  2.0
2  2  3.0
3  3  4.0
4  4  NaN
```

For more details and examples see the Intro to Data Structures documentation.

### 30.4.3 melt.data.frame

An expression using a data.frame called `cheese` in R where you want to reshape the data.frame:

#### 30.4. reshape / reshape2
cheese <- data.frame(
    first = c('John', 'Mary'),
    last = c('Doe', 'Bo'),
    height = c(5.5, 6.0),
    weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))

In Python, the `melt()` method is the R equivalent:

```python
In [32]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
                           ...: 'last': ['Doe', 'Bo'],
                           ...: 'height': [5.5, 6.0],
                           ...: 'weight': [130, 150]})

In [33]: pd.melt(cheese, id_vars=['first', 'last'])
Out[33]:
   first  last variable  value
0    John  Doe    height  5.5
1    Mary   Bo    height  6.0
2    John  Doe     weight 130.0
3    Mary   Bo     weight 150.0

In [34]: cheese.set_index(['first', 'last']).stack()  # alternative way
   
   →
   first  last
          John  Doe    height  5.5
          |         weight 130.0
          Mary   Bo    height  6.0
          |         weight 150.0

```

dtype: float64

For more details and examples see the reshaping documentation.

### 30.4.4 cast

In R `acast` is an expression using a data.frame called `df` in R to cast into a higher dimensional array:

```r
df <- data.frame(
    x = runif(12, 1, 168),
    y = runif(12, 7, 334),
    z = runif(12, 1.7, 20.7),
    month = rep(c(5, 6, 7), 4),
    week = rep(c(1, 2), 6)
)

mdf <- melt(df, id='month', "week")
acast(mdf, week ~ month ~ value, mean)
```

In Python the best way is to make use of `pivot_table()`:

```python
In [35]: df = pd.DataFrame({
    ...:      'x': np.random.uniform(1., 168., 12),
    ...:      'y': np.random.uniform(7., 334., 12),
    ...:  
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
....:     'z': np.random.uniform(1.7, 20.7, 12),
....:     'month': [5, 6, 7]*4,
....:     'week': [1, 2]*6
....: })
....:
In [36]: mdf = pd.melt(df, id_vars=['month', 'week'])

In [37]: pd.pivot_table(mdf, values='value', index=['variable','week'],
....:                  columns=['month'], aggfunc=np.mean)
....:
Out[37]:
   month 5 6 7
variable week
   x 1  114.00  132.23  65.81
      2  124.67  147.49  82.88
   y 1  225.64  301.86  91.71
      2  57.69  215.85  218.00
   z 1  17.79   7.12  17.68
      2  15.07  13.87  9.39

Similarly for `dcast` which uses a data.frame called `df` in R to aggregate information based on `Animal` and `FeedType`:

```r
df <- data.frame(
   Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
       'Animal2', 'Animal3'),
   FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
   Amount = c(10, 7, 4, 2, 5, 6, 2)
)
dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
  with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```python
In [38]: df = pd.DataFrame({
....:     'Animal': ['Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
....:                 'Animal2', 'Animal3'],
....:     'FeedType': ['A', 'B', 'A', 'A', 'B', 'B', 'A'],
....:     'Amount': [10, 7, 4, 2, 5, 6, 2],
....: })

In [39]: df.pivot_table(values='Amount', index='Animal', columns='FeedType', aggfunc='sum')
Out[39]:
   FeedType  A  B
Animal
Animal1  10.0 5.0
Animal2  2.0 13.0
Animal3  6.0  NaN
```

The second approach is to use the `groupby()` method:
In [40]: df.groupby(['Animal','FeedType'])['Amount'].sum()

Out[40]:
Animal  FeedType
Animal1 A  10
              B  5
Animal2 A  2
              B  13
Animal3 A  6
Name: Amount, dtype: int64

For more details and examples see the reshaping documentation or the groupby documentation.

### 30.4.5 factor

pandas has a data type for categorical data.

\[
cut(c(1,2,3,4,5,6), 3) \\
factor(c(1,2,3,2,2,3))
\]

In pandas this is accomplished with `pd.cut` and `astype("category")`:

In [41]: pd.cut(pd.Series([1,2,3,4,5,6]), 3)

Out[41]:
0   (0.995, 2.667]
1   (0.995, 2.667]
2   (2.667, 4.333]
3   (2.667, 4.333]
4   (4.333, 6.0]
5   (4.333, 6.0]
dtype: category
Categories (3, interval[float64]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.0]]

In [42]: pd.Series([1,2,3,2,2,3]).astype("category")

\[
→
0 1
1 2
2 3
3 2
4 2
5 3
\]
dtype: category
Categories (3, int64): [1, 2, 3]

For more details and examples see categorical introduction and the API documentation. There is also a documentation regarding the differences to R's factor.
Since many potential pandas users have some familiarity with SQL, this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Most of the examples will utilize the `tips` dataset found within pandas tests. We’ll read the data into a DataFrame called `tips` and assume we have a database table of the same name and structure.

```
In [3]: url = 'https://raw.github.com/pandas-dev/pandas/master/pandas/tests/data/tips.csv'
In [4]: tips = pd.read_csv(url)
In [5]: tips.head()
Out[5]:
          total_bill  tip    sex smoker  day      time  size
    0       16.99  1.01 Female   No  Sun   Dinner  2
    1       10.34  1.66    Male   No  Sun   Dinner  3
    2       21.01  3.50    Male   No  Sun   Dinner  3
    3       23.68  3.31    Male   No  Sun   Dinner  2
    4       24.59  3.61 Female   No  Sun   Dinner  4
```

### 31.1 SELECT

In SQL, selection is done using a comma-separated list of columns you’d like to select (or a `*` to select all columns):

```
SELECT total_bill, tip, smoker, time
FROM tips
LIMIT 5;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```
In [6]: tips[['total_bill', 'tip', 'smoker', 'time']].head(5)
Out[6]:
          total_bill  tip  smoker  time
    0       16.99  1.01 Female  Dinner
    1       10.34  1.66    Male  Dinner
    2       21.01  3.50    Male  Dinner
    3       23.68  3.31    Male  Dinner
    4       24.59  3.61 Female  Dinner
```

(continues on next page)
Calling the DataFrame without the list of column names would display all columns (akin to SQL’s *).

### 31.2 WHERE

Filtering in SQL is done via a WHERE clause.

```sql
SELECT * FROM tips WHERE time = 'Dinner' LIMIT 5;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```python
In [7]: tips[tips['time'] == 'Dinner'].head(5)
Out[7]:
<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>16.99</td>
<td>1.01</td>
<td>Female</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>10.34</td>
<td>1.66</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>21.01</td>
<td>3.50</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>23.68</td>
<td>3.31</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>24.59</td>
<td>3.61</td>
<td>Female</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>4</td>
</tr>
</tbody>
</table>
```

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```python
In [8]: is_dinner = tips['time'] == 'Dinner'
In [9]: is_dinner.value_counts()
Out[9]:
 True    176
False   68
Name: time, dtype: int64
In [10]: tips[is_dinner].head(5)
```

Just like SQL’s OR and AND, multiple conditions can be passed to a DataFrame using | (OR) and & (AND).

```sql
-- tips of more than $5.00 at Dinner meals
SELECT * FROM tips WHERE time = 'Dinner' AND tip > 5.00;
```
# tips of more than $5.00 at Dinner meals

In [11]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)]  

Out[11]:  
<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>39.42</td>
<td>7.58</td>

</tr>
<tr>
<td>183</td>
<td>20.69</td>
<td>5.00</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner 5</td>
</tr>
<tr>
<td>187</td>
<td>30.46</td>
<td>2.00</td>
<td>Male</td>
<td>Yes</td>
<td>Sun</td>
<td>Dinner 5</td>
</tr>
<tr>
<td>212</td>
<td>48.33</td>
<td>9.00</td>
<td>Male</td>
<td>No</td>
<td>Sat</td>
<td>Dinner 4</td>
</tr>
<tr>
<td>216</td>
<td>28.15</td>
<td>3.00</td>
<td>Male</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner 5</td>
</tr>
</tbody>
</table>

NULL checking is done using the notna() and isna() methods.

                           'col2': ['F', np.NaN, 'G', 'H', 'I']})  

In [14]: frame

Out[14]:  
<table>
<thead>
<tr>
<th>col1</th>
<th>col2</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>F</td>
</tr>
<tr>
<td>B</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>G</td>
</tr>
<tr>
<td>C</td>
<td>H</td>
</tr>
<tr>
<td>D</td>
<td>I</td>
</tr>
</tbody>
</table>
Assume we have a table of the same structure as our DataFrame above. We can see only the records where \texttt{col2} IS NULL with the following query:

```sql
SELECT *
FROM frame
WHERE col2 IS NULL;
```

In [15]: frame[frame['col2'].isna()]
Out[15]:
   col1 col2
0  1   B  NaN

Getting items where \texttt{col1} IS NOT NULL can be done with \texttt{notna()}.

```sql
SELECT *
FROM frame
WHERE col1 IS NOT NULL;
```

In [16]: frame[frame['col1'].notna()]
Out[16]:
   col1 col2
0  0   A   F
1  1   B  NaN
2  3   C   H
3  4   D   I

### 31.3 GROUP BY

In pandas, SQL's GROUP BY operations are performed using the similarly named \texttt{groupby()} method. \texttt{groupby()} typically refers to a process where we'd like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```sql
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female  87
Male  157
*/
```

The pandas equivalent would be:

```python
In [17]: tips.groupby('sex').size()
Out[17]:
sex
Female   87
Male   157
dtype: int64
```

Notice that in the pandas code we used \texttt{size()} and not \texttt{count()}. This is because \texttt{count()} applies the function to each column, returning the number of not null records within each.
In [18]: tips.groupby('sex').count()
Out[18]:
           total_bill  tip  smoker  day  time  size
sex
Female    87     87     87    87    87   87
Male      157    157    157   157   157   157

Alternatively, we could have applied the `count()` method to an individual column:

In [19]: tips.groupby('sex')['total_bill'].count()
Out[19]:
sex
Female    87
Male      157
Name: total_bill, dtype: int64

Multiple functions can also be applied at once. For instance, say we’d like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri  2.734737 19
Sat  2.993103 87
Sun  3.255132 76
Thur 2.771452 62
*/

In [20]: tips.groupby('day').agg({'tip': np.mean, 'day': np.size})
Out[20]:
         tip  day
day
Fri 2.734737 19
Sat 2.993103 87
Sun 3.255132 76
Thur 2.771452 62

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
/*
No smoker day
   No Fri  4  2.812500
   Sat 45 3.102889
   Sun 57 3.167895
   Thur 45 2.673778
Yes smoker day
   Yes Fri 15 2.714000
   Sat 42 2.875476
   Sun 19 3.516842
   Thur 17 3.030000
*/
In [21]: tips.groupby(['smoker', 'day']).agg({'tip': [np.size, np.mean]})
Out[21]:

<table>
<thead>
<tr>
<th>smoker</th>
<th>day</th>
<th>tip</th>
<th>size</th>
<th>mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>Fri</td>
<td>4.0</td>
<td>2.812500</td>
<td>2.812500</td>
</tr>
<tr>
<td></td>
<td>Sat</td>
<td>45.0</td>
<td>3.102889</td>
<td>3.102889</td>
</tr>
<tr>
<td></td>
<td>Sun</td>
<td>57.0</td>
<td>3.167895</td>
<td>3.167895</td>
</tr>
<tr>
<td></td>
<td>Thur</td>
<td>45.0</td>
<td>2.673778</td>
<td>2.673778</td>
</tr>
<tr>
<td>Yes</td>
<td>Fri</td>
<td>15.0</td>
<td>2.714000</td>
<td>2.714000</td>
</tr>
<tr>
<td></td>
<td>Sat</td>
<td>42.0</td>
<td>2.875476</td>
<td>2.875476</td>
</tr>
<tr>
<td></td>
<td>Sun</td>
<td>19.0</td>
<td>3.516842</td>
<td>3.516842</td>
</tr>
<tr>
<td></td>
<td>Thur</td>
<td>17.0</td>
<td>3.030000</td>
<td>3.030000</td>
</tr>
</tbody>
</table>

31.4 JOIN

JOINs can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

In [22]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
                            'value': np.random.randn(4)})

In [23]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
                            'value': np.random.randn(4)})

Assume we have two database tables of the same name and structure as our DataFrames.

Now let's go over the various types of JOINs.

31.4.1 INNER JOIN

```sql
SELECT *
FROM df1
INNER JOIN df2
ON df1.key = df2.key;
```

# merge performs an INNER JOIN by default
In [24]: pd.merge(df1, df2, on='key')
Out[24]:

<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-0.318214</td>
<td>0.543581</td>
</tr>
<tr>
<td>1</td>
<td>2.169960</td>
<td>-0.426067</td>
</tr>
<tr>
<td>2</td>
<td>2.169960</td>
<td>1.138079</td>
</tr>
</tbody>
</table>

`merge()` also offers parameters for cases when you'd like to join one DataFrame’s column with another DataFrame’s index.

In [25]: indexed_df2 = df2.set_index('key')

In [26]: pd.merge(df1, indexed_df2, left_on='key', right_index=True)

(continues on next page)
31.4.2 LEFT OUTER JOIN

```sql
-- show all records from df1
SELECT *
FROM df1
LEFT OUTER JOIN df2
  ON df1.key = df2.key;
```

```python
# show all records from df1
In [27]: pd.merge(df1, df2, on='key', how='left')
Out[27]:
   key  value_x  value_y
0  A  0.116174  NaN
1  B -0.318214  0.543581
2  C  0.285261  NaN
3  D  2.169960 -0.426067
4  D  2.169960  1.138079
```

31.4.3 RIGHT JOIN

```sql
-- show all records from df2
SELECT *
FROM df1
RIGHT OUTER JOIN df2
  ON df1.key = df2.key;
```

```python
# show all records from df2
In [28]: pd.merge(df1, df2, on='key', how='right')
Out[28]:
   key  value_x  value_y
0  B -0.318214  0.543581
1  D  2.169960 -0.426067
2  D  2.169960  1.138079
3  E  NaN     0.086073
```

31.4.4 FULL JOIN

pandas also allows for FULL JOINs, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINs are not supported in all RDBMS (MySQL).

```sql
-- show all records from both tables
SELECT *
FROM df1
FULL OUTER JOIN df2
  ON df1.key = df2.key;
```
31.5 UNION

UNION ALL can be performed using `concat()`.

In [30]: df1 = pd.DataFrame({'city': ['Chicago', 'San Francisco', 'New York City'],
                        'rank': range(1, 4)})

In [31]: df2 = pd.DataFrame({'city': ['Chicago', 'Boston', 'Los Angeles'],
                        'rank': [1, 4, 5]})

In [32]: pd.concat([df1, df2])
Out[32]:

<table>
<thead>
<tr>
<th>city</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chicago</td>
<td>1</td>
</tr>
<tr>
<td>San Francisco</td>
<td>2</td>
</tr>
<tr>
<td>New York City</td>
<td>3</td>
</tr>
<tr>
<td>Chicago</td>
<td>1</td>
</tr>
<tr>
<td>Boston</td>
<td>4</td>
</tr>
<tr>
<td>Los Angeles</td>
<td>5</td>
</tr>
</tbody>
</table>

SQL’s UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```sql
SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
/*
  city rank
  Chicago 1
  San Francisco 2
  New York City 3
  Chicago 1
  Boston 4
  Los Angeles 5
*/
```
FROM df2;
-- notice that there is only one Chicago record this time
/*
    city  rank
    Chicago 1
    San Francisco 2
    New York City 3
    Boston 4
    Los Angeles 5
*/

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

```python
In [33]: pd.concat([df1, df2]).drop_duplicates()
Out[33]:
   city  rank
0  Chicago 1
1  San Francisco 2
2  New York City 3
1  Boston 4
2  Los Angeles 5
```

### 31.6 Pandas equivalents for some SQL analytic and aggregate functions

#### 31.6.1 Top N rows with offset

```
-- MySQL
SELECT * FROM tips
ORDER BY tip DESC
LIMIT 10 OFFSET 5;
```

```python
In [34]: tips.nlargest(10+5, columns='tip').tail(10)
Out[34]:
   total_bill  tip  sex  smoker  day  time  size
0      183.0  23.17  Male   Yes  Sun  Dinner   4
1      214.0  28.17 Female   Yes  Sat  Dinner   3
2       47.0  32.40  Male     No  Sun  Dinner   4
3      239.0  29.03  Male     No  Sat  Dinner   3
4       88.0  24.71  Male     No  Thur  Lunch   2
5      181.0  23.33  Male   Yes  Sun  Dinner   4
6       44.0  30.40  Male     No  Sun  Dinner   4
7       52.0  34.81 Female     No  Sun  Dinner   4
8       85.0  34.83 Female     No  Thur  Lunch   4
9      211.0  25.89  Male   Yes  Sun  Dinner   4
```

#### 31.6.2 Top N rows per group

```
-- Oracle's ROW_NUMBER() analytic function
SELECT * FROM (  
```

(continues on next page)
SELECT
t.*, 
   ROW_NUMBER() OVER(PARTITION BY day ORDER BY total_bill DESC) AS rn
FROM tips t
WHERE rn < 3
ORDER BY day, rn;

In [35]: (tips.assign(rn=tips.sort_values(["total_bill"], ascending=False)
   ....:     .groupby(["day"])
   ....:     .cumcount() + 1)
   ....:     .query('rn < 3')
   ....:     .sort_values(["day","rn"])
   ....: )
   ....:
Out[35]:
         total_bill  tip  sex  smoker  day   time  size  rn
     95    40.17  4.73  Male   Yes   Fri  Dinner   4   1
     90    28.97  3.00  Male   Yes   Fri  Dinner   2   2
    170    50.81 10.00  Male   Yes   Sat  Dinner   3   1
    212    48.33  9.00  Male    No   Sat  Dinner   4   2
    156    48.17  5.00  Male    No   Sun  Dinner   6   1
    182    45.35  3.50  Male   Yes   Sun  Dinner   3   2
    197    43.11  5.00 Female   Yes  Thur  Lunch   4   1
    142    41.19  5.00  Male    No  Thur  Lunch   5   2

the same using rank(method='first') function

In [36]: (tips.assign(rnk=tips.groupby(["day"])['total_bill']
   ....:     .rank(method='first', ascending=False))
   ....:     .query('rnk < 3')
   ....:     .sort_values(["day","rnk"])
   ....: )
   ....:
Out[36]:
         total_bill  tip  sex  smoker  day   time  size  rnk
     95    40.17  4.73  Male   Yes   Fri  Dinner   4  1.0
     90    28.97  3.00  Male   Yes   Fri  Dinner   2  2.0
    170    50.81 10.00  Male   Yes   Sat  Dinner   3  1.0
    212    48.33  9.00  Male    No   Sat  Dinner   4  2.0
    156    48.17  5.00  Male    No   Sun  Dinner   6  1.0
    182    45.35  3.50  Male   Yes   Sun  Dinner   3  2.0
    197    43.11  5.00 Female   Yes  Thur  Lunch   4  1.0
    142    41.19  5.00  Male    No  Thur  Lunch   5  2.0

-- Oracle’s RANK() analytic function

SELECT * FROM ( 
   SELECT 
   t.*, 
   RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk
FROM tips t
WHERE tip < 2
)
WHERE rnk < 3
ORDER BY sex, rnk;

Let’s find tips with (rank < 3) per gender group for (tips < 2). Notice that when using rank(method='min')
function \texttt{rnk\_min}\) remains the same for the same \textit{tip} (as Oracle’s RANK() function)

\begin{verbatim}
In [37]: (tips[tips['tip'] < 2]
....:     .assign(rnk_min=tips.groupby(['sex'])[['tip']
....:                .rank(method='min'))
....:     .query('rnk_min < 3')
....:     .sort_values(['sex','rnk_min'])
....: )
....:
Out[37]:

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>rnk_min</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>3.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>1</td>
<td>1.0</td>
</tr>
<tr>
<td>92</td>
<td>5.75</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Fri</td>
<td>2</td>
<td>1.0</td>
</tr>
<tr>
<td>111</td>
<td>7.25</td>
<td>1.00</td>
<td>Female</td>
<td>No</td>
<td>Sat</td>
<td>1</td>
<td>1.0</td>
</tr>
<tr>
<td>236</td>
<td>12.60</td>
<td>1.00</td>
<td>Male</td>
<td>Yes</td>
<td>Sat</td>
<td>2</td>
<td>1.0</td>
</tr>
<tr>
<td>237</td>
<td>32.83</td>
<td>1.17</td>
<td>Male</td>
<td>Yes</td>
<td>Sat</td>
<td>2</td>
<td>2.0</td>
</tr>
</tbody>
</table>
\end{verbatim}

\section*{31.7 UPDATE}

UPDATE \textit{tips}

\begin{verbatim}
SET \textit{tip} = \textit{tip} \times 2
WHERE \textit{tip} < 2;
\end{verbatim}

\begin{verbatim}
In [38]: tips.loc[tips['tip'] < 2, 'tip'] *= 2
\end{verbatim}

\section*{31.8 DELETE}

DELETE FROM \textit{tips}

\begin{verbatim}
WHERE \textit{tip} > 9;
\end{verbatim}

In pandas we select the rows that should remain, instead of deleting them

\begin{verbatim}
In [39]: tips = tips.loc[tips['tip'] <= 9]
\end{verbatim}
For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```

**Note:** Throughout this tutorial, the pandas DataFrame will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the DataFrame. This is often used in interactive work (e.g. Jupyter notebook or terminal) - the equivalent in SAS would be:

```sas
proc print data=df(obs=5);
run;
```

### 32.1 Data Structures

#### 32.1.1 General Terminology Translation

<table>
<thead>
<tr>
<th>pandas</th>
<th>SAS</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame</td>
<td>data set</td>
</tr>
<tr>
<td>column</td>
<td>variable</td>
</tr>
<tr>
<td>row</td>
<td>observation</td>
</tr>
<tr>
<td>groupby</td>
<td>BY-group</td>
</tr>
<tr>
<td>NaN</td>
<td>.</td>
</tr>
</tbody>
</table>

A DataFrame in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS’s DATA step, can also be accomplished in pandas.
A `Series` is the data structure that represents one column of a `DataFrame`. SAS doesn’t have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column in the `DATA` step.

### 32.1.3 Index

Every `DataFrame` and `Series` has an Index - which are labels on the rows of the data. SAS does not have an exactly analogous concept. A data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed during the `DATA` step (_N_).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled `Index` or `MultiIndex` can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the `DataFrame` as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

### 32.2 Data Input / Output

#### 32.2.1 Constructing a DataFrame from Values

A SAS data set can be built from specified values by placing the data after a `datalines` statement and specifying the column names.

```plaintext
data df;
  input x y;
datalines;
  1 2
  3 4
  5 6 ;
run;
```

A pandas `DataFrame` can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```python
In [3]: df = pd.DataFrame({
    ...: 'x': [1, 3, 5],
    ...: 'y': [2, 4, 6]})
```

```plaintext
Out[4]:
x y
0 1 2
1 3 4
2 5 6
```

#### 32.2.2 Reading External Data

Like SAS, pandas provides utilities for reading in data from many formats. The `tips` dataset, found within the pandas tests (csv) will be used in many of the following examples.

SAS provides `PROC IMPORT` to read csv data into a data set.
The pandas method is `read_csv()`, which works similarly.

```python
In [5]: url = 'https://raw.github.com/pandas-dev/pandas/master/pandas/tests/data/tips.csv'

In [6]: tips = pd.read_csv(url)

In [7]: tips.head()
```

```
Out[7]:
   total_bill  tip  sex  smoker day    time  size
0   16.99    1.01 Female  No  Sun  Dinner   2
1   10.34    1.66   Male   No  Sun  Dinner   3
2   21.01    3.50   Male   No  Sun  Dinner   3
3   23.68    3.31   Male   No  Sun  Dinner   2
4   24.59    3.61 Female  No  Sun  Dinner   4
```

Like PROC IMPORT, read_csv can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```python
tips = pd.read_csv('tips.csv', sep='\t', header=None)
```

# alternatively, read_table is an alias to read_csv with tab delimiter

tips = pd.read_table('tips.csv', header=None)

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a `pd.read_` function. See the IO documentation for more details.

### 32.2.3 Exporting Data

The inverse of PROC IMPORT in SAS is PROC EXPORT

```python
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of `read_csv` is `to_csv()`, and other data formats follow a similar api.

```python
tips.to_csv('tips2.csv')
```

### 32.3 Data Operations

#### 32.3.1 Operations on Columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```python
data tips;
    set tips;
    total_bill = total_bill - 2;
    new_bill = total_bill / 2;
run;
```
pandas provides similar vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2.0
In [10]: tips.head()
Out[10]:
    total_bill  tip    sex smoker  day    time  size  new_bill
0        14.99  1.01 Female   No  Sun  Dinner    2   7.495
1          8.34  1.66   Male   No  Sun  Dinner    3   4.170
2         19.01  3.50   Male   No  Sun  Dinner    3   9.505
3         21.68  3.31   Male   No  Sun  Dinner    2  10.840
4         22.59  3.61 Female   No  Sun  Dinner    4  11.295
```

### 32.3.2 Filtering

Filtering in SAS is done with an `if` or `where` statement, on one or more columns.

```
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
/* equivalent in this case - where happens before the
   DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```
In [11]: tips[tips['total_bill'] > 10].head()
Out[11]:
    total_bill  tip    sex smoker  day    time  size
0        14.99  1.01 Female   No  Sun  Dinner    2
2         19.01  3.50   Male   No  Sun  Dinner    3
3         21.68  3.31   Male   No  Sun  Dinner    2
4         22.59  3.61 Female   No  Sun  Dinner    4
5         23.29  4.71   Male   No  Sun  Dinner    4
```

### 32.3.3 If/Then Logic

In SAS, if/then logic can be used to create new columns.

```
data tips;
  set tips;
  format bucket $4.;
  if total_bill < 10 then bucket = 'low';
  else bucket = 'high';
run;
```
The same operation in pandas can be accomplished using the `where` method from `numpy`.

```python
In [12]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')
In [13]: tips.head()
```

```
Out[13]:
  total_bill  tip    sex  smoker day   time  size  bucket
0    14.99  1.01  Female   No  Sun  Dinner     2  high
1     8.34  1.66    Male   No  Sun  Dinner     3  low
2    19.01  3.50    Male   No  Sun  Dinner     3  high
3    21.68  3.31    Male   No  Sun  Dinner     2  high
4    22.59  3.61  Female   No  Sun  Dinner     4  high
```

### 32.3.4 Date Functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```sas
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmddyy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  * shift date to beginning of next interval;
  date1_next = intnx('MONTH', date1, 1);
  * count intervals between dates;
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the `timeseries documentation` for more details.

```python
In [14]: tips['date1'] = pd.Timestamp('2013-01-15')
In [15]: tips['date2'] = pd.Timestamp('2015-02-15')
In [16]: tips['date1_year'] = tips['date1'].dt.year
In [17]: tips['date2_month'] = tips['date2'].dt.month
In [18]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
In [19]: tips['months_between'] = (tips['date2'].dt.to_period('M') -
                               tips['date1'].dt.to_period('M'))
In [20]: tips[['date1','date2','date1_year','date2_month','date1_next','months_between']].head()
```

```
Out[20]:
  date1      date2  date1_year  date2_month  date1_next  months_between
```

(continues on next page)
32.3.5 Selection of Columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

```sas
data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;

data tips;
  set tips;
  rename total_bill=total_bill_2;
run;
```

The same operations are expressed in pandas below.

```python
# keep
In [21]: tips[['sex', 'total_bill', 'tip']].head()
Out[21]:
          sex  total_bill  tip
0  Female   14.990000  1.01
1   Male     8.340000  1.66
2   Male    19.010000  3.50
3   Male    21.680000  3.31
4  Female    22.590000  3.61

# drop
In [22]: tips.drop('sex', axis=1).head()

→
          total_bill  tip  smoker  day  time  size
0  14.99  1.01 No Sun Dinner  2
1  8.34  1.66 No Sun Dinner  3
2 19.01  3.50 No Sun Dinner  3
3 21.68  3.31 No Sun Dinner  2
4 22.59  3.61 No Sun Dinner  4

# rename
In [23]: tips.rename(columns={'total_bill':'total_bill_2'}).head()

→
          total_bill_2  tip  sex  smoker  day  time  size
0  14.99  1.01 Female  No Sun Dinner  2
1  8.34  1.66 Male  No Sun Dinner  3
2 19.01  3.50 Male  No Sun Dinner  3
3 21.68  3.31 Male  No Sun Dinner  2
4 22.59  3.61 Female  No Sun Dinner  4
```
32.3.6 Sorting by Values

Sorting in SAS is accomplished via PROC SORT:

```sas
proc sort data=tips;
   by sex total_bill;
run;
```

Pandas objects have a `sort_values()` method, which takes a list of columns to sort by.

```
In [24]: tips = tips.sort_values(['sex', 'total_bill'])
In [25]: tips.head()
```

```
<table>
<thead>
<tr>
<th></th>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
</tr>
<tr>
<td>92</td>
<td>3.75</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Fri</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>111</td>
<td>5.25</td>
<td>1.00</td>
<td>Female</td>
<td>No</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
</tr>
<tr>
<td>145</td>
<td>6.35</td>
<td>1.50</td>
<td>Female</td>
<td>No</td>
<td>Thur</td>
<td>Lunch</td>
<td>2</td>
</tr>
<tr>
<td>135</td>
<td>6.51</td>
<td>1.25</td>
<td>Female</td>
<td>No</td>
<td>Thur</td>
<td>Lunch</td>
<td>2</td>
</tr>
</tbody>
</table>
```

32.4 String Processing

32.4.1 Length

SAS determines the length of a character string with the `LENGTHN` and `LENGTHC` functions. `LENGTHN` excludes trailing blanks and `LENGTHC` includes trailing blanks.

```
data _null_;  
set tips;       
put (LENGTHN(time)); 
put (LENGTHC(time));
run;
```

Python determines the length of a character string with the `len` function. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [26]: tips['time'].str.len().head()
Out[26]:
       Name: time, dtype: int64
        67     6
        92     6
       111     6
       145     5
       135     5
```

```
In [27]: tips['time'].str.rstrip().str.len().head()
```

```
<table>
<thead>
<tr>
<th></th>
<th>Name: time, dtype: int64</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>6</td>
</tr>
<tr>
<td>92</td>
<td>6</td>
</tr>
<tr>
<td>111</td>
<td>6</td>
</tr>
<tr>
<td>145</td>
<td>5</td>
</tr>
<tr>
<td>135</td>
<td>5</td>
</tr>
</tbody>
</table>
```

32.4. String Processing
### 32.4.2 Find

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```sas
data _null_;
set tips;
put (FINDW(sex,'ale'));
run;
```

Python determines the position of a character in a string with the `find` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [28]: tips['sex'].str.find("ale").head()
Out[28]:
   67   3
   92   3
  111   3
  145   3
  135   3
Name: sex, dtype: int64
```

### 32.4.3 Substring

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```sas
data _null_;
set tips;
put (substr(sex,1,1));
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [29]: tips['sex'].str[0:1].head()
Out[29]:
   67   F
   92   F
  111   F
  145   F
  135   F
Name: sex, dtype: object
```

### 32.4.4 Scan

The SAS `SCAN` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```sas
data firstlast;
input String $60. ;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
```

(continues on next page)
Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```python
In [30]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})
In [31]: firstlast['First_Name'] = firstlast['String'].str.split(" ", expand=True)[0]
In [32]: firstlast['Last_Name'] = firstlast['String'].str.rsplit(" ", expand=True)[0]
In [33]: firstlast
Out[33]:
     String  First_Name  Last_Name
0        John        John        John
1        Jane        Jane        Jane
```

### 32.4.5 Upcase, Lowcase, and Propcase

The SAS `UPCASE` `LOWCASE` and `PROPCASE` functions change the case of the argument.

```plaintext
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;;
run;
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```python
In [34]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})
In [35]: firstlast['string_up'] = firstlast['String'].str.upper()
In [36]: firstlast['string_low'] = firstlast['String'].str.lower()
In [37]: firstlast['string_prop'] = firstlast['String'].str.title()
In [38]: firstlast
Out[38]:
     String string_up  string_low  string_prop
0    John Smith      JOHN SMITH   john smith         John Smith
1    Jane Cook       JANE COOK    jane cook           Jane Cook
```

---

**32.4. String Processing**
32.5 Merging

The following tables will be used in the merge examples

```python
In [39]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
                         'value': np.random.randn(4))
```

```python
In [40]: df1
Out[40]:
key    value
0     A    -0.857326
1     B     1.075416
2     C     0.371727
3     D     1.065735
```

```python
In [41]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
                         'value': np.random.randn(4))
```

```python
In [42]: df2
Out[42]:
key    value
0     B    -0.227314
1     D     2.102726
2     D    -0.092796
3     E     0.094694
```

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```sas
proc sort data=df1;
    by key;
run;
proc sort data=df2;
    by key;
run;
data left_join inner_join right_join outer_join;
    merge df1(in=a) df2(in=b);
    if a and b then output inner_join;
    if a then output left_join;
    if b then output right_join;
    if a or b then output outer_join;
run;
```

Pandas DataFrames have a `merge()` method, which provides similar functionality. Note that the data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```python
In [43]: inner_join = df1.merge(df2, on=['key'], how='inner')
```

```python
In [44]: inner_join
Out[44]:
     key   value_x   value_y
0     B  1.075416 -0.227314
```

(continues on next page)
1  D  1.065735  2.102726  
2  D  1.065735  -0.092796  

In [45]: left_join = df1.merge(df2, on=['key'], how='left')

In [46]: left_join  
Out[46]:  
key   value_x   value_y  
0   A    -0.857326    NaN  
1   B    1.075416  -0.227314  
2   C     0.371727    NaN  
3   D    1.065735   2.102726  
4   D    1.065735  -0.092796  

In [47]: right_join = df1.merge(df2, on=['key'], how='right')

In [48]: right_join  
Out[48]:  
key   value_x   value_y  
0   B    1.075416  -0.227314  
1   D    1.065735   2.102726  
2   D    1.065735  -0.092796  
3   E     NaN      0.094694  

In [49]: outer_join = df1.merge(df2, on=['key'], how='outer')

In [50]: outer_join  
Out[50]:  
key   value_x   value_y  
0   A    -0.857326    NaN  
1   B    1.075416  -0.227314  
2   C     0.371727    NaN  
3   D    1.065735   2.102726  
4   D    1.065735  -0.092796  
5   E     NaN      0.094694  

32.6 Missing Data

Like SAS, pandas has a representation for missing data - which is the special float value NaN (not a number). Many of the semantics are the same, for example missing data propagates through numeric operations, and is ignored by default for aggregations.

In [51]: outer_join  
Out[51]:  
key   value_x   value_y  
0   A    -0.857326    NaN  
1   B    1.075416  -0.227314  
2   C     0.371727    NaN  
3   D    1.065735   2.102726  
4   D    1.065735  -0.092796  
5   E     NaN      0.094694  

In [52]: outer_join['value_x'] + outer_join['value_y']  

32.6. Missing Data
One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```plaintext
data outer_join_nulls;
set outer_join;
if value_x = .;
run;

data outer_join_no_nulls;
set outer_join;
if value_x ^= .;
run;
```

Which doesn’t work in pandas. Instead, the `pd.isna` or `pd.notna` functions should be used for comparisons.

```plaintext
In [54]: outer_join[pd.isna(outer_join['value_x'])]

Out[54]:

<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>E</td>
<td>NaN</td>
</tr>
</tbody>
</table>

In [55]: outer_join[pd.notna(outer_join['value_x'])]

Out[55]:

<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-0.857326</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>1.075416</td>
<td>-0.227314</td>
</tr>
<tr>
<td>2</td>
<td>0.371727</td>
<td>NaN</td>
</tr>
<tr>
<td>3</td>
<td>1.065735</td>
<td>2.102726</td>
</tr>
<tr>
<td>4</td>
<td>1.065735</td>
<td>-0.092796</td>
</tr>
</tbody>
</table>
```

Pandas also provides a variety of methods to work with missing data - some of which would be challenging to express in SAS. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the missing data documentation for more.

```plaintext
In [56]: outer_join.dropna()

Out[56]:

<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>B</td>
<td>-0.227314</td>
</tr>
<tr>
<td>3</td>
<td>D</td>
<td>2.102726</td>
</tr>
<tr>
<td>4</td>
<td>D</td>
<td>-0.092796</td>
</tr>
</tbody>
</table>

In [57]: outer_join.fillna(method='ffill')

```

(continues on next page)
In [58]: outer_join['value_x'].fillna(outer_join['value_x'].mean())

→

<table>
<thead>
<tr>
<th></th>
<th>value_x</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-0.857326</td>
</tr>
<tr>
<td>1</td>
<td>1.075416</td>
</tr>
<tr>
<td>2</td>
<td>0.371727</td>
</tr>
<tr>
<td>3</td>
<td>1.065735</td>
</tr>
<tr>
<td>4</td>
<td>1.065735</td>
</tr>
<tr>
<td>5</td>
<td>0.544257</td>
</tr>
</tbody>
</table>

Name: value_x, dtype: float64

32.7 GroupBy

32.7.1 Aggregation

SAS's PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```plaintext
proc summary data=tips nway;
   class sex smoker;
   var total_bill tip;
   output out=tips_summed sum=;
run;
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the groupby documentation for more details and examples.

```python
In [59]: tips_summed = tips.groupby(['sex', 'smoker'])[['total_bill', 'tip']].sum()

In [60]: tips_summed.head()
Out[60]:
   total_bill  tip
sex smoker
Female No 869.68 149.77
    Yes 527.27  96.74
Male  No 1725.75 302.00
   Yes 1217.07 183.07
```

32.7.2 Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.
pandas: powerful Python data analysis toolkit, Release 0.23.3

```r
proc summary data=tips missing nway;
   class smoker;
   var total_bill;
   output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
  by smoker;
run;

data tips;
  merge tips(in=a) smoker_means(in=b);
  by smoker;
  adj_total_bill = total_bill - group_bill;
  if a and b;
run;
```

Pandas `groupby` provides a transform mechanism that allows these type of operations to be succinctly expressed in one operation.

```r
In [61]: gb = tips.groupby('smoker')['total_bill']
In [62]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')
In [63]: tips.head()
```

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>adj_total_bill</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner</td>
<td>-17.686344</td>
</tr>
<tr>
<td>92</td>
<td>3.75</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Fri</td>
<td>Dinner</td>
<td>-15.006344</td>
</tr>
<tr>
<td>111</td>
<td>5.25</td>
<td>1.00</td>
<td>Female</td>
<td>No</td>
<td>Sat</td>
<td>Dinner</td>
<td>-11.938278</td>
</tr>
<tr>
<td>145</td>
<td>6.35</td>
<td>1.50</td>
<td>Female</td>
<td>No</td>
<td>Thur</td>
<td>Lunch</td>
<td>-10.838278</td>
</tr>
<tr>
<td>135</td>
<td>6.51</td>
<td>1.25</td>
<td>Female</td>
<td>No</td>
<td>Thur</td>
<td>Lunch</td>
<td>-10.678278</td>
</tr>
</tbody>
</table>

### 32.7.3 By Group Processing

In addition to aggregation, pandas `groupby` can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```r
proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;
```

In pandas this would be written as:

```r
In [64]: tips.groupby(['sex', 'smoker']).first()
```

```
<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>adj_total_bill</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>5.25</td>
<td>1.00</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
</tr>
</tbody>
</table>
```

(continues on next page)
32.8 Other Considerations

32.8.1 Disk vs Memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine’s memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the dask.dataframe library (currently in development) which provides a subset of pandas functionality for an on-disk DataFrame.

32.8.2 Data Interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```python
libname xportout xport 'transport-file.xpt';
data xportout.tips;
   set tips(rename=(total_bill=tbill));
   * xport variable names limited to 6 characters;
run;

df = pd.read_sas('transport-file.xpt')
df = pd.read_sas('binary-file.sas7bdat')
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```python
df = pd.read_sas('transport-file.xpt', format='xport')
df = pd.read_sas('binary-file.sas7bdat', format='sas7bdat')
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```python
# version 0.17, 10M rows
In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s

In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```
COMPARISON WITH STATA

For potential users coming from Stata this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows. This means that we can refer to the libraries as `pd` and `np`, respectively, for the rest of the document.

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```

**Note:** Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. Jupyter notebook or terminal) – the equivalent in Stata would be:

```stata
list in 1/5
```

### 33.1 Data Structures

#### 33.1.1 General Terminology Translation

<table>
<thead>
<tr>
<th>pandas</th>
<th>Stata</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame</td>
<td>data set</td>
</tr>
<tr>
<td>column</td>

#### 33.1.2 DataFrame / Series

A `DataFrame` in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.
A Series is the data structure that represents one column of a DataFrame. Stata doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column of a data set in Stata.

### 33.1.3 Index

Every DataFrame and Series has an Index – labels on the rows of the data. Stata does not have an exactly analogous concept. In Stata, a data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed with _n.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

### 33.2 Data Input / Output

#### 33.2.1 Constructing a DataFrame from Values

A Stata data set can be built from specified values by placing the data after an input statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({
...:     'x': [1, 3, 5],
...:     'y': [2, 4, 6])
...

In [4]: df
Out[4]:
     x  y
0  1  2
1  3  4
2  5  6
```

#### 33.2.2 Reading External Data

Like Stata, pandas provides utilities for reading in data from many formats. The tips data set, found within the pandas tests (csv) will be used in many of the following examples.

Stata provides import delimited to read csv data into a data set in memory. If the tips.csv file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```
The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```python
In [5]: url = 'https://raw.github.com/pandas-dev/pandas/master/pandas/tests/data/tips.csv'

In [6]: tips = pd.read_csv(url)

In [7]: tips.head()
Out[7]:
   total_bill  tip  sex  smoker  day   time  size
0      16.99  1.01 Female  No  Sun  Dinner    2
1      10.34  1.66   Male  No  Sun  Dinner    3
2      21.01  3.50   Male  No  Sun  Dinner    3
3      23.68  3.31   Male  No  Sun  Dinner    2
4      24.59  3.61 Female  No  Sun  Dinner    4
```

Like `import delimited`, `read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```python
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
# tips = pd.read_table('tips.csv', header=None)
```

Pandas can also read Stata data sets in `.dta` format with the `read_stata()` function.

```python
df = pd.read_stata('data.dta')
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the IO documentation for more details.

### 33.2.3 Exporting Data

The inverse of `import delimited` in Stata is `export delimited`.

```python
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```python
tips.to_csv('tips2.csv')
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```python
tips.to_stata('tips2.dta')
```

### 33.3 Data Operations

#### 33.3.1 Operations on Columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.
pandas provides similar vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the DataFrame.

```python
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2
In [10]: tips.head()
Out[10]:
   total_bill  tip    sex  smoker  day     time  size  new_bill
0     14.99  1.01  Female   No   Sun   Dinner  2   7.495
1      8.34  1.66   Male    No   Sun   Dinner  3   4.170
2     19.01  3.50   Male    No   Sun   Dinner  3   9.505
3     21.68  3.31   Male    No   Sun   Dinner  2  10.840
4     22.59  3.61  Female    No   Sun   Dinner  4  11.295
```

### 33.3.2 Filtering

Filtering in Stata is done with an `if` clause on one or more columns.

```stata
list if total_bill > 10
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```python
In [12]: tips[tips['total_bill'] > 10].head()
Out[12]:
   total_bill  tip    sex  smoker  day     time  size
0     14.99  1.01  Female   No   Sun   Dinner  2
2     19.01  3.50   Male    No   Sun   Dinner  3
3     21.68  3.31   Male    No   Sun   Dinner  2
4     22.59  3.61  Female    No   Sun   Dinner  4
```

### 33.3.3 If/Then Logic

In Stata, an `if` clause can also be used to create new columns.

```stata
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the `where` method from numpy.

```python
In [13]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')
In [14]: tips.head()
Out[14]:
   total_bill  tip    sex  smoker  day     time  size    bucket
0     14.99  1.01  Female   No   Sun   Dinner  2   high
```

(continues on next page)
### 33.3.4 Date Functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```stata
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")
generate date1_year = year(date1)
generate date2_month = month(date2)

t + shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)
list date1 date2 date1_year date2_month date1_next months_between
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the timeseries documentation for more details.

```python
In [15]: tips['date1'] = pd.Timestamp('2013-01-15')
In [16]: tips['date2'] = pd.Timestamp('2015-02-15')
In [17]: tips['date1_year'] = tips['date1'].dt.year
In [18]: tips['date2_month'] = tips['date2'].dt.month
In [19]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
In [20]: tips['months_between'] = (tips['date2'].dt.to_period('M') - tips['date1'].dt.to_period('M'))
In [21]: tips[['date1','date2','date1_year','date2_month','date1_next','months_between']].head()
```

### 33.3.5 Selection of Columns

Stata provides keywords to select, drop, and rename columns.

<table>
<thead>
<tr>
<th></th>
<th>Date</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8.34</td>
<td>Male</td>
</tr>
<tr>
<td>2</td>
<td>19.01</td>
<td>Male</td>
</tr>
<tr>
<td>3</td>
<td>21.68</td>
<td>Male</td>
</tr>
<tr>
<td>4</td>
<td>22.59</td>
<td>Female</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>1.66</th>
<th>No</th>
<th>Dinner</th>
<th>3</th>
<th>low</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3.50</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
<td>high</td>
</tr>
<tr>
<td>2</td>
<td>3.31</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
<td>high</td>
</tr>
<tr>
<td>3</td>
<td>3.61</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Date</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2013-01-15</td>
<td>2015-02-15</td>
</tr>
<tr>
<td>2</td>
<td>2013-01-15</td>
<td>2015-02-15</td>
</tr>
<tr>
<td>3</td>
<td>2013-01-15</td>
<td>2015-02-15</td>
</tr>
<tr>
<td>4</td>
<td>2013-01-15</td>
<td>2015-02-15</td>
</tr>
</tbody>
</table>
The same operations are expressed in pandas below. Note that in contrast to Stata, these operations do not happen in place. To make these changes persist, assign the operation back to a variable.

```python
# keep
In [22]: tips[['sex', 'total_bill', 'tip']].head()
Out[22]:
<table>
<thead>
<tr>
<th>sex</th>
<th>total_bill</th>
<th>tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>14.99</td>
<td>1.01</td>
</tr>
<tr>
<td>Male</td>
<td>8.34</td>
<td>1.66</td>
</tr>
<tr>
<td>Male</td>
<td>19.01</td>
<td>3.50</td>
</tr>
<tr>
<td>Male</td>
<td>21.68</td>
<td>3.31</td>
</tr>
<tr>
<td>Female</td>
<td>22.59</td>
<td>3.61</td>
</tr>
</tbody>
</table>

# drop
In [23]: tips.drop('sex', axis=1).head()

# rename
In [24]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
```

### 33.3.6 Sorting by Values

Sorting in Stata is accomplished via `sort`:

```
sort sex total_bill
```

Pandas objects have a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [25]: tips = tips.sort_values(['sex', 'total_bill'])
In [26]: tips.head()
Out[26]:
<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner 1</td>
<td></td>
</tr>
<tr>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner 1</td>
<td></td>
</tr>
<tr>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner 1</td>
<td></td>
</tr>
<tr>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner 1</td>
<td></td>
</tr>
<tr>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner 1</td>
<td></td>
</tr>
</tbody>
</table>
33.4 String Processing

33.4.1 Finding Length of String

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```plaintext
generate strlen_time = strlen(time)
generate strlen_time = ustrlen(time)
```

Python determines the length of a character string with the `len` function. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```plaintext
In [27]: tips['time'].str.len().head()
Out[27]:
   67    6
   92    6
  111    6
  145    5
  135    5
Name: time, dtype: int64

In [28]: tips['time'].str.rstrip().str.len().head()
   →
   67    6
   92    6
  111    6
  145    5
  135    5
Name: time, dtype: int64
```

33.4.2 Finding Position of Substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```plaintext
generate str_position = strpos(sex, "ale")
```

Python determines the position of a character in a string with the `find()` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```plaintext
In [29]: tips['sex'].str.find("ale").head()
Out[29]:
   67    3
```
33.4.3 Extracting Substring by Position

Stata extracts a substring from a string based on its position with the `substr()` function.

```stata
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```python
In [30]: tips['sex'].str[0:1].head()
Out[30]:
   67    F
   92    F
  111    F
  145    F
  135    F
Name: sex, dtype: object
```

33.4.4 Extracting nth Word

The Stata `word()` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```stata
clear
input str20 string
 "John Smith"
 "Jane Cook"
end

generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```python
In [31]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})
In [32]: firstlast['First_Name'] = firstlast['string'].str.split(" ", expand=True)[0]
In [33]: firstlast['Last_Name'] = firstlast['string'].str.rsplit(" ", expand=True)[0]
In [34]: firstlast
Out[34]:
   string  First_Name  Last_Name
0  John Smith       John   John
1   Jane Cook       Jane    Jane
```
### 33.4.5 Changing Case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```stata
clear
input str20 string
"John Smith"
"Jane Cook"
end
generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```python
In [35]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})
In [36]: firstlast['upper'] = firstlast['string'].str.upper()
In [37]: firstlast['lower'] = firstlast['string'].str.lower()
In [38]: firstlast['title'] = firstlast['string'].str.title()
In [39]: firstlast
Out[39]:
   string     upper     lower     title
0  John Smith  JOHN SMITH  john smith  John Smith
1     Jane Cook   JANE COOK    jane cook   Jane Cook
```

### 33.5 Merging

The following tables will be used in the merge examples.

```python
In [40]: df1 = pd.DataFrame({
                    'key': ['A', 'B', 'C', 'D'],
                    'value': np.random.randn(4))

In [41]: df1
Out[41]:
   key   value
0   A  0.885906
1   B  0.794848
2   C -0.943848
3   D  0.328609

In [42]: df2 = pd.DataFrame({
                    'key': ['B', 'D', 'D', 'E'],
                    'value': np.random.randn(4))

In [43]: df2
Out[43]:
   key   value
0   B -1.139409
1   D  0.998376
2   D -0.240105
3   E  0.423203
```

(continues on next page)
In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both DataFrame already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the _merge variable.

```stata
* First create df2 and save to disk
clear
input str1 key
B
D
D
E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
A
B
C
D
end
generate value = rnormal()

preserve
* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta
```

pandas DataFrames have a DataFrame.merge() method, which provides similar functionality. Note that different join types are accomplished via the how keyword.
33.6 Missing Data

Like Stata, pandas has a representation for missing data – the special float value `NaN` (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.
In [53]: outer_join['value_x'] + outer_join['value_y']

→
0    NaN
1  -0.840083
2    NaN
3  2.526176
4   0.383304
5    NaN
dtype: float64

In [54]: outer_join['value_x'].sum()

→
-1.3941243310085349

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

* Keep missing values
  list if value_x == .
* Keep non-missing values
  list if value_x != .

This doesn’t work in pandas. Instead, the `pd.isna()` or `pd.notna()` functions should be used for comparisons.

In [55]: outer_join[pd.isna(outer_join['value_x'])]
Out[55]:
key  value_x  value_y
5    E    NaN  0.283297

In [56]: outer_join[pd.notna(outer_join['value_x'])]
Out[56]:
key  value_x  value_y
0    A  0.885906    NaN
1    B  0.794848 -1.634931
2    C -0.943848    NaN
3    D  0.328609  2.197567
4    D  0.328609  0.054695

Pandas also provides a variety of methods to work with missing data – some of which would be challenging to express in Stata. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the missing data documentation for more.

# Drop rows with any missing value
In [57]: outer_join.dropna()
Out[57]:
key  value_x  value_y
1    B  0.794848 -1.634931
3    D  0.328609  2.197567
4    D  0.328609  0.054695

# Fill forwards
In [58]: outer_join.fillna(method='ffill')
In [58]:
key   value_x   value_y
0    A       0.885906  NaN
1    B     -0.794848 -1.634931
2    C    -0.043848 -1.634931
3    D      0.328609  2.197567
4    D      0.328609  0.054695
5    E      0.328609  0.283297

# Impute missing values with the mean
In [59]:
outer_join['value_x'].fillna(outer_join['value_x'].mean())

Out[59]:
key   value_x   value_y
0    A       0.885906  NaN
1    B     -0.794848 -1.634931
2    C    -0.043848 -1.634931
3    D      0.328609  2.197567
4    D      0.328609  0.054695
5    E      0.328609  0.283297

33.7 GroupBy

33.7.1 Aggregation

Stata’s collapse can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the groupby documentation for more details and examples.

```
In [60]:
tips_summed = tips.groupby(['sex', 'smoker'])[['total_bill', 'tip']].sum()

In [61]:
tips_summed.head()
Out[61]:
sex   smoker  total_bill  tip
Female No   869.68   149.77
          Yes   527.27    96.74
Male  No   1725.75  302.00
        Yes  1217.07   183.07
```

33.7.2 Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use bysort with egen(). For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
genenerate adj_total_bill = total_bill - group_bill
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

pandas groupby provides a transform mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [62]: gb = tips.groupby('smoker')['total_bill']

In [63]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')

In [64]: tips.head()
```

```
Out[64]:
       total_bill  tip  sex  smoker  day  time    size  adj_total_bill
67       1.07  1.00  Female  Yes  Sat  Dinner    1   -17.686344
92       3.75  1.00  Female  Yes  Fri  Dinner    2  -15.006344
111      5.25  1.00  Female   No  Sat  Dinner    1   -11.938278
145      6.35  1.50  Female   No  Thur  Lunch    2  -10.838278
135      6.51  1.25  Female   No  Thur  Lunch    2  -10.678278
```

33.7.3 By Group Processing

In addition to aggregation, pandas groupby can be used to replicate most other bysort processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [65]: tips.groupby(['sex','smoker']).first()
Out[65]:
       total_bill  tip  sex  smoker  day  time    size  adj_total_bill
            sex  smoker
Female   No     5.25  1.00  Sat  Dinner    1   -11.938278
         Yes    1.07  1.00  Sat  Dinner    1   -17.686344
Male     No     5.15  2.00  Thur  Lunch    2   -11.678278
         Yes    5.25  5.15  Sun  Dinner    2   -13.506344
```

33.8 Other Considerations

33.8.1 Disk vs Memory

Pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine’s memory. If out of core processing is needed, one possibility is the dask.dataframe library, which provides a subset of pandas functionality for an on-disk DataFrame.
This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in pandas.* namespace are public.

Some subpackages are public which include pandas.errors, pandas.plotting, and pandas.testing. Public functions in pandas.io and pandas.tseries submodules are mentioned in the documentation. pandas.api.types subpackage holds some public functions related to data types in pandas.

**Warning:** The pandas.core, pandas.compat, and pandas.util top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

### 34.1 Input/Output

#### 34.1.1 Pickling

**read_pickle**(path[, compression])

Load pickled pandas object (or any object) from file.

#### 34.1.1.1 pandas.read_pickle

pandas.read_pickle(path, compression='infer')

Load pickled pandas object (or any object) from file.

**Warning:** Loading pickled data received from untrusted sources can be unsafe. See here.

**Parameters**

- **path**: str
  File path where the pickled object will be loaded.

- **compression**: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default ‘infer’
  For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, xz or zip if path ends in `.gz`, `.bz2`, `.xz`, or `.zip` respectively, and no decompression otherwise.
  Set to None for no decompression.

  New in version 0.20.0.

**Returns**

- **unpickled**: [type of object stored in file]
See also:

**DataFrame.to_pickle**  Pickle (serialize) DataFrame object to file.

**Series.to_pickle**  Pickle (serialize) Series object to file.

**read_hdf**  Read HDF5 file into a DataFrame.

**read_sql**  Read SQL query or database table into a DataFrame.

**read_parquet**  Load a parquet object, returning a DataFrame.

**Examples**

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> pd.to_pickle(original_df, ".\dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> import os
>>> os.remove("./dummy.pkl")
```

### 34.1.2 Flat File

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_table(filepath_or_buffer[, sep,...])</code></td>
<td>Read general delimited file into DataFrame</td>
</tr>
<tr>
<td><code>read_csv(filepath_or_buffer[, sep,...])</code></td>
<td>Read CSV (comma-separated) file into DataFrame</td>
</tr>
<tr>
<td><code>read_fwf(filepath_or_buffer[, colspecs, widths])</code></td>
<td>Read a table of fixed-width formatted lines into DataFrame</td>
</tr>
<tr>
<td><code>read_msgpack(path_or_buf[, encoding, iterator])</code></td>
<td>Load msgpack pandas object from the specified file path</td>
</tr>
</tbody>
</table>
34.1.2.1 pandas.read_table

**pandas.read_table** (filepath_or_buffer, sep='\t', delimiter=None, header='infer', names=None, index_col=None, usecols=None, squeeze=False, prefix=None, mangle_dupe_cols=True, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skipinitialspace=False, skiprows=None, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False, infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False, iterator=False, chunksize=None, compression='infer', thousands=None, decimal=b'. ', lineterminator=None, quoting=0, escapechar=None, comment=None, encoding=None, dialect=None, tupleize_cols=None, error_bad_lines=True, warn_bad_lines=True, skipfooter=0, doublequote=True, delim_whitespace=False, low_memory=True, memory_map=False, float_precision=None)

Read general delimited file into DataFrame

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

- **filepath_or_buffer** [str, pathlib.Path, py._path.local.LocalPath or any \]

  object with a read() method (such as a file handle or StringIO)

  The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. For instance, a local file could be file://localhost/path/to/table.csv

  - **sep** : str, default t (tab-stop)
    
    Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\t\t'`

  - **delimiter** : str, default None
    
    Alternative argument name for sep.

  - **delim_whitespace** : boolean, default False

    Specifies whether or not whitespace (e.g. `' '` or `'\t'`) will be used as the sep. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the delimiter parameter.

    New in version 0.18.1: support for the Python parser.

  - **header** : int or list of ints, default 'infer'

    Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if
skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names : array-like, default None

List of column names to use. If file contains no header row, then you should explicitly pass header=None. Duplicates in this list will cause a UserWarning to be issued.

index_col : int or sequence or False, default None

Column to use as the row labels of the DataFrame. If a sequence is given, a MultiIndex is used. If you have a malformed file with delimiters at the end of each line, you might consider index_col=False to force pandas to _not_ use the first column as the index (row names)

usecols : list-like or callable, default None

Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze : boolean, default False

If the parsed data only contains one column then return a Series

prefix : str, default None

Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

mangle_dupe_cols : boolean, default True

Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’… ‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype : Type name or dict of column -> type, default None

Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use str or object together with suitable na_values settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine : {'c', 'python'}, optional

Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

converters : dict, default None

Dict of functions for converting values in certain columns. Keys can either be integers or column labels

true_values : list, default None
Values to consider as True

false_values : list, default None

Values to consider as False

skipinitialspace : boolean, default False

Skip spaces after delimiter.

skiprows : list-like or integer or callable, default None

Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be lambda x: x in [0, 2].

skipfooter : int, default 0

Number of lines at bottom of file to skip (Unsupported with engine='c')

nrows : int, default None

Number of rows of file to read. Useful for reading pieces of large files

na_values : scalar, str, list-like, or dict, default None

Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: '', '#N/A', '#N/A #N/A', '#NA', '-1.#IND', '-1.#QNaN', '-NaN', '-nan', '1.#IND', '1.#QNaN', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

keep_default_na : bool, default True

Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

• If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.

• If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.

• If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.

• If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter : boolean, default True

Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file

verbose : boolean, default False

Indicate number of NA values placed in non-numeric columns

skip_blank_lines : boolean, default True

If True, skip over blank lines rather than interpreting as NaN values
**parse_dates**: boolean or list of ints or names or list of lists or dict, default False

- boolean. If True -> try parsing the index.
- list of ints or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo': [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`.

Note: A fast-path exists for iso8601-formatted dates.

**infer_datetime_format**: boolean, default False

If True and `parse_dates` is enabled, pandas will attempt to infer the format of the date-time strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep_date_col**: boolean, default False

If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**date_parser**: function, default None

Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst**: boolean, default False

DD/MM format dates, international and European format

**iterator**: boolean, default False

Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

**chunksize**: int, default None

Return TextFileReader object for iteration. See the IO Tools docs for more information on `iterator` and `chunksize`.

**compression**: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default ‘infer’

For on-the-fly decompression of on-disk data. If 'infer' and `filepath_or_buffer` is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', or '.xz' (otherwise no decompression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for ‘zip’ and ‘xz’ compression.

**thousands**: str, default None

Thousands separator

**decimal**: str, default ‘.’
Character to recognize as decimal point (e.g. use ‘,’ for European data).

**float_precision**: string, default None

Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round_trip* for the round-trip converter.

**lineterminator**: str (length 1), default None

Character to break file into lines. Only valid with C parser.

**quotechar**: str (length 1), optional

The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting**: int or csv.QUOTE_* instance, default 0

Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

**doublequote**: boolean, default True

When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

**escapechar**: str (length 1), default None

One-character string used to escape delimiter when quoting is QUOTE_NONE.

**comment**: str, default None

Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='%', parsing #empty\n a,b,c 
 1,2,3 with header=0 will result in ‘a,b,c’ being treated as the header.

**encoding**: str, default None

Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings

**dialect**: str or csv.Dialect instance, default None

If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

**tupleize_cols**: boolean, default False

Deprecated since version 0.21.0: This argument will be removed and will always convert to MultiIndex

Leave a list of tuples on columns as is (default is to convert to a MultiIndex on the columns)

**error_bad_lines**: boolean, default True
Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned.

**warn_bad_lines**: boolean, default True

If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

**low_memory**: boolean, default True

Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the *dtype* parameter. Note that the entire file is read into a single DataFrame regardless, use the *chunksize* or *iterator* parameter to return the data in chunks. (Only valid with C parser)

**memory_map**: boolean, default False

If a filepath is provided for *filepath_or_buffer*, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**Returns**

*result* [DataFrame or TextParser]

### 34.1.2.2 pandas.read_csv

#### pandas.read_csv (filepath_or_buffer, sep=’,’ , delimiter=None, header=’infer’, names=None, index_col=None, usecols=None, squeeze=False, prefix=None, mangle_dupe_cols=True, skipinitialspace=False, skiprows=None, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False, infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False, iterator=False, chunksize=None, compression='infer', thousands=None, decimal=b'.', lineterminator=None, quotechar=None, quoting=0, escapechar=None, comment=None, encoding=None, dialect=None, tupleize_cols=None, error_bad_lines=True, warn_bad_lines=True, skipfooter=0, doublequote=True, delim_whitespace=False, low_memory=True, memory_map=False, float_precision=None)

Read CSV (comma-separated) file into DataFrame

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

**filepath_or_buffer** [str, pathlib.Path, py._path.local.LocalPath or any \]

**object with a read() method (such as a file handle or StringIO)**

The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. For instance, a local file could be `file://localhost/path/to/table.csv`

**sep**: str, default ‘,’

Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically
detect the separator by Python's built-in sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `\s+` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\r\t'`

**delimiter** : str, default None

Alternative argument name for sep.

**delim_whitespace** : boolean, default False

Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

**header** : int or list of ints, default 'infer'

Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

**names** : array-like, default None

List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list will cause a `UserWarning` to be issued.

**index_col** : int or sequence or False, default None

Column to use as the row labels of the DataFrame. If a sequence is given, a MultiIndex is used. If you have a malformed file with delimiters at the end of each line, you might consider `index_col=False` to force pandas to _not_ use the first column as the index (row names)

**usecols** : list-like or callable, default None

Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). For example, a valid list-like `usecols` parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so `usecols=[0, 1]` is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in ['foo', 'bar'] order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper()` in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** : boolean, default False
If the parsed data only contains one column then return a Series

**prefix** : str, default None

Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

**mangle_dupe_cols** : boolean, default True

Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’… ‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**dtype** : Type name or dict of column -> type, default None

Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use str or object together with suitable na_values settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** : {'c', 'python'}, optional

Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** : dict, default None

Dict of functions for converting values in certain columns. Keys can either be integers or column labels

**true_values** : list, default None

Values to consider as True

**false_values** : list, default None

Values to consider as False

**skipinitialspace** : boolean, default False

Skip spaces after delimiter.

**skiprows** : list-like or integer or callable, default None

Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be lambda x: x in [0, 2].

**skipfooter** : int, default 0

Number of lines at bottom of file to skip (Unsupported with engine='c')

**nrows** : int, default None

Number of rows of file to read. Useful for reading pieces of large files

**na_values** : scalar, str, list-like, or dict, default None

Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep_default_na** : bool, default True

Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:
• If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.

• If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.

• If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.

• If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

**`na_filter`**: boolean, default True

Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

**`verbose`**: boolean, default False

Indicate number of NA values placed in non-numeric columns.

**`skip_blank_lines`**: boolean, default True

If True, skip over blank lines rather than interpreting as NaN values.

**`parse_dates`**: boolean or list of ints or names or list of lists or dict, default False

- boolean. If True -> try parsing the index.
- list of ints or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1], [3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`.

Note: A fast-path exists for iso8601-formatted dates.

**`infer_datetime_format`**: boolean, default False

If True and `parse_dates` is enabled, pandas will attempt to infer the format of the date-time strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**`keep_date_col`**: boolean, default False

If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**`date_parser`**: function, default None

Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a
single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst**: boolean, default False

DD/MM format dates, international and European format

**iterator**: boolean, default False

Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

**chunksize**: int, default None

Return `TextFileReader` object for iteration. See the IO Tools docs for more information on iterator and chunksize.

For on-the-fly decompression of on-disk data. If ‘infer’ and `filepath_or_buffer` is path-like, then detect compression from the following extensions: `.gz`, `.bz2`, `.zip`, or `.xz` (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for ‘zip’ and ‘xz’ compression.

**thousands**: str, default None

Thousands separator

**decimal**: str, default ‘.’

Character to recognize as decimal point (e.g. use ‘,’ for European data).

**float_precision**: string, default None

Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.

**lineterminator**: str (length 1), default None

Character to break file into lines. Only valid with C parser.

**quotechar**: str (length 1), optional

The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting**: int or `csv.QUOTE_*` instance, default 0

Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

**doublequote**: boolean, default True

When `quotechar` is specified and quoting is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements INSIDE a field as a single `quotechar` element.

**escapechar**: str (length 1), default None

One-character string used to escape delimiter when quoting is `QUOTE_NONE`.

**comment**: str, default None
Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`. For example, if `comment='#'`, parsing "#empty\na,b,c\n1,2,3" with `header=0` will result in ‘a,b,c’ being treated as the header.

**encoding** : str, default None

Encoding to use for UTF when reading/writing (ex. ‘utf-8’). [List of Python standard encodings](https://docs.python.org/3/library/encodings.html)

**dialect** : str or csv.Dialect instance, default None

If provided, this parameter will override values (default or not) for the following parameters: `delimiter`, `doublequote`, `escapechar`, `skipinitialspace`, `quotechar`, and `quoting`. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

**tupleize_cols** : boolean, default False

Deprecated since version 0.21.0: This argument will be removed and will always convert to MultiIndex

Leave a list of tuples on columns as is (default is to convert to a MultiIndex on the columns)

**error_bad_lines** : boolean, default True

Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned.

**warn_bad_lines** : boolean, default True

If `error_bad_lines` is False, and `warn_bad_lines` is True, a warning for each “bad line” will be output.

**low_memory** : boolean, default True

Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single DataFrame regardless, use the `chunks` or `iterator` parameter to return the data in chunks. (Only valid with C parser)

**memory_map** : boolean, default False

If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**Returns**

- `result` [DataFrame or TextParser]

### 34.1.2.3 pandas.read_fwf

`pandas.read_fwf(filepath_or_buffer, colspecs='infer', widths=None, **kwds)`

Read a table of fixed-width formatted lines into DataFrame

Also supports optionally iterating or breaking of the file into chunks.
Parameters

filepath_or_buffer [str, pathlib.Path, py._path.local.LocalPath or any \]

object with a read() method (such as a file handle or StringIO)

The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file
URLs, a host is expected. For instance, a local file could be file://localhost/path/to/table.csv

colspecs : list of pairs (int, int) or ‘infer’. optional

A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-
open intervals (i.e., [from, to[ ). String value ‘infer’ can be used to instruct the parser to
try detecting the column specifications from the first 100 rows of the data which are not
being skipped via skiprows (default= ‘infer’).

widths : list of ints. optional

A list of field widths which can be used instead of ‘colspecs’ if the intervals are con-
tiguous.

delim_whitespace : boolean, default False

Specifies whether or not whitespace (e.g. ‘ ’ or ‘\t’) will be used as the sep.
Equivalent to setting sep=’\s+’ . If this option is set to True, nothing should be
passed in for the delimiter parameter.

New in version 0.18.1: support for the Python parser.

header : int or list of ints, default ‘infer’

Row number(s) to use as the column names, and the start of the data. Default be-
havior is to infer the column names: if no names are passed the behavior is identical
to header=0 and column names are inferred from the first line of the file, if col-
umn names are passed explicitly then the behavior is identical to header=None.
Explicitly pass header=0 to be able to replace existing names. The header can
be a list of integers that specify row locations for a multi-index on the columns e.g.
[0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this exam-
ple is skipped). Note that this parameter ignores commented lines and empty lines if
skip_blank_lines=True, so header=0 denotes the first line of data rather than
the first line of the file.

names : array-like, default None

List of column names to use. If file contains no header row, then you should explicitly
pass header=None. Duplicates in this list will cause a UserWarning to be issued.

index_col : int or sequence or False, default None

Column to use as the row labels of the DataFrame. If a sequence is given, a MultiIndex
is used. If you have a malformed file with delimiters at the end of each line, you might
consider index_col=False to force pandas to _not_ use the first column as the index (row
names)

usecols : list-like or callable, default None
Return a subset of the columns. If list-like, all elements must either be positional (i.e., integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** : boolean, default False

If the parsed data only contains one column then return a Series

**prefix** : str, default None

Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

**mangle_dupe_cols** : boolean, default True

Duplicate columns will be specified as ‘X’, ‘X.1’,...’X.N’, rather than ‘X’...’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**dtype** : Type name or dict of column -> type, default None

Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use str or object together with suitable na_values settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**converters** : dict, default None

Dict of functions for converting values in certain columns. Keys can either be integers or column labels

**true_values** : list, default None

Values to consider as True

**false_values** : list, default None

Values to consider as False

**skipinitialspace** : boolean, default False

Skip spaces after delimiter.

**skiprows** : list-like or integer or callable, default None

Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be lambda x: x in [0, 2].

**skipfooter** : int, default 0

Number of lines at bottom of file to skip (Unsupported with engine='c')

**nrows** : int, default None
Number of rows of file to read. Useful for reading pieces of large files

**na_values**: scalar, str, list-like, or dict, default None

Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ’-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep_default_na**: bool, default True

Whether or not to include the default NaN values when parsing the data. Depending on whether **na_values** is passed in, the behavior is as follows:

- If **keep_default_na** is True, and **na_values** are specified, **na_values** is appended to the default NaN values used for parsing.
- If **keep_default_na** is True, and **na_values** are not specified, only the default NaN values are used for parsing.
- If **keep_default_na** is False, and **na_values** are specified, only the NaN values specified **na_values** are used for parsing.
- If **keep_default_na** is False, and **na_values** are not specified, no strings will be parsed as NaN.

Note that if **na_filter** is passed in as False, the **keep_default_na** and **na_values** parameters will be ignored.

**na_filter**: boolean, default True

Detect missing value markers (empty strings and the value of **na_values**). In data without any NAs, passing **na_filter=False** can improve the performance of reading a large file

**verbose**: boolean, default False

Indicate number of NA values placed in non-numeric columns

**skip_blank_lines**: boolean, default True

If True, skip over blank lines rather than interpreting as NaN values

**parse_dates**: boolean or list of ints or names or list of lists or dict, default False

- boolean. If True -> try parsing the index.
- list of ints or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {‘foo’ : [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use **pd.to_datetime** after **pd.read_csv**

Note: A fast-path exists for iso8601-formatted dates.

**infer_datetime_format**: boolean, default False

If True and **parse_dates** is enabled, pandas will attempt to infer the format of the date-time strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.
**keep_date_col**: boolean, default False

If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**date_parser**: function, default None

Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst**: boolean, default False

DD/MM format dates, international and European format

**iterator**: boolean, default False

Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

**chunksize**: int, default None

Return `TextFileReader` object for iteration. See the IO Tools docs for more information on `iterator` and `chunksize`.

**compression**: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default ‘infer’

For on-the-fly decompression of on-disk data. If ‘infer’ and `filepath_or_buffer` is path-like, then detect compression from the following extensions: `.gz`, `.bz2`, `.zip`, or `.xz` (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for ‘zip’ and ‘xz’ compression.

**thousands**: str, default None

Thousands separator

**decimal**: str, default ‘.’

Character to recognize as decimal point (e.g. use ‘,’ for European data).

**float_precision**: string, default None

Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

**lineterminator**: str (length 1), default None

Character to break file into lines. Only valid with C parser.

**quotechar**: str (length 1), optional

The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting**: int or `csv.QUOTE_*` instance, default 0

Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).
doublequote : boolean, default True

   When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar : str (length 1), default None

   One-character string used to escape delimiter when quoting is QUOTE_NONE.

comment : str, default None

   Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='
', parsing #empty\n\n,a,b,c\n\n1,2,3 with header=0 will result in ‘a,b,c’ being treated as the header.

encoding : str, default None

   Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings

dialect : str or csv.Dialect instance, default None

   If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

tupleize_cols : boolean, default False

   Deprecated since version 0.21.0: This argument will be removed and will always convert to MultiIndex

   Leave a list of tuples on columns as is (default is to convert to a MultiIndex on the columns)

error_bad_lines : boolean, default True

   Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned.

warn_bad_lines : boolean, default True

   If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

low_memory : boolean, default True

   Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)

memory_map : boolean, default False

   If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.
Returns
result [DataFrame or TextParser]

34.1.2.4 pandas.read_msgpack

pandas.read_msgpack (path_or_buf, encoding='utf-8', iterator=False, **kwargs)

Load msgpack pandas object from the specified file path

Parameters
path_or_buf [string File path, BytesIO like or string]
encoding: Encoding for decoding msgpack str type
iterator : boolean, if True, return an iterator to the unpacker
(default is False)

Returns
obj [type of object stored in file]

34.1.3 Clipboard

read_clipboard([sep]) Read text from clipboard and pass to read_table.

34.1.3.1 pandas.read_clipboard

pandas.read_clipboard(sep='\s+', **kwargs)

Read text from clipboard and pass to read_table. See read_table for the full argument list

Parameters sep : str, default 's+'.
A string or regex delimiter. The default of 's+' denotes one or more whitespace characters.

Returns
parsed [DataFrame]

34.1.4 Excel

read_excel(io[, sheet_name, header, names, ...]) Read an Excel table into a pandas DataFrame
ExcelFile.parse([sheet_name, header, names, ...]) Parse specified sheet(s) into a DataFrame
34.1.4.1 pandas.read_excel

```python
pandas.read_excel(io, sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=True, **kwds)
```

Read an Excel table into a pandas DataFrame

**Parameters**

- **io**: string, path object (pathlib.Path or py._path.local.LocalPath), file-like object, pandas ExcelFile, or xlrd workbook. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. For instance, a local file could be `file://localhost/path/to/workbook.xlsx`

- **sheet_name**: string, int, mixed list of strings/ints, or None, default 0
  
  Strings are used for sheet names, Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets.
  
  Specify None to get all sheets.

  str/int -> DataFrame is returned. list/None -> Dict of DataFrames is returned, with keys representing sheets.

  Available Cases
  
  • Defaults to 0 -> 1st sheet as a DataFrame
  • 1 -> 2nd sheet as a DataFrame
  • “Sheet1” -> 1st sheet as a DataFrame
  • [0,1,”Sheet5“] -> 1st, 2nd & 5th sheet as a dictionary of DataFrames
  • None -> All sheets as a dictionary of DataFrames

- **header**: int, list of ints, default 0
  
  Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a MultiIndex. Use None if there is no header.

- **names**: array-like, default None
  
  List of column names to use. If file contains no header row, then you should explicitly pass header=None

- **index_col**: int, list of ints, default None
  
  Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a MultiIndex. If a subset of data is selected with `usecols`, `index_col` is based on the subset.

- **parse_cols**: int or list, default None
  
  Deprecated since version 0.21.0: Pass in `usecols` instead.

- **usecols**: int or list, default None
  
  • If None then parse all columns,
• If int then indicates last column to be parsed
• If list of ints then indicates list of column numbers to be parsed
• If string then indicates comma separated list of Excel column letters and column ranges (e.g. “A:E” or “A,C,E:F”). Ranges are inclusive of both sides.

**squeeze** : boolean, default False

If the parsed data only contains one column then return a Series

**dtype** : Type name or dict of column -> type, default None

Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use object to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

New in version 0.20.0.

**engine** : string, default None

If io is not a buffer or path, this must be set to identify io. Acceptable values are None or xlrd

**converters** : dict, default None

Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

**true_values** : list, default None

Values to consider as True

New in version 0.19.0.

**false_values** : list, default None

Values to consider as False

New in version 0.19.0.

**skiprows** : list-like

Rows to skip at the beginning (0-indexed)

**nrows** : int, default None

Number of rows to parse

New in version 0.23.0.

**na_values** : scalar, str, list-like, or dict, default None

Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘N/A’, ‘#N/A’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep_default_na** : bool, default True

If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they’re appended to.

**verbose** : boolean, default False

Indicate number of NA values placed in non-numeric columns
thousands : str, default None

Thousands separator for parsing string columns to numeric. Note that this parameter
is only necessary for columns stored as TEXT in Excel, any numeric columns will
automatically be parsed, regardless of display format.

column : str, default None

Comments out remainder of line. Pass a character or characters to this argument to
indicate comments in the input file. Any data between the comment string and the end
of the current line is ignored.

skip_footer : int, default 0

Deprecated since version 0.23.0: Pass in skipfooter instead.

skipfooter : int, default 0

Rows at the end to skip (0-indexed)

convert_float : boolean, default True

convert integral floats to int (i.e., 1.0 -> 1). If False, all numeric data will be read in as
floats: Excel stores all numbers as floats internally

Returns parsed : DataFrame or Dict of DataFrames

DataFrame from the passed in Excel file. See notes in sheet_name argument for more
information on when a Dict of Dataframes is returned.

Examples

An example DataFrame written to a local file

```python
>>> df_out = pd.DataFrame([('string1', 1),
...                         ('string2', 2),
...                         ('string3', 3)],
...                         columns=['Name', 'Value'])
>>> df_out
   Name Value
0  string1    1
1  string2    2
2  string3    3
>>> df_out.to_excel('tmp.xlsx')
```

The file can be read using the file name as string or an open file object:

```python
>>> pd.read_excel('tmp.xlsx')
   Name  Value
0  string1    1
1  string2    2
2  string3    3
```

```python
>>> pd.read_excel(open('tmp.xlsx','rb'))
   Name  Value
0  string1    1
1  string2    2
2  string3    3
```

Index and header can be specified via the index_col and header arguments.
```python
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None)
   0 1 2
0 NaN Name Value
1 0.0 string1 1
2 1.0 string2 2
3 2.0 string3 3
```

Column types are inferred but can be explicitly specified

```python
>>> pd.read_excel('tmp.xlsx', dtype={'Name':str, 'Value':float})
   Name  Value
0  string1   1.0
1  string2   2.0
2  string3   3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```python
>>> pd.read_excel('tmp.xlsx', na_values=['string1', 'string2'])
   Name  Value
0  NaN   1
1  NaN   2
2  string3   3
```

Comment lines in the excel input file can be skipped using the `comment` kwarg

```python
>>> df = pd.DataFrame({'a': ['1', '#2'], 'b': ['2', '3']})
>>> df.to_excel('tmp.xlsx', index=False)
>>> pd.read_excel('tmp.xlsx')
   a  b
0 1  2
1 #2 3
```

```python
>>> pd.read_excel('tmp.xlsx', comment='#')
   a  b
0 1  2
```

### 34.1.4.2 pandas.ExcelFile.parse

ExcelFile.parse(sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=True, **kwds)

Parse specified sheet(s) into a DataFrame

Equivalent to read_excel(ExcelFile, ...) See the read_excel docstring for more info on accepted parameters

### 34.1.5 JSON

read_json(path_or_buf, orient, typ, dtype, ...) Convert a JSON string to pandas object
pandas: powerful Python data analysis toolkit, Release 0.23.3

### 34.1.5.1 pandas.read_json

`pandas.read_json(path_or_buf=None, orient=None, typ='frame', dtype=True, convert_axes=True, convert_dates=True, keep_default_dates=True, numpy=False, precise_float=False, date_unit=None, encoding=None, lines=False, chunksize=None, compression='infer')`

Convert a JSON string to pandas object

**Parameters**
- **path_or_buf**: a valid JSON string or file-like, default: None
- **orient**: string
  - Indication of expected JSON string format. Compatible JSON strings can be produced by `to_json()` with a corresponding orient value. The set of possible orients is:
  - 'split': dict like `{index -> [index], columns -> [columns], data -> [values]}`
  - 'records': list like `[{column -> value}, ... , {column -> value}]`
  - 'index': dict like `{index -> {column -> value}}`
  - 'columns': dict like `{column -> {index -> value}}`
  - 'values': just the values array
  - The allowed and default values depend on the value of the `typ` parameter.
    - when `typ == 'series'`,
      - allowed orients are {'split','records','index'}
      - default is 'index'
      - The Series index must be unique for orient 'index'.
    - when `typ == 'frame'`,
      - allowed orients are {'split','records','index', 'columns', 'values', 'table'}
      - default is 'columns'
      - The DataFrame index must be unique for orients 'index' and 'columns'.
      - The DataFrame columns must be unique for orients 'index','columns', and 'records'.
  - New in version 0.23.0: ‘table’ as an allowed value for the orient argument
- **typ**: [type of object to recover (series or frame), default ‘frame’]
- **dtype**: boolean or dict, default True
  - If True, infer dtypes, if a dict of column to dtype, then use those, if False, then don’t infer dtypes at all, applies only to the data.
- **convert_axes**: boolean, default True
  - Try to convert the axes to the proper dtypes.
convert_dates : boolean, default True

List of columns to parse for dates; If True, then try to parse datelike columns default is True; a column label is datelike if
• it ends with ' _at',
• it ends with ' _time',
• it begins with 'timestamp',
• it is 'modified', or
• it is 'date'

keep_default_dates : boolean, default True

If parsing dates, then parse the default datelike columns

numpy : boolean, default False

Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

precise_float : boolean, default False

Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality

date_unit : string, default None

The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

lines : boolean, default False

Read the file as a json object per line.

New in version 0.19.0.

encoding : str, default is 'utf-8'

The encoding to use to decode py3 bytes.

New in version 0.19.0.

chunksize: integer, default None

Return JsonReader object for iteration. See the line-delimited json docs for more information on chunksize. This can only be passed if lines=True. If this is None, the file will be read into memory all at once.

New in version 0.21.0.

compression : {'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'

For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip or xz if path_or_buf is a string ending in '.gz', '.bz2', '.zip', or 'xz', respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.21.0.

Returns

result  [Series or DataFrame, depending on the value of typ.]
See also:

*DataFrame.to_json*

**Notes**

Specific to `orient='table'`, if a DataFrame with a literal *Index* name of `index` gets written with `to_json()`, the subsequent read operation will incorrectly set the *Index* name to `None`. This is because `index` is also used by `DataFrame.to_json()` to denote a missing *Index* name, and the subsequent `read_json()` operation cannot distinguish between the two. The same limitation is encountered with a `MultiIndex` and any names beginning with `'level_'`.

**Examples**

```python
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                   index=[ 'row 1', 'row 2'],
...                   columns=[ 'col 1', 'col 2'])

Encoding/decoding a Dataframe using 'split' formatted JSON:

```python
>>> df.to_json(orient='split')
"{"columns": ["col 1","col 2"],
 "index": ["row 1","row 2"],
 "data": [{"a","b"},{"c","d"}]}

>>> pd.read_json(_, orient='split')
col 1 col 2
row 1 a b
row 2 c d
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> df.to_json(orient='index')
"{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}

>>> pd.read_json(_, orient='index')
col 1 col 2
row 1 a b
row 2 c d
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"},{"col 1":"c","col 2":"d"}]

>>> pd.read_json(_, orient='records')
col 1 col 2
0 a b
1 c d
```

Encoding with Table Schema

```python
>>> df.to_json(orient='table')
"{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

(continued from previous page)

"primaryKey": "index",
"pandas_version": "0.20.0"},
"data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
{"index": "row 2", "col 1": "c", "col 2": "d"}]}'

json_normalize(data[, record_path, meta, . . . ])
build_table_schema(data[, index, . . . ])

“Normalize” semi-structured JSON data into a flat table
Create a Table schema from data.

34.1.5.2 pandas.io.json.json_normalize
pandas.io.json.json_normalize(data, record_path=None, meta=None, meta_prefix=None,
record_prefix=None, errors=’raise’, sep=’.’)
“Normalize” semi-structured JSON data into a flat table
Parameters data : dict or list of dicts
Unserialized JSON objects
record_path : string or list of strings, default None
Path in each object to list of records. If not passed, data will be assumed to be an array
of records
meta : list of paths (string or list of strings), default None
Fields to use as metadata for each record in resulting table
record_prefix : string, default None
If True, prefix records with dotted (?) path, e.g. foo.bar.field if path to records is [‘foo’,
‘bar’]
meta_prefix [string, default None]
errors : {‘raise’, ‘ignore’}, default ‘raise’
• ‘ignore’ : will ignore KeyError if keys listed in meta are not always present
• ‘raise’ : will raise KeyError if keys listed in meta are not always present
New in version 0.20.0.
sep : string, default ‘.’
Nested records will generate names separated by sep, e.g., for sep=’.’, { ‘foo’ : { ‘bar’ :
0 } } -> foo.bar
New in version 0.20.0.
Returns
frame [DataFrame]
Examples

34.1. Input/Output

1363


```python
>>> from pandas.io.json import json_normalize

>>> data = [{
    'id': 1,
    'name': {
        'first': 'Coleen',
        'last': 'Volk'
    },
    ...
    'name': {
        'given': 'Mose',
        'family': 'Regner'
    },
    ...
    'id': 2,
    'name': 'Faye Raker'
}

>>> json_normalize(data)

id  name.name.family  name.first  name.given  name.last
    0 NaN                NaN         NaN        NaN
    1 NaN                NaN        Regner     NaN        NaN
    2 2.0                Faye Raker  NaN        NaN        NaN

>>> data = [{
    'state': 'Florida',
    ...
    'shortname': 'FL',
    ...
    'info': {
        ...
        'governor': 'Rick Scott'
    }
    ...
    'counties': [{
        'name': 'Dade',
        'population': 12345,
        ...
    },
    ...
    'name': 'Broward',
    'population': 400000,
    ...
    'name': 'Palm Beach',
    'population': 600000}
}

>>> result = json_normalize(data, 'counties', ['state', 'shortname', 
    ...
    ['info', 'governor']])

>>> result

name  population  info.governor  state  shortname
    0 Dade         12345          Rick Scott     Florida  FL
    1 Broward     400000          Rick Scott     Florida  FL
    2 Palm Beach  600000          Rick Scott     Florida  FL
    3 Summit      1234           John Kasich    Ohio     OH
    4 Cuyahoga    1337            John Kasich    Ohio     OH

>>> data = {'A': [1, 2]}

>>> json_normalize(data, 'A', record_prefix='Prefix.')

Prefix.0
0 1
1 2
```

### 34.1.3.5 pandas.io.json.build_table_schema

`pandas.io.json.build_table_schema(data, index=True, primary_key=None, version=True)`  
Create a Table schema from `data`.

**Parameters**

- `data` [Series, DataFrame]  
  - Whether to include `data.index` in the schema.
- `index` : bool, default True  
  - Whether to include `data.index` in the schema.
- `primary_key` : bool or None, default True  
  - column names to designate as the primary key. The default `None` will set `primaryKey` to the index level or levels if the index is unique.
version : bool, default True

Whether to include a field pandas_version with the version of pandas that generated the
schema.

Returns

schema [dict]

Notes

See _as_json_table_type for conversion types. Timedeltas as converted to ISO8601 duration format with 9
decimal places after the seconds field for nanosecond precision.
Categoricals are converted to the any dtype, and use the enum field constraint to list the allowed values. The
ordered attribute is included in an ordered field.

Examples

```python
>>> df = pd.DataFrame({
... 'A': [1, 2, 3],
... 'B': ['a', 'b', 'c'],
... 'C': pd.date_range('2016-01-01', freq='d', periods=3),
... }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'},
{'name': 'A', 'type': 'integer'},
{'name': 'B', 'type': 'string'},
{'name': 'C', 'type': 'datetime'},
'pandas_version': '0.20.0',
'primaryKey': ['idx']}
```

34.1.6 HTML

| read_html(io[, match, flavor, header, ...]) | Read HTML tables into a list of DataFrame objects. |

34.1.6.1 pandas.read_html

pandas.read_html(io, match='.+', flavor=None, header=None, index_col=None, skiprows=None, 
attrs=None, parse_dates=False, tupleize_cols=None, thousands='.', encoding=None, 
decimal='.', converters=None, na_values=None, keep_default_na=True, 
displayed_only=True)

Read HTML tables into a list of DataFrame objects.

Parameters

- io : str or file-like
  A URL, a file-like object, or a raw string containing HTML. Note that lxml only accepts
  the http, ftp and file url protocols. If you have a URL that starts with 'https' you
  might try removing the 's'.

- match : str or compiled regular expression, optional
  The set of tables containing regular expression this regex or string will be returned. Unless
the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to ‘.+’ (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between Beautiful Soup and lxml.

**flavor**: str or None, container of strings

The parsing engine to use. ‘bs4’ and ‘html5lib’ are synonymous with each other, they are both there for backwards compatibility. The default of None tries to use lxml to parse and if that fails it falls back on bs4 + html5lib.

**header**: int or list-like or None, optional

The row (or list of rows for a *MultiIndex*) to use to make the columns headers.

**index_col**: int or list-like or None, optional

The column (or list of columns) to use to create the index.

**skiprows**: int or list-like or slice or None, optional

0-based. Number of rows to skip after parsing the column integer. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.

**attrs**: dict or None, optional

This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or Beautiful Soup. However, these attributes must be valid HTML table attributes to work correctly. For example,

```python
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the ‘id’ HTML tag attribute is a valid HTML attribute for *any* HTML tag as per this document.

```python
attrs = {'asdf': 'table'}
```

is *not* a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found here. A working draft of the HTML 5 spec can be found here. It contains the latest information on table attributes for the modern web.

**parse_dates**: bool, optional

See `read_csv()` for more details.

**tupleize_cols**: bool, optional

If False try to parse multiple header rows into a *MultiIndex*, otherwise return raw tuples. Defaults to False.

Deprecated since version 0.21.0: This argument will be removed and will always convert to MultiIndex

**thousands**: str, optional

Separator to use to parse thousands. Defaults to ‘,’.

**encoding**: str or None, optional
The encoding used to decode the web page. Defaults to None. ‘None’ preserves the previous encoding behavior, which depends on the underlying parser library (e.g., the parser library will try to use the encoding provided by the document).

**decimal**: str, default ‘.’
Character to recognize as decimal point (e.g. use ‘,’ for European data).
New in version 0.19.0.

**converters**: dict, default None
Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.
New in version 0.19.0.

**na_values**: iterable, default None
Custom NA values
New in version 0.19.0.

**keep_default_na**: bool, default True
If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they’re appended to
New in version 0.19.0.

**display_only**: bool, default True
Whether elements with “display: none” should be parsed
New in version 0.23.0.

**Returns**

- **dfs** [list of DataFrames]

See also:

```
pandas.read_csv
```

**Notes**

Before using this function you should read the *gotchas about the HTML parsing libraries.*

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the `header=0` argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for `<table>` elements and only for `<tr>` and `<th>` rows and `<td>` elements within each `<tr>` or `<th>` element in the table. `<td>` stands for “table data”.

Similar to `read_csv()` the `header` argument is applied after `skiprows` is applied.

This function will always return a list of `DataFrame` or it will fail, e.g., it will not return an empty list.
Examples

See the read_html documentation in the IO section of the docs for some examples of reading in HTML tables.

34.1.7 HDFStore: PyTables (HDF5)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_hdf(path_or_buf[, key, mode])</code></td>
<td>Read from the store, close it if we opened it.</td>
</tr>
<tr>
<td><code>HDFStore.put(key, value[, format, append])</code></td>
<td>Store object in HDFStore</td>
</tr>
<tr>
<td><code>HDFStore.append(key, value[, format, ...])</code></td>
<td>Append to Table in file.</td>
</tr>
<tr>
<td><code>HDFStore.get(key)</code></td>
<td>Retrieve pandas object stored in file.</td>
</tr>
<tr>
<td><code>HDFStore.select(key[, where, start, stop, ...])</code></td>
<td>Retrieve pandas object stored in file, optionally based on where criteria</td>
</tr>
<tr>
<td><code>HDFStore.info()</code></td>
<td>print detailed information on the store</td>
</tr>
<tr>
<td><code>HDFStore.keys()</code></td>
<td>Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore.</td>
</tr>
</tbody>
</table>

34.1.7.1 pandas.read_hdf

```
pandas.read_hdf (path_or_buf, key=None, mode='r', **kwargs)
```

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria

Parameters

- **path_or_buf**: string, buffer or path object
  - Path to the file to open, or an open pandas.HDFStore object. Supports any object implementing the `__fspath__` protocol. This includes `pathlib.Path` and `py._path.local.LocalPath` objects.
  - New in version 0.19.0: support for `pathlib`, `py.path`.
  - New in version 0.21.0: support for `__fspath__` protocol.

- **key**: object, optional
  - The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

- **mode**: {'r', 'r+', 'a'}, optional
  - Mode to use when opening the file. Ignored if `path_or_buf` is a pandas.HDFStore. Default is 'r'.

- **where**: list, optional
  - A list of Term (or convertible) objects.

- **start**: int, optional
  - Row number to start selection.

- **stop**: int, optional
  - Row number to stop selection.

- **columns**: list, optional
  - A list of columns names to return.

- **iterator**: bool, optional
Return an iterator object.

**chunksize** : int, optional

Number of rows to include in an iteration when using an iterator.

**errors** : str, default ‘strict’

Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

****kwags

Additional keyword arguments passed to HDFStore.

**Returns item** : object

The selected object. Return type depends on the object stored.

**See also:**

*pandas.DataFrame.to_hdf* write a HDF file from a DataFrame

*pandas.HDFStore* low-level access to HDF files

**Examples**

```python
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

### 34.1.7.2 pandas.HDFStore.put

**HDFStore.put(key, value, format=None, append=False, **kwags)**

Store object in HDFStore

**Parameters**

**key** [object]

**value** [{Series, DataFrame, Panel}]

**format** : ‘fixed(f)|table(t)’, default is ‘fixed’

**fixed(f)** [Fixed format] Fast writing/reading. Not-appendable, nor searchable

**table(t)** [Table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data

**append** : boolean, default False

This will force Table format, append the input data to the existing.

**data_columns** : list of columns to create as data columns, or True to use all columns. See here # noqa

**encoding** [default None, provide an encoding for strings]

**dropna** : boolean, default False, do not write an ALL nan row to the store settable by the option ‘io.hdf.dropna_table’
34.1.7.3 pandas.HDFStore.append

HDFStore.append (key, value, format=None, append=True, columns=None, dropna=None, **kwargs)

Append to Table in file. Node must already exist and be Table format.

Parameters

- **key** [object]
- **value** [{Series, DataFrame, Panel}]
- **format**: ‘table’ is the default
  - **table(t)** [table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data
- **append**: boolean, default True, append the input data to the existing
- **data_columns**: list of columns, or True, default None
  - List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See here.
- **min_itemsize** [dict of columns that specify minimum string sizes]
- **nan_rep** [string to use as string nan representation]
- **chunksize** [size to chunk the writing]
- **expectedrows** [expected TOTAL row size of this table]
- **encoding** [default None, provide an encoding for strings]
- **dropna**: boolean, default False, do not write an ALL nan row to the store settable by the option ‘io.hdf.dropna_table’

Notes

Does not check if data being appended overlaps with existing data in the table, so be careful

34.1.7.4 pandas.HDFStore.get

HDFStore.get (key)

Retrieve pandas object stored in file

Parameters

- **key** [object]

Returns

- **obj** [type of object stored in file]
34.1.7.5 pandas.HDFStore.select

HDFStore.select(key, where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, auto_close=False, **kwargs)

Retrieve pandas object stored in file, optionally based on where criteria

Parameters

- **key** [object]
- **where** [list of Term (or convertible) objects, optional]
- **start** [integer (defaults to None), row number to start selection]
- **stop** [integer (defaults to None), row number to stop selection]
- **columns** : a list of columns that if not None, will limit the return
- **columns**
- **iterator** [boolean, return an iterator, default False]
- **chunksize** [nrows to include in iteration, return an iterator]
- **auto_close** : boolean, should automatically close the store when finished, default is False

Returns

The selected object

34.1.7.6 pandas.HDFStore.info

HDFStore.info()

print detailed information on the store

New in version 0.21.0.

34.1.7.7 pandas.HDFStore.keys

HDFStore.keys()

Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore. These are ABSOLUTE path-names (e.g. have the leading ‘/’)

34.1.8 Feather

read_feather(path[, nthreads])

Load a feather-format object from the file path

34.1.8.1 pandas.read_feather

pandas.read_feather(path[, nthreads=1])

Load a feather-format object from the file path

Parameters

- **path** [string file path, or file-like object]
**nthreads**: int, default 1

Number of CPU threads to use when reading to pandas.DataFrame

**Returns**

type of object stored in file

### 34.1.9 Parquet

**read_parquet**(path[, engine, columns])

Load a parquet object from the file path, returning a DataFrame.

#### 34.1.9.1 pandas.read_parquet

**pandas.read_parquet**(path, engine='auto', columns=None, **kwargs)

Load a parquet object from the file path, returning a DataFrame.

**Parameters**

- **path**: string
  
  File path

- **columns**: list, default=None
  
  If not None, only these columns will be read from the file.

- **engine**: {'auto', 'pyarrow', 'fastparquet'}, default ‘auto’
  
  Parquet library to use. If ‘auto’, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

**kwargs are passed to the engine

**Returns**

DataFrame

### 34.1.10 SAS

**read_sas**(filepath_or_buffer[, format, ...])

Read SAS files stored as either XPORT or SAS7BDAT format files.

#### 34.1.10.1 pandas.read_sas

**pandas.read_sas**(filepath_or_buffer, format=None, index=None, encoding=None, chunksize=None, iterator=False)

Read SAS files stored as either XPORT or SAS7BDAT format files.

**Parameters**

- **filepath_or_buffer**: string or file-like object
  
  Path to the SAS file.

- **format**: string {'xport', 'sas7bdat'} or None
  
  If None, file format is inferred. If ‘xport’ or ‘sas7bdat’, uses the corresponding format.

- **index**: identifier of index column, defaults to None
Identifier of column that should be used as index of the DataFrame.

**encoding** : string, default is None

Encoding for text data. If None, text data are stored as raw bytes.

**chunksize** : int

Read file chunksize lines at a time, returns iterator.

**iterator** : bool, defaults to False

If True, returns an iterator for reading the file incrementally.

**Returns**

DataFrame if iterator=False and chunksize=None, else SAS7BDATReader
or XportReader

### 34.1.11 SQL

| read_sql_table(table_name, con[, schema, ...]) | Read SQL database table into a DataFrame. |
| read_sql_query(sql, con[, index_col, ...]) | Read SQL query into a DataFrame. |
| read_sql(sql, con[, index_col, ...]) | Read SQL query or database table into a DataFrame. |

### 34.1.12 Google BigQuery

| read_gbq(query[, project_id, index_col, ...]) | Load data from Google BigQuery. |

#### 34.1.12.1 pandas.read_gbq

```python
pandas.read_gbq(query, project_id=None, index_col=None, col_order=None, reauth=False, verbose=None, private_key=None, dialect='legacy', **kwargs)
```

Load data from Google BigQuery.

This function requires the pandas-gbq package.

Authentication to the Google BigQuery service is via OAuth 2.0.

- If “private_key” is not provided:
  
  By default “application default credentials” are used.
  
  If default application credentials are not found or are restrictive, user account credentials are used. In this case, you will be asked to grant permissions for product name ‘pandas GBQ’.

- If “private_key” is provided:
  
  Service account credentials will be used to authenticate.

**Parameters**

**query** : str

SQL-Like Query to return data values.

**project_id** : str

Google BigQuery Account project ID.

**index_col** : str, optional
Name of result column to use for index in results DataFrame.

col_order : list(str), optional
    List of BigQuery column names in the desired order for results DataFrame.

reauth : boolean, default False
    Force Google BigQuery to reauthenticate the user. This is useful if multiple accounts are used.

private_key : str, optional
    Service account private key in JSON format. Can be file path or string contents. This is useful for remote server authentication (eg. Jupyter/IPython notebook on remote host).

dialect : str, default 'legacy'
    SQL syntax dialect to use. Value can be one of:

    'legacy'   Use BigQuery’s legacy SQL dialect. For more information see BigQuery Legacy SQL Reference.

    'standard' Use BigQuery’s standard SQL, which is compliant with the SQL 2011 standard. For more information see BigQuery Standard SQL Reference.

verbose : boolean, deprecated
    Deprecated in Pandas-GBQ 0.4.0. Use the logging module to adjust verbosity instead.

kwargs : dict
    Arbitrary keyword arguments. configuration (dict): query config parameters for job processing. For example:

    configuration = {'query': {'useQueryCache': False}}

    For more information see BigQuery SQL Reference

Returns df: DataFrame
    DataFrame representing results of query.

See also:

pandas_gbq.read_gbq  This function in the pandas-gbq library.

pandas.DataFrame.to_gbq  Write a DataFrame to Google BigQuery.

34.1.13 STATA

read_stata(filepath_or_buffer[, ...])  Read Stata file into DataFrame.

34.1.13.1 pandas.read_stata

pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, encoding=None, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False)  Read Stata file into DataFrame.

Parameters filepath_or_buffer : string or file-like object
    Path to .dta file or object implementing a binary read() functions.
convert_dates : boolean, defaults to True
Convert date variables to DataFrame time values.
convert_categoricals : boolean, defaults to True
Read value labels and convert columns to Categorical/Factor variables.
encoding : string, None or encoding
Encoding used to parse the files. None defaults to latin-1.
index_col : string, optional, default: None
Column to set as index.
convert_missing : boolean, defaults to False
Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.
preserve_dtypes : boolean, defaults to True
Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).
columns : list or None
Columns to retain. Columns will be returned in the given order. None returns all columns.
order_categoricals : boolean, defaults to True
Flag indicating whether converted categorical data are ordered.
chunksize : int, default None
Return StataReader object for iterations, returns chunks with given number of lines.
iterator : boolean, default False
Return StataReader object.

Returns
DataFrame or StataReader

See also:

`pandas.io.stata.StataReader` low-level reader for Stata data files
`pandas.DataFrame.to_stata` export Stata data files

**Examples**

Read a Stata dta file:

```python
>>> import pandas as pd
>>> df = pd.read_stata('filename.dta')
```

Read a Stata dta file in 10,000 line chunks:
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...   do_something(chunk)

StataReader.data(**kwargs) (DEPRECATED) Reads observations from Stata file, converting them into a dataframe

StataReader.data_label() Returns data label of Stata file

StataReader.value_labels() Returns a dict, associating each variable name a dict, associating each value its corresponding label

StataReader.variable_labels() Returns variable labels as a dict, associating each variable name with corresponding label

StataWriter.write_file()

34.1.13.2 pandas.io.stata.StataReader.data

StataReader.data(**kwargs)
Reads observations from Stata file, converting them into a dataframe

Deprecated since version This: is a legacy method. Use read in new code.

Parameters convert_dates : boolean, defaults to True
  Convert date variables to DataFrame time values.

convert_categoricals : boolean, defaults to True
  Read value labels and convert columns to Categorical/Factor variables.

index_col : string, optional, default: None
  Column to set as index.

convert_missing : boolean, defaults to False
  Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

preserve_dtypes : boolean, defaults to True
  Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

columns : list or None
  Columns to retain. Columns will be returned in the given order. None returns all columns.

order_categoricals : boolean, defaults to True
  Flag indicating whether converted categorical data are ordered.

Returns
  DataFrame
34.1.13.3 pandas.io.stata.StataReader.data_label

StataReader.data_label()
Returns data label of Stata file

34.1.13.4 pandas.io.stata.StataReader.value_labels

StataReader.value_labels()
Returns a dict, associating each variable name a dict, associating each value its corresponding label

34.1.13.5 pandas.io.stata.StataReader.variable_labels

StataReader.variable_labels()
Returns variable labels as a dict, associating each variable name with corresponding label

34.1.13.6 pandas.io.stata.StataWriter.write_file

StataWriter.write_file()

34.2.1.1 pandas.melt

pandas.melt(frame, id_vars=None, value_vars=None, var_name=None, value_name='value',
col_level=None)

“Unpivots” a DataFrame from wide format to long format, optionally leaving identifier variables set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

frame [DataFrame]

id_vars : tuple, list, or ndarray, optional
    Column(s) to use as identifier variables.

value_vars : tuple, list, or ndarray, optional
    Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.

var_name : scalar
    Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.

value_name : scalar, default ‘value’
    Name to use for the ‘value’ column.

col_level : int or string, optional
    If columns are a MultiIndex then use this level to melt.

See also:
DataFrame.melt, pivot_table, DataFrame.pivot

Examples

>>> import pandas as pd
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                    'B': {0: 1, 1: 3, 2: 5},
...                    'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6

>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B   1
1  b         B   3
2  c         B   5

>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a         B   1
(continues on next page)
The names of ‘variable’ and ‘value’ columns can be customized:

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'],
     ...        var_name='myVarname', value_name='myValname')
      A     myVarname     myValname
    0  a       B          1
    1  b       B          3
    2  c       B          5
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
     A  B  C  D  E  F
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
  A     variable  value
0  a       B      1
1  b       B      3
2  c       B      5
```

```
>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
         (A, D) variable_0 variable_1  value
0     a         B       E      1
1     b         B       E      3
2     c         B       E      5
```

### 34.2.1.2 pandas.pivot

`pandas.pivot(index, columns, values)`

Produce ‘pivot’ table based on 3 columns of this DataFrame. Uses unique values from index / columns and fills with values.

**Parameters**

- `index` : ndarray
  
  Labels to use to make new frame’s index

- `columns` : ndarray
  
  Labels to use to make new frame’s columns

- `values` : ndarray
  
  Values to use for populating new frame’s values

**Returns**

- `DataFrame`
See also:

`DataFrame.pivot_table` generalization of pivot that can handle duplicate values for one index/column pair

Notes

Obviously, all 3 of the input arguments must have the same length

34.2.1.3 pandas.pivot_table

```
pandas.pivot_table(data, values=None, index=None, columns=None, aggfunc='mean',
                   fill_value=None, margins=False, dropna=True, margins_name='All')
```

Create a spreadsheet-style pivot table as a DataFrame. The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame

Parameters

- `data` [DataFrame]
- `values` [column to aggregate, optional]
- `index` : column, Grouper, array, or list of the previous
  - If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- `columns` : column, Grouper, array, or list of the previous
  - If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- `aggfunc` : function, list of functions, dict, default numpy.mean
  - If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions
- `fill_value` : scalar, default None
  - Value to replace missing values with
- `margins` : boolean, default False
  - Add all row / columns (e.g. for subtotal / grand totals)
- `dropna` : boolean, default True
  - Do not include columns whose entries are all NaN
- `margins_name` : string, default ‘All’
  - Name of the row / column that will contain the totals when margins is True.

Returns

- `table` [DataFrame]

See also:
**DataFrame.pivot** pivot without aggregation that can handle non-numeric data

**Examples**

```python
>>> df = pd.DataFrame({
    "A": ["foo", "foo", "foo", "foo", "foo",
          "bar", "bar", "bar", "bar"],
    "B": ["one", "one", "one", "two", "two",
          "one", "one", "two", "two"],
    "C": ["small", "large", "large", "small",
          "small", "large", "small", "large"],
    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7]
})

>>> df
   A    B   C  D
0  foo  one  small  1
1  foo  one  large  2
2  foo  one  large  2
3  foo  two  small  3
4  foo  two  small  3
5  bar  one  large  4
6  bar  one  small  5
7  bar  two  small  6
8  bar  two  large  7

>>> table = pivot_table(df, values='D', index=['A', 'B'],
                       columns=['C'], aggfunc=np.sum)

>>> table
   C  large  small
   A  B
bar  one   4.0   5.0
    two   7.0   6.0
foo  one   4.0   1.0
    NaN   6.0

>>> table = pivot_table(df, values='D', index=['A', 'B'],
                       columns=['C'], aggfunc=np.sum)

>>> table
   C  large  small
   A  B
bar  one   4.0   5.0
    two   7.0   6.0
foo  one   4.0   1.0
    NaN   6.0

>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                       aggfunc={'D': np.mean,
                                'E': [np.min, np.max, np.mean]})

>>> table
    D   E
    mean  max  median  min
   A  C
bar  large  5.500000  16  14.5  13
   small  5.500000  15  14.5  14
foo  large  2.000000  10  9.5   9
   small  2.333333  12  11.0   8
```

34.2. General functions
34.2.1.4 pandas.crosstab

Compute a simple cross-tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

**Parameters**

- **index**: array-like, Series, or list of arrays/Series
  Values to group by in the rows
- **columns**: array-like, Series, or list of arrays/Series
  Values to group by in the columns
- **values**: array-like, optional
  Array of values to aggregate according to the factors. Requires `aggfunc` be specified.
- **aggfunc**: function, optional
  If specified, requires `values` be specified as well
- **rownames**: sequence, default None
  If passed, must match number of row arrays passed
- **colnames**: sequence, default None
  If passed, must match number of column arrays passed
- **margins**: boolean, default False
  Add row/column margins (subtotals)
- **margins_name**: string, default ‘All’
  Name of the row / column that will contain the totals when margins is True.
  New in version 0.21.0.
- **dropna**: boolean, default True
  Do not include columns whose entries are all NaN
- **normalize**: boolean, ['all', 'index', 'columns'], or {0,1}, default False
  Normalize by dividing all values by the sum of values.
  - If passed ‘all’ or `True`, will normalize over all values.
  - If passed ‘index’ will normalize over each row.
  - If passed ‘columns’ will normalize over each column.
  - If margins is `True`, will also normalize margin values.
  New in version 0.18.1.

**Returns**

- **crosstab** [DataFrame]
Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have all of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren’t overlapping indexes an empty DataFrame will be returned.

Examples

```python
>>> a = np.array(["foo", "foo", "foo", "foo", "bar", "bar",
... "bar", "bar", "foo", "foo", "foo"], dtype=object)
>>> b = np.array(["one", "one", "one", "two", "one", "one",
... "two", "two", "two", "one"], dtype=object)
>>> c = np.array(["dull", "dull", "shiny", "dull", "dull", "shiny",
... "shiny", "dull", "shiny", "shiny", "shiny"],
... dtype=object)

```pd.crosstab(a, [b, c], rownames=["a"], colnames=["b", "c"])

```...
... b one two
c dull shiny dull shiny
a bar 1 2 1 0
foo 2 2 1 2
```

```python
>>> foo = pd.Categorical(["a", "b"], categories=["a", "b", "c"])
>>> bar = pd.Categorical(["d", "e"], categories=["d", "e", "f"])
>>> pd.crosstab(foo, bar)
... # 'c' and 'f' are not represented in the data,
... # but they still will be counted in the output

```...
... col_0 d e f
... row_0 a 1 0 0
... b 0 1 0
... c 0 0 0
```

34.2.1.5 pandas.cut

pandas.cut(x, bins, right=True, labels=None, retbins=False, precision=3, include_lowest=False, duplicates='raise')

Bin values into discrete intervals.

Use `cut` when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

Parameters

- **x**: array-like
  - The input array to be binned. Must be 1-dimensional.

- **bins**: int, sequence of scalars, or pandas.IntervalIndex
  - The criteria to bin by.
pandas: powerful Python data analysis toolkit, Release 0.23.3

- int: Defines the number of equal-width bins in the range of $x$. The range of $x$ is extended by .1% on each side to include the minimum and maximum values of $x$.

- sequence of scalars: Defines the bin edges allowing for non-uniform width. No extension of the range of $x$ is done.

- IntervalIndex: Defines the exact bins to be used.

right: bool, default True

Indicates whether $bins$ includes the rightmost edge or not. If right == True (the default), then the $bins$ [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when $bins$ is an IntervalIndex.

labels: array or bool, optional

Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when $bins$ is an IntervalIndex.

rethbins: bool, default False

Whether to return the bins or not. Useful when bins is provided as a scalar.

precision: int, default 3

The precision at which to store and display the bins labels.

include_lowest: bool, default False

Whether the first interval should be left-inclusive or not.

duplicates: {default 'raise', 'drop'}, optional

If bin edges are not unique, raise ValueError or drop non-uniques. New in version 0.23.0.

Returns out: pandas.Categorical, Series, or ndarray

An array-like object representing the respective bin for each value of $x$. The type depends on the value of labels.

- True (default): returns a Series for Series $x$ or a pandas.Categorical for all other inputs. The values stored within are Interval dtype.

- sequence of scalars: returns a Series for Series $x$ or a pandas.Categorical for all other inputs. The values stored within are whatever the type in the sequence is.

- False: returns an ndarray of integers.

bins: numpy.ndarray or IntervalIndex

The computed or specified bins. Only returned when rethbins=True. For scalar or sequence $bins$, this is an ndarray with the computed bins. If set duplicates=drop, $bins$ will drop non-unique bin. For an IntervalIndex $bins$, this is equal to $bins$.

See also:

qcut Discretize variable into equal-sized buckets based on rank or based on sample quantiles.
pandas.Categorical Array type for storing data that come from a fixed set of values.
Series One-dimensional array with axis labels (including time series).
pandas.IntervalIndex Immutable Index implementing an ordered, sliceable set.
Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or pandas.Categorical object.

Examples

Discretize into three equal-sized bins.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
...
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
```

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
...
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
array([0.994, 3. , 5. , 7. ])
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical’s categories are labels and is ordered.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, labels=['bad', 'medium', 'good'])
[bad, good, medium, medium, good, bad]
Categories (3, object): [bad < medium < good]
```

`labels=False` implies you just want the bins back.

```python
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:

```python
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
... index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
...
a (1.992, 4.667)
b (1.992, 4.667)
c (4.667, 7.333)
d (7.333, 10.0)
e (7.333, 10.0)
dtype: category
Categories (3, interval[float64]): [(1.992, 4.667] < (4.667, ...
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```python
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
... index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
...
(a 0.0
```

(continues on next page)
Use `drop` optional when bins is not unique

```python
>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True, right=False, duplicates='drop')
...  (a 0.0
   b 1.0
   c 2.0
   d 3.0
   e 3.0
dtype: float64, array([0, 2, 4, 6, 8]))
```

Passing an IntervalIndex for `bins` results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```python
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0, 1], NaN, (2, 3], (4, 5]]
Categories (3, interval[int64]): [(0, 1] < (2, 3] < (4, 5)]
```

### 34.2.1.6 pandas.qcut

`pandas.qcut(x, q, labels=None, retbins=False, precision=3, duplicates='raise')`

Quantile-based discretization function. Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

#### Parameters

- `x` [1d ndarray or Series]
- `q`: integer or array of quantiles
  - Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles
- `labels`: array or boolean, default None
  - Used as labels for the resulting bins. Must be of the same length as the resulting bins.
  - If False, return only integer indicators of the bins.
- `retbins`: bool, optional
  - Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.
- `precision`: int, optional
  - The precision at which to store and display the bins labels
- `duplicates`: {default ‘raise’, ‘drop’}, optional
If bin edges are not unique, raise ValueError or drop non-uniques.

New in version 0.20.0.

**Returns** out : Categorical or Series or array of integers if labels is False

The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.

**bins** : ndarray of floats

Returned only if retbins is True.

**Notes**

Out of bounds values will be NA in the resulting Categorical object

**Examples**

```python
>>> pd.qcut(range(5), 4)
...
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```python
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad"])
...
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```python
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```

### 34.2.1.7 pandas.merge

pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)

Merge DataFrame objects by performing a database-style join operation by columns or indexes.

If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

**Parameters**

left [DataFrame]

right [DataFrame]

how : {'left', 'right', 'outer', 'inner'}, default ‘inner’

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically

---

34.2. General functions
inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys

**on**: label or list

Column or index level names to join on. These must be found in both DataFrames. If `on` is `None` and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

**left_on**: label or list, or array-like

Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

**right_on**: label or list, or array-like

Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

**left_index**: boolean, default `False`

Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

**right_index**: boolean, default `False`

Use the index from the right DataFrame as the join key. Same caveats as `left_index`.

**sort**: boolean, default `False`

Sort the join keys lexicographically in the result DataFrame. If `False`, the order of the join keys depends on the join type (how keyword).

**suffixes**: 2-length sequence (tuple, list, . . .)

Suffix to apply to overlapping column names in the left and right side, respectively.

**copy**: boolean, default `True`

If `False`, do not copy data unnecessarily.

**indicator**: boolean or string, default `False`

If `True`, adds a column to output DataFrame called “_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left_only” for observations whose merge key only appears in ‘left’ DataFrame, “right_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

**validate**: string, default `None`

If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.
New in version 0.21.0.

**Returns** merged : DataFrame

The output type will the be same as ‘left’, if it is a subclass of DataFrame.

See also:

merge_ordered, merge_asof, DataFrame.join

**Notes**

Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0

**Examples**

```python
>>> A
   lkey value
0 foo 1
1 bar 2
2 baz 3
3 foo 4

>>> B
   rkey value
0 foo 5
1 bar 6
2 qux 7
3 bar 8

>>> A.merge(B, left_on='lkey', right_on='rkey', how='outer')
   lkey value_x rkey value_y
0   foo    1.0    foo    5.0
1   bar    2.0    bar    6.0
2   baz    3.0     NaN     NaN
3   foo    4.0    foo    5.0
4   bar    2.0    bar    8.0
5     NaN    NaN    qux    7.0
```

### 34.2.1.8 pandas.merge_ordered

`pandas.merge_ordered(left=None, right=None, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('_x', '_y'), how='outer')`

Perform merge with optional filling/interpolation designed for ordered data like time series data. Optionally perform group-wise merge (see examples)

**Parameters**

- **left** [DataFrame]
- **right** [DataFrame]
- **on** : label or list
  Field names to join on. Must be found in both DataFrames.
- **left_on** : label or list, or array-like
  Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns
- **right_on** : label or list, or array-like
  Field names to join on in right DataFrame or vector/list of vectors per left_on docs
- **left_by** : column name or list of column names
Group left DataFrame by group columns and merge piece by piece with right DataFrame

**right_by**: column name or list of column names

Group right DataFrame by group columns and merge piece by piece with left DataFrame

**fill_method**: {'ffill', None}, default None

Interpolation method for data

**suffixes**: 2-length sequence (tuple, list, ...)

Suffix to apply to overlapping column names in the left and right side, respectively

**how**: {'left', 'right', 'outer', 'inner'}, default 'outer'

- left: use only keys from left frame (SQL: left outer join)
- right: use only keys from right frame (SQL: right outer join)
- outer: use union of keys from both frames (SQL: full outer join)
- inner: use intersection of keys from both frames (SQL: inner join)

New in version 0.19.0.

**Returns merged**: DataFrame

The output type will be same as 'left', if it is a subclass of DataFrame.

**See also:**

`merge`, `merge_asof`

**Examples**

```python
codeมาจากPython
>>> A
key  lvalue group
0   a    1     a
1   c    2     a
2   e    3     a
3   a    1     b
4   c    2     b
5   e    3     b

>>> B
key  rvalue
0   b    1
1   c    2
2   d    3
3   e    3
4   b    1
5   c    2

>>> merge_ordered(A, B, fill_method='ffill', left_by='group')
group  key  lvalue  rvalue
0     a    a    1    NaN
1     a    b    1    1.0
2     a    c    2    2.0
3     a    d    2    3.0
4     a    e    3    3.0
5     b    a    1    NaN
6     b    b    1    1.0
7     b    c    2    2.0
8     b    d    2    3.0
9     b    e    3    3.0
```

1390 Chapter 34. API Reference
34.2.1.9 pandas.merge_asof

**pandas.merge_asof**

```python
pandas.merge_asof(left, right, on=None, left_on=None, right_on=None, left_index=False,
right_index=False, by=None, left_by=None, right_by=None, suffixes=('_x',
'_y'), tolerance=None, allow_exact_matches=True, direction='backward')
```

Perform an asof merge. This is similar to a left-join except that we match on nearest key rather than equal keys.

Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

New in version 0.19.0.

**Parameters**

- **left** [DataFrame]
- **right** [DataFrame]
- **on** : label
  
  Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.

- **left_on** : label
  
  Field name to join on in left DataFrame.

- **right_on** : label
  
  Field name to join on in right DataFrame.

- **left_index** : boolean
  
  Use the index of the left DataFrame as the join key.
  
  New in version 0.19.2.

- **right_index** : boolean
  
  Use the index of the right DataFrame as the join key.
  
  New in version 0.19.2.

- **by** : column name or list of column names
  
  Match on these columns before performing merge operation.

- **left_by** : column name
  
  Field names to match on in the left DataFrame.
  
  New in version 0.19.2.
right_by : column name

Field names to match on in the right DataFrame.

New in version 0.19.2.

suffixes : 2-length sequence (tuple, list, . . . )

Suffix to apply to overlapping column names in the left and right side, respectively.

tolerance : integer or Timedelta, optional, default None

Select asof tolerance within this range; must be compatible with the merge index.

allow_exact_matches : boolean, default True

• If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
• If False, don’t match the same ‘on’ value (i.e., stricly less-than / strictly greater-than)

direction : ‘backward’ (default), ‘forward’, or ‘nearest’

Whether to search for prior, subsequent, or closest matches.

New in version 0.20.0.

Returns

merged  [DataFrame]

See also:
merge, merge_ordered

Examples

```python
>>> left = pd.DataFrame({"a": [1, 5, 10], "left_val": ['a', 'b', 'c']})
>>> left
   a  left_val
0   1       a
1   5       b
2  10       c

>>> right = pd.DataFrame({"a": [1, 2, 3, 6, 7],
                        ...
                        'right_val': [1, 2, 3, 6, 7]})
>>> right
   a  right_val
0   1         1
1   2         2
2   3         3
3   6         6
4   7         7

>>> pd.merge_asof(left, right, on='a')
   a  left_val  right_val
0   1       a         1
1   5       b         3
2  10       c         7
```
>>> pd.merge_asof(left, right, on='a', allow_exact_matches=False)
   a  left_val  right_val
 0  1         a          NaN
 1  5         b          3.0
 2 10        c          7.0

>>> pd.merge_asof(left, right, on='a', direction='forward')
   a  left_val  right_val
 0  1         a          1.0
 1  5         b          6.0
 2 10        c          NaN

>>> pd.merge_asof(left, right, on='a', direction='nearest')
   a  left_val  right_val
 0  1         a           1
 1  5         b           6
 2 10        c           7

We can use indexed DataFrames as well.

>>> left = pd.DataFrame({'left_val': ['a', 'b', 'c']}, index=[1, 5, 10])
>>> left
   left_val
1     a
5     b
10    c

>>> right = pd.DataFrame({'right_val': [1, 2, 3, 6, 7]}, index=[1, 2, 3, 6, 7])
>>> right
   right_val
1       1
2       2
3       3
6       6
7       7

>>> pd.merge_asof(left, right, left_index=True, right_index=True)
   left_val  right_val
1         a       1
5         b       3
10        c       7

Here is a real-world times-series example

>>> quotes
   time  ticker  bid  ask
0  2016-05-25 13:30:00.023  GOOG   720.50  720.93
1  2016-05-25 13:30:00.023  MSFT   51.95   51.96
2  2016-05-25 13:30:00.030  MSFT   51.97   51.98
3  2016-05-25 13:30:00.041  MSFT   51.99   52.00
4  2016-05-25 13:30:00.048  GOOG   720.50   720.93
5  2016-05-25 13:30:00.049  AAPL   97.99   98.01
6  2016-05-25 13:30:00.072  GOOG   720.50   720.88
7  2016-05-25 13:30:00.075  MSFT   52.01   52.03
By default we are taking the asof of the quotes

```
>>> pd.merge_asof(trades, quotes,
...    on='time',
...    by='ticker')
```

```
time ticker price quantity bid ask
0 2016-05-25 13:30:00.023 MSFT 51.95 75 51.95 51.96
1 2016-05-25 13:30:00.038 MSFT 51.95 155 51.97 51.98
2 2016-05-25 13:30:00.048 GOOG 720.77 100 720.50 720.93
3 2016-05-25 13:30:00.048 GOOG 720.92 100 720.50 720.93
4 2016-05-25 13:30:00.048 AAPL 98.00 100 NaN NaN
```

We only asof within 2ms between the quote time and the trade time

```
>>> pd.merge_asof(trades, quotes,
...    on='time',
...    by='ticker',
...    tolerance=pd.Timedelta('2ms'))
```

```
time ticker price quantity bid ask
0 2016-05-25 13:30:00.023 MSFT 51.95 75 NaN NaN
1 2016-05-25 13:30:00.038 MSFT 51.95 155 51.97 51.98
2 2016-05-25 13:30:00.048 GOOG 720.77 100 NaN NaN
3 2016-05-25 13:30:00.048 GOOG 720.92 100 NaN NaN
4 2016-05-25 13:30:00.048 AAPL 98.00 100 NaN NaN
```

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. However prior data will propagate forward

```
>>> pd.merge_asof(trades, quotes,
...    on='time',
...    by='ticker',
...    tolerance=pd.Timedelta('10ms'),
...    allow_exact_matches=False)
```

```
time ticker price quantity bid ask
0 2016-05-25 13:30:00.023 MSFT 51.95 75 NaN NaN
1 2016-05-25 13:30:00.038 MSFT 51.95 155 51.97 51.98
2 2016-05-25 13:30:00.048 GOOG 720.77 100 NaN NaN
3 2016-05-25 13:30:00.048 GOOG 720.92 100 NaN NaN
4 2016-05-25 13:30:00.048 AAPL 98.00 100 NaN NaN
```

34.2.1.10 pandas.concat

`pandas.concat(objs, axis=0, join='outer', join_axes=None, ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, sort=None, copy=True)`  
Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.
Parameters `objs` : a sequence or mapping of Series, DataFrame, or Panel objects

If a dict is passed, the sorted keys will be used as the keys argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised

`axis` : {0/'index', 1/'columns'}, default 0

The axis to concatenate along

`join` : {'inner', 'outer'}, default ‘outer’

How to handle indexes on other axis(es)

`join_axes` : list of Index objects

Specific indexes to use for the other n - 1 axes instead of performing inner/outer set logic

`ignore_index` : boolean, default False

If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, . . . , n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

`keys` : sequence, default None

If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level

`levels` : list of sequences, default None

Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys

`names` : list, default None

Names for the levels in the resulting hierarchical index

`verify_integrity` : boolean, default False

Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation

`sort` : boolean, default None

Sort non-concatenation axis if it is not already aligned when join is ‘outer’. The current default of sorting is deprecated and will change to not-sorting in a future version of pandas.

Explicitly pass `sort=True` to silence the warning and sort. Explicitly pass `sort=False` to silence the warning and not sort.

This has no effect when `join='inner'`, which already preserves the order of the non-concatenation axis.

New in version 0.23.0.

`copy` : boolean, default True

If False, do not copy data unnecessarily

Returns `concatenated` : object, type of `objs`
When concatenating all Series along the index (axis=0), a Series is returned. When `objs` contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (axis=1), a DataFrame is returned.

**See also:**

`Series.append`, `DataFrame.append`, `DataFrame.join`, `DataFrame.merge`

**Notes**

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found [here](#).

**Examples**

Combine two Series.

```python
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the `ignore_index` option to True.

```python
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
3    d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the `keys` option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1  0    a
    1    b
s2  0    c
    1    d
dtype: object
```

Label the index keys you create with the `names` option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'],
...            names=['Series name', 'Row ID'])
Series name    Row ID
s1  0    a
    1    b
s2  0    c
    1    d
dtype: object
```

Combine two DataFrame objects with identical columns.
Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```python
>>> df3 = pd.DataFrame([[c, 3, 'cat'], [d, 4, 'dog']],
                      columns=['letter', 'number', 'animal'])
>>> pd.concat([df1, df3])
animal letter number
0 NaN a 1
1 NaN b 2
0 cat c 3
1 dog d 4
```

Combine DataFrame objects with overlapping columns and return only those that are shared by passing inner to the join keyword argument.

```python
>>> pd.concat([df1, df3], join="inner")
letter number
0 a 1
1 b 2
0 c 3
1 d 4
```

Combine DataFrame objects horizontally along the x axis by passing in axis=1.

```python
>>> df4 = pd.DataFrame([['bird', 'polly'], ['monkey', 'george']],
                      columns=['animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
letter number animal name
0 a 1 bird polly
1 b 2 monkey george
```

Prevent the result from including duplicate index values with the verify_integrity option.
```python
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df5
0  a  1
>>> df6 = pd.DataFrame([2], index=['a'])
>>> df6
0  a  2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
  ...  
ValueError: Indexes have overlapping values: ['a']
```

### 34.2.1.11 pandas.get_dummies

**pandas.get_dummies**(data=None, prefix=None, prefix_sep='_', dummy_na=False, columns=None, sparse=False, drop_first=False, dtype=None)

Convert categorical variable into dummy/indicator variables

**Parameters**

- **data** [array-like, Series, or DataFrame]
- **prefix** : string, list of strings, or dict of strings, default None
  String to append DataFrame column names. Pass a list with length equal to the number of columns when calling `get_dummies` on a DataFrame. Alternatively, `prefix` can be a dictionary mapping column names to prefixes.
- **prefix_sep** : string, default `_`
  If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with `prefix`.
- **dummy_na** : bool, default False
  Add a column to indicate NaNs, if False NaNs are ignored.
- **columns** : list-like, default None
  Column names in the DataFrame to be encoded. If `columns` is None then all the columns with object or category dtype will be converted.
- **sparse** : bool, default False
  Whether the dummy columns should be sparse or not. Returns SparseDataFrame if `data` is a Series or if all columns are included. Otherwise returns a DataFrame with some SparseBlocks.
- **drop_first** : bool, default False
  Whether to get k-1 dummies out of k categorical levels by removing the first level.
  New in version 0.18.0.
- **dtype** : dtype, default np.uint8
  Data type for new columns. Only a single dtype is allowed.
  New in version 0.23.0.

**Returns**

- **dummies** [DataFrame or SparseDataFrame]
See also:

*Series.str.get_dummies*

**Examples**

```python
>>> import pandas as pd
>>> s = pd.Series(list('abca'))

>>> pd.get_dummies(s)
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0

>>> s1 = ['a', 'b', np.nan]

>>> pd.get_dummies(s1)
   a  b
0  1  0
1  0  1
2  0  0

>>> pd.get_dummies(s1, dummy_na=True)
   a  b  NaN
0  1  0  0
1  0  1  0
2  0  0  1

>>> df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['b', 'a', 'c'], ...
                    'C': [1, 2, 3]})

>>> pd.get_dummies(df, prefix=['col1', 'col2'])
   C  col1_a  col1_b  col2_a  col2_b  col2_c
0  1       1       0       0       1       0
1  2       0       1       1       0       0
2  3       1       0       0       0       1

>>> pd.get_dummies(pd.Series(list('abcaa')))  
   a  b  c
0  0  0  0
1  1  0  0
2  0  0  1
3  0  0  0
4  1  0  0

>>> pd.get_dummies(pd.Series(list('abcaa')), drop_first=True)
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0
```

34.2. General functions 1399
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> pd.get_dummies(pd.Series(list('abc')), dtype=float)
a  b  c
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

### 34.2.1.12 pandas.factorize

`pandas.factorize(values, sort=False, order=None, na_sentinel=-1, size_hint=None)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

**Parameters**

- **values**: sequence
  A 1-D sequence. Sequences that aren’t pandas objects are coerced to ndarrays before factorization.

- **sort**: bool, default False
  Sort `uniques` and shuffle `labels` to maintain the relationship.

- **order**: deprecated since version 0.23.0: This parameter has no effect and is deprecated.

- **na_sentinel**: int, default -1
  Value to mark “not found”.

- **size_hint**: int, optional
  Hint to the hashtable sizer.

**Returns**

- **labels**: ndarray
  An integer ndarray that’s an indexer into `uniques`. `uniques.take(labels)` will have the same values as `values`.

- **uniques**: ndarray, Index, or Categorical
  The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an `Index` is returned. Otherwise, a 1-D ndarray is returned.

**Note:** Even if there’s a missing value in `values`, `uniques` will not contain an entry for it.

**See also:**

- `pandas.cut` Discretize continuous-valued array.
- `pandas.unique` Find the unique value in an array.
Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `labels` will be shuffled so that the relationship is maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `labels` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
```

```
>>> labels
array([0, 0, 1])
>>> uniques
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
```

```
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

### 34.2.1.13 pandas.unique

```
pandas.unique (values)
```

Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than `numpy.unique`. Includes NA values.
Parameters
values [1d array-like]

Returns unique values.

• If the input is an Index, the return is an Index
• If the input is a Categorical dtype, the return is a Categorical
• If the input is a Series/ndarray, the return will be an ndarray

See also:
pandas.Index.unique, pandas.Series.unique

Examples

```python
>>> pd.unique(pd.Series([2, 1, 3, 3]))
aarray([2, 1, 3])

>>> pd.unique(pd.Series([2] + [1] * 5))
aarray([2, 1])

>>> pd.unique(Series([pd.Timestamp('20160101'), ...
... pd.Timestamp('20160101')]))
aarray(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'), ...
... pd.Timestamp('20160101', tz='US/Eastern')]))
aarray([Timestamp('2016-01-01 00:00:00-05:00', tz='US/Eastern')],
dtype=object)

>>> pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'), ...
... pd.Timestamp('20160101', tz='US/Eastern')]))
DatetimeIndex(['2016-01-01 00:00:00-05:00'],
dtype='datetime64[ns, US/Eastern]', freq=None)

>>> pd.unique(list('baabc'))
aarray(['b', 'a', 'c'], dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```python
>>> pd.unique(Series(pd.Categorical(list('baabc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```python
>>> pd.unique(Series(pd.Categorical(list('baabc'), ...
... categories=list('abc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```
An array of tuples

```python
>>> pd.unique([('a', 'b'), ('b', 'a'), ('a', 'c'), ('b', 'a')])
array([('a', 'b'), ('b', 'a'), ('a', 'c')], dtype=object)
```

### 34.2.1.14 pandas.wide_to_long

The `pandas.wide_to_long` function converts wide panel data to long format. It is less flexible but more user-friendly than `melt`. With stubnames ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2,..., B-suffix1, B-suffix2,... You specify what you wish to call this suffix in the resulting long format with `j` (for example `j='year'`). Each row of these wide variables are assumed to be uniquely identified by `i` (can be a single column name or a list of column names). All remaining variables in the data frame are left intact.

**Parameters**

- **df**: DataFrame
  - The wide-format DataFrame
- **stubnames**: str or list-like
  - The stub name(s). The wide format variables are assumed to start with the stub names.
- **i**: str or list-like
  - Column(s) to use as id variable(s)
- **j**: str
  - The name of the subobservation variable. What you wish to name your suffix in the long format.
- **sep**: str, default `""`
  - A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying `sep='-'`.

New in version 0.20.0.

- **suffix**: str, default `\d+`
  - A regular expression capturing the wanted suffixes. `\d+` captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class `\D+`. You can also further disambiguate suffixes, for example, if your wide variables are of the form Aone, Btwo,..., and you have an unrelated column Arating, you can ignore the last one by specifying `suffix='(!?one|two)'`.

New in version 0.20.0.

**Returns**

DataFrame
A DataFrame that contains each stub name as a variable, with new index (i, j)

Notes

All extra variables are left untouched. This simply uses pandas.melt under the hood, but is hard-coded to “do the right thing” in a typical case.

Examples

```
>>> import pandas as pd
>>> import numpy as np
>>> np.random.seed(123)
>>> df = pd.DataFrame({
... "A1970": {0: "a", 1: "b", 2: "c"},
... "A1980": {0: "d", 1: "e", 2: "f"},
... "B1970": {0: 2.5, 1: 1.2, 2: .7},
... "B1980": {0: 3.2, 1: 1.3, 2: .1},
... "X": dict(zip(range(3), np.random.randn(3)))
... })
>>> df["id"] = df.index
>>> df
0     a       d  2.5    3.2  -1.085631  0
1     b       e  1.2    1.3    0.997345  1
2     c       f  0.7    0.1    0.282978  2
>>> pd.wide_to_long(df, stubnames="A", "B", i="id", j="year")
...   X  A  B
id year
0 1970 -1.085631 a 2.5
1 1970  0.997345 b 1.2
2 1970  0.282978 c 0.7
0 1980 -1.085631 d 3.2
1 1980  0.997345 e 1.3
2 1980  0.282978 f 0.1
```

With multiple id columns

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht1': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
birth  famid  ht1  ht2
0     1      1  2.8  3.4
1     2      1  2.9  3.8
2     3      1  2.2  2.9
3     1      2  2.0  3.2
4     2      2  1.8  2.8
5     3      2  1.9  2.4
6     1      3  2.2  3.3
7     2      3  2.3  3.4
8     3      3  2.1  2.9
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
```

Going from long back to wide just takes some creative use of unstack

```python
>>> w = l.unstack()
>>> w.columns = w.columns.map('{0[0]}{0[1]}'.format)
>>> w.reset_index()
```

Less wieldy column names are also handled

```python
>>> np.random.seed(0)
>>> df = pd.DataFrame({'A(quarterly)-2010': np.random.rand(3),
                     ... 'A(quarterly)-2011': np.random.rand(3),
                     ... 'B(quarterly)-2010': np.random.rand(3),
                     ... 'B(quarterly)-2011': np.random.rand(3),
                     ... 'X' : np.random.randint(3, size=3))
>>> df['id'] = df.index
>>> df
```

34.2. General functions
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> pd.wide_to_long(df, ['A(quarterly)', 'B(quarterly)'], i='id',
...                j='year', sep='-',
...                X A(quarterly) B(quarterly)
...                id year
0 2010 0 0.548814 0.437587
1 2010 1 0.715189 0.891773
2 2010 1 0.602763 0.963663
0 2011 0 0.544883 0.383442
1 2011 1 0.423655 0.791725
2 2011 1 0.645894 0.528895
```

If we have many columns, we could also use a regex to find our stubnames and pass that list on to `wide_to_long`

```python
>>> stubnames = sorted(set([match[0] for match in df.columns.str.findall(r'\[A-B]\(.\*)').values if match != []])
>>> list(stubnames)
['A(quarterly)', 'B(quarterly)']
```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```python
>>> df = pd.DataFrame(
...    {'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht_one': [2.8, 2.9, 2.2, 1.8, 2.8, 2.4, 2.2, 2.3, 2.1],
...     'ht_two': [2.8, 2.9, 2.2, 1.8, 2.8, 2.4, 2.2, 2.3, 2.1]}
... )
>>> df
    birth  famid  ht_one  ht_two
0      1    1     2.8       3.4
1      2    1     2.9       3.8
2      3    1     2.2       2.9
3      1    2     2.0       3.2
4      2    2     1.8       2.8
5      3    2     1.9       2.4
6      1    3     2.2       3.3
7      2    3     2.3       3.4
8      3    3     2.1       2.9
```

```python
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',
...                sep='_', suffix='\w')
>>> l
    ...                                    ht
    famid birth age
1     1 one 2.8
    two 3.4
2     2 one 2.9
    two 3.8
3     3 one 2.2
    two 2.9
```

</tr>
<tr>
<td>notnull(obj)</td>
<td>Detect non-missing values for an array-like object.</td>
</tr>
</tbody>
</table>

34.2.2.1 pandas.isna

pandas.isna(obj)

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters** obj: scalar or array-like

Object to check for null or missing values.

**Returns** bool or array-like of bool

For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**

notna boolean inverse of pandas.isna.

Series.isna Detect missing values in a Series.

DataFrame.isna Detect missing values in a DataFrame.

Index.isna Detect missing values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False
```

```python
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.
For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0   1   2
0   ant  bee  cat
1   dog  None  fly
>>> pd.isna(df)
   0   1   2
0  False False False
1  False  True False
```

34.2.2.2 pandas.isnull

**pandas.isnull (obj)**

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

obj: scalar or array-like

Object to check for null or missing values.

**Returns**

bool or array-like of bool

For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**

notna boolean inverse of pandas.isna.

Series.isna Detect missing values in a Series.

DataFrame.isna Detect missing values in a DataFrame.
**Index.isna** Detect missing values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False
```

```python
>>> pd.isna(np.nan)
True
```

Ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
"2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([('ant', 'bee', 'cat'), ['dog', None, 'fly']])
>>> df
     0  1  2
0  ant bee cat
1   dog None fly
>>> pd.isna(df)
     0  1  2
0  False False False
1  False True False
```

```python
>>> pd.isna(df[1])
     0  1
0  False
1  True
Name: 1, dtype: bool
```

### 34.2.2.3 pandas.notna

**pandas.notna** *(obj)*

Detect non-missing values for an array-like object.
This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- **obj**: array-like or object value
  
  Object to check for *not* null or non-missing values.

**Returns**

- **bool or array-like of bool**
  
  For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

- **isna** boolean inverse of pandas.notna.
- **Series.notna** Detect valid values in a Series.
- **DataFrame.notna** Detect valid values in a DataFrame.
- **Index.notna** Detect valid values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.notna('dog')
True
```

```python
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None,...
                           '2017-07-08'])
>>> index
DateTimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True, True, False, True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
```

(continues on next page)
1  dog  None  fly
>>> pd.notna(df)
   0  1  2
0  True  True  True
1  True  False  True

>>> pd.notna(df[1])
0  True
1  False
Name: 1, dtype: bool

34.2.4 pandas.notnull

pandas.notnull(obj)
Detect non-missing values for an array-like object.
This function takes a scalar or array-like object and dictates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters:
- obj: array-like or object value
Object to check for not null or non-missing values.

Returns:
- bool or array-like of bool
For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:
- isna boolean inverse of pandas.notna.
- Series.notna Detect valid values in a Series.
- DataFrame.notna Detect valid values in a DataFrame.
- Index.notna Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.notna('dog')
True
```

```python
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

array([[ True, False,  True],
       [ True,  True, False]])

For indexes, an ndarray of booleans is returned.

>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None,
...     '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True, True, False,  True])

For Series and DataFrame, the same type is returned, containing booleans.

>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
  0 1 2
0 ant bee cat
1 dog None fly
>>> pd.notna(df)
 0 1 2
0 True True True
1 True False True

34.2.3 Top-level conversions

**to_numeric**(arg[, errors, downcast]) Convert argument to a numeric type.

34.2.3.1 pandas.to_numeric

pandas.to_numeric(arg, errors='raise', downcast=None)

Convert argument to a numeric type.

Parameters

arg [list, tuple, 1-d array, or Series]

errors : {'ignore', 'raise', 'coerce'}, default 'raise'

- If 'raise', then invalid parsing will raise an exception
- If 'coerce', then invalid parsing will be set as NaN
- If 'ignore', then invalid parsing will return the input

downcast : {'integer', 'signed', 'unsigned', 'float'}, default None

If not None, and if the data has been successfully cast to a numerical dtype (or if the
data was numeric to begin with), downcast that resulting data to the smallest numerical
dtype possible according to the following rules:
• ‘integer’ or ‘signed’: smallest signed int dtype (min.: np.int8)
• ‘unsigned’: smallest unsigned int dtype (min.: np.uint8)
• ‘float’: smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the ‘errors’ input.

In addition, downcasting will only occur if the size of the resulting data’s dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

New in version 0.19.0.

Returns ret : numeric if parsing succeeded.

Return type depends on input. Series if Series, otherwise ndarray

See also:

pandas.DataFrame.astype Cast argument to a specified dtype.
pandas.to_datetime Convert argument to datetime.
pandas.to_timedelta Convert argument to timedelta.
numpy.ndarray.astype Cast a numpy array to a specified type.

Examples

Take separate series and convert to numeric, coercing when told to

```python
>>> import pandas as pd
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0     1
1     2

34.2.4.1 pandas.to_datetime

`pandas.to_datetime(arg[, errors='raise', dayfirst=False, yearfirst=False, utc=None, box=True, format=None, exact=True, unit=None, infer_datetime_format=False, origin='unix', cache=False])`

Convert argument to datetime.

Parameters:
- **arg**: integer, float, string, datetime, list, tuple, 1-d array, Series
- **errors**: {'ignore', 'raise', 'coerce'}, default 'raise'
  - If 'raise', then invalid parsing will raise an exception
  - If 'coerce', then invalid parsing will be set as NaT
  - If 'ignore', then invalid parsing will return the input
- **dayfirst** : boolean, default False
  - Specify a date parse order if arg is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: dayfirst=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).
- **yearfirst** : boolean, default False
  - Specify a date parse order if arg is str or its list-likes.
  - If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.  
  - If both dayfirst and yearfirst are True, yearfirst is preceded (same as dateutil).
  - Warning: yearfirst=True is not strict, but will prefer to parse with year first (this is a known bug, based on dateutil behavior).
- **utc** : boolean, default None
  - New in version 0.16.1.
Return UTC DatetimeIndex if True (converting any tz-aware datetime.datetime objects as well).

**box** : boolean, default True
- If True returns a DatetimeIndex
- If False returns ndarray of values.

**format** : string, default None
- strptime to parse time, eg “%d/%m/%Y", note that “%f” will parse all the way up to nanoseconds.

**exact** : boolean, True by default
- If True, require an exact format match.
- If False, allow the format to match anywhere in the target string.

**unit** : string, default ‘ns’
- unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit='ms' and origin='unix' (the default), this would calculate the number of milliseconds to the unix epoch start.

**infer_datetime_format** : boolean, default False
- If True and no format is given, attempt to infer the format of the datetime strings, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

**origin** : scalar, default is ‘unix’
- Define the reference date. The numeric values would be parsed as number of units (defined by unit) since this reference date.
  - If ‘unix’ (or POSIX) time; origin is set to 1970-01-01.
  - If ‘julian’, unit must be ‘D’, and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
  - If Timestamp convertible, origin is set to Timestamp identified by origin.
- New in version 0.20.0.

**cache** : boolean, default False
- If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.
  - New in version 0.23.0.

**Returns**
- ret : datetime if parsing succeeded.
- Return type depends on input:
  - list-like: DatetimeIndex
  - Series: Series of datetime64 dtype
  - scalar: Timestamp

In case when it is not possible to return designated types (e.g. when any element of input is before Timestamp.min or after Timestamp.max) return will have datetime.datetime type (or corresponding array/Series).
See also:

`pandas.DataFrame.astype` Cast argument to a specified dtype.

`pandas.to_timedelta` Convert argument to timedelta.

**Examples**

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like (`'year'`, `'month'`, `'day'`, `'minute'`, `'second'`, `'ms'`, `'us'`, `'ns'`) or plurals of the same.

```python
>>> df = pd.DataFrame({'year': [2015, 2016],
                   'month': [2, 3],
                   'day': [4, 5]})
```

```python
>>> pd.to_datetime(df)
0  2015-02-04
1  2016-03-05
dtype: datetime64[ns]
```

If a date does not meet the timestamp limitations, passing `errors='ignore'` will return the original input instead of raising any exception.

Passing `errors='coerce'` will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```python
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
```

```python
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing `infer_datetime_format=True` can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```python
```

```python
>>> s.head()
0    3/11/2000
1    3/12/2000
2    3/13/2000
3    3/11/2000
4    3/12/2000
dtype: object
```

```python
>>> %timeit pd.to_datetime(s,infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
```

```python
>>> %timeit pd.to_datetime(s,infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```python
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
```

```python
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```
Warning: For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

```python
>>> pd.to_datetime([1, 2, 3], unit='D',
                  origin=pd.Timestamp('1960-01-01'))
0 1960-01-02
1 1960-01-03
2 1960-01-04
```

### 34.2.4.2 pandas.to_timedelta

**pandas.to_timedelta** *(arg, unit='ns', box=True, errors='raise')*

Convert argument to timedelta

**Parameters**

- **arg** [string, timedelta, list, tuple, 1-d array, or Series]
- **unit** : unit of the arg (D,h,m,s,ms,us,ns) denote the unit, which is an integer/float number
- **box** : boolean, default True
  - If True returns a Timedelta/TimedeltaIndex of the results
  - If False returns a np.timedelta64 or ndarray of values of dtype timedelta64[ns]
- **errors** : {'ignore', 'raise', 'coerce'}, default 'raise'
  - If 'raise', then invalid parsing will raise an exception
  - If 'coerce', then invalid parsing will be set as NaT
  - If 'ignore', then invalid parsing will return the input

**Returns**

- **ret** [timedelta64/arrays of timedelta64 if parsing succeeded]

**See also:**

- **pandas.DataFrame.astype** Cast argument to a specified dtype.
- **pandas.to_datetime** Convert argument to datetime.

**Examples**

Parsing a single string to a Timedelta:

```python
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
```

Parsing a list or array of strings:

```python
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us'])
Timedelta('0 days 00:00:00.000015')
```
Converting numbers by specifying the `unit` keyword argument:

```python
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],
dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
dtype='timedelta64[ns]', freq=None)
```

### 34.2.4.3 pandas.date_range

**pandas.date_range** *(start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, **kwargs)*

Return a fixed frequency DatetimeIndex.

**Parameters**

- `start`: str or datetime-like, optional
  - Left bound for generating dates.

- `end`: str or datetime-like, optional
  - Right bound for generating dates.

- `periods`: integer, optional
  - Number of periods to generate.

- `freq`: str or DateOffset, default ‘D’ (calendar daily)
  - Frequency strings can have multiples, e.g. ‘5H’. See [here](#) for a list of frequency aliases.

- `tz`: str or tzinfo, optional
  - Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong_Kong’. By default, the resulting DatetimeIndex is timezone-naive.

- `normalize`: bool, default False
  - Normalize start/end dates to midnight before generating date range.

- `name`: str, default None
  - Name of the resulting DatetimeIndex.

- `closed`: {None, ‘left’, ‘right’}, optional
  - Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).

**Returns**

- `rng` [DatetimeIndex]

**See also:**

- [here](#)
**pandas.DatetimeIndex** An immutable container for datetimes.

**pandas.timedelta_range** Return a fixed frequency TimedeltaIndex.

**pandas.period_range** Return a fixed frequency PeriodIndex.

**pandas.interval_range** Return a fixed frequency IntervalIndex.

**Notes**

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting DatetimeIndex will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see this link.

**Examples**

**Specifying the values**

The next four examples generate the same DatetimeIndex, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```python
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
              dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```python
>>> pd.date_range(start='1/1/2018', periods=8)
              dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```python
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
               '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
               '2018-04-27 00:00:00'], freq=None)
```

**Other Parameters**

Changed the `freq` (frequency) to `M` (month end frequency).

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
               '2018-05-31'],
              dtype='datetime64[ns]', freq='M')
```
Multiples are allowed

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
               '2019-01-31'],
dtype='datetime64[ns]', freq='3M')
```

`freq` can also be specified as an Offset object.

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
               '2019-01-31'],
dtype='datetime64[ns]', freq='3M')
```

Specify `tz` to set the timezone.

```python
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
               '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
               '2018-01-05 00:00:00+09:00'],
dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

`closed` controls whether to include `start` and `end` that are on the boundary. The default includes boundary points on either end.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
dtype='datetime64[ns]', freq='D')
```

Use `closed='left'` to exclude `end` if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
dtype='datetime64[ns]', freq='D')
```

Use `closed='right'` to exclude `start` if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
dtype='datetime64[ns]', freq='D')
```

### 34.2.4.4 pandas.bdate_range

`pandas.bdate_range` returns a fixed frequency DatetimeIndex, with business day as the default frequency.

**Parameters**
- `start`: string or datetime-like, default None
  - Left bound for generating dates
- `end`: string or datetime-like, default None
  - Right bound for generating dates
- `periods`: integer, default None
  - Number of periods to generate
- `freq`: string or DateOffset, default ‘B’ (business daily)
Frequency strings can have multiples, e.g. ‘5H’

**tz**: string or None

Time zone name for returning localized DatetimeIndex, for example Asia/Beijing

**normalize**: bool, default False

Normalize start/end dates to midnight before generating date range

**name**: string, default None

Name of the resulting DatetimeIndex

**weekmask**: string or None, default None

Weekmask of valid business days, passed to numpy.busdaycalendar, only used when custom frequency strings are passed. The default value None is equivalent to ‘Mon Tue Wed Thu Fri’

New in version 0.21.0.

**holidays**: list-like or None, default None

Dates to exclude from the set of valid business days, passed to numpy.busdaycalendar, only used when custom frequency strings are passed

New in version 0.21.0.

**closed**: string, default None

Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None)

**Returns**

rng [DatetimeIndex]

**Notes**

Of the four parameters: start, end, periods, and freq, exactly three must be specified. Specifying freq is a requirement for bdate_range. Use date_range if specifying freq is not desired.

To learn more about the frequency strings, please see this link.

### 34.2.4.5 pandas.period_range

**pandas.period_range** (start=None, end=None, periods=None, freq='D', name=None)

Return a fixed frequency PeriodIndex, with day (calendar) as the default frequency

**Parameters**

**start**: string or period-like, default None

Left bound for generating periods

**end**: string or period-like, default None

Right bound for generating periods

**periods**: integer, default None

Number of periods to generate

**freq**: string or DateOffset, default ‘D’ (calendar daily)

Frequency alias
name : string, default None

Name of the resulting PeriodIndex

Returns

prng  [PeriodIndex]

Notes

Of the three parameters: start, end, and periods, exactly two must be specified.

To learn more about the frequency strings, please see this link.

Examples

```python
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05',
             '2017-06', '2017-07', '2017-08', '2017-09',
             '2017-10', '2017-11', '2017-12', '2018-01'],
            dtype='period[M]', freq='M')
```

If start or end are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the period_range constructor.

```python
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
                   end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]', freq='M')
```

34.2.4.6 pandas.timedelta_range

pandas.timedelta_range(start=None, end=None, periods=None, freq=None, name=None, closed=None)

Return a fixed frequency TimedeltaIndex, with day as the default frequency

Parameters start : string or timedelta-like, default None

Left bound for generating timedeltas

end : string or timedelta-like, default None

Right bound for generating timedeltas

periods : integer, default None

Number of periods to generate

freq : string or DateOffset, default ‘D’ (calendar daily)

Frequency strings can have multiples, e.g. ‘5H’

name : string, default None

Name of the resulting TimedeltaIndex

closed : string, default None

Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None)
Returns

rng [TimedeltaIndex]

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `TimedeltaIndex` will have `periods` linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see this link.

Examples

```python
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```python
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the `TimedeltaIndex`. Only fixed frequencies can be passed, non-fixed frequencies such as 'M' (month end) will raise.

```python
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                '1 days 18:00:00', '2 days 00:00:00'],
               dtype='timedelta64[ns]', freq='6H')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                '5 days 00:00:00'],
               dtype='timedelta64[ns]', freq=None)
```

34.2.4.7 pandas.infer_freq

pandas.infer_freq(index, warn=True)

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

Parameters

- `index`: DatetimeIndex or TimedeltaIndex
  - if passed a Series will use the values of the series (NOT THE INDEX)
- `warn` [boolean, default True]

Returns

- `freq`: string or None
  - None if no discernible frequency
  - TypeError if the index is not datetime-like
  - ValueError if there are less than three values.
34.2.5 Top-level dealing with intervals

\texttt{interval\_range}([start, end, periods, freq, \ldots ]) \quad \text{Return a fixed frequency IntervalIndex}

34.2.5.1 pandas.interval_range

\texttt{pandas.interval\_range} (start=None, end=None, periods=None, freq=None, name=None, closed='right')

Return a fixed frequency IntervalIndex

**Parameters**

- \texttt{start} : numeric or datetime-like, default None
  
  Left bound for generating intervals

- \texttt{end} : numeric or datetime-like, default None
  
  Right bound for generating intervals

- \texttt{periods} : integer, default None
  
  Number of periods to generate

- \texttt{freq} : numeric, string, or DateOffset, default None
  
  The length of each interval. Must be consistent with the type of \texttt{start} and \texttt{end}, e.g. 2 for numeric, or ‘5H’ for datetime-like. Default is 1 for numeric and ‘D’ (calendar daily) for datetime-like.

- \texttt{name} : string, default None
  
  Name of the resulting IntervalIndex

- \texttt{closed} : {‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’
  
  Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

- \texttt{rng} [IntervalIndex]

**See also:**

\texttt{IntervalIndex} an Index of intervals that are all closed on the same side.

**Notes**

Of the four parameters \texttt{start}, \texttt{end}, \texttt{periods}, and \texttt{freq}, exactly three must be specified. If \texttt{freq} is omitted, the resulting IntervalIndex will have periods linearly spaced elements between \texttt{start} and \texttt{end}, inclusively.

To learn more about datetime-like frequency strings, please see this link.

**Examples**

Numeric \texttt{start} and \texttt{end} is supported.

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
closed='right', dtype='interval[int64]')
```
Additionally, datetime-like input is also supported.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
                   end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
               (2017-01-03, 2017-01-04]
            closed='right', dtype='interval[datetime64[ns]]')
```

The `freq` parameter specifies the frequency between the left and right endpoints of the individual intervals within the `IntervalIndex`. For numeric `start` and `end`, the frequency must also be numeric.

```python
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]
            closed='right', dtype='interval[float64]')
```

Similarly, for datetime-like `start` and `end`, the frequency must be convertible to a DateOffset.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
                    end=pd.Timestamp('2017-01-04'),
                    freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
               (2017-03-01, 2017-04-01]
            closed='right', dtype='interval[datetime64[ns]]')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]
            closed='right',
            dtype='interval[float64]')
```

The `closed` parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```python
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([(1, 2], [2, 3], [3, 4], [4, 5]
               closed='both',
               dtype='interval[int64]')
```

### 34.2.6 Top-level evaluation

**`eval`**

```python
eval(expr[, parser, engine, truediv, ...])
```

Evaluate a Python expression as a string using various backends.

#### 34.2.6.1 pandas.eval

**`pandas.eval`**

```python
pandas.eval(expr='pandas', engine=None, truediv=True, local_dict=None, global_dict=None, resolvers=(), level=0, target=None, inplace=False)
```

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: `+`, `-`, `*`, `/`, `**`, `%`, `//` (python engine only) along with the following boolean operations: `|` (or), `&` (and), and `~` (not). Additionally, the 'pandas' parser allows the use of `and`, `or`, and `not` with the same semantics as the corresponding bitwise operators. Series and DataFrame objects are supported and behave as they would with plain ol’ Python evaluation.

**Parameters**

- **expr** : str or unicode

  The expression to evaluate. This string cannot contain any Python statements, only
Python expressions.

**parser** : string, default ‘pandas’, {'pandas', 'python'}

The parser to use to construct the syntax tree from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the [enhancing performance documentation](https://pandas.pydata.org/pandas-docs/stable/user_guide/performance.html) for more details.

**engine** : string or None, default ‘numexpr’, {'python', 'numexpr'}

The engine used to evaluate the expression. Supported engines are

- None : tries to use numexpr, falls back to python
- 'numexpr' : This default engine evaluates pandas objects using numexpr for large speed ups in complex expressions with large frames.
- 'python' : Performs operations as if you had eval'd in top level python. This engine is generally not that useful.

More backends may be available in the future.

**truediv** : bool, optional

Whether to use true division, like in Python >= 3

**local_dict** : dict or None, optional

A dictionary of local variables, taken from locals() by default.

**global_dict** : dict or None, optional

A dictionary of global variables, taken from globals() by default.

**resolvers** : list of dict-like or None, optional

A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the `query()` method to inject the `DataFrame.index` and `DataFrame.columns` variables that refer to their respective `DataFrame` instance attributes.

**level** : int, optional

The number of prior stack frames to traverse and add to the current scope. Most users will not need to change this parameter.

**target** : object, optional, default None

This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then target must support item assignment with string keys, and if a copy is being returned, it must also support `.copy()`.

**inplace** : bool, default False

If target is provided, and the expression mutates target, whether to modify target inplace. Otherwise, return a copy of target with the mutation.

**Returns**

- `ndarray`, `numeric scalar`, `DataFrame`, `Series`

**Raises** `ValueError`

There are many instances where such an error can be raised:
• target=None, but the expression is multiline.
• The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:

\[ a = b + 1 \]
\[ a + 2 \]

Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of \( a + 2 \).
• inplace=True, but the expression is missing item assignment.
• Item assignment is provided, but the target does not support string item assignment.
• Item assignment is provided and inplace=False, but the target does not support the .copy() method

See also:
pandas.DataFrame.query, pandas.DataFrame.eval

Notes

The dtype of any objects involved in an arithmetic % operation are recursively cast to float64.

See the enhancing performance documentation for more details.

34.2.7 Testing

\texttt{test([extra_args])}

34.2.7.1 pandas.test

\texttt{pandas.test(extra_args=\texttt{None})}

34.3 Series

34.3.1 Constructor

\texttt{Series([data, index, dtype, name, copy, ...])} One-dimensional ndarray with axis labels (including time series).

34.3.1.1 pandas.Series

\texttt{class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fast-path=\texttt{False})}

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *) align values based on their associated index values-- they need not be the
same length. The result index will be the sorted union of the two indexes.

**Parameters**

- **data**: array-like, dict, or scalar value
  
  Contains data stored in Series
  
  Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.

- **index**: array-like or Index (1d)
  
  Values must be hashable and have the same length as `data`. Non-unique index values are allowed. Will default to RangelIndex (0, 1, 2, ..., n) if not provided. If both a dict and index sequence are used, the index will override the keys found in the dict.

- **dtype**: numpy.dtype or None
  
  If None, dtype will be inferred

- **copy**: boolean, default False
  
  Copy input data

**Attributes**

- **T**: return the transpose, which is by definition self

- **asobject**: Return object Series which contains boxed values.

- **at**: Access a single value for a row/column label pair.

- **axes**: Return a list of the row axis labels.

- **base**: return the base object if the memory of the underlying data is shared

- **blocks**: (DEPRECATED) Internal property, property synonym for as_blocks()

- **data**: return the data pointer of the underlying data

- **dtypes**: return the dtypes object of the underlying data

- **flags**: return the dtype of the underlying data

- **findex**: return if the data is sparse

- **findex**: return if the data is dense

- **hasnans**: return if I have any nans; enables various perf speedups

- **iat**: Access a single value for a row/column pair by integer position.

- **iloc**: Purely integer-location based indexing for selection by position.

- **index**: The index (axis labels) of the Series.

- **is_monotonic**: Return boolean if values in the object are monotonic_increasing

- **is_monotonic_decreasing**: Return boolean if values in the object are monotonic_decreasing

- **is_monotonic_increasing**: Return boolean if values in the object are monotonic_increasing

- **is_unique**: Return boolean if values in the object are unique

- **itemsize**: return the size of the dtypes of the item of the underlying data

### pandas.Series.T

Series.T

Return the transpose, which is by definition self.

### pandas.Series.asobject

Series.asobject

Return object Series which contains boxed values.

Deprecated since version 0.23.0: Use `astype(object)` instead.

this is an internal non-public method

### pandas.Series.at

Series.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use at if you only need to get or set a single value in a DataFrame or Series.

**Raises KeyError**

When label does not exist in DataFrame

**See also:**

- DataFrame.iat: Access a single value for a row/column pair by integer position
- DataFrame.loc: Access a group of rows and columns by label(s)
- Series.at: Access a single value using a label

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                   index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
```

(continues on next page)
Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```

**pandas.Series.axes**

Series.axes
Return a list of the row axis labels

**pandas.Series.base**

Series.base
return the base object if the memory of the underlying data is shared

**pandas.Series.blocks**

Series.blocks
Internal property, property synonym for as_blocks()
Depreciated since version 0.21.0.

**pandas.Series.data**

Series.data
return the data pointer of the underlying data

**pandas.Series.dtype**

Series.dtype
return the dtype object of the underlying data
pandas.Series.dtypes

Series.dtypes  
return the dtype object of the underlying data

pandas.Series.flags

Series.flags

pandas.Series.ftype

Series.ftype  
return if the data is sparseldense

pandas.Series.ftypes

Series.ftypes  
return if the data is sparseldense

pandas.Series.hasnans

Series.hasnans  
return if I have any nans; enables various perf speedups

pandas.Series.iat

Series.iat  
Access a single value for a row/column pair by integer position.
Similar to iloc, in that both provide integer-based lookups. Use iat if you only need to get or set a single value in a DataFrame or Series.

Raises IndexError

When integer position is out of bounds

See also:

DataFrame.at Access a single value for a row/column label pair

DataFrame.loc Access a group of rows and columns by label(s)

Examples
```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
   columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30

Get value at specified row/column pair

>>> df.iat[1, 2]
1

Set value at specified row/column pair

>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10

Get value within a series

>>> df.loc[0].iat[1]
2

**pandas.Series.iloc**

**Series.iloc**

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at Selection by Position

**pandas.Series.index**

**Series.index**

The index (axis labels) of the Series.
pandas.Series.is_monotonic

Series.is_monotonic

Return boolean if values in the object are monotonic_increasing

New in version 0.19.0.

Returns

is_monotonic [boolean]

pandas.Series.is_monotonic_decreasing

Series.is_monotonic_decreasing

Return boolean if values in the object are monotonic_decreasing

New in version 0.19.0.

Returns

is_monotonic_decreasing [boolean]

pandas.Series.is_monotonic_increasing

Series.is_monotonic_increasing

Return boolean if values in the object are monotonic_increasing

New in version 0.19.0.

Returns

is_monotonic [boolean]

pandas.Series.is_unique

Series.is_unique

Return boolean if values in the object are unique

Returns

is_unique [boolean]

pandas.Series.itemsize

Series.itemsize

return the size of the dtype of the item of the underlying data

pandas.Series.ix

Series.ix

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers.
*.ix[] supports mixed integer and label based access. It is primarily label based, but will fall back to
integer positional access unless the corresponding axis is of integer type.

*.ix is the most general indexer and will support any of the inputs in .loc and .iloc. .ix also supports
floating point label schemes. .ix is exceptionally useful when dealing with mixed positional and label
based hierarchical indexes.

However, when an axis is integer based, ONLY label based access and not positional access is supported.
Thus, in such cases, it’s usually better to be explicit and use .iloc or .loc.

See more at Advanced Indexing.

**pandas.Series.loc**

Series.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and never as an integer
  position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, both the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns
  valid output for indexing (one of the above)

See more at Selection by Label

**Raises KeyError:**

when any items are not found

See also:

*DataFrame.at* Access a single value for a row/column label pair

*DataFrame.iloc* Access group of rows and columns by integer position(s)

*DataFrame.xs* Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

*Series.loc* Access group of values using labels

**Examples**

**Getting values**
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=['cobra', 'viper', 'sidewinder'],
...                   columns=['max_speed', 'shield'])

>>> df
    max_speed  shield
   cobra      1       2
   viper      4       5
   sidewinder 7       8

Single label. Note this returns the row as a Series.

>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64

List of labels. Note using [[]] returns a DataFrame.

>>> df.loc[['viper', 'sidewinder']]
    max_speed  shield
   viper      4       5
   sidewinder 7       8

Single label for row and column

>>> df.loc['cobra', 'shield']
2

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

>>> df.loc['cobra':'viper', 'max_speed']
   cobra 1
   viper 4
Name: max_speed, dtype: int64

Boolean list with the same length as the row axis

>>> df.loc[[False, False, True]]
    max_speed  shield
   sidewinder 7       8

Conditional that returns a boolean Series

>>> df.loc[df['shield'] > 6]
    max_speed  shield
   sidewinder 7       8

Conditional that returns a boolean Series with column labels specified

>>> df.loc[df['shield'] > 6, ['max_speed']]
    max_speed
   sidewinder 7

Callable that returns a boolean Series
Setting values

Set value for all items matching the list of labels

```python
>>> df.loc[[lambda df: df['shield'] == 8]
max_speed  shield
sidewinder 7 8
```

Set value for an entire row

```python
>>> df.loc['cobra'] = 10
>>> df
max_speed  shield
cobra 10 10
viper 4 50
sidewinder 7 50
```

Set value for an entire column

```python
>>> df.loc[:, 'max_speed'] = 30
>>> df
max_speed  shield
cobra 30 10
viper 30 50
sidewinder 30 50
```

Set value for rows matching callable condition

```python
>>> df.loc[df['shield'] > 35] = 0
>>> df
max_speed  shield
cobra 30 10
viper 0 0
sidewinder 0 0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
... index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
max_speed  shield
7 1 2
8 4 5
9 7 8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.
>>> df.loc[7:9]
  max_speed  shield
7     1      2
8     4      5
9     7      8

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
>>> tuples = [
... ('cobra', 'mark i'), ('cobra', 'mark ii'),
... ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
... ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
... [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
          max_speed  shield
    cobra mark i      12     2
         mark ii      0     4
    sidewinder mark i    10    20
               mark ii     1     4
        viper mark ii      7     1
              mark iii    16    36

Single label. Note this returns a DataFrame with a single index.

```python
>>> df.loc['cobra']
  max_speed  shield
mark i      12     2
mark ii      0     4
```  

Single index tuple. Note this returns a Series.

```python
>>> df.loc[('cobra', 'mark ii')]
max_speed   0
shield      4
Name: (cobra, mark ii), dtype: int64
```  

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```python
>>> df.loc['cobra', 'mark i']
  max_speed  shield
mark i      12     2
```

Single tuple. Note using ```[]``` returns a DataFrame.

```python
>>> df.loc[['cobra', 'mark ii']]
          max_speed  shield
    cobra, mark ii      0     4
```  

Single tuple for the index with a single label for the column
>>> df.loc[('cobra', 'mark i'), 'shield']
2
Slice from index tuple to single label

```python
>>> df.loc[('cobra', 'mark i'):'viper']
```

<table>
<thead>
<tr>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td>mark i</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
</tr>
<tr>
<td>sidewinder</td>
<td>mark i</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
</tr>
<tr>
<td>viper</td>
<td>mark i</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
</tr>
</tbody>
</table>

Slice from index tuple to index tuple

```python
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
```

<table>
<thead>
<tr>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td>mark i</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
</tr>
<tr>
<td>sidewinder</td>
<td>mark i</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
</tr>
<tr>
<td>viper</td>
<td>mark i</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
</tr>
</tbody>
</table>

**pandas.Series.nbytes**

Series.nbytes

return the number of bytes in the underlying data

**pandas.Series.ndim**

Series.ndim

return the number of dimensions of the underlying data, by definition 1

**pandas.Series.shape**

Series.shape

return a tuple of the shape of the underlying data

**pandas.Series.size**

Series.size

return the number of elements in the underlying data

**pandas.Series.strides**

Series.strides

return the strides of the underlying data
pandas.Series.values

Series.values
Return Series as ndarray or ndarray-like depending on the dtype

Returns
arr [numpy.ndarray or ndarray-like]

Examples

```python
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])

>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)

>>> pd.Series(list('aabc')).astype('category').values
[a, a, b, c]
Categories (3, object): [a, b, c]
```

Timezone aware datetime data is converted to UTC:

```python
>>> pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
      '2013-01-02T05:00:00.000000000',
      '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>add(other[, level, fill_value, axis])</td>
<td>Addition of series and other, element-wise (binary operator add).</td>

<td>Cast a pandas object to a specified dtype dtype.</td>
</tr>
<tr>
<td><code>at_time(time[, asof])</code></td>
<td>Select values at particular time of day (e.g. 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>autocorr(lag)</code></td>
<td>Lag-N autocorrelation</td>
</tr>
<tr>
<td><code>between(left, right[, inclusive])</code></td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td><code>between_time(start_time, end_time[, ...])</code></td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>bfill([axis, inplace, limit, downcast])</code></td>
<td>Synonym for DataFrame.fillna(method='bfill')</td>
</tr>
<tr>
<td><code>bool()</code></td>
<td>Return the bool of a single element PandasObject.</td>
</tr>
<tr>
<td><code>cat</code></td>
<td>alias of pandas.core.arrays.categorical.CategoricalAccessor</td>
</tr>
<tr>
<td><code>clip([lower, upper, axis, inplace])</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>clip_lower(threshold[, axis, inplace])</code></td>
<td>Return copy of the input with values below a threshold truncated.</td>
</tr>
<tr>
<td><code>clip_upper(threshold[, axis, inplace])</code></td>
<td>Return copy of input with values above given value(s) truncated.</td>
</tr>
<tr>
<td><code>combine(other, func[, fill_value])</code></td>
<td>Perform elementwise binary operation on two Series using given function with optional fill value when an index is missing from one Series or the other</td>
</tr>
<tr>
<td><code>combine_first(other)</code></td>
<td>Combine Series values, choosing the calling Series’s values first.</td>
</tr>
<tr>
<td><code>compound([axis, skipna, level])</code></td>
<td>Return the compound percentage of the values for the requested axis</td>
</tr>
<tr>
<td><code>compress(condition, *args, **kwargs)</code></td>
<td>Return selected slices of an array along given axis as a Series</td>

### pandas.Series.abs

**Series.abs()**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns abs**

Series/DataFrame containing the absolute value of each element.

**See also:**

`numpy.absolute` calculate the absolute value element-wise.

**Notes**

For complex inputs, \(1.2 + 1j\), the absolute value is \(\sqrt{a^2 + b^2}\).  

**Examples**

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0   1.10
1   2.00
2   3.33
3   4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.
pandas: powerful Python data analysis toolkit, Release 0.23.3

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
```

**pandas.Series.add**

Series.add(other, level=None, fill_value=None, axis=0)

Addition of series and other, element-wise (binary operator add).

Equivalent to `series + other`, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** : None or float value, default None (NaN)
  
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- **result** [Series]
See also:

`Series.radd`

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

`pandas.Series.add_prefix`

`Series.add_prefix(prefix)`

Prefix labels with string `prefix`.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

- **Parameters**
  - `prefix` : str
    
    The string to add before each label.

- **Returns**
  - `Series` or `DataFrame`
    
    New Series or DataFrame with updated labels.

See also:

`Series.add_suffix` Suffix row labels with string `suffix`.

`DataFrame.add_suffix` Suffix column labels with string `suffix`.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0 1
1 2
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
2  3
3  4
dtype: int64
```

```python
>>> s.add_prefix('item_')
item_0  1
item_1  2
item_2  3
item_3  4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df

A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```python
>>> df.add_prefix('col_')

col_A  col_B
0   1   3
1   2   4
2   3   5
3   4   6
```

**pandas.Series.add_suffix**

**Series.add_suffix(suffix)**

Suffix labels with string `suffix`.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**

- `suffix`: str

  The string to add after each label.

**Returns**

Series or DataFrame

New Series or DataFrame with updated labels.

**See also:**

- Series.add_prefix  Prefix row labels with string `prefix`.
- DataFrame.add_prefix Prefix column labels with string `prefix`.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0  1
1  2
2  3
```

(continues on next page)
3  4
dtype: int64

```python
>>> s.add_suffix('_item')
0_item 1
1_item 2
2_item 3
3_item 4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```python
>>> df.add_suffix('_col')
   A_col  B_col
0     1     3
1     2     4
2     3     5
3     4     6
```

### pandas.Series.agg

`Series.agg(func, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

**Parameters**

- `func`: function, string, dictionary, or list of string/functions
  - Function to use for aggregating the data. If a function, must either work when passed a `Series` or when passed to `Series.apply`. For a `DataFrame`, can pass a dict, if the keys are `DataFrame` column names.
  - Accepted combinations are:
    - string function name.
    - function.
    - list of functions.
    - dict of column names -> functions (or list of functions).

- `axis`: {0 or 'index'}
  - Parameter needed for compatibility with `DataFrame`.

- `*args`: Positional arguments to pass to `func`.

- `**kwargs`: Keyword arguments to pass to `func`.
Returns

aggregated [Series]

See also:

pandas.Series.apply, pandas.Series.transform

Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = Series(np.random.randn(10))
>>> s.agg('min')
-1.301805
>>> s.agg(['min', 'max'])
min  -1.301805
max   1.127688
dtype: float64
```

pandas.Series.aggregate

Series.aggregate (func, axis=0, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters func : function, string, dictionary, or list of string/functions

Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply. For a DataFrame, can pass a dict, if the keys are DataFrame column names.

Accepted combinations are:

• string function name.
• function.
• list of functions.
• dict of column names -> functions (or list of functions).

axis : {0 or ‘index’}

Parameter needed for compatibility with DataFrame.

*args

Positional arguments to pass to func.

**kwargs
Keyword arguments to pass to `func`.

**Returns**

aggregated [Series]

See also:

`pandas.Series.apply`, `pandas.Series.transform`

**Notes**

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```python
>>> s = Series(np.random.randn(10))

>>> s.agg('min')
-1.301805

>>> s.agg(['min', 'max'])
min  -1.301805
max  1.127688
dtype: float64
```

**pandas.Series.align**

Series.align (other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)

Align two objects on their axes with the specified join method for each axis Index

**Parameters**

- other [DataFrame or Series]
- join [‘outer’, ‘inner’, ‘left’, ‘right’], default ‘outer’
- axis : allowed axis of the other object, default None
- level : int or level name, default None
- copy : boolean, default True
- fill_value : scalar, default np.NaN
- method : str, default None
- limit : None, fill_axis=0, broadcast_axis=0
- fill_axis : 0
- broadcast_axis : None

Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

Value to use for missing values. Defaults to NaN, but can be any “compatible” value

Method : [str, default None]
limit [int, default None]

fill_axis : {0 or ‘index’}, default 0
Filling axis, method and limit

broadcast_axis : {0 or ‘index’}, default None
Broadcast values along this axis, if aligning two objects of different dimensions

Returns (left, right) : (Series, type of other)
Aligned objects

pandas.Series.all

Series.all (axis=0, bool_only=None, skipna=True, level=None, **kwargs)
Return whether all elements are True, potentially over an axis.

Returns True if all elements within a series or along a Dataframe axis are non-zero, not-empty or not-False.

Parameters axis : {0 or ‘index’, 1 or ‘columns’, None}, default 0
Indicate which axis or axes should be reduced.
• 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

skipna : boolean, default True
Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

bool_only : boolean, default None
Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**kwargs : any, default None
Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

all [scalar or Series (if level specified)]

See also:

pandas.Series.all Return True if all elements are True
pandas.DataFrame.any Return True if one (or more) elements are True
Examples

Series

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
```

DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
col1  True
col2  False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0   True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

`pandas.Series.any`

Series.any(
`axis=0, bool_only=None, skipna=True, level=None, **kwargs`)  
Return whether any element is True over requested axis.

Unlike `DataFrame.all()`, this performs an or operation. If any of the values along the specified axis is True, this will return True.

**Parameters**

- **axis**: {0 or ‘index’, 1 or ‘columns’, None}, default 0
  - Indicate which axis or axes should be reduced.
    - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
    - 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
    - None : reduce all axes, return a scalar.

- **skipna**: boolean, default True
pandas: powerful Python data analysis toolkit, Release 0.23.3

Exclude NA/null values. If an entire row/column is NA, the result will be NA.
level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into
a scalar.
bool_only : boolean, default None
Include only boolean columns. If None, will attempt to use everything, then use only
boolean data. Not implemented for Series.
**kwargs : any, default None
Additional keywords have no effect but might be accepted for compatibility with
NumPy.
Returns
any [scalar or Series (if level specified)]
See also:
pandas.DataFrame.all Return whether all elements are True.
Examples
Series
For Series input, the output is a scalar indicating whether any element is True.
>>> pd.Series([True, False]).any()
True

DataFrame
Whether each column contains at least one True element (the default).
>>> df =
>>> df
A B
0 1 0
1 2 2

pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
C
0
0

>>> df.any()
A
True
B
True
C
False
dtype: bool

Aggregating over the columns.
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
A B
0
True 1
1 False 2

34.3. Series

1455


>>> df.any(axis='columns')
0 True  
1 True  
dtype: bool

>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})

>>> df
   A  B
0  True 1
1  False 0

>>> df.any(axis='columns')
0 True  
1 False 
dtype: bool

Aggregating over the entire DataFrame with axis=None.

>>> df.any(axis=None)
True

any for an empty DataFrame is an empty Series.

>>> pd.DataFrame([]).any()
Series([], dtype: bool)

pandas.Series.append

Series.append(to_append, ignore_index=False, verify_integrity=False)

Concatenate two or more Series.

Parameters

- to_append [Series or list/tuple of Series]
- ignore_index : boolean, default False
  If True, do not use the index labels.
  New in version 0.19.0.
- verify_integrity : boolean, default False
  If True, raise Exception on creating index with duplicates

Returns

appended [Series]

See also:

- pandas.concat General function to concatenate DataFrame, Series or Panel objects

Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.
Examples

```python
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
0    1
1    2  
2    3
0    4
1    5
2    6
dtype: int64

>>> s1.append(s3)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64

With `ignore_index` set to True:

```python
>>> s1.append(s2, ignore_index=True)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `verify_integrity` set to True:

```python
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```

**pandas.Series.apply**

`Series.apply(func, convert_dtype=True, args=(), **kwds)`

Invoke function on values of Series. Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

**Parameters**

- `func` [function]
- `convert_dtype` : boolean, default True
  - Try to find better dtype for elementwise function results. If False, leave as dtype=object
- `args` : tuple
  - Positional arguments to pass to function in addition to the value
Additional keyword arguments will be passed as keywords to the function.

Returns

y [Series or DataFrame if func returns a Series]

See also:

Series.map For element-wise operations
Series.agg only perform aggregating type operations
Series.transform only perform transforming type operations

Examples

Create a series with typical summer temperatures for each city.

```python
>>> import pandas as pd
>>> import numpy as np
>>> series = pd.Series([20, 21, 12], index=['London', 'New York', 'Helsinki'])
>>> series
London 20
New York 21
Helsinki 12
dtype: int64
```

Square the values by defining a function and passing it as an argument to apply().

```python
>>> def square(x):
...     return x**2
>>> series.apply(square)
London 400
New York 441
Helsinki 144
dtype: int64
```

Square the values by passing an anonymous function as an argument to apply().

```python
>>> series.apply(lambda x: x**2)
London 400
New York 441
Helsinki 144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the args keyword.

```python
>>> def subtract_custom_value(x, custom_value):
...     return x-custom_value
>>> series.apply(subtract_custom_value, args=(5,))
London 15
New York 16
Helsinki 7
dtype: int64
```
Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```python
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x+=kwargs[month]
...     return x

>>> series.apply(add_custom_values, june=30, july=20, august=25)
London 95
New York 96
Helsinki 87
dtype: int64
```

Use a function from the Numpy library.

```python
>>> series.apply(np.log)
London  2.995732
New York 3.044522
Helsinki 2.484907
dtype: float64
```

**pandas.Series.argmax**

Series.argmax(axis=0, skipna=True, *args, **kwargs)

Deprecated since version 0.21.0:

‘argmax’ is deprecated, use ‘idxmax’ instead. The behavior of ‘argmax’ will be corrected to return the positional maximum in the future. Use ‘series.values.argmax’ to get the position of the maximum now.

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

Parameters

- **skipna**: boolean, default True
  Exclude NA/null values. If the entire Series is NA, the result will be NA.
- **axis**: int, default 0
  For compatibility with DataFrame.idxmax. Redundant for application on Series.
- **args, **kwargs
  Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

- **idxmax**: [Index of maximum of values.]

Raises

- **ValueError**
  If the Series is empty.

See also:

- **numpy.argmax** Return indices of the maximum values along the given axis.
- **DataFrame.idxmax** Return index of first occurrence of maximum over requested axis.
- **Series.idxmin** Return index label of the first occurrence of minimum of values.
Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```python
>>> s = pd.Series(data=[1, None, 4, 3, 4],
        index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B      NaN
C    4.0
D    3.0
E    4.0
dtype: float64

>>> s.idxmax()
'C'
```

If `skipna` is False and there is an NA value in the data, the function returns `nan`.

```python
>>> s.idxmax(skipna=False)
nan
```

`pandas.Series.argmin`

`Series.argmin(axis=None, skipna=True, *args, **kwargs)`

Deprecated since version 0.21.0:

‘argmin’ is deprecated, use ‘idxmin’ instead. The behavior of ‘argmin’ will be corrected to return the positional minimum in the future. Use ‘series.values.argmin’ to get the position of the minimum now.

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

**Parameters**

- `skipna` : boolean, default True
  
  Exclude NA/null values. If the entire Series is NA, the result will be NA.

- `axis` : int, default 0
  
  For compatibility with DataFrame.idxmin. Redundant for application on Series.

- `*args, **kwargs`
  
  Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- `idxmin` [Index of minimum of values.]

**Raises**

- `ValueError`
  
  If the Series is empty.

See also:
numpy.argmin  Return indices of the minimum values along the given axis.

DataFrame.idxmin  Return index of first occurrence of minimum over requested axis.

Series.idxmax  Return index label of the first occurrence of maximum of values.

Notes

This method is the Series version of ndarray.argmin. This method returns the label of the minimum, while ndarray.argmin returns the position. To get the position, use series.values.argmin().

Examples

```python
>>> s = pd.Series(data=[1, None, 4, 1],
                 index=['A', 'B', 'C', 'D'])
>>> s
A 1.0
B NaN
C 4.0
D 1.0
dtype: float64

>>> s.idxmin()
'A'

If skipna is False and there is an NA value in the data, the function returns nan.

>>> s.idxmin(skipna=False)
nan
```

pandas.Series.argsort

Series.argsort (axis=0, kind='quicksort', order=None)

Overrides ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

Parameters

axis [int (can only be zero)]

kind : {'mergesort', 'quicksort', 'heapsort'}, default 'quicksort'

Choice of sorting algorithm. See np.sort for more information. ‘mergesort’ is the only stable algorithm

order [ignored]

Returns

argsorted [Series, with -1 indicated where nan values are present]

See also:

numpy.ndarray.argsort
pandas.Series.as_blocks

Series.as_blocks(copy=True)
Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.
Deprecation since version 0.21.0.

NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in as_matrix)

Parameters

- copy [boolean, default True]

Returns

- values [a dict of dtype -> Constructor Types]

pandas.Series.as_matrix

Series.as_matrix(columns=None)
Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use DataFrame.values() instead.

Parameters columns: list, optional, default: None
If None, return all columns, otherwise, returns specified columns.

Returns values: ndarray
If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

See also:
pandas.DataFrame.values

Notes

Return is NOT a Numpy-matrix, rather, a Numpy-array.
The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By numpy.find_common_type convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `.values`.

pandas.Series.asfreq

Series.asfreq(freq=None, method=None, how=None, normalize=False, fill_value=None)
Convert TimeSeries to specified frequency.
Optionally provide filling method to pad/backfill missing values.
Returns the original data conformed to a new index with the specified frequency. resample is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

**Parameters**

- **freq**: [DateOffset object, or string]
- **method**: {'backfill'/’bfill’, ‘pad’/’ffill’}, default None
  
  Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  
  - ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
  - ‘backfill’ / ‘bfill’: use NEXT valid observation to fill

- **how**: {'start', 'end'}, default end
  
  For PeriodIndex only, see PeriodIndex.asfreq

- **normalize**: bool, default False
  
  Whether to reset output index to midnight

- **fill_value**: scalar, optional
  
  Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

  New in version 0.20.0.

**Returns**

- **converted**: [type of caller]

See also:

- **reindex**

**Notes**

To learn more about the frequency strings, please see this link.

**Examples**

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
      s
2000-01-01 00:00:00  0.0
2000-01-01 00:01:00  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:03:00  3.0
```

Upsample the series into 30 second bins.
```python
>>> df.asfreq(freq='30S')
                 s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    NaN
2000-01-01 00:03:00    3.0
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
                 s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')
                s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

**pandas.Series.asof**

```
Series.asof( where, subset=None)
```

The last row without any NaN is taken (or the last row without NaN considering only the subset of columns in the case of a DataFrame)

New in version 0.19.0: For DataFrame

If there is no good value, NaN is returned for a Series a Series of NaN values for a DataFrame

**Parameters**

- `where` [date or array of dates]
- `subset` : string or list of strings, default None
  if not None use these columns for NaN propagation

**Returns**

- `where` is scalar
  - value or NaN if input is Series
  - Series if input is DataFrame

- `where` is Index: same shape object as input
See also:

merge_asof

Notes

Dates are assumed to be sorted Raises if this is not the case

pandas.Series.astype

Series.astype (dtype, copy=True, errors='raise', **kwargs)
Cast a pandas object to a specified dtype dtype.

Parameters
dtype : data type, or dict of column name -> data type
Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.
copy: bool, default True.
Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).
errors: {'raise', 'ignore'}, default 'raise'.
Control raising of exceptions on invalid data for provided dtype.
  • raise: allow exceptions to be raised
  • ignore: suppress exceptions. On error return original object
New in version 0.20.0.
raise_on_error: raise on invalid input
  Deprecated since version 0.20.0: Use errors instead

Returns

casted [type of caller]

See also:

pandas.to_datetime Convert argument to datetime.
pandas.to_timedelta Convert argument to timedelta.
pandas.to_numeric Convert argument to a numeric type.
numpy.ndarray.astype Cast a numpy array to a specified type.

Examples
Convert to categorical type:

```python
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> ser.astype('category', ordered=True, categories=[2, 1])
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1  # note that s1[0] has changed too
0    10
1    2
dtype: int64
```

**pandas.Series.at_time**

`Series.at_time(time, asof=False)`

Select values at particular time of day (e.g. 9:30AM).

- **Parameters**
  - `time` [datetime.time or string]

- **Returns**
  - `values_at_time` [type of caller]

- **Raises** `TypeError`

  If the index is not a `DatetimeIndex`

- **See also**:
  - `between_time` Select values between particular times of the day
  - `first` Select initial periods of time series based on a date offset
last  Select final periods of time series based on a date offset

**DatetimeIndex.indexer_at_time** Get just the index locations for values at particular time of the day

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
       A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4

>>> ts.at_time('12:00')
      A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

**pandas.Series.autocorr**

Series.autocorr(lag=1)

Lag-N autocorrelation

**Parameters**

- **lag**: int, default 1
  
  Number of lags to apply before performing autocorrelation.

**Returns**

- **autocorr**: float

**pandas.Series.between**

Series.between(left, right, inclusive=True)

Return boolean Series equivalent to left <= series <= right.

This function returns a boolean vector containing True wherever the corresponding Series element is between the boundary values left and right. NA values are treated as False.

**Parameters**

- **left**: scalar
  
  Left boundary.

- **right**: scalar
  
  Right boundary.

- **inclusive**: bool, default True
  
  Include boundaries.

**Returns**

- **Series**: Each element will be a boolean.
See also:

- **pandas.Series.gt** Greater than of series and other
- **pandas.Series.lt** Less than of series and other

Notes

This function is equivalent to \((\text{left} \leq \text{ser}) \& \& (\text{ser} \leq \text{right})\)

Examples

```python
>>> s = pd.Series([2, 0, 4, 8, np.nan])

Boundary values are included by default:
```
>>> s.between(1, 4)
0   True
1   False
2   True
3   False
4   False
dtype: bool
```

With `inclusive` set to `False` boundary values are excluded:
```
>>> s.between(1, 4, inclusive=False)
0   True
1   False
2   False
3   False
4   False
dtype: bool
```

`left` and `right` can be any scalar value:
```
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0   False
1   True
2   True
3   False
dtype: bool
```

**pandas.Series.between_time**

Series \(\text{between\_time}\) \((\text{start\_time}, \text{end\_time}, \text{include\_start}=\text{True, include\_end}=\text{True})\)

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are not between the two times.

Parameters

- **start_time** [datetime.time or string]
**end_time** [datetime.time or string]

**include_start** [boolean, default True]

**include_end** [boolean, default True]

**Returns**

values_between_time [type of caller]

**Raises** TypeError

If the index is not a *DatetimeIndex*

**See also:**

*at_time* Select values at a particular time of the day

*first* Select initial periods of time series based on a date offset

*last* Select final periods of time series based on a date offset

*DatetimeIndex.indexer_between_time* Get just the index locations for values between particular times of the day

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4

>>> ts.between_time('0:15', '0:45')
   A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
```

You get the times that are not between two times by setting `start_time` later than `end_time`:

```python
>>> ts.between_time('0:45', '0:15')
   A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4
```

**pandas.Series.bfill**

Series.bfill *(axis=None, inplace=False, limit=None, downcast=None)*

Synonym for *DataFrame.fillna(method='bfill')*

**pandas.Series.bool**

Series.bool()

Return the bool of a single element PandasObject.
This must be a boolean scalar value, either True or False. Raise a ValueError if the PandasObject does not have exactly 1 element, or that element is not boolean.

**pandas.Series.cat**

*Series.cat()*  
Accessor object for categorical properties of the Series values.  
Be aware that assigning to `categories` is a *inplace* operation, while all methods return new categorical data per default (but can be called with `inplace=True`).

**Parameters**

- **data** [Series or CategoricalIndex]

**Examples**

```python
>>> s.cat.categories
>>> s.cat.categories = list('abc')
>>> s.cat.rename_categories(list('cab'))
>>> s.cat.reorder_categories(list('cab'))
>>> s.cat.add_categories(['d','e'])
>>> s.cat.remove_categories(['d'])
>>> s.cat.remove_unused_categories()
>>> s.cat.set_categories(list('abcde'))
>>> s.cat.as_ordered()
>>> s.cat.as_unordered()
```

**pandas.Series.clip**

*Series.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)*  
Trim values at input threshold(s).  
Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- **lower** : float or array_like, default None  
  Minimum threshold value. All values below this threshold will be set to it.

- **upper** : float or array_like, default None  
  Maximum threshold value. All values above this threshold will be set to it.

- **axis** : int or string axis name, optional  
  Align object with lower and upper along the given axis.

- **inplace** : boolean, default False  
  Whether to perform the operation in place on the data.  
  New in version 0.21.0.

- ***args, **kwargs**
  Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns** *Series or DataFrame*
pandas: powerful Python data analysis toolkit, Release 0.23.3

Same type as calling object with the values outside the clip boundaries replaced

See also:

- **clip_lower** Clip values below specified threshold(s).
- **clip_upper** Clip values above specified threshold(s).

**Examples**

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
      col_0  col_1
0         9    -2
1        -3    -7
2         0     6
3        -1     8
4         5    -5

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
      col_0  col_1
0         6    -2
1        -3    -4
2         0     6
3        -1     6
4         5    -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64

>>> df.clip(t, t + 4, axis=0)
      col_0  col_1
0         6     2
1        -3    -4
2         0     3
3         6     8
4         5     3
```

**pandas.Series.clip_lower**

*Series.clip_lower*(threshold, axis=None, inplace=False)

Return copy of the input with values below a threshold truncated.

**Parameters**

- **threshold** : numeric or array-like
Minimum value allowed. All values below threshold will be set to this value.

- float: every value is compared to threshold.
- array-like: The shape of threshold should match the object it’s compared to. When self is a Series, threshold should be the length. When self is a DataFrame, threshold should 2-D and the same shape as self for axis=None, or 1-D and the same length as the axis being compared.

**axis**: {0 or ‘index’, 1 or ‘columns’}, default 0

Align self with threshold along the given axis.

**inplace**: boolean, default False

Whether to perform the operation in place on the data.

New in version 0.21.0.

**Returns**

- clipped [same type as input]

**See also:**

- Series.clip Return copy of input with values below and above thresholds truncated.
- Series.clip_upper Return copy of input with values above threshold truncated.

**Examples**

Series single threshold clipping:

```python
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip_lower(8)
0    8
1    8
2    8
3    8
4    9
dtype: int64
```

Series clipping element-wise using an array of thresholds. threshold should be the same length as the Series.

```python
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip_lower(elemwise_thresholds)
0    5
1    8
2    7
3    8
4    9
dtype: int64
```

DataFrames can be compared to a scalar.

```python
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
       A  B
0    1  2
```

(continues on next page)
Or to an array of values. By default, `threshold` should be the same shape as the DataFrame.

```python
>>> df.clip_lower(np.array([[3, 4], [2, 2], [6, 2]]))
  A  B
0  3  4
1  3  4
2  6  6
```

Control how `threshold` is broadcast with `axis`. In this case `threshold` should be the same length as the axis specified by `axis`.

```python
>>> df.clip_lower(np.array([3, 3, 5]), axis='index')
  A  B
0  3  3
1  3  4
2  5  6
```

```python
>>> df.clip_lower(np.array([4, 5]), axis='columns')
  A  B
0  4  5
1  4  5
2  5  6
```

### pandas.Series.clip_upper

**Series.clip_upper**  
*(threshold, axis=None, inplace=False)*  
Return copy of input with values above given value(s) truncated.

**Parameters**

- **threshold** [float or array_like]  
- **axis** : int or string axis name, optional  
  - Align object with threshold along the given axis.  
- **inplace** : boolean, default False  
  - Whether to perform the operation in place on the data  
  - New in version 0.21.0.

**Returns**

- **clipped** [same type as input]

**See also:**

- **clip**
pandas.Series.combine

Series.combine(other, func, fill_value=nan)
Perform elementwise binary operation on two Series using given function with optional fill value when an index is missing from one Series or the other

Parameters

other [Series or scalar value]
func : function
Function that takes two scalars as inputs and return a scalar
fill_value [scalar value]

Returns

result [Series]

See also:

Series.combine_first Combine Series values, choosing the calling Series’s values first

Examples

```python
>>> s1 = Series([1, 2])
>>> s2 = Series([0, 3])
>>> s1.combine(s2, lambda x1, x2: x1 if x1 < x2 else x2)
0 0
1 2
dtype: int64
```

pandas.Series.combine_first

Series.combine_first(other)
Combine Series values, choosing the calling Series’s values first. Result index will be the union of the two indexes

Parameters

other [Series]

Returns

combined [Series]

See also:

Series.combine Perform elementwise operation on two Series using a given function

Examples
```python
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4])
>>> s1.combine_first(s2)
0   1.0
1   4.0
dtype: float64
```

### pandas.Series.compound

The `pandas.Series.compound()` method returns the compound percentage of the values for the requested axis.

**Parameters**

- **axis** ([index (0)])
- **skipna** : boolean, default True
  - Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  - If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar
- **numeric_only** : boolean, default None
  - Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **compounded** [scalar or Series (if level specified)]

### pandas.Series.compress

The `pandas.Series.compress()` method returns selected slices of an array along given axis as a Series.

**See also:**

- `numpy.ndarray.compress`

### pandas.Series.consolidate

The `pandas.Series.consolidate()` method computes NDFrame with “consolidated” internals (data of each dtype grouped together in a single ndarray).

**Deprecated since version 0.20.0**: Consolidate will be an internal implementation only.

### pandas.Series.convert_objects

The `pandas.Series.convert_objects()` method attempts to infer better dtype for object columns.

**Deprecated since version 0.21.0**
Parameters convert_dates : boolean, default True
If True, convert to date where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.

convert_numeric : boolean, default False
If True, attempt to coerce to numbers (including strings), with unconvertible values becoming NaN.

convert_timedeltas : boolean, default True
If True, convert to timedelta where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.

copy : boolean, default True
If True, return a copy even if no copy is necessary (e.g. no conversion was done). Note: This is meant for internal use, and should not be confused with inplace.

Returns
converted [same as input object]

See also:
pandas.to_datetime Convert argument to datetime.
pandas.to_timedelta Convert argument to timedelta.
pandas.to_numeric Return a fixed frequency timedelta index, with day as the default.

pandas.Series.copy

copy(deep=True)
Series copy
Make a copy of this object’s indices and data.

When deep=True (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When deep=False, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters deep : bool, default True
Make a deep copy, including a copy of the data and the indices. With deep=False, neither the indices nor the data are copied.

Returns copy : Series, DataFrame or Panel
Object type matches caller.

Notes
When deep=True, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to copy.deepcopy in the Standard Library, which recursively copies object data (see examples below).
While Index objects are copied when deep=True, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.

**Examples**

```python
g = pd.Series([1, 2], index=['a', 'b'])
g
a 1
b 2
dtype: int64

g_copy = g.copy()
g_copy
a 1
b 2
dtype: int64
```

**Shallow copy versus default (deep) copy:**

```python
g = pd.Series([1, 2], index=['a', 'b'])
depth = g.copy()
shallow = g.copy(deep=False)

shallow
a 1
b 2
dtype: int64
```

Shallow copy shares data and index with original.

```python
shallow is shallow
False
shallow.values is shallow.values and shallow.index is shallow.index
True
```

Deep copy has own copy of data and index.

```python
shallow is shallow
False
shallow.values is shallow.values or shallow.index is shallow.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
shallow[0] = 3
shallow[1] = 4
shallow
a 3
b 4
dtype: int64
```

```python
shallow
a 3
b 4
dtype: int64
```

```python
depth
a 1
b 2
dtype: int64
```
Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0  [10, 2]
1  [3, 4]
dtype: object
>>> deep
0  [10, 2]
1  [3, 4]
dtype: object
```

**pandas.Series.corr**

```
Series.corr (other, method='pearson', min_periods=None)
```

Compute correlation with other Series, excluding missing values

**Parameters**

- **other** [Series]
- **method** : {'pearson', 'kendall', 'spearman'}
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
- **min_periods** : int, optional
  Minimum number of observations needed to have a valid result

**Returns**

- **correlation** [float]

**pandas.Series.count**

```
Series.count (level=None)
```

Return number of non-NA/null observations in the Series

**Parameters**

- **level** : int or level name, default None
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series

**Returns**

- **nobs** [int or Series (if level specified)]

**pandas.Series.cov**

```
Series.cov (other, min_periods=None)
```

Compute covariance with Series, excluding missing values
Parameters

other [Series]

min_periods : int, optional
    Minimum number of observations needed to have a valid result

Returns

covariance [float]
    Normalized by N-1 (unbiased estimator).

pandas.Series.cummax

Series.cummax(*args, **kwargs)
    Return cumulative maximum over a DataFrame or Series axis.

    Returns a DataFrame or Series of the same size containing the cumulative maximum.

    Parameters

    axis : {0 or ‘index’, 1 or ‘columns’}, default 0
        The index or the name of the axis. 0 is equivalent to None or ‘index’.

    skipna : boolean, default True
        Exclude NA/null values. If an entire row/column is NA, the result will be NA.

    *args, **kwargs :
        Additional keywords have no effect but might be accepted for compatibility with NumPy.

    Returns

cummax [scalar or Series]

See also:

pandas.core.window.Expanding.max Similar functionality but ignores NaN values.

Series.max Return the maximum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0   2.0
1   NaN
2   5.0
3  -1.0
4
```

(continues on next page)
By default, NA values are ignored.

```python
>>> s.cummax()
0  2.0
1  NaN
2  5.0
3  5.0
4  5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummax(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummax()
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```python
>>> df.cummax(axis=1)
   A  B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```
pandas.Series.cummin

Series.cummin(axis=None, skipna=True, *args, **kwargs)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis : {0 or ‘index’, 1 or ‘columns’}, default 0
The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna : boolean, default True
Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs :
Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

cummin [scalar or Series]

See also:

pandas.core.window.Expanding.min  Similar functionality but ignores NaN values.
Series.min Return the minimum over Series axis.
Series.cummax Return cumulative maximum over Series axis.
Series.cummin Return cumulative minimum over Series axis.
Series.cumsum Return cumulative sum over Series axis.
Series.cumprod Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0  2.0
1  NaN
2  2.0
3 -1.0
4 -1.0
dtype: float64
```

To include NA values in the operation, use skipna=False
>>> s.cummin(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
                     ... [3.0, np.nan],
                     ... [1.0, 0.0]],
                     columns=list('AB'))
>>> df
   A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

By default, iterates over rows and finds the minimum in each column. This is equivalent to axis=None or axis='index'.

>>> df.cummin()
   A   B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0

To iterate over columns and find the minimum in each row, use axis=1

>>> df.cummin(axis=1)
   A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

pandas.Series.cumprod

Series.cumprod(axis=None, skipna=True, *args, **kwargs)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters axis : {0 or ‘index’, 1 or ‘columns’}, default 0

The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna : boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs :

Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns
cumprod [scalar or Series]

See also:

pandas.core.window.Expanding.prod  Similar functionality but ignores NaN values.
Series.prod  Return the product over Series axis.
Series.cummax  Return cumulative maximum over Series axis.
Series.cummin  Return cumulative minimum over Series axis.
Series.cumsum  Return cumulative sum over Series axis.
Series.cumprod  Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
0  2.0
1  NaN
2  10.0
3 -10.0
4  -0.0
dtype: float64
```

To include NA values in the operation, use skipna=False

```python
>>> s.cumprod(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A   B
0  2.0  1.0
```
1 3.0 NaN
2 1.0 0.0

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
df.cumprod()
```

A B
0 2.0 1.0
1 6.0 NaN
2 6.0 0.0

To iterate over columns and find the product in each row, use `axis=1`

```python
df.cumprod(axis=1)
```

A B
0 2.0 2.0
1 3.0 NaN
2 1.0 0.0

**pandas.Series.cumsum**

Series.cumsum (axis=None, skipna=True, *args, **kwargs)  
Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

**Parameters**  
axis : {0 or ‘index’, 1 or ‘columns’}, default 0  
The index or the name of the axis. 0 is equivalent to None or ‘index’.  
skipna : boolean, default True  
Exclude NA/null values. If an entire row/column is NA, the result will be NA.  
*args, **kwargs :  
Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**  
cumsum [scalar or Series]

**See also:**  
pandas.core.window.Expanding.sum  
Similar functionality but ignores NaN values.  
Series.sum  
Return the sum over Series axis.  
Series.cummax  
Return cumulative maximum over Series axis.  
Series.cummin  
Return cumulative minimum over Series axis.  
Series.cumsum  
Return cumulative sum over Series axis.  
Series.cumprod  
Return cumulative product over Series axis.
Examples

Series

>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2    5.0
3   -1.0
4    0.0
dtype: float64

By default, NA values are ignored.

>>> s.cumsum()
0    2.0
1   NaN
2    7.0
3    6.0
4    6.0
dtype: float64

To include NA values in the operation, use `skipna=False`

>>> s.cumsum(skipna=False)
0    2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0   NaN
2  1.0  0.0

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

>>> df.cumsum()
   A    B
0  2.0  1.0
1  5.0   NaN
2  6.0  1.0

To iterate over columns and find the sum in each row, use `axis=1`
>>> df.cumsum(axis=1)
   A  B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0

pandas.Series.describe

Series.describe(percentiles=None, include=None, exclude=None)
Generates descriptive statistics that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles : list-like of numbers, optional
The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include : ‘all’, list-like of dtypes or None (default), optional
A white list of data types to include in the result. Ignored for Series. Here are the options:

- ‘all’ : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

exclude : list-like of dtypes or None (default), optional,
A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.

Returns

summary: Series/DataFrame of summary statistics

See also:

Dataframe.count, Dataframe.max, Dataframe.min, Dataframe.mean, Dataframe.std, Dataframe.select_dtypes
Notes

For numeric data, the result’s index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value’s frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count    4
unique   3
top      a
freq     2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count    3
unique   2
top 2010-01-01 00:00:00
```

(continues on next page)
Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({
    'object': ['a', 'b', 'c'],
    'numeric': [1, 2, 3],
    'categorical': pd.Categorical(['d', 'e', 'f'])
})
```

```python
>>> df.describe()
```

```
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
```

```
categorical numeric object
count 3 3.0 3
unique 3 NaN 3
top f NaN c
freq 1 NaN 1
mean NaN 2.0 NaN
std NaN 1.0 NaN
min NaN 1.0 NaN
25% NaN 1.5 NaN
50% NaN 2.0 NaN
75% NaN 2.5 NaN
max NaN 3.0 NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
```

```
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
```

```
count 3.0
```
Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[np.object])
```
```
<table>
<thead>
<tr>
<th></th>
<th>count</th>
<th>unique</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>3</td>
<td>3</td>
<td>c</td>
</tr>
</tbody>
</table>

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
```
```
<table>
<thead>
<tr>
<th></th>
<th>count</th>
<th>unique</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>3</td>
<td>3</td>
<td>f</td>
</tr>
</tbody>
</table>
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
```
```
<table>
<thead>
<tr>
<th></th>
<th>count</th>
<th>unique</th>
<th>top</th>
<th>freq</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>3</td>
<td>3</td>
<td>f</td>
<td>1</td>
</tr>
</tbody>
</table>
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.object])
```
```
<table>
<thead>
<tr>
<th></th>
<th>count</th>
<th>unique</th>
<th>top</th>
<th>freq</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>3</td>
<td>3</td>
<td>f</td>
<td>1</td>
</tr>
</tbody>
</table>
```

### pandas.Series.diff

**Series.diff(periods=1)**

First discrete difference of element.
Calculates the difference of a Series element compared with another element in the Series (default is
element in previous row).

**Parameters**

- **periods**: int, default 1
  
  Periods to shift for calculating difference, accepts negative values.

**Returns**

- **diffed**: [Series]

**See also:**

- `Series.pct_change` Percent change over given number of periods.
- `Series.shift` Shift index by desired number of periods with an optional time freq.
- `DataFrame.diff` First discrete difference of object

**Examples**

**Difference with previous row**

```python
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0   NaN
1   0.0
2   1.0
3   1.0
4   2.0
5   3.0
dtype: float64
```

**Difference with 3rd previous row**

```python
>>> s.diff(periods=3)
0   NaN
1   NaN
2   NaN
3   2.0
4   4.0
5   6.0
dtype: float64
```

**Difference with following row**

```python
>>> s.diff(periods=-1)
0   0.0
1  -1.0
2  -1.0
3  -2.0
4  -3.0
5   NaN
dtype: float64
```
**pandas.Series.div**

Series.div(other, level=None, fill_value=None, axis=0)

Floating division of series and other, element-wise (binary operator `truediv`).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** : None or float value, default None (NaN)
  
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- **result** [Series]

**See also:**

`Series.rtruediv`

**Examples**

```python
gap> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
gap> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
```

```python
gap> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
gap> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
```

```python
gap> a.add(b, fill_value=0)
a  2.0
b  1.0
c  1.0
d  1.0
e  NaN
dtype: float64
```

**pandas.Series.divide**

Series.divide(other, level=None, fill_value=None, axis=0)

Floating division of series and other, element-wise (binary operator `truediv`).
Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` : None or float value, default None (NaN)
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- `level` : int or name
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- `result` [Series]

**See also:**

`Series.rtruediv`

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0  
b 1.0  
c 1.0  
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
  
c 1.0
d 1.0
e NaN
dtype: float64
```

**Series.divmod**

Series.divmod `other`, `level=None`, `fill_value=None`, `axis=0`

Integer division and modulo of series and other, element-wise (binary operator `divmod`).

Equivalent to `series divmod other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**
other [Series or scalar value]

fill_value : None or float value, default None (NaN)

Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]

See also:

Series.None

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d     NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b     NaN
d    1.0
e     NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e     NaN
dtype: float64
```

pandas.Series.dot

Series.dot(other)

Matrix multiplication with DataFrame or inner-product with Series objects. Can also be called using self @ other in Python >= 3.5.

Parameters

other [Series or DataFrame]

Returns

dot_product [scalar or Series]
pandas.Series.drop

Series.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

**Parameters**

- **labels**: single label or list-like
  - Index labels to drop.
- **axis**: 0, default 0
  - Redundant for application on Series.
- **index, columns**: None
  - Redundant for application on Series, but index can be used instead of labels.
  - New in version 0.21.0.
- **level**: int or level name, optional
  - For MultiIndex, level for which the labels will be removed.
- **inplace**: bool, default False
  - If True, do operation inplace and return None.
- **errors**: {'ignore', 'raise'}, default 'raise'
  - If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

dropped [pandas.Series]

**Raises**

- KeyError
  - If none of the labels are found in the index.

**See also:**

- Series.reindex Return only specified index labels of Series.
- Series.dropna Return series without null values.
- Series.drop_duplicates Return Series with duplicate values removed.
- DataFrame.drop Drop specified labels from rows or columns.

**Examples**

```python
>>> s = pd.Series(data=np.arange(3), index=['A','B','C'])
>>> s
A 0
B 1
C 2
dtype: int64
```

Drop labels B and C
>>> s.drop(labels=['B', 'C'])
A 0
dtype: int64

Drop 2nd level label in MultiIndex Series

>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
... ['speed', 'weight', 'length']],
... labels=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
... [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
... index=midx)
>>> s
lama speed 45.0
    weight 200.0
    length 1.2
cow speed 30.0
    weight 250.0
    length 1.5
falcon speed 320.0
    weight 1.0
    length 0.3
dtype: float64

>>> s.drop(labels='weight', level=1)
lama speed 45.0
    length 1.2
cow speed 30.0
    length 1.5
falcon speed 320.0
    length 0.3
dtype: float64

pandas.Series.drop_duplicates

Series.drop_duplicates (keep='first', inplace=False)
Return Series with duplicate values removed.

Parameters
keep: {'first', 'last', False}, default 'first'
  • 'first': Drop duplicates except for the first occurrence.
  • 'last': Drop duplicates except for the last occurrence.
  • False: Drop all duplicates.
inplace: boolean, default False
  If True, performs operation inplace and returns None.

Returns
deduplicated [Series]

See also:
Index.drop_duplicates equivalent method on Index
DataFrame.drop_duplicates equivalent method on DataFrame
**Series.duplicated** related method on Series, indicating duplicate Series values.

**Examples**

Generate an Series with duplicated entries.

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
                   name='animal')
```

```python
>>> s
0  lama
1  cow
2  lama
3  beetle
4  lama
5  hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```python
>>> s.drop_duplicates()
0  lama
1  cow
3  beetle
5  hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.

```python
>>> s.drop_duplicates(keep='last')
1  cow
3  beetle
4  lama
5  hippo
Name: animal, dtype: object
```

The value False for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to True performs the operation inplace and returns None.

```python
>>> s.drop_duplicates(keep=False, inplace=True)
```

```python
>>> s
1  cow
3  beetle
5  hippo
Name: animal, dtype: object
```

**pandas.Series.dropna**

Series.dropna (axis=0, inplace=False, **kwargs)

Return a new Series with missing values removed.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters axis : {0 or ‘index’}, default 0

There is only one axis to drop values from.
inplace : bool, default False
If True, do operation inplace and return None.

**kwargs
Not in use.

Returns Series
Series with NA entries dropped from it.

See also:

* Series.isna Indicate missing values.
* Series.notna Indicate existing (non-missing) values.
* Series.fillna Replace missing values.
* DataFrame.dropna Drop rows or columns which contain NA values.
* Index.dropna Drop missing indices.

Examples

```python
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0  1.0
1   2.0
2  NaN
dtype: float64

Drop NA values from a Series.
```
```python
>>> ser.dropna()
0  1.0
1  2.0
dtype: float64
```

Keep the Series with valid entries in the same variable.

```python
>>> ser.dropna(inplace=True)
>>> ser
0  1.0
1  2.0
dtype: float64
```

Empty strings are not considered NA values. None is considered an NA value.

```python
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0  NaN
1   2
2  NaT
3  None
4  I stay
dtype: object
```

(continues on next page)
Ser.dropna()

1  2
3
5  I stay
dtype: object

pandas.Series.dt

Series.dt()

Accessor object for datetimelike properties of the Series values.

Examples

```python
>>> s.dt.hour
>>> s.dt.second
>>> s.dt.quarter
```

Returns a Series indexed like the original Series. Raises TypeError if the Series does not contain datetimelike values.

pandas.Series.duplicated

Series.duplicated(keep='first')

Indicate duplicate Series values.

Duplicated values are indicated as True values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

Parameters keep : {‘first’, ‘last’, False}, default ‘first’

- ‘first’ : Mark duplicates as True except for the first occurrence.
- ‘last’ : Mark duplicates as True except for the last occurrence.
- False : Mark all duplicates as True.

Returns

pandas.core.series.Series

See also:

pandas.Index.duplicated Equivalent method on pandas.Index
pandas.DataFrame.duplicated Equivalent method on pandas.DataFrame
pandas.Series.drop_duplicates Remove duplicate values from Series

Examples

By default, for each set of duplicated values, the first occurrence is set on False and all others on True:
Animal lama, cow, lama, beetle, lama

Duplicated:
0 False
1 False
2 True
3 False
4 True
dtype: bool

which is equivalent to

animals.duplicated(keep='first')
0 False
1 False
2 True
3 False
4 True
dtype: bool

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

animals.duplicated(keep='last')
0 True
1 False
2 True
3 False
4 False
dtype: bool

By setting keep on False, all duplicates are True:

animals.duplicated(keep=False)
0 True
1 False
2 True
3 False
4 True
dtype: bool

**pandas.Series.eq**

Series.eq(other, level=None, fill_value=None, axis=0)

Equal to of series and other, element-wise (binary operator eq).

Equivalent to series == other, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value**: None or float value, default None (NaN)

    Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]

See also:

Series.None

Examples

```python
g = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
g
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
g = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
g
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
g.add(b, fill_value=0)
ga 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

pandas.Series.equals

Series.equals(other)

Determines if two NDFrame objects contain the same elements. NaNs in the same location are considered equal.

pandas.Series.ewm

Series.ewm(com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0)

Provides exponential weighted functions

New in version 0.18.0.

Parameters

- com : float, optional
  Specify decay in terms of center of mass, \( \alpha = 1/(1 + com) \), for \( com \geq 0 \)
- span : float, optional
  Specify decay in terms of span, \( \alpha = 2/(span + 1) \), for \( span \geq 1 \)
- halflife : float, optional
Specify decay in terms of half-life, $\alpha = 1 - \exp(\log(0.5)/\text{halflife})$, for halflife > 0

**alpha**: float, optional

Specify smoothing factor $\alpha$ directly, $0 < \alpha \leq 1$

New in version 0.18.0.

**min_periods**: int, default 0

Minimum number of observations in window required to have a value (otherwise result is NA).

**adjust**: boolean, default True

Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average)

**ignore_na**: boolean, default False

Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior

**Returns**

a Window sub-classed for the particular operation

See also:

**rolling** Provides rolling window calculations

**expanding** Provides expanding transformations.

**Notes**

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When adjust is True (default), weighted averages are calculated using weights $(1-\alpha)^{(n-1)}$, $(1-\alpha)^{(n-2)}$, $\ldots$, $1-\alpha$, 1.

When adjust is False, weighted averages are calculated recursively as:

```
weighted_average[0] = arg[0];
weighted_average[i] = (1-\alpha)*weighted_average[i-1] + \alpha*arg[i].
```

When ignore_na is False (default), weights are based on absolute positions. For example, the weights of $x$ and $y$ used in calculating the final weighted average of $[x, None, y]$ are $(1-\alpha)^2$ and 1 (if adjust is True), and $(1-\alpha)^2$ and $\alpha$ (if adjust is False).

When ignore_na is True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of $x$ and $y$ used in calculating the final weighted average of $[x, None, y]$ are $1-\alpha$ and 1 (if adjust is True), and $1-\alpha$ and $\alpha$ (if adjust is False).

More details can be found at http://pandas.pydata.org/pandas-docs/stable/computation.html#exponentially-weighted-windows

**Examples**

34.3. Series

1501
```python
>>> df = DataFrame({'B': [0, 1, 2, np.nan, 4]})
   B
0  0
1  1
2  2
3  NaN
4  4

>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

**pandas.Series.expanding**

Series.expanding(min_periods=1, center=False, axis=0)
Provides expanding transformations.

New in version 0.18.0.

**Parameters**

- **min_periods**: int, default 1
  
  Minimum number of observations in window required to have a value (otherwise result is NA).

- **center**: boolean, default False
  
  Set the labels at the center of the window.

- **axis**: [int or string, default 0]

**Returns**

a Window sub-classed for the particular operation

See also:

- **rolling** Provides rolling window calculations
- **ewm** Provides exponential weighted functions

**Notes**

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

**Examples**
>>> df = DataFrame({'B': [0, 1, 2, np.nan, 4]})
    B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.expanding(2).sum()
    B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0

**pandas.Series.factorize**

`Series.factorize(sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

- **Parameters**
  - `sort`: boolean, default False
    
    Sort `uniques` and shuffle `labels` to maintain the relationship.
  - `na_sentinel`: int, default -1
    
    Value to mark “not found”.

- **Returns**
  - `labels`: ndarray
    
    An integer ndarray that’s an indexer into `uniques`. `uniques.take(labels)` will have the same values as `values`.
  - `uniques`: ndarray, Index, or Categorical
    
    The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an `Index` is returned. Otherwise, a 1-D ndarray is returned.

**Note:** Even if there’s a missing value in `values`, `uniques` will not contain an entry for it.

- **See also:**
  
  - `pandas.cut` Discretize continuous-valued array.
  - `pandas.unique` Find the unique value in an array.

- **Examples**

  These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.
```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With sort=True, the uniques will be sorted, and labels will be shuffled so that the relationship is maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in labels with na_sentinel (−1 by default). Note that missing values are never included in uniques.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of uniques will differ. For Categoricals, a Categorical is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in uniques.categories, despite not being present in cat.values.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

### pandas.Series.ffill

Series.ffill(\texttt{axis=None, inplace=False, limit=None, downcast=None})

Synonym for DataFrame.fillna(method='ffill')
pandas.Series.fillna

**Series.fillna(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, **kwargs)**

Fill NA/NaN values using the specified method

**Parameters**

- **value** : scalar, dict, Series, or DataFrame
  Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). (values not in the dict/Series/DataFrame will not be filled). This value cannot be a list.

- **method** : {'backfill', 'bfill', 'pad', 'ffill', None}, default None
  Method to use for filling holes in reindexed Series
  pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

- **axis** : [0 or ‘index’]

- **inplace** : boolean, default False
  If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

- **limit** : int, default None
  If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast** : dict, default is None
  A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

**Returns**

- **filled** [Series]

See also:

- **interpolate** Fill NaN values using interpolation.
- **reindex, asfreq**

**Examples**

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                    columns=list('ABCD'))
>>> df
     A   B   C   D
0  NaN  2.0  NaN  0.0
1  NaN  3.0  NaN  1.0
```
Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
    A   B   C   D
0  0.0  2.0  0.0  0.0
1  3.0  4.0  0.0  1.0
2  0.0  0.0  0.0  5.0
3  0.0  3.0  0.0  4.0
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method='ffill')
    A   B   C   D
0  NaN  2.0  NaN  0.0
1  3.0  4.0  NaN  1.0
2  3.0  4.0  NaN  5.0
3  3.0  3.0  NaN  4.0
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}

>>> df.fillna(value=values)
    A   B   C   D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  2.0  1.0
2  0.0  1.0  2.0  5.0
3  0.0  3.0  2.0  4.0
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
    A   B   C   D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  NaN  1.0
2  NaN  1.0  NaN  5.0
3  NaN  3.0  NaN  4.0
```

**pandas.Series.filter**

`s.Series.filter(items=None, like=None, regex=None, axis=None)`

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items**: list-like
  
  List of info axis to restrict to (must not all be present)

- **like**: string
  
  Keep info axis where “arg in col == True”

- **regex**: string (regular expression)
Keep info axis with re.search(regex, col) == True

axis : int or string axis name

The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame

Returns

same type as input object

See also:

pandas.DataFrame.loc

Notes

The items, like, and regex parameters are enforced to be mutually exclusive. axis defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df
one  two  three
mouse 1  2  3
rabbit 4  5  6
```

```python
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
one  three
mouse 1  3
rabbit 4  6
```

```python
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
one  three
mouse 1  3
rabbit 4  6
```

```python
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
one  two  three
rabbit 4  5  6
```

pandas.Series.first

Series.first(offset)

Convenience method for subsetting initial periods of time series data based on a date offset.

Parameters

offset [string, DateOffset, dateutil.relativedelta]

Returns
subset [type of caller]

**Raises** `TypeError`

If the index is not a `DatetimeIndex`

See also:

- `last` Select final periods of time series based on a date offset
- `at_time` Select values at a particular time of the day
- `between_time` Select values between particular times of the day

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
       A
2018-04-09    1
2018-04-11    2
2018-04-13    3
2018-04-15    4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
       A
2018-04-09    1
2018-04-11    2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

**pandas.Series.first_valid_index**

`Series.first_valid_index()`

Return index for first non-NA/null value.

**Returns**

- `scalar` [type of index]

**Notes**

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

**pandas.Series.floordiv**

`Series.floordiv(other, level=None, fill_value=None, axis=0)`

Integer division of series and other, element-wise (binary operator `floordiv`).

Equivalent to `series // other`, but with support to substitute a `fill_value` for missing data in one of the inputs.
Parameters

- **other** [Series or scalar value]
- **fill_value** : None or float value, default None (NaN)
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
  Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

- **result** [Series]

See also:

- `Series.rfloordiv`

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64

>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e   NaN
dtype: float64
```

**pandas.Series.from_array**

- **classmethod Series.from_array**(arr, index=None, name=None, dtype=None, copy=False, fastpath=False)
  Construct Series from array.
  Deprecated since version 0.23.0: Use `pd.Series(..)` constructor instead.
pandas.Series.from_csv

**classmethod pandas.Series.from_csv**(path, sep=' ', parse_dates=True, header=None, index_col=0, encoding=None, infer_datetime_format=False)

Read CSV file.

Deprecated since version 0.21.0: Use `pandas.read_csv()` instead.

It is preferable to use the more powerful `pandas.read_csv()` for most general purposes, but `from_csv` makes for an easy roundtrip to and from a file (the exact counterpart of `to_csv`), especially with a time Series.

This method only differs from `pandas.read_csv()` in some defaults:

- `index_col` is 0 instead of `None` (take first column as index by default)
- `header` is `None` instead of 0 (the first row is not used as the column names)
- `parse_dates` is `True` instead of `False` (try parsing the index as datetime by default)

With `pandas.read_csv()`, the option `squeeze=True` can be used to return a Series like `from_csv`.

**Parameters**

- **path** [string file path or file handle / StringIO]
- **sep** : string, default `,'`
  - Field delimiter
- **parse_dates** : boolean, default True
  - Parse dates. Different default from `read_table`
- **header** : int, default `None`
  - Row to use as header (skip prior rows)
- **index_col** : int or sequence, default 0
  - Column to use for index. If a sequence is given, a MultiIndex is used. Different default from `read_table`
- **encoding** : string, optional
  - a string representing the encoding to use if the contents are non-ascii, for python versions prior to 3
- **infer_datetime_format** : boolean, default False
  - If True and `parse_dates` is True for a column, try to infer the datetime format based on the first datetime string. If the format can be inferred, there often will be a large parsing speed-up.

**Returns**

- **y** [Series]

**See also:**

`pandas.read_csv`
pandas.Series.ge

Series.ge(other, level=None, fill_value=None, axis=0)

Greater than or equal to of series and other, element-wise (binary operator ge).

Equivalent to series >= other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value : None or float value, default None (NaN)

Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]

See also:

Series.None

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
shape: (5,)
  a  b  c  d  e
0  2.0 1.0 1.0 1.0 NaN
dtype: float64
```

pandas.Series.get

Series.get(key, default=None)

Get item from object for given key (DataFrame column, Panel slice, etc.). Returns default value if not
found.

**Parameters**

- **key** [object]

**Returns**

- **value** [type of items contained in object]

---

**pandas.Series.get_dtype_counts**

`pandas.Series.get_dtype_counts()`

Return counts of unique dtypes in this object.

**Returns** `dtype` : Series

Series with the count of columns with each dtype.

**See also:**

- `dtypes` Return the dtypes in this object.

---

**Examples**

```python
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0    a    1   1.0
1    b    2   2.0
2    c    3   3.0

>>> df.get_dtype_counts()
float64  1
int64    1
object   1
dtype: int64
```

---

**pandas.Series.get_ftype_counts**

`pandas.Series.get_ftype_counts()`

Return counts of unique ftypes in this object.

**Deprecation**

Since version 0.23.0.

This is useful for SparseDataFrame or for DataFrames containing sparse arrays.

**Returns** `dtype` : Series

Series with the count of columns with each type and sparsity (dense/sparse)

**See also:**

- `ftypes` Return ftypes (indication of sparse/dense and dtype) in this object.
Examples

```python
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str int float
0   a   1   1.0
1   b   2   2.0
2   c   3   3.0
```

```python
>>> df.get_ftype_counts()
float64:dense 1
int64:dense 1
object:dense 1
dtype: int64
```

### pandas.Series.get_value

Series.get_value(label, takeable=False)

Quickly retrieve single value at passed index label

Deprecated since version 0.21.0: Please use .at[] or .iat[] accessors.

**Parameters**

- **label** [object]
- **takeable** [interpret the index as indexers, default False]

**Returns**

- **value** [scalar value]

### pandas.Series.get_values

Series.get_values()

same as values (but handles sparseness conversions); is a view

### pandas.Series.groupby

Series.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=False, observed=False, **kwargs)

Group series using mapper (dict or key function, apply given function to group, return result as series) or by a series of columns.

**Parameters** **by** : mapping, function, label, or list of labels

Used to determine the groups for the groupby. If `by` is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see .align() method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted a (single) key.

- **axis** [int, default 0]
level : int, level name, or sequence of such, default None

If the axis is a MultiIndex (hierarchical), group by a particular level or levels

as_index : boolean, default True

For aggregated output, return object with group labels as the index. Only relevant for
Dataframe input. as_index=False is effectively “SQL-style” grouped output

sort : boolean, default True

Sort group keys. Get better performance by turning this off. Note this does not influence
the order of observations within each group. groupby preserves the order of rows within
each group.

group_keys : boolean, default True

When calling apply, add group keys to index to identify pieces

squeeze : boolean, default False

reduce the dimensionality of the return type if possible, otherwise return a consistent
type

observed : boolean, default False

This only applies if any of the groupers are Categoricals If True: only show observed
values for categorical groupers. If False: show all values for categorical groupers.
New in version 0.23.0.

Returns

GroupBy object

See also:

resample Convenience method for frequency conversion and resampling of time series.

Notes

See the user guide for more.

Examples

DataFrame results

```python
>>> data.groupby(func, axis=0).mean()
>>> data.groupby(['col1', 'col2'])['col3'].mean()
```

DataFrame with hierarchical index

```python
>>> data.groupby(['col1', 'col2']).mean()
```

pandas.Series.gt

Series.gt (other, level=None, fill_value=None, axis=0)

Greater than of series and other, element-wise (binary operator gt).
Equivalent to \texttt{series > other}, but with support to substitute a \texttt{fill_value} for missing data in one of
the inputs.

**Parameters**

- \texttt{other} [Series or scalar value]

- \texttt{fill_value} : None or float value, default None (NaN)

  Fill existing missing (NaN) values, and any new element needed for successful Series
  alignment, with this value before computation. If data in both corresponding Series
  locations is missing the result will be missing

- \texttt{level} : int or name

  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- \texttt{result} [Series]

**See also:**

Series.None

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.add(b, fill_value=0)
a  2.0
b  1.0
c  1.0
d  1.0
e  NaN
dtype: float64
```

**pandas.Series.head**

Series.\texttt{head}(n=5)

Return the first \textit{n} rows.

This function returns the first \textit{n} rows for the object based on position. It is useful for quickly testing if your
object has the right type of data in it.

**Parameters** \texttt{n} : int, default 5
Number of rows to select.

Returns \texttt{obj\_head} : type of caller

The first $n$ rows of the caller object.

See also:

\texttt{pandas.DataFrame.tail} Returns the last $n$ rows.

Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
                     'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
animal
0 alligator
1  bee
2  falcon
3  lion
4  monkey
5  parrot
6  shark
7  whale
8  zebra

Viewing the first 5 lines

```python
>>> df.head()
animal
0 alligator
1  bee
2  falcon
3  lion
4  monkey

Viewing the first $n$ lines (three in this case)

```python
>>> df.head(3)
animal
0 alligator
1  bee
2  falcon
```

\texttt{pandas.Series.hist}

\texttt{Series.hist} \((by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, **kwds)\)

Draw histogram of the input series using matplotlib

Parameters \texttt{by} : object, optional

If passed, then used to form histograms for separate groups

\texttt{ax} : matplotlib axis object

If not passed, uses gca()
grid : boolean, default True
    Whether to show axis grid lines
xlabels : int, default None
    If specified changes the x-axis label size
xrot : float, default None
    rotation of x axis labels
ylabels : int, default None
    If specified changes the y-axis label size
yrot : float, default None
    rotation of y axis labels
figsize : tuple, default None
    figure size in inches by default
bins : integer or sequence, default 10
    Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
bins: integer, default 10
    Number of histogram bins to be used
**kwds** : keywords
    To be passed to the actual plotting function

See also:

matplotlib.axes.Axes.hist  Plot a histogram using matplotlib.

pandas.Series.idxmax

Series.idxmax (axis=0, skipna=True, *args, **kwargs)
    Return the row label of the maximum value.
    If multiple values equal the maximum, the first row label with that value is returned.

Parameters

skipna : boolean, default True
    Exclude NA/null values. If the entire Series is NA, the result will be NA.
axis : int, default 0
    For compatibility with DataFrame.idxmax. Redundant for application on Series.
*args, **kwargs
    Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

idxmax [Index of maximum of values.]

Raises

ValueError
If the Series is empty.

See also:

- `numpy.argmax` Return indices of the maximum values along the given axis.
- `DataFrame.idxmax` Return index of first occurrence of maximum over requested axis.
- `Series.idxmin` Return index label of the first occurrence of minimum of values.

Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```python
>>> s = pd.Series(data=[1, None, 4, 3, 4],
                 index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B     NaN
C    4.0
D    3.0
E    4.0
dtype: float64

>>> s.idxmax()
'C'

If `skipna` is False and there is an NA value in the data, the function returns `nan`.

```python
>>> s.idxmax(skipna=False)
nan
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

Raises ValueError

If the Series is empty.

See also:

numpy.argmin Return indices of the minimum values along the given axis.

DataFrame.idxmin Return index of first occurrence of minimum over requested axis.

Series.idxmax Return index label of the first occurrence of maximum of values.

Notes

This method is the Series version of ndarray.argmin. This method returns the label of the minimum, while ndarray.argmin returns the position. To get the position, use series.values.argmin().

Examples

```python
>>> s = pd.Series(data=[1, None, 4, 1],
                 index=['A', 'B', 'C', 'D'])

>>> s
A    1.0
B     NaN
C    4.0
D    1.0
dtype: float64

>>> s.idxmin()
'A'
```

If `skipna` is False and there is an NA value in the data, the function returns `nan`.

```python
>>> s.idxmin(skipna=False)
nan
```

**pandas.Series.infer_objects**

Series.infer_objects() Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

Returns

converted [same type as input object]

See also:

pandas.to_datetime Convert argument to datetime.

pandas.to_timedelta Convert argument to timedelta.

pandas.to_numeric Convert argument to numeric type
Examples

```python
>>> df = pd.DataFrame( { "A": ["a", 1, 2, 3] })
>>> df = df.iloc[1:]
>>> df
   A
0  1
1  2
2  3

>>> df.dtypes
A  object
dtype: object

>>> df.infer_objects().dtypes
A  int64
dtype: object
```

**pandas.Series.interpolate**

```
Series.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)
```

Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrames/Series with a MultiIndex.

**Parameters**

  - ‘linear’: ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes. default
  - ‘time’: interpolation works on daily and higher resolution data to interpolate given length of interval
  - ‘index’, ‘values’: use the actual numerical values of the index
  - ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘barycentric’, ‘polynomial’ is passed to `scipy.interpolate.interp1d`. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. `df.interpolate(method='polynomial', or- der=4)`. These use the actual numerical values of the index.
  - ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ are all wrappers around the scipy interpolation methods of similar names. These use the actual numerical values of the index. For more information on their behavior, see the scipy documentation and tutorial documentation
  - ‘from_derivatives’ refers to BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18

New in version 0.18.1: Added support for the ‘akima’ method Added interpolate method ‘from_derivatives’ which replaces ‘piecewise_polynomial’ in scipy 0.18; backwards-compatible with scipy < 0.18

- **axis**: {0, 1}, default 0

1520 Chapter 34. API Reference
• 0: fill column-by-column
• 1: fill row-by-row

**limit** : int, default None.

Maximum number of consecutive NaNs to fill. Must be greater than 0.

**limit_direction** : [{'forward', 'backward', 'both'}, default 'forward']

**limit_area** : {'inside', 'outside'}, default None

• None: (default) no fill restriction
• ‘inside’ Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’ Only fill NaNs outside valid values (extrapolate).

If limit is specified, consecutive NaNs will be filled in this direction.

New in version 0.21.0.

**inplace** : bool, default False

Update the NDFrame in place if possible.

**downcast** : optional, ‘infer’ or None, defaults to None

Downcast dtypes if possible.

**kwargs** [keyword arguments to pass on to the interpolating function.]

Returns

Series or DataFrame of same shape interpolated at the NaNs

See also:

*reindex, replace, fillna*

**Examples**

Filling in NaNs

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s.interpolate()
0   0
1   1
2   2
3   3
dtype: float64
```

**pandas.Series.isin**

Series.isin(*values*)

Check whether *values* are contained in Series.

Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of *values* exactly.

**Parameters** *values* : set or list-like
The sequence of values to test. Passing in a single string will raise a `TypeError`. Instead, turn a single string into a list of one element.

New in version 0.18.1: Support for values as a set.

**Returns**

`isin` [Series (bool dtype)]

**Raises** `TypeError`

- If `values` is a string

See also:

`pandas.DataFrame.isin` equivalent method on DataFrame

**Examples**

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0   True
1   True
2   True
3  False
4   True
5  False
Name: animal, dtype: bool
```

Passing a single string as `s.isin('lama')` will raise an error. Use a list of one element instead:

```python
>>> s.isin(['lama'])
0   True
1  False
2   True
3  False
4   True
5  False
Name: animal, dtype: bool
```

**pandas.Series.isna**

`Series.isna()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.Nan`, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns** `Series`

Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:
Series.isnull alias of isna
Series.notna boolean inverse of isna
Series.dropna omit axes labels with missing values
isna top-level isna

Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                          pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age  born             name    toy
0    5.0 NaT         Alfred     None
1    6.0 1939-05-27   Batman  Batmobile
2  NaN 1940-04-25       Joker
```

```python
>>> df.isna()
   age  born             name    toy
0  False   True         False   True
1  False  False         False  False
2   True  False         False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0     5.0
1     6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
1  False
2   True
dtype: bool
```

pandas.Series.isnull

Series.isnull()
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.nan, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns Series
Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

- **Series.isnull** alias of isna
- **Series.notna** boolean inverse of isna
- **Series.dropna** omit axes labels with missing values
- **isna** top-level isna

**Examples**

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.nan],
... 'born': [pd.NaT, pd.Timestamp('1939-05-27'),
... pd.Timestamp('1940-04-25')],
... 'name': ['Alfred', 'Batman', ''],
... 'toy': [None, 'Batmobile', 'Joker']})
```

```python
>>> df
   age    born         name  toy
0   5.0  NaT  Alfred  None
1   6.0 1939-05-27  Batman  Batmobile
2 nan 1940-04-25    Joker
```

```python
>>> df.isna()
    age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.nan])
```

```python
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
1  False
2   True
dtype: bool
```

**pandas.Series.item**

*Series.item()*

return the first element of the underlying data as a python scalar
pandas.Series.items

Series.items()
Lazily iterate over (index, value) tuples

pandas.Series.iteritems

Series.iteritems()
Lazily iterate over (index, value) tuples

pandas.Series.keys

Series.keys()
Alias for index

pandas.Series.kurt

Series.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwags)
Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1

Parameters
axis [{index (0)}]

skipna : boolean, default True
Exclude NA/null values when computing the result.

level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
kurt [scalar or Series (if level specified)]

pandas.Series.kurtosis

Series.kurtosis(axis=None, skipna=None, level=None, numeric_only=None, **kwags)
Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1

Parameters
axis [{index (0)}]

skipna : boolean, default True
Exclude NA/null values when computing the result.
level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

numeric_only : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

kurt [scalar or Series (if level specified)]

pandas.Series.last

Series.last(offset)

Convenience method for subsetting final periods of time series data based on a date offset.

Parameters

offset [string, DateOffset, dateutil.relativedelta]

Returns

subset [type of caller]

Raises TypeError

If the index is not a DatetimeIndex

See also:

first Select initial periods of time series based on a date offset

at_time Select values at a particular time of the day

between_time Select values between particular times of the day

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
     A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
   A
2018-04-13  3
2018-04-15  4

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

```
pandas.Series.last_valid_index

Series.last_valid_index()

Return index for last non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

pandas.Series.le

Series.le(other, level=None, fill_value=None, axis=0)

Less than or equal to of series and other, element-wise (binary operator le).

Equivalent to series <= other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value : None or float value, default None (NaN)

Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]

See also:

Series.None

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=["a", "b", "c", "d"])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=["a", "b", "d", "e"])
>>> b
a    1.0
b    NaN
d    1.0
```

(continues on next page)
a.add(b, fill_value=0)

a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64

**panda.Series.lt**

Series.lt (other, level=None, fill_value=None, axis=0)

Less than of series and other, element-wise (binary operator lt).

Equivalent to series < other, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
  - **fill_value** : None or float value, default None (NaN)
    - Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
  - **level** : int or name
    - Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- **result** [Series]

**See also:**

Series.None

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
```

(continues on next page)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64

**pandas.Series.mad**

**Series.mad**(axis=None, skipna=None, level=None)

Return the mean absolute deviation of the values for the requested axis.

**Parameters**

- **axis** [{index (0)}]
- **skipna** : boolean, default True
  - Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  - If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** : boolean, default None
  - Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **mad** [scalar or Series (if level specified)]

**pandas.Series.map**

**Series.map**(arg, na_action=None)

Map values of Series using input correspondence (a dict, Series, or function).

**Parameters**

- **arg** : function, dict, or Series
  - Mapping correspondence.
- **na_action** : {None, ‘ignore’}
  - If ‘ignore’, propagate NA values, without passing them to the mapping correspondence.

**Returns**

- **y** : Series
  - Same index as caller.

**See also:**

- **Series.apply** For applying more complex functions on a Series.
- **DataFrame.apply** Apply a function row-/column-wise.
- **DataFrame.applymap** Apply a function elementwise on a whole DataFrame.
Notes

When `arg` is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a `dict` subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN:

```
>>> from collections import Counter
>>> counter = Counter()
>>> counter['bar'] += 1
>>> y.map(counter)
1  0
2  1
3  0
dtype: int64
```

Examples

Map inputs to outputs (both of type `Series`):  
```
>>> x = pd.Series([1, 2, 3], index=['one', 'two', 'three'])
>>> x
one     1
two     2
three   3
dtype: int64

>>> y = pd.Series(['foo', 'bar', 'baz'], index=[1, 2, 3])
>>> y
1   foo
2   bar
3   baz

>>> x.map(y)
one   foo
two   bar
three baz
```

If `arg` is a dictionary, return a new Series with values converted according to the dictionary’s mapping:

```
>>> z = {1: 'A', 2: 'B', 3: 'C'}

>>> x.map(z)
one   A
two   B
three C
```

Use `na_action` to control whether NA values are affected by the mapping function.

```
>>> s = pd.Series([1, 2, 3, np.nan])

>>> s2 = s.map('this is a string {}'.format, na_action=None)
0  this is a string 1.0
1  this is a string 2.0
2  this is a string 3.0
```

(continues on next page)
```
3   this is a string nan
dtype: object
```

```python
>>> s3 = s.map('this is a string {}'.format, na_action='ignore')
0   this is a string 1.0
1   this is a string 2.0
2   this is a string 3.0
3    NaN
dtype: object
```

**pandas.Series.mask**

Series.mask (cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)

Return an object of same shape as self and whose corresponding entries are from self where `cond` is False and otherwise are from `other`.

**Parameters**

- **cond** : boolean NDFrame, array-like, or callable
  - Where `cond` is False, keep the original value. Where True, replace with corresponding value from `other`. If `cond` is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn’t check it).
  - New in version 0.18.1: A callable can be used as cond.

- **other** : scalar, NDFrame, or callable
  - Entries where `cond` is True are replaced with corresponding value from `other`. If other is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn’t check it).
  - New in version 0.18.1: A callable can be used as other.

- **inplace** : boolean, default False
  - Whether to perform the operation in place on the data

- **axis** [alignment axis if needed, default None]

- **level** [alignment level if needed, default None]

- **errors** : str, {'raise', 'ignore'}, default 'raise'
  - `raise`: allow exceptions to be raised
  - `ignore`: suppress exceptions. On error return original object
  - Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

- **try_cast** : boolean, default False
  - try to cast the result back to the input type (if possible),

- **raise_on_error** : boolean, default True
  - Whether to raise on invalid data types (e.g. trying to where on strings)
  - Deprecated since version 0.21.0.
Returns

   wh [same type as caller]

See also:

   DataFrame.where()

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is False the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the mask documentation in indexing.

Examples

>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0

>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN

>>> s.where(s > 1, 10)
0  10.0
1  10.0
2    2.0
3    3.0
4    4.0

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A   B
0  0  -1
1 -2   3
2 -4  -5
3  6  -7
4 -8   9

>>> df.where(m, -df) == np.where(m, df, -df)
   A   B
0  True True

(continues on next page)
pandas.Series.max

Series.max (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

This method returns the maximum of the values in the object. If you want the index of the maximum, use idxmax. This is the equivalent of the numpy.ndarray method argmax.

Parameters

axis [{index (0)}]

skipna : boolean, default True

Exclude NA/null values when computing the result.

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

numeric_only : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

max [scalar or Series (if level specified)]

pandas.Series.mean

Series.mean (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the mean of the values for the requested axis

Parameters

axis [{index (0)}]

skipna : boolean, default True

Exclude NA/null values when computing the result.

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- mean [scalar or Series (if level specified)]

### pandas.Series.median

**Series.median (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)**

Return the median of the values for the requested axis

**Parameters**

- axis [{index (0)}]
- skipna : boolean, default True
  
  Exclude NA/null values when computing the result.
- level : int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar
- numeric_only : boolean, default None
  
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- median [scalar or Series (if level specified)]

### pandas.Series.memory_usage

**Series.memory_usage (index=True, deep=False)**

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of object dtype.

**Parameters**

- index : bool, default True
  
  Specifies whether to include the memory usage of the Series index.
- deep : bool, default False
  
  If True, introspect the data deeply by interrogating object dtypes for system-level memory consumption, and include it in the returned value.

**Returns**

- int
  
  Bytes of memory consumed.

See also:

- `numpy.ndarray.nbytes` Total bytes consumed by the elements of the array.
- `DataFrame.memory_usage` Bytes consumed by a DataFrame.
Examples

```python
>>> s = pd.Series(range(3))
>>> s.memory_usage()
104
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```python
>>> s.memory_usage(index=False)
24
```

The memory footprint of object values is ignored by default:

```python
>>> s = pd.Series(['a', 'b'])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
96
>>> s.memory_usage(deep=True)
212
```

**pandas.Series.min**

Series.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

This method returns the minimum of the values in the object. If you want the index of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

**Parameters**

- **axis**: [index (0)]
- **skipna**: boolean, default True
  Exclude NA/null values when computing the result.
- **level**: int or level name, default None
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar
- **numeric_only**: boolean, default None
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **min**: [scalar or Series (if level specified)]

**pandas.Series.mod**

Series.mod(other, level=None, fill_value=None, axis=0)

Modulo of series and other, element-wise (binary operator mod).

Equivalent to series % other, but with support to substitute a fill_value for missing data in one of the inputs.
Parameters

other [Series or scalar value]

fill_value : None or float value, default None (NaN)

Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]

See also:

Series.rmod

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
>>> a.add(b, fill_value=0)
0    2.0
1    1.0
2    1.0
3   NaN
dtype: float64
```

pandas.Series.mode

Series.mode()

Return the mode(s) of the dataset.

Always returns Series even if only one value is returned.

Returns

Modes [Series (sorted)]
**pandas.Series.mul**

`Series.mul(other, level=None, fill_value=None, axis=0)`

Multiplication of series and other, element-wise (binary operator `mul`).

Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value`: None or float value, default None (NaN)
  
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- `level` : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- `result` [Series]

**See also:**

`Series.rmul`

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e   NaN
dtype: float64
```

**pandas.Series.multiply**

`Series.multiply(other, level=None, fill_value=None, axis=0)`

Multiplication of series and other, element-wise (binary operator `mul`).
Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` : None or float value, default None (NaN)
  
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

- `level` : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

result [Series]

**See also:**

`Series.rmul`

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

**pandas.Series.ne**

`Series.ne(other, level=None, fill_value=None, axis=0)`

Not equal to of series and other, element-wise (binary operator `ne`).

Equivalent to `series != other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**
**other** [Series or scalar value]

**fill_value** : None or float value, default None (NaN)

Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

**result** [Series]

**See also:**

Series.None

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

**pandas.Series.nlargest**

Series.nlargest *(n=5, keep='first')*

Return the largest n elements.

**Parameters**

**n** : int

Return this many descending sorted values

**keep** : {'first', 'last'}, default 'first'

Where there are duplicate values: - first : take the first occurrence. - last : take the last occurrence.

**Returns**

**top_n** : Series
The n largest values in the Series, in sorted order

See also:

Series.nsmallest

Notes

Faster than .sort_values(ascending=False).head(n) for small n relative to the size of the Series object.

Examples

```python
>>> import pandas as pd
>>> import numpy as np
>>> s = pd.Series(np.random.randn(10**6))
>>> s.nlargest(10)  # only sorts up to the N requested
219921  4.644710
 82124  4.608745
 421689  4.564644
 425277  4.447014
 718691  4.414137
 43154  4.403520
 283187  4.313922
 595519  4.273635
 503969  4.250236
 121637  4.240952
dtype: float64
```

**pandas.Series.nonzero**

Series.nonzero()  
Return the integer indices of the elements that are non-zero

This method is equivalent to calling numpy.nonzero on the series data. For compatibility with NumPy, the return value is the same (a tuple with an array of indices for each dimension), but it will always be a one-item tuple because series only have one dimension.

See also:

numpy.nonzero

Examples

```python
>>> s = pd.Series([0, 3, 0, 4])
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
1  3
3  4
dtype: int64
```
```python
>>> s = pd.Series([0, 3, 0, 4], index=['a', 'b', 'c', 'd'])
# same return although index of s is different
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
b 3
d 4
dtype: int64
```

**pandas.Series.notna**

Series.notna()  
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

**Returns** Series  
Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

- **Series.notnull** alias of notna  
- **Series.isna** boolean inverse of notna  
- **Series.dropna** omit axes labels with missing values  
- **notna** top-level notna

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],  
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),  
...                             pd.Timestamp('1940-04-25')],  
...                     'name': ['Alfred', 'Batman', ''],  
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age   born            name   toy
0   5.0  NaT    Alfred     None
1   6.0 1939-05-27  Batman  Batmobile
2  NaN  1940-04-25  Batman   Joker
```

```python
>>> df.notna()
   age   born            name   toy
0   True  False   True    True
1   True   True   True    True
2  False   True   True    True
```

Show which entries in a Series are not NA.

```python
```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2  NaN
dtype: float64

>>> ser.notna()
0   True
1   True
2  False
dtype: bool
```

**pandas.Series.notnull**

Series.notnull()  
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

**Returns**  
Series

Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

Series.notnull alias of notna  
Series.isna boolean inverse of notna  
Series.dropna omit axes labels with missing values  
notna top-level notna

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],  
    ...                        'born': [pd.NaT, pd.Timestamp('1939-05-27'),  
    ...                         pd.Timestamp('1940-04-25')],  
    ...                        'name': ['Alfred', 'Batman', ''],  
    ...                        'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age  born     name  toy
0  5.0  NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25    Joker
```
Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0   True
1   True
2  False
dtype: bool
```

**pandas.Series.nsmallest**

The function `Series.nsmallest(n=5, keep='first')` returns the smallest `n` elements in a Series. It has the following parameters:

- **n**: int
  Return this many ascending sorted values

- **keep**: {'first', 'last'}, default 'first'
  Where there are duplicate values: - first: take the first occurrence. - last: take the last occurrence.

**Returns** `bottom_n`: Series
The `n` smallest values in the Series, in sorted order.

**Notes**
Faster than `sort_values().head(n)` for small `n` relative to the size of the Series object.

**Examples**

```
>>> import pandas as pd
>>> import numpy as np
>>> s = pd.Series(np.random.randn(10**6))
>>> s.nsmallest(10)  # only sorts up to the N requested
288532  -4.954580
```

(continues on next page)
pandas.Series.nunique

Series.nunique(dropna=True)
Return number of unique elements in the object.
Excludes NA values by default.

Parameters
  dropna : boolean, default True
  Don’t include NaN in the count.

Returns
  nunique [int]

pandas.Series.pct_change

Series.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)
Percentage change between the current and a prior element.
Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters
  periods : int, default 1
  Periods to shift for forming percent change.
  fill_method : str, default ‘pad’
  How to handle NAs before computing percent changes.
  limit : int, default None
  The number of consecutive NAs to fill before stopping.
  freq : DateOffset, timedelta, or offset alias string, optional
  Increment to use from time series API (e.g. ‘M’ or BDay()).

**kwargs
  Additional keyword arguments are passed into DataFrame.shift or Series.shift.

Returns
  chg : Series or DataFrame
  The same type as the calling object.

See also:

  Series.diff Compute the difference of two elements in a Series.
**DataFrame.diff** Compute the difference of two elements in a DataFrame.

**Series.shift** Shift the index by some number of periods.

**DataFrame.shift** Shift the index by some number of periods.

## Examples

### Series

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64

>>> s.pct_change()
0     NaN
1  0.011111
2 -0.065934
dtype: float64

>>> s.pct_change(periods=2)
0     NaN
1     NaN
2 -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0  90.0
1  91.0
2  NaN
3  85.0
dtype: float64

>>> s.pct_change(fill_method='ffill')
0  NaN
1  0.011111
2  0.000000
3 -0.065934
dtype: float64
```

### DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13],
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
```

(continues on next page)
Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```python
>>> df.pct_change(axis='columns')
   2016  2015  2014
GOOG  NaN -0.151997 -0.086016
APPL  NaN  0.337604  0.012002
```

### pandas.Series.pipe

```
Series.pipe(func, *args, **kwargs)
```

Apply func(self, *args, **kwargs)

**Parameters**

- `func`: function
  - function to apply to the NDFrame. `args` and `kwargs` are passed into `func`. Alternatively a `(callable, data_keyword)` tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the NDFrame.

- `args`: iterable, optional
  - positional arguments passed into `func`.

- `kwargs`: mapping, optional
  - a dictionary of keyword arguments passed into `func`.

**Returns**

- `object` [the return type of `func`.]

**See also:**

- `pandas.DataFrame.apply`, `pandas.DataFrame.applymap`, `pandas.Series.map`
Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
... .pipe(g, arg1=a)
... .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```python
>>> (df.pipe(h)
... .pipe(g, arg1=a)
... .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

### pandas.Series.plot

Series.plot(kind='line', ax=None, figsize=None, use_index=True, title=None, grid=False, legend=False, style=None, logx=False, logy=False, loglog=False, xticks=None, yticks=None, xlim=None, ylim=None, rot=None, fontsize=None, colormap=None, table=False, yerr=None, xerr=None, label=None, secondary_y=False, **kwds)

Make plots of Series using matplotlib / pylab.

*New in version 0.17.0:* Each plot kind has a corresponding method on the Series.plot accessor: `s.plot(kind='line')` is equivalent to `s.plot.line()`.

**Parameters**

- **data** [Series]
- **kind** : str
  - ‘line’ : line plot (default)
  - ‘bar’ : vertical bar plot
  - ‘barh’ : horizontal bar plot
  - ‘hist’ : histogram
  - ‘box’ : boxplot
  - ‘kde’ : Kernel Density Estimation plot
  - ‘density’ : same as ‘kde’
  - ‘area’ : area plot
  - ‘pie’ : pie plot
- **ax** : matplotlib axes object
  If not passed, uses gca()
figsize [a tuple (width, height) in inches]

use_index : boolean, default True
    Use index as ticks for x axis

title : string or list
    Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and subplots is True, print each item in the list above the corresponding subplot.

grid : boolean, default None (matlab style default)
    Axis grid lines

legend : False/True/'reverse'
    Place legend on axis subplots

style : list or dict
    matplotlib line style per column

logx : boolean, default False
    Use log scaling on x axis

logy : boolean, default False
    Use log scaling on y axis

loglog : boolean, default False
    Use log scaling on both x and y axes

xticks : sequence
    Values to use for the xticks

yticks : sequence
    Values to use for the yticks

xlim [2-tuple/list]

ylim [2-tuple/list]

rot : int, default None
    Rotation for ticks (xticks for vertical, yticks for horizontal plots)

fontsize : int, default None
    Font size for xticks and yticks

colormap : str or matplotlib colormap object, default None
    Colormap to select colors from. If string, load colormap with that name from matplotlib.

colorbar : boolean, optional
    If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots)

position : float
    Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)
table : boolean, Series or DataFrame, default False

If True, draw a table using the data in the DataFrame and the data will be transposed to
meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to
draw a table.

yerr : DataFrame, Series, array-like, dict and str

See Plotting with Error Bars for detail.

xerr [same types as yerr.]

label [label argument to provide to plot]

secondary_y : boolean or sequence of ints, default False

If True then y-axis will be on the right

mark_right : boolean, default True

When using a secondary_y axis, automatically mark the column labels with “(right)” in
the legend

**kwds : keywords

Options to pass to matplotlib plotting method

Returns

axes [matplotlib.axes.Axes or numpy.ndarray of them]

Notes

• See matplotlib documentation online for more on this subject

• If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword.
  From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.Series.pop

Series.pop (item)
Return item and drop from frame. Raise KeyError if not found.

Parameters item : str

Column label to be popped

Returns

popped [Series]

Examples

>>> df = pd.DataFrame({'falcon': 'bird', '389.0'),
...                     'parrot': 'bird', 24.0),
...                     'lion': 'mammal', 80.5),
...                     'monkey': 'mammal', np.nan}),
...                     columns=('name', 'class', 'max_speed'))
>>> df
   name  class  max_speed
0  falcon   bird     389.0
1   parrot   bird      24.0
2     lion  mammal     80.5
3    monkey  mammal      NaN

>>> df.pop('class')
0  bird
1  bird
2  mammal
3  mammal
Name: class, dtype: object

>>> df
   name  max_speed
0  falcon     389.0
1   parrot     24.0
2     lion     80.5
3    monkey      NaN

pandas.Series.pow

Series.pow(other, level=None, fill_value=None, axis=0)

Exponential power of series and other, element-wise (binary operator pow).  Equivalent to series ** other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value : None or float value, default None (NaN)

Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]

See also:

Series.rpow

Examples

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])

>>> a
0    1.0
Name: a, dtype: float64
a 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64

**pandas.Series.prod**

Series.prod (axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)  
Return the product of the values for the requested axis

**Parameters**

- **axis** [[index (0)]]
- **skipna** : boolean, default True
  
  Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into
  a scalar
- **numeric_only** : boolean, default None
  
  Include only float, int, boolean columns. If None, will attempt to use everything, then
  use only numeric data. Not implemented for Series.
- **min_count** : int, default 0
  
  The required number of valid values to perform the operation. If fewer than
  min_count non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an
all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**Returns**

- **prod** [scalar or Series (if level specified)]

**Examples**

By default, the product of an empty or all-NA Series is 1
```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.Series.product**

Series.product(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values for the requested axis

**Parameters**

- **axis** [{index (0)}]
- **skipna** : boolean, default True
  
  Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar
- **numeric_only** : boolean, default None
  
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** : int, default 0
  
  The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**Returns**

- **prod** [scalar or Series (if level specified)]

**Examples**

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```
This can be controlled with the `min_count` parameter:

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

### pandas.Series.ptp

**Series.ptp**

```
Series.ptp(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
```

**Returns the difference between the maximum value and the minimum value in the object.** This is the equivalent of the `numpy.ndarray` method `ptp`.

**Parameters**

- `axis` : default None
- `skipna` : boolean, default True
- `level` : int or level name, default None
- `numeric_only` : boolean, default None

**Returns**

- `ptp` : scalar or Series (if level specified)

### pandas.Series.put

**Series.put**

```
Series.put(*args, **kwargs)
```

Applies the `put` method to its `values` attribute if it has one.

**See also:**

- `numpy.ndarray.put`

### pandas.Series.quantile

**Series.quantile**

```
Series.quantile(q=0.5, interpolation='linear')
```

Return value at the given quantile, a la `numpy.percentile`.

**Parameters**

- `q` : float or array-like, default 0.5 (50% quantile)
0 <= q <= 1, the quantile(s) to compute

**interpolation** : ['linear', 'lower', 'higher', 'midpoint', 'nearest']

New in version 0.18.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:

- linear: \(i + (j - i) \times \text{fraction}\), where fraction is the fractional part of the index surrounded by i and j.
- lower: \(i\).
- higher: \(j\).
- nearest: \(i\) or \(j\) whichever is nearest.
- midpoint: \((i + j) / 2\).

**Returns quantile**: float or Series

if q is an array, a Series will be returned where the index is q and the values are the quantiles.

See also:

*pandas.core.window.Rolling.quantile*

**Examples**

```python
>>> s = Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25 1.75
0.50 2.50
0.75 3.25
dtype: float64
```

**pandas.Series.radd**

Series.radd(\(\text{other, level=None, fill_value=None, axis=0}\))

Addition of series and other, element-wise (binary operator radd).

Equivalent to other + series, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value**: None or float value, default None (Na\(\text{N}\))
  
  Fill existing missing (Na\(\text{N}\)) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level
pandas: powerful Python data analysis toolkit, Release 0.23.3

Returns

result [Series]

See also:

Series.add

Examples

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64

pandas.Series.rank

Series.rank (axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)  
Compute numerical data ranks (1 through n) along axis. Equal values are assigned a rank that is the average of the ranks of those values.

Parameters

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - index to direct ranking
- **method**: {'average', 'min', 'max', 'first', 'dense'}
  - average: average rank of group
  - min: lowest rank in group
  - max: highest rank in group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups
- **numeric_only**: boolean, default None
  - Include only float, int, boolean data. Valid only for DataFrame or Panel objects
- **na_option**: {'keep', 'top', 'bottom'}
• keep: leave NA values where they are
• top: smallest rank if ascending
• bottom: smallest rank if descending
  ascending : boolean, default True
    False for ranks by high (1) to low (N)
  pct : boolean, default False
    Computes percentage rank of data

Returns
  ranks [same type as caller]

pandas.Series.ravel

Series.ravel(order='C')
  Return the flattened underlying data as an ndarray

See also:
  numpy.ndarray.ravel

pandas.Series.rdiv

Series.rdiv(other, level=None, fill_value=None, axis=0)
  Floating division of series and other, element-wise (binary operator rtruediv).
  Equivalent to other / series, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters
  other [Series or scalar value]
  fill_value : None or float value, default None (NaN)
    Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
  level : int or name
    Broadcast across a level, matching Index values on the passed MultiIndex level

Returns
  result [Series]

See also:
  Series.truediv

Examples
```python
def add(b, fill_value=0):
    return a.add(b, fill_value=0)
```

## pandas.Series.reindex

### pandas.Series.reindex

**Series.reindex(index=None, **kwargs)**

Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False

**Parameters**

- **index**: array-like, optional (should be specified using keywords)
  
  New labels / index to conform to. Preferably an Index object to avoid duplicating data

- **method**: {None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}, optional
  
  method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

  - default: don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap

- **copy**: boolean, default True
  
  Return a new object, even if the passed indexes are the same

- **level**: int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

- **fill_value**: scalar, default np.NaN
  
  Value to use for missing values. Defaults to NaN, but can be any “compatible” value

- **limit**: int, default None
  
  Maximum number of consecutive elements to forward or backward fill
tolerance : optional

Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs}(\text{index[indexer]} - \text{target}) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

Returns

reindexed [Series]

Examples

DataFrame.reindex supports two calling conventions

* (index=index_labels, columns=column_labels, ...)
* (labels, axis=('index', 'columns'), ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
g = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
g = pd.DataFrame({
... 'http_status': [200, 200, 404, 404, 301],
... 'response_time': [0.04, 0.02, 0.07, 0.08, 1.0],
... index=g}
g = df

<table>
<thead>
<tr>
<th>http_status</th>
<th>response_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>200</td>
</tr>
<tr>
<td>Chrome</td>
<td>200</td>
</tr>
<tr>
<td>Safari</td>
<td>404</td>
</tr>
<tr>
<td>IE10</td>
<td>404</td>
</tr>
<tr>
<td>Konqueror</td>
<td>301</td>
</tr>
</tbody>
</table>
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
g = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
... 'Chrome']
g = df.reindex(g)

<table>
<thead>
<tr>
<th>http_status</th>
<th>response_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Safari</td>
<td>404.0</td>
</tr>
<tr>
<td>Iceweasel</td>
<td>NaN</td>
</tr>
<tr>
<td>Comodo Dragon</td>
<td>NaN</td>
</tr>
<tr>
<td>IE10</td>
<td>404.0</td>
</tr>
<tr>
<td>Chrome</td>
<td>200.0</td>
</tr>
</tbody>
</table>
```

We can fill in the missing values by passing a value to the keyword fill_value. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.
>>> df.reindex(new_index, fill_value=0)

<table>
<thead>
<tr>
<th></th>
<th>http_status</th>
<th>response_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Safari</td>
<td>404</td>
<td>0.07</td>
</tr>
<tr>
<td>Iceweasel</td>
<td>0</td>
<td>0.00</td>
</tr>
<tr>
<td>Comodo Dragon</td>
<td>0</td>
<td>0.00</td>
</tr>
<tr>
<td>IE10</td>
<td>404</td>
<td>0.08</td>
</tr>
<tr>
<td>Chrome</td>
<td>200</td>
<td>0.02</td>
</tr>
</tbody>
</table>

>>> df.reindex(new_index, fill_value='missing')

<table>
<thead>
<tr>
<th></th>
<th>http_status</th>
<th>response_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Safari</td>
<td>404</td>
<td>0.07</td>
</tr>
<tr>
<td>Iceweasel</td>
<td>missing</td>
<td>missing</td>
</tr>
<tr>
<td>Comodo Dragon</td>
<td>missing</td>
<td>missing</td>
</tr>
<tr>
<td>IE10</td>
<td>404</td>
<td>0.08</td>
</tr>
<tr>
<td>Chrome</td>
<td>200</td>
<td>0.02</td>
</tr>
</tbody>
</table>

We can also reindex the columns.

>>> df.reindex(columns=['http_status', 'user_agent'])

<table>
<thead>
<tr>
<th>http_status</th>
<th>user_agent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>200</td>
</tr>
<tr>
<td>Chrome</td>
<td>200</td>
</tr>
<tr>
<td>Safari</td>
<td>404</td>
</tr>
<tr>
<td>IE10</td>
<td>404</td>
</tr>
<tr>
<td>Konqueror</td>
<td>301</td>
</tr>
</tbody>
</table>

Or we can use “axis-style” keyword arguments

>>> df.reindex([{'http_status', 'user_agent'}], axis="columns")

<table>
<thead>
<tr>
<th>http_status</th>
<th>user_agent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>200</td>
</tr>
<tr>
<td>Chrome</td>
<td>200</td>
</tr>
<tr>
<td>Safari</td>
<td>404</td>
</tr>
<tr>
<td>IE10</td>
<td>404</td>
</tr>
<tr>
<td>Konqueror</td>
<td>301</td>
</tr>
</tbody>
</table>

To further illustrate the filling functionality in reindex, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```python
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
... index=date_index)
>>> df2
```

<table>
<thead>
<tr>
<th></th>
<th>prices</th>
</tr>
</thead>
<tbody>
<tr>
<td>2010-01-01</td>
<td>100</td>
</tr>
<tr>
<td>2010-01-02</td>
<td>101</td>
</tr>
<tr>
<td>2010-01-03</td>
<td>NaN</td>
</tr>
<tr>
<td>2010-01-04</td>
<td>100</td>
</tr>
<tr>
<td>2010-01-05</td>
<td>89</td>
</tr>
<tr>
<td>2010-01-06</td>
<td>88</td>
</tr>
</tbody>
</table>

Suppose we decide to expand the dataframe to cover a wider date range.

```python
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
```

<table>
<thead>
<tr>
<th></th>
<th>prices</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-12-29</td>
<td>NaN</td>
</tr>
</tbody>
</table>

(continues on next page)
The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to backpropagate the last valid value to fill the NaN values, pass bfill as an argument to the method keyword.

```python
>>> df2.reindex(date_index2, method='bfill')
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the user guide for more.

**pandas.Series.reindex_axis**

```python
Series.reindex_axis(labels, axis=0, **kwargs)
```
Conform Series to new index with optional filling logic.

Deprecated since version 0.21.0: Use `Series.reindex` instead.

**pandas.Series.reindex_like**

```python
Series.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)
```
Return an object with matching indices to myself.

**Parameters**

- **other** [Object]
- **method** [string or None]
- **copy** [boolean, default True]
- **limit** : int, default None
Maximum number of consecutive labels to fill for inexact matches.

**tolerance**: optional

Maximum distance between labels of the other object and this object for inexact matches. Can be list-like.

New in version 0.21.0: (list-like tolerance)

**Returns**

reindexed [same as input]

**Notes**

Like calling `s.reindex(index=other.index, columns=other.columns, method=...)`

---

**pandas.Series.rename**

$pandas.Series.rename(index=None, **kwargs)$

Alter Series index labels or name

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

Alternatively, change `Series.name` with a scalar value.

See the user guide for more.

**Parameters**

- **index**: scalar, hashable sequence, dict-like or function, optional
  - dict-like or functions are transformations to apply to the index. Scalar or hashable sequence-like will alter the `Series.name` attribute.
- **copy**: boolean, default True
  - Also copy underlying data
- **inplace**: boolean, default False
  - Whether to return a new Series. If True then value of copy is ignored.
- **level**: int or level name, default None
  - In case of a MultiIndex, only rename labels in the specified level.

**Returns**

renamed [Series (new object)]

**See also:**

$pandas.Series.rename_axis$

---

**Examples**

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0  1
1  2
```
pandas.Series.rename_axis

Series.rename_axis (mapper, axis=0, copy=True, inplace=False)  
Alter the name of the index or columns.

Parameters mapper : scalar, list-like, optional  
Value to set as the axis name attribute.

axis : {0 or ‘index’, 1 or ‘columns’}, default 0  
The index or the name of the axis.

copy : boolean, default True  
Also copy underlying data.

inplace : boolean, default False  
Modifies the object directly, instead of creating a new Series or DataFrame.

Returns renamed : Series, DataFrame, or None  
The same type as the caller or None if inplace is True.

See also:

pandas.Series.rename Alter Series index labels or name  
pandas.DataFrame.rename Alter DataFrame index labels or name  
pandas.Index.rename Set new names on index

Notes

Prior to version 0.21.0, rename_axis could also be used to change the axis labels by passing a mapping or scalar. This behavior is deprecated and will be removed in a future version. Use rename instead.
Examples

Series

```python
>>> s = pd.Series([1, 2, 3])
>>> s.rename_axis("foo")
foo
0  1
1  2
2  3
dtype: int64
```

DataFrame

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename_axis("foo")
   A  B
foo
0  1  4
1  2  5
2  3  6
```

```python
>>> df.rename_axis("bar", axis="columns")
   bar  A  B
0     1  4
1     2  5
2     3  6
```

**pandas.Series.reorder_levels**

Series.reorder_levels(order)

Rearrange index levels using input order. May not drop or duplicate levels

Parameters

- **order**: list of int representing new level order.
  (reference level by number or key)

- **axis**: where to reorder levels

Returns

- type of caller (new object)

**pandas.Series.repeat**

Series.repeat(repeats, *args, **kwargs)

Repeat elements of an Series. Refer to numpy.ndarray.repeat for more information about the repeats argument.

See also:

- numpy.ndarray.repeat
`pandas.Series.replace`

```
Series.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')
```

Replace values given in `to_replace` with `value`.

Values of the Series are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

**Parameters**

- **to_replace**: `str`, `regex`, `list`, `dict`, `Series`, `int`, `float`, or `None`
  How to find the values that will be replaced.
  - numeric, `str` or `regex`:
    - numeric: numeric values equal to `to_replace` will be replaced with `value`
    - `str`: string exactly matching `to_replace` will be replaced with `value`
    - `regex`: regexs matching `to_replace` will be replaced with `value`
  - `list` of `str`, `regex`, or `numeric`:
    - First, if `to_replace` and `value` are both lists, they must be the same length.
    - Second, if `regex=True` then all of the strings in both lists will be interpreted as regexs otherwise they will match directly. This doesn’t matter much for `value` since there are only a few possible substitution regexes you can use.
    - `str`, `regex` and numeric rules apply as above.
  - `dict`:
    - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the `value` parameter should be `None`.
    - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in `value`. The `value` parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
    - For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The `value` parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
  - `None`:
    - This means that the `regex` argument must be a string, compiled regular expression, or list, `dict`, `ndarray` or `Series` of such elements. If `value` is also `None` then this must be a nested dictionary or `Series`.

See the examples section for examples of each of these.

- **value**: `scalar`, `dict`, `list`, `str`, `regex`, default `None`
  Value to replace any values matching `to_replace` with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.
inplace : boolean, default False

If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit : int, default None

Maximum size gap to forward or backward fill.

regex : bool or same types as to_replace, default False

Whether to interpret to_replace and/or value as regular expressions. If this is True then to_replace must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case to_replace must be None.

method : {'pad', 'ffill', 'bfill', None}

The method to use when for replacement, when to_replace is a scalar, list or tuple and value is None.

Changed in version 0.23.0: Added to DataFrame.

Returns Series

Object after replacement.

Raises AssertionError

• If regex is not a bool and to_replace is not None.

TypeError

• If to_replace is a dict and value is not a list, dict, ndarray, or Series
• If to_replace is None and regex is not compilable into a regular expression or is a list, dict, ndarray, or Series.
• When replacing multiple bool or datetime64 objects and the arguments to to_replace does not match the type of the value being replaced

ValueError

• If a list or an ndarray is passed to to_replace and value but they are not the same length.

See also:

Series.fillna Fill NA values

Series.where Replace values based on boolean condition

Series.str.replace Simple string replacement.

Notes

• Regex substitution is performed under the hood with re.sub. The rules for substitution for re.sub are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.
• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
• When dict is used as the to_replace value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar ‘to_replace’ and ‘value’

```python
>>> a = pd.Series([0, 1, 2, 3, 4])
>>> a.replace(0, 5)
0 5
1 1
2 2
3 3
4 4
dtype: int64

>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
... 'B': [5, 6, 7, 8, 9],
... 'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

List-like ‘to_replace’

```python
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e

>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e

>>> s.replace([1, 2], method='bfill')
0  0
1  3
2  3
3  3
4  4
dtype: int64
```
dict-like `to_replace`

```python
>>> df.replace({0: 10, 1: 100})
    A  B  C
0  10  5  a
1  100 6  b
2   2  7  c
3   3  8  d
4   4  9  e
```

```python
>>> df.replace({'A': 0, 'B': 5}, 100)
    A  B  C
0  100 100  a
1    1  6  b
2    2  7  c
3    3  8  d
4    4  9  e
```

```python
>>> df.replace({'A': {0: 100, 4: 400}})
    A  B  C
0  100  5  a
1    1  6  b
2    2  7  c
3    3  8  d
4  400  9  e
```

Regular expression `to_replace`

```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
    A  B
0 new abc
1   foo new
2  bait xyz
```

```python
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
    A  B
0 new abc
1   foo bar
2  bait xyz
```

```python
>>> df.replace(regex=r'^ba.$', value='new')
    A  B
0 new abc
1   foo new
2  bait xyz
```

```python
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
    A  B
0 new abc
1   xyz new
2  bait xyz
```

(continues on next page)
Note that when replacing multiple bool or datetime64 objects, the data types in the to_replace parameter must match the data type of the value being replaced:

```python
>>> df = pd.DataFrame({'A': [True, False, True],
                      'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False})  # raises
Traceback (most recent call last):
  ...  
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a TypeError because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the to_replace parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
When one uses a dict as the to_replace value, it is like the value(s) in the dict are equal to the value parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):
```
```
>>> s.replace({'a': None})
0 10
1 10
2 10
3 b
4 b
dtype: object
When value=None and to_replace is a scalar, list or tuple, replace uses the method parameter (default 'pad') to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:
```
```
```python
>>> s.replace('a', None)
0 10
1 10
2 10
3 b
4 b
dtype: object
```

**pandas.Series.resample**

Series.resample(rule, how=None, axis=0, fill_method=None, closed=None, label=None, convention='start', kind=None, loffset=None, limit=None, base=0, on=None, level=None)

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or pass datetime-like values to the on or level keyword.
Parameters  

**rule**: string  
the offset string or object representing target conversion

**axis**: [int, optional, default 0]  

**closed**: ['right', 'left']  
Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

**label**: ['right', 'left']  
Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

**convention**: {'start', 'end', 's', 'e'}  
For PeriodIndex only, controls whether to use the start or end of rule

**kind**: {'timestamp', 'period'}, optional  
Pass ‘timestamp’ to convert the resulting index to a DateTimeIndex or ‘period’ to convert it to a PeriodIndex. By default the input representation is retained.

**loffset**: timedelta  
Adjust the resampled time labels

**base**: int, default 0  
For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0

**on**: string, optional  
For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

New in version 0.19.0.

**level**: string or int, optional  
For a MultiIndex, level (name or number) to use for resampling. Level must be datetime-like.

New in version 0.19.0.

Returns

Resampler object

See also:

**groupby** Group by mapping, function, label, or list of labels.
Notes

See the user guide for more.

To learn more about the offset strings, please see this link.

Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.
Upsample the series into 30 second bins and fill the NaN values using the pad method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 0
2000-01-01 00:01:00 1
2000-01-01 00:01:30 1
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 1
2000-01-01 00:01:00 1
2000-01-01 00:01:30 2
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like)+5

>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00 8
2000-01-01 00:03:00 17
2000-01-01 00:06:00 26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword convention can be used to control whether to use the start or end of rule.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
                        freq='A',
                        periods=2))

>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64
```

Resample by month using 'start' convention. Values are assigned to the first month of the period.

```
>>> s.resample('M', convention='start').asfreq().head()
2012-01 1.0
2012-02 NaN
2012-03 NaN
2012-04 NaN
```
Resample by month using ‘end’ convention. Values are assigned to the last month of the period.

```python
>>> s.resample('M', convention='end').asfreq()
2012-12 1.0
2013-01 NaN
2013-02 NaN
2013-03 NaN
2013-04 NaN
2013-05 NaN
2013-06 NaN
2013-07 NaN
2013-08 NaN
2013-09 NaN
2013-10 NaN
2013-11 NaN
2013-12 2.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> df = pd.DataFrame(data=9*range(4), columns=['a', 'b', 'c', 'd'])
>>> df['time'] = pd.date_range('1/1/2000', periods=9, freq='T')
>>> df.resample('3T', on='time').sum()
          a  b  c  d
time
2000-01-01 00:00:00  0  3  6  9
2000-01-01 00:03:00  0  3  6  9
2000-01-01 00:06:00  0  3  6  9
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on level the resampling needs to take place.

```python
>>> time = pd.date_range('1/1/2000', periods=5, freq='T')
>>> df2 = pd.DataFrame(data=10*range(4), columns=['a', 'b', 'c', 'd'],
                      index=pd.MultiIndex.from_product([time, [1, 2]])
                     )
>>> df2.resample('3T', level=0).sum()
          a  b  c  d
2000-01-01 00:00:00  0  6 12 18
2000-01-01 00:03:00  0  4  8 12
```

**pandas.Series.reset_index**

Series.reset_index(level=None, drop=False, name=None, inplace=False)

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

**Parameters**

- **level**: int, str, tuple, or list, default optional
For a Series with a MultiIndex, only remove the specified levels from the index.
Removes all levels by default.

**drop**: bool, default False

Just reset the index, without inserting it as a column in the new DataFrame.

**name**: object, optional

The name to use for the column containing the original Series values. Uses
self.name by default. This argument is ignored when drop is True.

**inplace**: bool, default False

Modify the Series in place (do not create a new object).

**Returns** Series or DataFrame

When drop is False (the default), a DataFrame is returned. The newly created
columns will come first in the DataFrame, followed by the original Series values.
When drop is True, a Series is returned. In either case, if inplace=True, no
value is returned.

**See also**:

*DataFrame.reset_index*  Analogous function for DataFrame.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4], name='foo',
                 index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))
```

Generate a DataFrame with default index.

```python
>>> s.reset_index()
  idx  foo
0  a   1
1  b   2
2  c   3
3  d   4
```

To specify the name of the new column use name.

```python
>>> s.reset_index(name='values')
  idx  values
0  a    1
1  b    2
2  c    3
3  d    4
```

To generate a new Series with the default set drop to True.

```python
>>> s.reset_index(drop=True)
0  1
1  2
2  3
3  4
Name: foo, dtype: int64
```
To update the Series in place, without generating a new one set `inplace` to True. Note that it also requires `drop=True`.

```python
>>> s.reset_index(inplace=True, drop=True)
```

```python
>>> s
0 1
1 2
2 3
3 4
Name: foo, dtype: int64
```

The `level` parameter is interesting for Series with a multi-level index.

```python
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
...           np.array(['one', 'two', 'one', 'two'])]
```

```python
>>> s2 = pd.Series([0, 1, 2, 3], name='foo',
...                 index=pd.MultiIndex.from_arrays(arrays,
...                                                names=['a', 'b']))
```

To remove a specific level from the Index, use `level`.

```python
>>> s2.reset_index(level='a')
```

```python
     a  b
one bar 0
two bar 1
one baz 2
two baz 3
```

If `level` is not set, all levels are removed from the Index.

```python
>>> s2.reset_index()
```

```python
     a  b  foo
0  bar one 0
1  bar two 1
2  baz one 2
3  baz two 3
```

**pandas.Series.rfloordiv**

Series `rfloordiv` (other, level=None, fill_value=None, axis=0)

Integer division of series and other, element-wise (binary operator `rfloordiv`).

Equivalent to `other // series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` : None or float value, default None (NaN)
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- `level` : int or name
Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]

See also:

Series.floordiv

Examples

```python
def add(b):
    a.add(b, fill_value=0)
```

pandas.Series.rmod

Series.rmod(other, level=None, fill_value=None, axis=0)

Modulo of series and other, element-wise (binary operator rmod).

Equivalent to other % series, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value : None or float value, default None (NaN)

Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

Returns

result [Series]
See also:

Series.mod

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64

>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

**pandas.Series.rolling**

Series.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)

Provides rolling window calculations.

New in version 0.18.0.

**Parameters**

- **window** : int, or offset
  Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.
  
  If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. This is new in 0.19.0

- **min_periods** : int, default None
  Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, this will default to 1.

- **center** : boolean, default False
  Set the labels at the center of the window.

- **win_type** : string, default None
  Provide a window type. If None, all points are evenly weighted. See the notes below for further information.

- **on** : string, optional
  For a DataFrame, column on which to calculate the rolling window, rather than the index
**closed** : string, default None

Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. For offset-based windows, it defaults to ‘right’. For fixed windows, defaults to ‘both’. Remaining cases not implemented for fixed windows.

New in version 0.20.0.

**axis** [int or string, default 0]

**Returns**

a Window or Rolling sub-classed for the particular operation

**See also:**

*expanding*  Provides expanding transformations.

*ewm* Provides exponential weighted functions

**Notes**

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see this link.

The recognized win_types are:

* boxcar
* triang
* blackman
* hamming
* bartlett
* parzen
* bohman
* blackmanharris
* nuttall
* barthann
* kaiser (needs beta)
* gaussian (needs std)
* general_gaussian (needs power, width)
* slepian (needs width).

If `win_type=None` all points are evenly weighted. To learn more about different window types see `scipy.signal window functions`.
Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

Rolling sum with a window length of 2, using the ‘triang’ window type.

```python
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  1.0
2  2.5
3  NaN
4  NaN
```n

Rolling sum with a window length of 2, min_periods defaults to the window length.

```python
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```n

Same as above, but explicitly set the min_periods

```python
>>> df.rolling(2, min_periods=1).sum()
   B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```n

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                    index=[pd.Timestamp('20130101 09:00:00'),
                           pd.Timestamp('20130101 09:00:02'),
                           pd.Timestamp('20130101 09:00:03'),
                           pd.Timestamp('20130101 09:00:05'),
                           pd.Timestamp('20130101 09:00:06')])
>>> df
       B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```
Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```python
>>> df.rolling('2s').sum()
   B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

**pandas.Series.round**

```python
Series.round(decimals=0, *args, **kwargs)
```
Round each value in a Series to the given number of decimals.

- **Parameters**
  - `decimals` : int
    - Number of decimal places to round to (default: 0). If decimals is negative, it specifies the number of positions to the left of the decimal point.

- **Returns**
  - Series object

- **See also:**
  - `numpy.around`, `DataFrame.round`

**pandas.Series.rpow**

```python
Series.rpow(other, level=None, fill_value=None, axis=0)
```
Exponential power of series and other, element-wise (binary operator rpow).

Equivalent to `other ** series`, but with support to substitute a fill_value for missing data in one of the inputs.

- **Parameters**
  - `other` [Series or scalar value]
  - `fill_value` : None or float value, default None (NaN)
    - Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
  - `level` : int or name
    - Broadcast across a level, matching Index values on the passed MultiIndex level

- **Returns**
  - `result` [Series]

- **See also:**
  - `Series.pow`
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

**pandas.Series.rsub**

Series.rsub(other, level=None, fill_value=None, axis=0)

Subtraction of series and other, element-wise (binary operator rsub).

Equivalent to other - series, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** : None or float value, default None (NaN)
  
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

result [Series]

**See also:**

Series.sub

**Examples**
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
```

```python
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

**pandas.Series.rtruediv**

Series.rtruediv(other, level=None, fill_value=None, axis=0)

Floating division of series and other, element-wise (binary operator rtruediv).

Equivalent to other / series, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** : None or float value, default None (NaN)
  
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- **result** [Series]

**See also:**

Series.truediv

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
```

(continues on next page)
b  1.0
c  1.0
d  NaN
dtype: float64

```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64

b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
```

```python
>>> a.add(b, fill_value=0)
a  2.0
b  1.0
c  1.0
d  1.0
e  NaN
dtype: float64
```

### pandas.Series.sample

`Series.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)`

Return a random sample of items from an axis of object.

You can use `random_state` for reproducibility.

**Parameters**

- **n**: int, optional
  - Number of items from axis to return. Cannot be used with `frac`. Default = 1 if `frac` = None.

- **frac**: float, optional
  - Fraction of axis items to return. Cannot be used with `n`.

- **replace**: boolean, optional
  - Sample with or without replacement. Default = False.

- **weights**: str or ndarray-like, optional
  - Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. inf and -inf values not allowed.

- **random_state**: int or numpy.random.RandomState, optional
  - Seed for the random number generator (if int), or numpy RandomState object.

- **axis**: int or string, optional
  - Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames, 1 for Panels).
Returns

A new object of same type as caller.

Examples

Generate an example Series and DataFrame:

```python
>>> s = pd.Series(np.random.randn(50))
>>> s.head()
0  -0.038497
1   1.820773
2  -0.972766
3  -1.598270
4  -1.095526
dtype: float64
```

```python
df = pd.DataFrame(np.random.randn(50, 4), columns=list('ABCD'))
>>> df.head()
      A         B         C         D
0  0.016443  -2.318952  -0.566372  -1.028078
1 -1.051921   0.438836   0.658280  -0.175797
2 -1.243569  -0.364626  -0.215065   0.057736
3  1.768216   0.404512  -0.385604  -1.457834
4  1.072446  -1.137172   0.314194  -0.046661
```

Next extract a random sample from both of these objects...

3 random elements from the Series:

```python
>>> s.sample(n=3)
27  -0.994689
55  -1.049016
67   -0.224565
dtype: float64
```

And a random 10% of the DataFrame with replacement:

```python
>>> df.sample(frac=0.1, replace=True)
      A         B         C         D
35   1.981780   0.142106   1.817165  -0.290805
49  -1.336199  -0.448634  -0.789640   0.217116
40   0.823173  -0.078816   1.009536   1.015108
15   1.421154  -0.055301  -1.922594  -0.019696
  6  -0.148339   0.832938   1.787600  -1.383767
```

You can use random state for reproducibility:

```python
>>> df.sample(random_state=1)
      A         B         C         D
37  -2.027662   0.103611   0.237496  -0.165867
43  -0.259323  -0.583426   1.516140  -0.479118
12  -1.686325  -0.579510   0.985195  -0.460286
  8   1.167946   0.429082   1.215742  -1.636041
  9   1.197475  -0.864188   1.554031  -1.505264
```
**pandas.Series.searchsorted**

`Series.searchsorted(value, side='left', sorter=None)`  
Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series `self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

**Parameters**

- `value`: array_like  
  Values to insert into `self`.
- `side`: {'left', 'right'}, optional  
  If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- `sorter`: 1-D array_like, optional  
  Optional array of integer indices that sort `self` into ascending order. They are typically the result of `np.argsort`.

**Returns**

- `indices`: array of ints  
  Array of insertion points with the same shape as `value`.

**See also:**

- `numpy.searchsorted`

**Notes**

Binary search is used to find the required insertion points.

**Examples**

```python
>>> x = pd.Series([1, 2, 3])
>>> x
0   1
1   2
2   3
dtype: int64

>>> x.searchsorted(4)
array([3])

>>> x.searchsorted([0, 4])
array([0, 3])

>>> x.searchsorted([1, 3], side='left')
array([0, 2])

>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```
>>> x = pd.Categorical(['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]

>>> x.searchsorted('bread')
array([1]) # Note: an array, not a scalar

>>> x.searchsorted(['bread'], side='right')
array([3])

**pandas.Series.select**

Series.select (crit, axis=0)
Return data corresponding to axis labels matching criteria

Deprecated since version 0.21.0: Use df.loc[df.index.map(crit)] to select via labels

Parameters
- crit : function
  To be called on each index (label). Should return True or False
- axis : int

Returns
- selection : [type of caller]

**pandas.Series.sem**

Series.sem (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters
- axis : [index (0)]
- skipna : boolean, default True
  Exclude NA/null values. If an entire row/column is NA, the result will be NA
- level : int or level name, default None
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar
- ddof : int, default 1
  Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- numeric_only : boolean, default None
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
pandas.Series.set_axis

Series.set_axis (labels, axis=0, inplace=None)
Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now labels and axis, consistent with the rest of pandas API. Previously, the axis and labels arguments were respectively the first and second positional arguments.

**Parameters**

labels : list-like, Index
The values for the new index.

axis : {0 or ‘index’, 1 or ‘columns’}, default 0
The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace : boolean, default None
Whether to return a new %klass%s instance.

**Warning:** inplace=None currently falls back to True, but in a future version, will default to False. Use inplace=True explicitly rather than relying on the default.

**Returns**

renamed : %klass%s or None
An object of same type as caller if inplace=False, None otherwise.

See also:

**pandas.DataFrame.rename_axis** Alter the name of the index or columns.

**Examples**

Series

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0 1
1 2
2 3
dtype: int64

>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a 1
b 2
c 3
dtype: int64
```

The original object is not modified.
DataFrame

```python
>>> s
0 1
1 2
2 3
dtype: int64
```

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```python
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
```

```plaintext
A  B
a 1 4
b 2 5
c 3 6
```

Change the column labels.

```python
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
```

```plaintext
I  II
0 1 4
1 2 5
2 3 6
```

Now, update the labels inplace.

```python
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
```

```plaintext
i  ii
0 1 4
1 2 5
2 3 6
```

**pandas.Series.set_value**

Series.set_value(label, value, takeable=False)

Quickly set single value at passed label. If label is not contained, a new object is created with the label placed at the end of the result index.

Deprecated since version 0.21.0: Please use .at[] or .iat[] accessors.

**Parameters**

- **label**: object
  Partial indexing with MultiIndex not allowed
- **value**: object
  Scalar value
- **takeable**: [interpret the index as indexers, default False]

**Returns**

- **series**: Series
  If label is contained, will be reference to calling Series, otherwise a new object
**pandas.Series.shift**

Series.shift(*periods=1, freq=None, axis=0*)

Shift index by desired number of periods with an optional time freq

**Parameters**

- **periods**: int
  
  Number of periods to move, can be positive or negative

- **freq**: DateOffset, timedelta, or time rule string, optional
  
  Increment to use from the tseries module or time rule (e.g. ‘EOM’). See Notes.

- **axis**: [{0 or ‘index’}]

**Returns**

- **shifted**: [Series]

**Notes**

If freq is specified then the index values are shifted but the data is not realigned. That is, use freq if you would like to extend the index when shifting and preserve the original data.

**pandas.Series.skew**

Series.skew(*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return unbiased skew over requested axis Normalized by N-1

**Parameters**

- **axis**: [{index (0)}]

- **skipna**: boolean, default True
  
  Exclude NA/null values when computing the result.

- **level**: int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

- **numeric_only**: boolean, default None
  
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **skew**: [scalar or Series (if level specified)]

**pandas.Series.slice_shift**

Series.slice_shift(*periods=1, axis=0*)

Equivalent to shift without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

**Parameters**

- **periods**: int
Number of periods to move, can be positive or negative

**Returns**

*shifted* [same type as caller]

**Notes**

While the `slice_shift` is faster than `shift`, you may pay for it later during alignment.

**pandas.Series.sort_index**

`Series.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True)`

Sort Series by index labels.

Returns a new Series sorted by label if `inplace` argument is `False`, otherwise updates the original series and returns None.

**Parameters**

- **axis**: int, default 0
  
  Axis to direct sorting. This can only be 0 for Series.

- **level**: int, optional

  If not None, sort on values in specified index level(s).

- **ascending**: bool, default True

  Sort ascending vs. descending.

- **inplace**: bool, default False

  If True, perform operation in-place.

- **kind**: {'quicksort', 'mergesort', 'heapsort'}, default ‘quicksort’

  Choice of sorting algorithm. See also `numpy.sort()` for more information. ‘mergesort’ is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

- **na_position**: {'first', 'last'}, default ‘last’

  If ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end. Not implemented for MultiIndex.

- **sort_remaining**: bool, default True

  If true and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

**Returns**

pandas.Series

The original Series sorted by the labels

**See also:**

- `DataFrame.sort_index`  Sort DataFrame by the index
- `DataFrame.sort_values`  Sort DataFrame by the value
- `Series.sort_values`  Sort Series by the value
Examples

```python
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1  c
2  b
3  a
4  d
dtype: object

Sort Descending
```
pandas.Series.sort_values

Series.sort_values

Series.sort_values(axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last')

Sort by the values.

Sort a Series in ascending or descending order by some criterion.

**Parameters**

- **axis**: {0 or ‘index’}, default 0
  - Axis to direct sorting. The value ‘index’ is accepted for compatibility with DataFrame.sort_values.
- **ascending**: bool, default True
  - If True, sort values in ascending order, otherwise descending.
- **inplace**: bool, default False
  - If True, perform operation in-place.
- **kind**: {'quicksort', 'mergesort' or 'heapsort'}, default ‘quicksort’
  - Choice of sorting algorithm. See also numpy.sort() for more information. ‘mergesort’ is the only stable algorithm.
- **na_position**: {'first' or 'last'}, default ‘last’
  - Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.

**Returns**

Series

Series ordered by values.

**See also:**

- Series.sort_index Sort by the Series indices.
- DataFrame.sort_values Sort DataFrame by the values along either axis.
- DataFrame.sort_index Sort DataFrame by indices.

**Examples**

```python
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0    NaN
1    1.0
```

(continues on next page)
Sort values ascending order (default behaviour)

```python
>>> import pandas as pd
>>> s = pd.Series([2, 0, 4, 10, 5])
>>> s
0    NaN
1    1.0
2    3.0
3    5.0
4    10.0
Name: 0, dtype: float64
```

```python
>>> s.sort_values(ascending=True)
1    1.0
2    3.0
4    5.0
3    10.0
0    NaN
Name: 0, dtype: float64
```

Sort values descending order

```python
>>> s.sort_values(ascending=False)
3    10.0
4    5.0
2    3.0
1    1.0
0    NaN
Name: 0, dtype: float64
```

Sort values inplace

```python
>>> s.sort_values(ascending=False, inplace=True)
>>> s
0    NaN
1    1.0
2    3.0
4    5.0
3    10.0
Name: 0, dtype: float64
```

Sort values putting NAs first

```python
>>> s.sort_values(na_position='first')
0    NaN
1    1.0
2    3.0
4    5.0
3    10.0
Name: 0, dtype: float64
```

Sort a series of strings

```python
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0    z
1    b
2    d
3    a
4    c
Name: 0, dtype: object
```
```python
>>> s.sort_values()
3   a
1   b
4   c
2   d
0   z
dtype: object
```

### pandas.Series.sortlevel

**Series.sortlevel** (level=0, ascending=True, sort_remaining=True)

Sort Series with MultiIndex by chosen level. Data will be lexicographically sorted by the chosen level followed by the other levels (in order).

Deprecated since version 0.20.0: Use `Series.sort_index()`

**Parameters**

- **level**: [int or level name, default None]
- **ascending**: [bool, default True]

**Returns**

- **sorted**: [Series]

**See also:**

`Series.sort_index`

### pandas.Series.squeeze

**Series.squeeze** (axis=None)

Squeeze length 1 dimensions.

**Parameters**

- **axis**: None, integer or string axis name, optional

  The axis to squeeze if 1-sized.

  New in version 0.20.0.

**Returns**

- **scalar if 1-sized, else original object**

### pandas.Series.std

**Series.std** (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- **axis**: [index (0)]
- **skipna**: boolean, default True

  Exclude NA/null values. If an entire row/column is NA, the result will be NA
level : int or level name, default None
    If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

ddof : int, default 1
    Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only : boolean, default None
    Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

std [scalar or Series (if level specified)]

pandas.Series.str

Series.str()
    Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

Examples

```python
>>> s.str.split('_
```
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

`pandas.Series.subtract`

Series `subtract` (`other`, `level=None`, `fill_value=None`, `axis=0`)  
Subtraction of series and other, element-wise (binary operator `sub`).  
Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` : None or float value, default None (NaN)
  
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

- `level` : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

- `result` [Series]

See also:

`Series.rsub`

**Examples**
```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64

>>> a.add(b, fill_value=0)
```

**pandas.Series.sum**

Series.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the sum of the values for the requested axis

**Parameters**

- **axis** [{index (0)}]
- **skipna** : boolean, default True
  - Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  - If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar
- **numeric_only** : boolean, default None
  - Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** : int, default 0
  - The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**New in version 0.22.0:** Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**Returns**

- **sum** [scalar or Series (if level specified)]
Examples

By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you’d like the sum of an empty series to be NaN, pass `min_count=1`.

```python
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0
```

```python
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

**pandas.Series.swapaxes**

`Series.swapaxes(axis1, axis2, copy=True)`

Interchange axes and swap values axes appropriately

Returns

- `y` [same as input]

**pandas.Series.swaplevel**

`Series.swaplevel(i=-2, j=-1, copy=True)`

Swap levels i and j in a MultiIndex

Parameters

- `i, j` : int, string (can be mixed)
  
  Level of index to be swapped. Can pass level name as string.

Returns

- `swapped` [Series]
  
  .. versionchanged:: 0.18.1

  The indexes i and j are now optional, and default to the two innermost levels of the index.

**pandas.Series.tail**

`Series.tail(n=5)`

Return the last `n` rows.

This function returns last `n` rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.
Parameters \( n \) : int, default 5

Number of rows to select.

Returns type of caller

The last \( n \) rows of the caller object.

See also:

*pandas.DataFrame.head* The first \( n \) rows of the caller object.

Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
   'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1       bee
2  falcon
3      lion
4  monkey
5    parrot
6    shark
7    whale
8    zebra

Viewing the last 5 lines

```python
>>> df.tail()
   animal
4  monkey
5    parrot
6    shark
7    whale
8    zebra
```

Viewing the last \( n \) lines (three in this case)

```python
>>> df.tail(3)
   animal
6    shark
7    whale
8    zebra
```

*pandas.Series.take*

`Series.take(indices, axis=0, convert=None, is_copy=True, **kwargs)`

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters `indices` : array-like

An array of ints indicating which positions to take.
axis : {0 or ‘index’, 1 or ‘columns’, None}, default 0

The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

convert : bool, default True

Whether to convert negative indices into positive ones. For example, −1 would map to the len(axis) − 1. The conversions are similar to the behavior of indexing a regular Python list.

Deprecated since version 0.21.0: In the future, negative indices will always be converted.

is_copy : bool, default True

Whether to return a copy of the original object or not.

**kwargs

For compatibility with numpy.take(). Has no effect on the output.

Returns taken : type of caller

An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion',  'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=['name', 'class', 'max_speed'],
...                     index=[0, 2, 3, 1])

>>> df
   name   class  max_speed
0   falcon   bird      389.0
2   parrot   bird       24.0
3    lion  mammal       80.5
1  monkey  mammal         NaN

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That’s because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

>>> df.take([0, 3])
   name   class  max_speed
0   falcon   bird      389.0
1  monkey  mammal         NaN

Take elements at indices 1 and 2 along the axis 1 (column selection).
We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
  name  class  max_speed
1  monkey  mammal  NaN
3    lion  mammal   80.5
```

### pandas.Series.to_clipboard

`Series.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel**: bool, default True
  - True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
  - False, write a string representation of the object to the clipboard.

- **sep**: str, default ' \	 '
  - Field delimiter.

- **kwargs**
  - These parameters will be passed to DataFrame.to_csv.

**See also**:

- **DataFrame.to_csv**: Write a DataFrame to a comma-separated values (csv) file.

- **read_clipboard**: Read text from clipboard and pass to read_table.

### Notes

Requirements for your platform.

- Linux: `xclip`, or `xsel` (with `gtk` or `PyQt4` modules)
- Windows: none
- OS X: none

### Examples

Copy the contents of a DataFrame to the clipboard.
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6

We can omit the the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

**pandas.Series.to_csv**

`Series.to_csv(path=None, index=True, sep=',', na_rep='', float_format=None, header=False, index_label=None, mode='w', encoding=None, compression=None, date_format=None, decimal='.`)

Write Series to a comma-separated values (csv) file

**Parameters**

- **path**: string or file handle, default None
  
  File path or object, if None is provided the result is returned as a string.

- **na_rep**: string, default “
  
  Missing data representation

- **float_format**: string, default None
  
  Format string for floating point numbers

- **header**: boolean, default False
  
  Write out series name

- **index**: boolean, default True
  
  Write row names (index)

- **index_label**: string or sequence, default None
  
  Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

- **mode**: [Python write mode, default ‘w’]
  
  Field delimiter for the output file.

- **sep**: character, default “,”
  
  Field delimiter for the output file.

- **encoding**: string, optional
  
  a string representing the encoding to use if the contents are non-ascii, for python versions prior to 3

- **compression**: string, optional
  
  compression
A string representing the compression to use in the output file. Allowed values are ‘gzip’, ‘bz2’, ‘zip’, ‘xz’. This input is only used when the first argument is a filename.

date_format: string, default None
Format string for datetime objects.

decimal: string, default ‘.’
Character recognized as decimal separator. E.g. use ‘,’ for European data

**pandas.Series.to_dense**

```
Series.to_dense()
```
Return dense representation of NDFrame (as opposed to sparse)

**pandas.Series.to_dict**

```
Series.to_dict(into=<class 'dict'>)
```
Convert Series to {label -> value} dict or dict-like object.

**Parameters into**: class, default dict

The collections.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

**Returns**

value_dict [collections.Mapping]

**Examples**

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<type 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

**pandas.Series.to_excel**

```
Series.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True)
```
Write Series to an excel sheet

New in version 0.20.0.
Parameters excel_writer : string or ExcelWriter object
    File path or existing ExcelWriter

sheet_name : string, default ‘Sheet1’
    Name of sheet which will contain DataFrame

na_rep : string, default ‘’
    Missing data representation

float_format : string, default None
    Format string for floating point numbers

columns : sequence, optional
    Columns to write

header : boolean or list of string, default True
    Write out the column names. If a list of strings is given it is assumed to be aliases for the column names

index : boolean, default True
    Write row names (index)

index_label : string or sequence, default None
    Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow :
    upper left cell row to dump data frame

startcol :
    upper left cell column to dump data frame

eengine : string, default None
    write engine to use - you can also set this via the options io.excel.xlsx.writer, io.excel.xls.writer, and io.excel.xlsm.writer.

merge_cells : boolean, default True
    Write MultiIndex and Hierarchical Rows as merged cells.

encoding : string, default None
    encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep : string, default ‘inf’
    Representation for infinity (there is no native representation for infinity in Excel)

freeze_panes : tuple of integer (length 2), default None
    Specifies the one-based bottommost row and rightmost column that is to be frozen
    New in version 0.20.0.
Notes

If passing an existing ExcelWriter object, then the sheet will be added to the existing workbook. This can be used to save different DataFrames to one workbook:

```python
>>> writer = pd.ExcelWriter('output.xlsx')
>>> df1.to_excel(writer,'Sheet1')
>>> df2.to_excel(writer,'Sheet2')
>>> writer.save()
```

For compatibility with to_csv, to_excel serializes lists and dicts to strings before writing.

pandas.Series.to_frame

`Series.to_frame(name=None)`

Convert Series to DataFrame

**Parameters**

- `name`: object, default None

  The passed name should substitute for the series name (if it has one).

**Returns**

- `data_frame`: [DataFrame]

pandas.Series.to_hdf

`Series.to_hdf(path_or_buf, key, **kwargs)`

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.

For more information see the user guide.

**Parameters**

- `path_or_buf`: str or pandas.HDFStore

  File path or HDFStore object.

- `key`: str

  Identifier for the group in the store.

- `mode`: {'a', 'w', 'r+'}, default 'a'

  Mode to open file:
  - 'w': write, a new file is created (an existing file with the same name would be deleted).
  - 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
  - 'r+': similar to 'a', but the file must already exist.

- `format`: {'fixed', 'table'}, default 'fixed'
Possible values:

- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

**append**: bool, default False

For Table formats, append the input data to the existing.

**data_columns**: list of columns or True, optional

List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via Data Columns*. Applicable only to format='table'.

**complevel**: {0-9}, optional

Specifies a compression level for data. A value of 0 disables compression.

**complib**: {'zlib', 'lz4', 'bzip2', 'blosc'}, default ‘zlib’

Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.

**fletcher32**: bool, default False

If applying compression use the fletcher32 checksum.

**dropna**: bool, default False

If true, ALL nan rows will not be written to store.

**errors**: str, default ‘strict’

Specifies how encoding and decoding errors are to be handled. See the errors argument for *open()* for a full list of options.

See also:

- **DataFrame.read_hdf** Read from HDF file.
- **DataFrame.to_parquet** Write a DataFrame to the binary parquet format.
- **DataFrame.to_sql** Write to a sql table.
- **DataFrame.to_feather** Write out feather-format for DataFrames.
- **DataFrame.to_csv** Write out to a csv file.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                     index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')

Reading from HDF file:

>>> pd.read_hdf('data.h5', 'df')
A  B
0 1 4
1 2 5
2 3 6
3 4 6

>>> pd.read_hdf('data.h5', 's')
0 1
1 2
2 3
3 4
dtype: int64

Deleting file with data:

>>> import os

>>> os.remove('data.h5')

pandas.Series.to_json

Series.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10,
force_ascii=True, date_unit='ms', default_handler=None, lines=False,
compression=None, index=True)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX time-
tamps.

Parameters path_or_buf : string or file handle, optional

File path or object. If not specified, the result is returned as a string.

orient : string

Indication of expected JSON string format.

• Series
  – default is ‘index’
  – allowed values are: {'split','records','index'}

• DataFrame
  – default is ‘columns’
  – allowed values are: {'split','records','index','columns','values'}

• The format of the JSON string
  – ‘split’ : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [val-
  ues]}
  – ‘records’ : list like [{column -> value}, ... , {column -> value}]
  – ‘index’ : dict like {index -> [column -> value]}
  – ‘columns’ : dict like {column -> {index -> value}}
– ‘values’ : just the values array
– ‘table’ : dict like {‘schema’: {schema}, ‘data’: {data}} describing the data, and the data component is like orient=’records’.

Changed in version 0.20.0.

date_format : {None, ‘epoch’, ‘iso’}

Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient=’table’, the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision : int, default 10

The number of decimal places to use when encoding floating point values.

force_ascii : boolean, default True

Force encoded string to be ASCII.

date_unit : string, default ‘ms’ (milliseconds)

The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler : callable, default None

Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines : boolean, default False

If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

New in version 0.19.0.

A string representing the compression to use in the output file, only used when the first argument is a filename.

New in version 0.21.0.

index : boolean, default True

Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

New in version 0.23.0.

See also:
pandas.read_json

Examples

```python
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                   index=['row 1', 'row 2'],
...                   columns=['col 1', 'col 2'])
>>> df.to_json(orient='split')
```

(continues on next page)
Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> df.to_json(orient='records')
'[
{"col 1": "a", "col 2": "b"},
{"col 1": "c", "col 2": "d"}]
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> df.to_json(orient='index')
'[
"row 1":{"col 1": "a", "col 2": "b"},
"row 2":{"col 1": "c", "col 2": "d"}]
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> df.to_json(orient='columns')
'[
{"col 1": "row 1": "a", "row 2": "c"},
{"col 2": "row 1": "b", "row 2": "d"}]
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> df.to_json(orient='values')
'[
["a", "b"],
["c", "d"]
]
```

Encoding with Table Schema

```python
>>> df.to_json(orient='table')
'{"schema": {
"fields": [{"name": "index", "type": "string"},
{"name": "col 1", "type": "string"},
{"name": "col 2", "type": "string"}],
"primaryKey": "index",
"pandas_version": "0.20.0"},
"data": [{
"index": "row 1",
"col 1": "a",
"col 2": "b"},
{"index": "row 2",
"col 1": "c",
"col 2": "d"}]
```

```python
pandas.Series.to_latex
```

```
Series.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='. ', multicolumn=None, multicolumn_format=None, multirow=None)
```

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires \usepackage{booktabs}.

Changed in version 0.20.2: Added to Series

to_latex-specific options:

- **bold_rows** [boolean, default False] Make the row labels bold in the output
- **column_format** [str, default None] The columns format as specified in LaTeX table format e.g `rcl` for 3 columns
- **longtable** [boolean, default will be read from the pandas config module] Default: False. Use a longtable environment instead of tabular. Requires adding a \usepackage{longtable} to your LaTeX preamble.
pandas.Series.to_msgpack

Series.to_msgpack(path_or_buf=None, encoding='utf-8', **kwargs)
msgpack (serialize) object to input file path

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

Parameters

path : string File path, buffer-like, or None
if None, return generated string
append : boolean whether to append to an existing msgpack
        (default is False)
compress : type of compressor (zlib or blosc), default to None (no compression)

pandas.Series.to_period

Series.to_period(freq=None, copy=True)
Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed)

Parameters

freq [string, default]

Returns

ts [Series with PeriodIndex]
**pandas.Series.to_pickle**

Series.to_pickle(path, compression='infer', protocol=4)

Pickle (serialize) object to file.

**Parameters**

- **path**: str
  
  File path where the pickled object will be stored.

- **compression**: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'
  
  A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

  New in version 0.20.0.

- **protocol**: int
  
  Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [R27] paragraph 12.1.2). The possible values for this parameter depend on the version of Python. For Python 2.x, possible values are 0, 1, 2. For Python>=3.0, 3 is a valid value. For Python >= 3.4, 4 is a valid value. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

  New in version 0.21.0.

**See also:**

- **read_pickle** Load pickled pandas object (or any object) from file.

- **DataFrame.to_hdf** Write DataFrame to an HDF5 file.

- **DataFrame.to_sql** Write DataFrame to a SQL database.

- **DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

**Examples**

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```python
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```
>>> import os
>>> os.remove("./dummy.pkl")

**pandas.Series.to_sparse**

`Series.to_sparse(kind='block', fill_value=None)`

Convert Series to SparseSeries

**Parameters**

- **kind** : `{'block', 'integer'}`
- **fill_value** : `float`, defaults to NaN (missing)

**Returns**

- **sp** : `SparseSeries`

**pandas.Series.to_sql**

`Series.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [R28] are supported. Tables can be newly created, appended to, or overwritten.

**Parameters**

- **name** : `string`
  Name of SQL table.
- **con** : `sqlalchemy.engine.Engine` or `sqlite3.Connection`
  Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for `sqlite3.Connection` objects.
- **schema** : `string`, optional
  Specify the schema (if database flavor supports this). If None, use default schema.
- **if_exists** : `{'fail', 'replace', 'append'}`, default ‘fail’
  How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
- **index** : `boolean`, default True
  Write DataFrame index as a column. Uses `index_label` as the column name in the table.
- **index_label** : `string` or sequence, default None
  Column label for index column(s). If None is given (default) and `index` is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **chunksize** : `int`, optional
Rows will be written in batches of this size at a time. By default, all rows will be written at once.

**dtype** : dict, optional

Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**Raises** ValueError

When the table already exists and **if_exists** is ‘fail’ (the default).

**See also:**

*pandas.read_sql* read a DataFrame from a table

**References**

[R28], [R29]

**Examples**

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3

>>> df.to_sql('users', con=engine)
```

```python
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```python
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
```

```python
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'), (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just `df1`.

```python
>>> df1.to_sql('users', con=engine, if_exists='replace',
...            index_label='id')
```

```python
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```
Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
def = pd.DataFrame({"A": [1, None, 2]})
def
A
0  1.0
1  NaN
2  2.0
```

```python
from sqlalchemy.types import Integer

def.to_sql('integers', con=engine, index=False,
  ...  
dtype={"A": Integer()})
```

```python
engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

### pandas.Series.to_string

`Series.to_string(buf=None, na_rep='NaN', float_format=None, header=True, index=True, length=False, dtype=False, name=False, max_rows=None)`

Render a string representation of the Series

- **Parameters**
  - `buf`: StringIO-like, optional
    - buffer to write to
  - `na_rep`: string, optional
    - string representation of NAN to use, default ‘NaN’
  - `float_format`: one-parameter function, optional
    - formatter function to apply to columns’ elements if they are floats default None
  - `header`: boolean, default True
    - Add the Series header (index name)
  - `index`: bool, optional
    - Add index (row) labels, default True
  - `length`: boolean, default False
    - Add the Series length
  - `dtype`: boolean, default False
    - Add the Series dtype
  - `name`: boolean, default False
    - Add the Series name if not None
  - `max_rows`: int, optional
    - Maximum number of rows to show before truncating. If None, show all.

- **Returns**
  - `formatted` [string (if not buffer passed)]
pandas.Series.to_timestamp

`Series.to_timestamp(freq=None, how='start', copy=True)`

Cast to datetimeindex of timestamps, at beginning of period

**Parameters**

- `freq`: string, default frequency of PeriodIndex
  - Desired frequency
- `how`: {'s', 'e', 'start', 'end'}
  - Convention for converting period to timestamp; start of period vs. end

**Returns**

- `ts` [Series with DatetimeIndex]

pandas.Series.to_xarray

`Series.to_xarray()`

Return an xarray object from the pandas object.

**Returns**

- a DataArray for a Series
- a Dataset for a DataFrame
- a DataArray for higher dims

**Notes**

See the xarray docs

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 1, 2],
                    'B': ['foo', 'bar', 'foo'],
                    'C': np.arange(4.,7)})
>>> df
   A  B    C
0  1  foo  4.0
1  1  bar  5.0
2  2  foo  6.0

>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (index: 3)
Coordinates:
* index (index) int64 0 1 2
Data variables:
  A (index) int64 1 1 2
  B (index) object 'foo' 'bar' 'foo'
  C (index) float64 4.0 5.0 6.0
```
```python
>>> df = pd.DataFrame({'A' : [1, 1, 2],
                    'B' : ['foo', 'bar', 'foo'],
                    'C' : np.arange(4.,7)}
).set_index(['B', 'A'])

>>> df
       C
B A     
foo 1  4.0
bar 1  5.0
foo 2  6.0

>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (A: 2, B: 2)
Coordinates:
   * B (B) object 'bar' 'foo'
   * A (A) int64 1 2
Data variables:
   C (B, A) float64 5.0 nan 4.0 6.0

>>> p = pd.Panel(np.arange(24).reshape(4,3,2),
                items=list('ABCD'),
                major_axis=pd.date_range('20130101', periods=3),
                minor_axis=['first', 'second'])

>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 2 (minor_axis)
    Items axis: A to D

  [20, 21],
  [22, 23]]])
Coordinates:
   * items (items) object 'A' 'B' 'C' 'D'
   * major_axis (major_axis) datetime64[ns] 2013-01-01 2013-01-02 2013-01-03
   * minor_axis (minor_axis) object 'first' 'second'

pandas.Series.tolist

Series.tolist()
Return a list of the values.
These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

See also:

numpy.ndarray.tolist

pandas.Series.transform

Series.transform(func, *args, **kwargs)

Call function producing a like-indexed NDFrame and return a NDFrame with the transformed values

New in version 0.20.0.

Parameters

func : callable, string, dictionary, or list of string/callables

To apply to column

Accepted Combinations are:

• string function name

• function

• list of functions

• dict of column names -> functions (or list of functions)

Returns

transformed [NDFrame]

See also:

pandas.NDFrame.aggregate, pandas.NDFrame.apply

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                    index=pd.date_range('1/1/2000', periods=10))
df.iloc[3:7] = np.nan

>>> df.transform(lambda x: (x - x.mean()) / x.std())
                     A          B          C
2000-01-01  0.579457  1.236184  0.123424
2000-01-02  0.370357 -0.605875 -1.231325
2000-01-03  1.455756 -0.277446  0.288967
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08 -0.498658  1.274522  1.642524
2000-01-09 -0.540524 -1.012676 -0.828968
2000-01-10 -1.366388 -0.614710  0.005378
```
**pandas.Series.transpose**

Series.transpose(*args, **kwargs)

return the transpose, which is by definition self

**pandas.Series.truediv**

Series.truediv(other, level=None, fill_value=None, axis=0)

Floating division of series and other, element-wise (binary operator truediv).

Equivalent to series / other, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** : None or float value, default None (NaN)
  Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing
- **level** : int or name
  Broadcast across a level, matching Index values on the passed MultiIndex level

**Returns**

result [Series]

**See also:**

Series.rtruediv

**Examples**

```python
data.txt
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.add(b, fill_value=0)
a  2.0
b  1.0
c  1.0
d  1.0
e  NaN
dtype: float64
```
pandas.Series.truncate

Series.truncate(before=None, after=None, axis=None, copy=True)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- **before**: date, string, int
  - Truncate all rows before this index value.

- **after**: date, string, int
  - Truncate all rows after this index value.

- **axis**: {0 or ‘index’, 1 or ‘columns’}, optional
  - Axis to truncate. Truncates the index (rows) by default.

- **copy**: boolean, default is True,
  - Return a copy of the truncated section.

**Returns**

The truncated Series or DataFrame.

**See also:**

- **DataFrame.loc** Select a subset of a DataFrame by label.
- **DataFrame.iloc** Select a subset of a DataFrame by position.

**Notes**

If the index being truncated contains only datetime values, **before** and **after** may be specified as strings instead of Timestamps.

**Examples**

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
                    'B': ['f', 'g', 'h', 'i', 'j'],
                    'C': ['k', 'l', 'm', 'n', 'o'],
                    index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o

>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.
For Series, only rows can be truncated.

```python
df['A'].truncate(before=2, after=4)
```

The index values in `truncate` can be datetimes or string dates.

```python
dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
df = pd.DataFrame(index=dates, data={'A': 1})
df.tail()
```

Because the index is a DatetimeIndex containing only dates, we can specify `before` and `after` as strings. They will be coerced to Timestamps before truncation.

```python
df.truncate(before=pd.Timestamp('2016-01-05'), after=pd.Timestamp('2016-01-10')).tail()
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```python
df.loc['2016-01-05':'2016-01-10', :].tail()
```
pandas.Series.tshift

Series.tshift (periods=1, freq=None, axis=0)
Shift the time index, using the index’s frequency if available.

Parameters
- **periods**: int
  Number of periods to move, can be positive or negative
- **freq**: DateOffset, timedelta, or time rule string, default None
  Increment to use from the tseries module or time rule (e.g. ‘EOM’)
- **axis**: int or basestring
  Corresponds to the axis that contains the Index

Returns
- **shifted**: [NDFrame]

Notes
If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.Series.tz_convert

Series.tz_convert (tz, axis=0, level=None, copy=True)
Convert tz-aware axis to target time zone.

Parameters
- **tz**: [string or pytz.timezone object]
- **axis**: [the axis to convert]
- **level**: int, str, default None
  If axis ia a MultiIndex, convert a specific level. Otherwise must be None
- **copy**: boolean, default True
  Also make a copy of the underlying data

Raises **TypeError**
If the axis is tz-naive.

pandas.Series.tz_localize

Series.tz_localize (tz, axis=0, level=None, copy=True, ambiguous='raise')
Localize tz-naive TimeSeries to target time zone.
Parameters

tz  [string or pytz.timezone object]
axis [the axis to localize]
level : int, str, default None
    If axis ia a MultiIndex, localize a specific level. Otherwise must be None
copy : boolean, default True
    Also make a copy of the underlying data
ambiguous : ‘infer’, bool-ndarray, ‘NaT’, default ‘raise’
    • ‘infer’ will attempt to infer fall dst-transition hours based on order
    • bool-ndarray where True signifies a DST time, False designates a non-DST time (note
      that this flag is only applicable for ambiguous times)
    • ‘NaT’ will return NaT where there are ambiguous times
    • ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

Raises TypeError
    If the TimeSeries is tz-aware and tz is not None.

pandas.Series.unique

Series.unique()
Return unique values of Series object.
Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns ndarray or Categorical
The unique values returned as a NumPy array. In case of categorical data type,
returned as a Categorical.

See also:
pandas.unique top-level unique method for any 1-d array-like object.
Index.unique return Index with unique values from an Index object.

Examples

```python
gpd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```python
gpd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```python
gpd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern') for _ in range(3)]).unique()
array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
dtype=object)
```

An unordered Categorical will return categories in the order of appearance.
```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]

Categories (3, object): [b, a, c]

An ordered Categorical preserves the category ordering.

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
... ordered=True)).unique()
[b, a, c]

Categories (3, object): [a < b < c]
```

### pandas.Series.unstack

**`Series.unstack(level=-1, fill_value=None)`**

Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame. The level involved will automatically get sorted.

**Parameters**

- `level`: int, string, or list of these, default last level
  - Level(s) to unstack, can pass level name
- `fill_value`: replace NaN with this value if the unstack produces
  - missing values

**Returns**

- `unstacked` [DataFrame]

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4],
... index=pd.MultiIndex.from_product([['one', 'two'], ['a', 'b']]))
>>> s
one a 1
   b 2
two a 3
   b 4
dtype: int64

>>> s.unstack(level=-1)
a b
one 1 2
two 3 4

>>> s.unstack(level=0)
one two
   a 1 3
   b 2 4
```
pandas.Series.update

Series.update(other)
Modify Series in place using non-NA values from passed Series. Aligns on index

Parameters

other [Series]

Examples

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0 4
1 5
2 6
dtype: int64
```

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0 d
1 b
2 e
dtype: object
```

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0 4
1 5
2 6
dtype: int64
```

If other contains NaNs the corresponding values are not updated in the original Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0 4
1 2
2 6
dtype: int64
```

pandas.Series.valid

Series.valid(inplace=False, **kwargs)
Return Series without null values.

Deprecated since version 0.23.0: Use Series.dropna() instead.
pandas.Series.value_counts

```
Series.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)
```

Returns object containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

**Parameters**

- **normalize**: boolean, default False
  
  If True then the object returned will contain the relative frequencies of the unique values.

- **sort**: boolean, default True
  
  Sort by values

- **ascending**: boolean, default False
  
  Sort in ascending order

- **bins**: integer, optional
  
  Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data

- **dropna**: boolean, default True
  
  Don’t include counts of NaN.

**Returns**

- **counts**: [Series]

pandas.Series.var

```
System.var(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
```

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

**Parameters**

- **axis**: [index (0)]

- **skipna**: boolean, default True
  
  Exclude NA/null values. If an entire row/column is NA, the result will be NA

- **level**: int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

- **ddof**: int, default 1
  
  Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

- **numeric_only**: boolean, default None
  
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
Returns

var [scalar or Series (if level specified)]

**pandas.Series.view**

Series.view(dtype=None)

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

**Parameters**

dtype : data type

Data type object or one of their string representations.

**Returns**

Series

A new Series object as a view of the same data in memory.

See also:

numpy.ndarray.view Equivalent numpy function to create a new view of the same data in memory.

Notes

Series are instantiated with dtype=float64 by default. While numpy.ndarray.view() will return a view with the same data type as the original array, Series.view() (without specified dtype) will try using float64 and may fail if the original data type size in bytes is not the same.

Examples

```python
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0   -2
1   -1
2    0
3    1
4    2
dtype: int8
```

The 8 bit signed integer representation of -1 is \texttt{0b11111111}, but the same bytes represent 255 if read as an 8 bit unsigned integer:

```python
>>> us = s.view('uint8')
>>> us
0   254
1   255
2    0
3    1
4    2
dtype: uint8
```

The views share the same underlying values:
>>> us[0] = 128
>>> s
0  -128
1   -1
2    0
3    1
4    2
dtype: int8

**pandas.Series.where**

`Series.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)`

Return an object of same shape as self and whose corresponding entries are from self where `cond` is True and otherwise are from `other`.

**Parameters**

- **cond**: boolean NDFrame, array-like, or callable
  
  Where `cond` is True, keep the original value. Where False, replace with corresponding value from `other`. If `cond` is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn’t check it).
  
  New in version 0.18.1: A callable can be used as cond.

- **other**: scalar, NDFrame, or callable
  
  Entries where `cond` is False are replaced with corresponding value from `other`. If other is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn’t check it).
  
  New in version 0.18.1: A callable can be used as other.

- **inplace**: boolean, default False
  
  Whether to perform the operation in place on the data

- **axis** [alignment axis if needed, default None]

- **level** [alignment level if needed, default None]

- **errors** : str, {‘raise’, ‘ignore’}, default ‘raise’
  
  - **raise**: allow exceptions to be raised
  
  - **ignore**: suppress exceptions. On error return original object
  
  Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

- **try_cast**: boolean, default False
  
  try to cast the result back to the input type (if possible).

- **raise_on_error**: boolean, default True
  
  Whether to raise on invalid data types (e.g. trying to where on strings)

**Returns**
wh [same type as caller]

See also:

`DataFrame.mask()`

Notes

The `where` method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `True` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in `indexing`.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1      1.0
2      2.0
3      3.0
4      4.0

>>> s.mask(s > 0)
0      0.0
1     NaN
2     NaN
3     NaN
4     NaN

>>> s.where(s > 1, 10)
0    10.0
1    10.0
2      2.0
3      3.0
4      4.0

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0  -1
1 -2   3
2 -4  -5
3  6  -7
4 -8   9

>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
```
```python
>>> df.where(m, -df) == df.mask(~m, -df)
A  B
0 True True
1 True True
2 True True
3 True True
4 True True
```

**pandas.Series.xs**

**Series.xs** *(key, axis=0, level=None, drop_level=True)*  
Returns a cross-section (row(s) or column(s)) from the Series/DataFrame. Defaults to cross-section on the rows (axis=0).

**Parameters**  
- **key**: object  
  Some label contained in the index, or partially in a MultiIndex  
- **axis**: int, default 0  
  Axis to retrieve cross-section on  
- **level**: object, defaults to first n levels (n=1 or len(key))  
  In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.  
- **drop_level**: boolean, default True  
  If False, returns object with same levels as self.

**Returns**  
- **xs**: [Series or DataFrame]

**Notes**

xs is only for getting, not setting values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of xs functionality, see *MultiIndex Slicers*

**Examples**

```python
>>> df
   A  B  C
a 4  5  2
b 4  0  9
c 9  7  3
>>> df.xs('a')
   A  B  C
A 4
B 5
C 2
```
Name: a

```python
>>> df.xs('C', axis=1)
a  2
b  9
c  3
Name: C
```

```python
>>> df
first  second  third
bar    one    1  4  1  8  9
two    one    1  7  5  5  0
baz    one    1  6  6  8  0
two    one    1  7  5  5  0
baz    one    1  6  6  8  0
three  one    1  6  6  8  0
three  two    2  5  3  5  3
```

```python
>>> df.xs(('baz', 'three'))
A  B  C  D
third
2  5  3  5  3
```

```python
>>> df.xs('one', level=1)
A  B  C  D
first  third
bar  1  4  1  8  9
baz  1  6  6  8  0
```

```python
>>> df.xs(('baz', 2), level=[0, 'third'])
A  B  C  D
second  third
three  5  3  5  3
```

### 34.3.2 Attributes

**Axes**

- **Series.index**
  - The index (axis labels) of the Series.

- **Series.values**
  - Return Series as ndarray or ndarray-like depending on the dtype

- **Series.dtype**
  - return the dtype object of the underlying data

- **Series.itype**
  - return if the data is sparse

- **Series.shape**
  - return a tuple of the shape of the underlying data

- **Series nbytes**
  - return the number of bytes in the underlying data

- **Series.ndim**
  - return the number of dimensions of the underlying data, by definition 1

- **Series.size**
  - return the number of elements in the underlying data

- **Series.strides**
  - return the strides of the underlying data

- **Series.itemsize**
  - return the size of the dtype of the item of the underlying data

- **Series.base**
  - return the base object if the memory of the underlying data is shared

- **Series.T**
  - return the transpose, which is by definition self

- **Series.memory_usage([index, deep])**
  - Return the memory usage of the Series.

- **Series.hasnans**
  - return if I have any nans; enables various perf speedups

<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Series.loc</strong></td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td><strong>Series.iloc</strong></td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td><strong>Series.<strong>iter</strong>()</strong></td>
<td>Return an iterator of the values.</td>
</tr>
<tr>
<td><strong>Series.iteritems()</strong></td>
<td>Lazily iterate over (index, value) tuples</td>
</tr>
<tr>
<td><strong>Series.items()</strong></td>
<td>Lazily iterate over (index, value) tuples</td>
</tr>
<tr>
<td><strong>Series.keys()</strong></td>
<td>Alias for index</td>
</tr>
<tr>
<td><strong>Series.pop(item)</strong></td>
<td>Return item and drop from frame.</td>
</tr>
<tr>
<td><strong>Series.item()</strong></td>
<td>return the first element of the underlying data as a python scalar</td>
</tr>
<tr>
<td><strong>Series.xs(key[, axis, level, drop_level])</strong></td>
<td>Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.</td>
</tr>
</tbody>
</table>

34.3.4.1 pandas.Series.__iter__

Series.__iter__()  
Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

For more information on .at, .iat, .loc, and .iloc, see the indexing documentation.

34.3.5 Binary operator functions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Series.add(other[, level, fill_value, axis])</strong></td>
<td>Addition of series and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td><strong>Series.sub(other[, level, fill_value, axis])</strong></td>
<td>Subtraction of series and other, element-wise (binary operator sub).</td>
</tr>
<tr>
<td><strong>Series.mul(other[, level, fill_value, axis])</strong></td>
<td>Multiplication of series and other, element-wise (binary operator mul).</td>
</tr>
<tr>
<td><strong>Series.div(other[, level, fill_value, axis])</strong></td>
<td>Floating division of series and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><strong>Series.truediv(other[, level, fill_value, axis])</strong></td>
<td>Floating division of series and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><strong>Series.floordiv(other[, level, fill_value, axis])</strong></td>
<td>Integer division of series and other, element-wise (binary operator floordiv).</td>
</tr>
<tr>
<td><strong>Series.mod(other[, level, fill_value, axis])</strong></td>
<td>Modulo of series and other, element-wise (binary operator mod).</td>
</tr>
<tr>
<td><strong>Series.pow(other[, level, fill_value, axis])</strong></td>
<td>Exponential power of series and other, element-wise (binary operator pow).</td>
</tr>
<tr>
<td><strong>Series.radd(other[, level, fill_value, axis])</strong></td>
<td>Addition of series and other, element-wise (binary operator radd).</td>
</tr>
<tr>
<td><strong>Series.rsub(other[, level, fill_value, axis])</strong></td>
<td>Subtraction of series and other, element-wise (binary operator rsub).</td>
</tr>
<tr>
<td><strong>Series.rmul(other[, level, fill_value, axis])</strong></td>
<td>Multiplication of series and other, element-wise (binary operator rmul).</td>
</tr>
<tr>
<td><strong>Series.rdiv(other[, level, fill_value, axis])</strong></td>
<td>Floating division of series and other, element-wise (binary operator rtruediv).</td>
</tr>
</tbody>
</table>

Continued on next page
Table 30 – continued from previous page

- `Series.rtruediv(other[, level, fill_value, axis])`: Floating division of series and other, element-wise (binary operator `rtruediv`).
- `Series.rfloordiv(other[, level, fill_value, ...])`: Integer division of series and other, element-wise (binary operator `rfloordiv`).
- `Series.rmod(other[, level, fill_value, axis])`: Modulo of series and other, element-wise (binary operator `rmod`).
- `Series.rpow(other[, level, fill_value, axis])`: Exponential power of series and other, element-wise (binary operator `rpow`).
- `Series.combine(other, func[, fill_value])`: Perform elementwise binary operation on two Series using given function with optional fill value when an index is missing from one Series or the other.
- `Series.combine_first(other)`: Combine Series values, choosing the calling Series’s values first.
- `Series.round([decimals])`: Round each value in a Series to the given number of decimals.
- `Series.lt(other[, level, fill_value, axis])`: Less than of series and other, element-wise (binary operator `lt`).
- `Series.gt(other[, level, fill_value, axis])`: Greater than of series and other, element-wise (binary operator `gt`).
- `Series.le(other[, level, fill_value, axis])`: Less than or equal to of series and other, element-wise (binary operator `le`).
- `Series.ge(other[, level, fill_value, axis])`: Greater than or equal to of series and other, element-wise (binary operator `ge`).
- `Series.ne(other[, level, fill_value, axis])`: Not equal to of series and other, element-wise (binary operator `ne`).
- `Series.eq(other[, level, fill_value, axis])`: Equal to of series and other, element-wise (binary operator `eq`).
- `Series.product([axis, skipna, level, ...])`: Return the product of the values for the requested axis.
- `Series.dot(other)`: Matrix multiplication with DataFrame or inner-product with Series objects.

34.3.6 Function application, GroupBy & Window

- `Series.apply(func[, convert_dtype, args])`: Invoke function on values of Series.
- `Series.agg(func[, axis])`: Aggregate using one or more operations over the specified axis.
- `Series.aggregate(func[, axis])`: Aggregate using one or more operations over the specified axis.
- `Series.transform(func, *args, **kwargs)`: Call function producing a like-indexed NDFrame and return a NDFrame with the transformed values.
- `Series.map(arg[, na_action])`: Map values of Series using input correspondence (a dict, Series, or function).
- `Series.groupby([by, axis, level, as_index, ...])`: Group series using mapper (dict or key function, apply given function to group, return result as series) or by a series of columns.
- `Series.rolling(window[, min_periods, ...])`: Provides rolling window calculations.
- `Series.exponentiating([min_periods, center, axis])`: Provides expanding transformations.
- `Series.ewm([com, span, halflife, alpha, ...])`: Provides exponential weighted functions.
- `Series.pipe(func, *args, **kwargs)`: Apply func(self, *args, **kwargs).
### 34.3.7 Computations / Descriptive Stats

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>Series.all([axis, bool_only, skipna, level])</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>Series.any([axis, bool_only, skipna, level])</code></td>
<td>Return whether any element is True over requested axis.</td>
</tr>
<tr>
<td><code>Series.autocorr(lag)</code></td>
<td>Lag-N autocorrelation</td>
</tr>
<tr>
<td><code>Series.between(left, right[, inclusive])</code></td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td><code>Series.clip([lower, upper, axis, inplace])</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>Series.clip_lower(threshold[, axis, inplace])</code></td>
<td>Return copy of the input with values below a threshold truncated.</td>
</tr>
<tr>
<td><code>Series.clip_upper(threshold[, axis, inplace])</code></td>
<td>Return copy of input with values above given value(s) truncated.</td>
</tr>
<tr>
<td><code>Series.corr(other[, method, min_periods])</code></td>
<td>Compute correlation with other Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.count([level])</code></td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td><code>Series.cov(other[, min_periods])</code></td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.cummax([axis, skipna])</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cummin([axis, skipna])</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumprod([axis, skipna])</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumsum([axis, skipna])</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.describe([percentiles, include, exclude])</code></td>
<td>Generates descriptive statistics that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.</td>
</tr>
<tr>
<td><code>Series.diff([periods])</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>Series.factorize([sort, na_sentinel])</code></td>
<td>Encode the object as an enumerated type or categorical variable.</td>
</tr>
<tr>
<td><code>Series.kurt([axis, skipna, level, numeric_only])</code></td>
<td>Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0).</td>
</tr>
<tr>
<td><code>Series.mad([axis, skipna, level])</code></td>
<td>Return the mean absolute deviation of the values for the requested axis.</td>
</tr>
<tr>
<td><code>Series.max([axis, skipna, level])</code></td>
<td>Return the mean absolute deviation of the values for the requested axis.</td>
</tr>
<tr>
<td><code>Series.mean([axis, skipna, level, numeric_only])</code></td>
<td>This method returns the maximum of the values in the object.</td>
</tr>
<tr>
<td><code>Series.median([axis, skipna, level, ...])</code></td>
<td>Return the median of the values for the requested axis.</td>
</tr>
<tr>
<td><code>Series.min([axis, skipna, level, numeric_only])</code></td>
<td>This method returns the minimum of the values in the object.</td>
</tr>
<tr>
<td><code>Series.mode()</code></td>
<td>Return the mode(s) of the dataset.</td>
</tr>
<tr>
<td><code>Series.nlargest([n, keep])</code></td>
<td>Return the largest (n) elements.</td>
</tr>
<tr>
<td><code>Series.nsmallest([n, keep])</code></td>
<td>Return the smallest (n) elements.</td>
</tr>
<tr>
<td><code>Series.pct_change([periods, fill_method, ...])</code></td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><code>Series.prod([axis, skipna, level, ...])</code></td>
<td>Return the product of the values for the requested axis</td>
</tr>
</tbody>
</table>

### 34.3.8 Reindexing / Selection / Label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.align()</code></td>
<td>Align two objects on their axes with the specified join method for each axis Index</td>
</tr>
<tr>
<td><code>Series.drop()</code></td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td><code>Series.drop_duplicates()</code></td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td><code>Series.equals()</code></td>
<td>Indicate duplicate Series values.</td>
</tr>
<tr>
<td><code>Series.first()</code></td>
<td>Convenience method for subsetting initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.head()</code></td>
<td>Return the first (n) rows.</td>
</tr>
<tr>
<td><code>Series.idxmax()</code></td>
<td>Return the row label of the maximum value.</td>
</tr>
<tr>
<td><code>Series.idxmin()</code></td>
<td>Return the row label of the minimum value.</td>
</tr>
<tr>
<td><code>Series.isin()</code></td>
<td>Check whether (values) are contained in Series.</td>
</tr>
<tr>
<td><code>Series.last()</code></td>
<td>Convenience method for subsetting final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.reindex()</code></td>
<td>Conform Series to new index with optional filling logic, placing NA/Nan in locations having no value in the previous index.</td>
</tr>
</tbody>
</table>
### Table 33 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.reindex_like()</code></td>
<td>Return an object with matching indices to myself.</td>
</tr>
<tr>
<td><code>Series.rename()</code></td>
<td>Alter Series index labels or name.</td>
</tr>
<tr>
<td><code>Series.rename_axis()</code></td>
<td>Alter the name of the index or columns.</td>
</tr>
<tr>
<td><code>Series.reset_index()</code></td>
<td>Generate a new DataFrame or Series with the index reset.</td>
</tr>
<tr>
<td><code>Series.sample()</code></td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td><code>Series.select()</code></td>
<td>(DEPRECATED) Return data corresponding to axis labels matching criteria.</td>
</tr>
<tr>
<td><code>Series.set_axis()</code></td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td><code>Series.take()</code></td>
<td>Return the elements in the given positional indices along an axis.</td>
</tr>
<tr>
<td><code>Series.tail()</code></td>
<td>Return the last $n$ rows.</td>
</tr>
<tr>
<td><code>Series.truncate()</code></td>
<td>Truncate a Series or DataFrame before and after some index value.</td>
</tr>
<tr>
<td><code>Series.where()</code></td>
<td>Return an object of same shape as self and whose corresponding entries are from self where <code>cond</code> is True and otherwise are from <code>other</code>.</td>
</tr>
<tr>
<td><code>Series.mask()</code></td>
<td>Return an object of same shape as self and whose corresponding entries are from self where <code>cond</code> is False and otherwise are from <code>other</code>.</td>
</tr>
<tr>
<td><code>Series.add_prefix()</code></td>
<td>Prefix labels with string <code>prefix</code>.</td>
</tr>
<tr>
<td><code>Series.add_suffix()</code></td>
<td>Suffix labels with string <code>suffix</code>.</td>
</tr>
<tr>
<td><code>Series.filter()</code></td>
<td>Subset rows or columns of dataframe according to labels in the specified index.</td>
</tr>
<tr>
<td><code>Series.isna()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>Series.notna()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>Series.dropna()</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>Series.fillna()</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>Series.interpolate()</code></td>
<td>Interpolate values according to different methods.</td>
</tr>
<tr>
<td><code>Series.argsort()</code></td>
<td>Overrides ndarray.argsort.</td>
</tr>
<tr>
<td><code>Series.argmin()</code></td>
<td>(DEPRECATED) ..</td>
</tr>
<tr>
<td><code>Series.argmax()</code></td>
<td>(DEPRECATED) ..</td>
</tr>
<tr>
<td><code>Series.reorder_levels()</code></td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><code>Series.sort_values()</code></td>
<td>Sort by the values.</td>
</tr>
<tr>
<td><code>Series.sort_index()</code></td>
<td>Sort Series by index labels.</td>
</tr>
<tr>
<td><code>Series.swaplevel()</code></td>
<td>Swap levels $i$ and $j$ in a MultiIndex.</td>
</tr>
<tr>
<td><code>Series.unstack()</code></td>
<td>Unstack, a.k.a.</td>
</tr>
<tr>
<td><code>Series.searchsorted()</code></td>
<td>Find indices where elements should be inserted to maintain order.</td>
</tr>
<tr>
<td><code>Series.ravel()</code></td>
<td>Return the flattened underlying data as an ndarray.</td>
</tr>
<tr>
<td><code>Series.repeat()</code></td>
<td>Repeat elements of an Series.</td>
</tr>
<tr>
<td><code>Series.squeeze()</code></td>
<td>Squeeze length 1 dimensions.</td>
</tr>
</tbody>
</table>

### 34.3.9 Missing data handling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.isna()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>Series.notna()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>Series.dropna()</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>Series.fillna()</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>Series.interpolate()</code></td>
<td>Interpolate values according to different methods.</td>
</tr>
</tbody>
</table>

### 34.3.10 Reshaping, sorting

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.argsort()</code></td>
<td>Overrides ndarray.argsort.</td>
</tr>
<tr>
<td><code>Series.argmin()</code></td>
<td>(DEPRECATED) ..</td>
</tr>
<tr>
<td><code>Series.argmax()</code></td>
<td>(DEPRECATED) ..</td>
</tr>
<tr>
<td><code>Series.reorder_levels()</code></td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><code>Series.sort_values()</code></td>
<td>Sort by the values.</td>
</tr>
<tr>
<td><code>Series.sort_index()</code></td>
<td>Sort Series by index labels.</td>
</tr>
<tr>
<td><code>Series.swaplevel()</code></td>
<td>Swap levels $i$ and $j$ in a MultiIndex.</td>
</tr>
<tr>
<td><code>Series.unstack()</code></td>
<td>Unstack, a.k.a.</td>
</tr>
<tr>
<td><code>Series.searchsorted()</code></td>
<td>Find indices where elements should be inserted to maintain order.</td>
</tr>
<tr>
<td><code>Series.ravel()</code></td>
<td>Return the flattened underlying data as an ndarray.</td>
</tr>
<tr>
<td><code>Series.repeat()</code></td>
<td>Repeat elements of an Series.</td>
</tr>
<tr>
<td><code>Series.squeeze()</code></td>
<td>Squeeze length 1 dimensions.</td>
</tr>
</tbody>
</table>
Table 35 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.view([dtype])</code></td>
<td>Create a new view of the Series.</td>
</tr>
<tr>
<td><code>Series.sortlevel([level, ascending, ...])</code></td>
<td>(DEPRECATED) Sort Series with MultiIndex by chosen level.</td>
</tr>
</tbody>
</table>

### 34.3.11 Combining / joining / merging

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.append(to_append[, ignore_index, ...])</code></td>
<td>Concatenate two or more Series.</td>
</tr>
<tr>
<td><code>Series.replace([to_replace, value, inplace, ...])</code></td>
<td>Replace values given in <code>to_replace</code> with <code>value</code>.</td>
</tr>
<tr>
<td><code>Series.update(other)</code></td>
<td>Modify Series in place using non-NA values from passed Series.</td>
</tr>
</tbody>
</table>

### 34.3.12 Time series-related

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.asfreq(freq[, method, how, ...])</code></td>
<td>Convert TimeSeries to specified frequency.</td>
</tr>
<tr>
<td><code>Series.asof(where[, subset])</code></td>
<td>The last row without any NaN is taken (or the last row without NaN considering only the subset of columns in the case of a DataFrame)</td>
</tr>
<tr>
<td><code>Series.shift([periods, freq, axis])</code></td>
<td>Shift index by desired number of periods with an optional time freq</td>
</tr>
<tr>
<td><code>Series.first_valid_index()</code></td>
<td>Return index for first non-NA/null value.</td>
</tr>
<tr>
<td><code>Series.last_valid_index()</code></td>
<td>Return index for last non-NA/null value.</td>
</tr>
<tr>
<td><code>Series.resample(rule[, how, axis, ...])</code></td>
<td>Convenience method for frequency conversion and resampling of time series.</td>
</tr>
<tr>
<td><code>Series.tz_convert(tz[, axis, level, copy])</code></td>
<td>Convert tz-aware axis to target time zone.</td>
</tr>
<tr>
<td><code>Series.tz_localize(tz[, axis, level, copy, ...])</code></td>
<td>Localize tz-naive TimeSeries to target time zone.</td>
</tr>
<tr>
<td><code>Series.at_time(time[, asof])</code></td>
<td>Select values at particular time of day (e.g. 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>Series.between_time(start_time, end_time[, ...])</code></td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>Series.tshift([periods, freq, axis])</code></td>
<td>Shift the time index, using the index’s frequency if available.</td>
</tr>
<tr>
<td><code>Series.slice_shift([periods, axis])</code></td>
<td>Equivalent to <code>shift</code> without copying data.</td>
</tr>
</tbody>
</table>

### 34.3.13 Datetimelike Properties

`Series.dt` can be used to access the values of the series as datetimelike and return several properties. These can be accessed like `Series.dt.<property>`.

**Datetime Properties**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.dt.date</code></td>
<td>Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).</td>
</tr>
<tr>
<td><code>Series.dt.time</code></td>
<td>Returns numpy array of datetime.time.</td>
</tr>
<tr>
<td><code>Series.dt.year</code></td>
<td>The year of the datetime</td>
</tr>
<tr>
<td><code>Series.dt.month</code></td>
<td>The month as January=1, December=12</td>
</tr>
<tr>
<td><code>Series.dt.day</code></td>
<td>The days of the datetime</td>
</tr>
<tr>
<td><code>Series.dt.hour</code></td>
<td>The hours of the datetime</td>
</tr>
<tr>
<td><code>Series.dt.minute</code></td>
<td>The minutes of the datetime</td>
</tr>
<tr>
<td><code>Series.dt.second</code></td>
<td>The seconds of the datetime</td>
</tr>
</tbody>
</table>

Continued on next page
Table 38 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.microsecond</td>
<td>The microseconds of the datetime</td>
</tr>
<tr>
<td>Series.dt.nanosecond</td>
<td>The nanoseconds of the datetime</td>
</tr>
<tr>
<td>Series.dt.week</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>Series.dt.weekofyear</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>Series.dt.dayofweek</td>
<td>The day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>Series.dt.weekday</td>
<td>The day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>Series.dt.dayofyear</td>
<td>The ordinal day of the year</td>
</tr>
<tr>
<td>Series.dt.quarter</td>
<td>The quarter of the date</td>
</tr>
<tr>
<td>Series.dt.is_month_start</td>
<td>Logical indicating if first day of month (defined by frequency)</td>
</tr>
<tr>
<td>Series.dt.is_month_end</td>
<td>Indicator for whether the date is the last day of the month.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_start</td>
<td>Indicator for whether the date is the first day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_end</td>
<td>Indicator for whether the date is the last day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_year_start</td>
<td>Indicate whether the date is the first day of a year.</td>
</tr>
<tr>
<td>Series.dt.is_year_end</td>
<td>Indicate whether the date is the last day of the year.</td>
</tr>
<tr>
<td>Series.dt.is_leap_year</td>
<td>Boolean indicator if the date belongs to a leap year.</td>
</tr>
<tr>
<td>Series.dt.daysinmonth</td>
<td>The number of days in the month</td>
</tr>
<tr>
<td>Series.dt.days_in_month</td>
<td>The number of days in the month</td>
</tr>
<tr>
<td>Series.dt.tz</td>
<td></td>
</tr>
<tr>
<td>Series.dt.freq</td>
<td></td>
</tr>
</tbody>
</table>

34.3.13.1 pandas.Series.dt.date

Series.dt.date
Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

34.3.13.2 pandas.Series.dt.time

Series.dt.time
Returns numpy array of datetime.time. The time part of the Timestamps.

34.3.13.3 pandas.Series.dt.year

Series.dt.year
The year of the datetime

34.3.13.4 pandas.Series.dt.month

Series.dt.month
The month as January=1, December=12

34.3.13.5 pandas.Series.dt.day

Series.dt.day
The days of the datetime
34.3.13.6 pandas.Series.dt.hour

Series.dt.hour
The hours of the datetime

34.3.13.7 pandas.Series.dt.minute

Series.dt.minute
The minutes of the datetime

34.3.13.8 pandas.Series.dt.second

Series.dt.second
The seconds of the datetime

34.3.13.9 pandas.Series.dt.microsecond

Series.dt.microsecond
The microseconds of the datetime

34.3.13.10 pandas.Series.dt.nanosecond

Series.dt.nanosecond
The nanoseconds of the datetime

34.3.13.11 pandas.Series.dt.week

Series.dt.week
The week ordinal of the year

34.3.13.12 pandas.Series.dt.weekofyear

Series.dt.weekofyear
The week ordinal of the year

34.3.13.13 pandas.Series.dt.dayofweek

Series.dt.dayofweek
The day of the week with Monday=0, Sunday=6

34.3.13.14 pandas.Series.dt.weekday

Series.dt.weekday
The day of the week with Monday=0, Sunday=6
34.3.13.15 pandas.Series.dt.dayofyear

Series.dt.dayofyear
The ordinal day of the year

34.3.13.16 pandas.Series.dt.quarter

Series.dt.quarter
The quarter of the date

34.3.13.17 pandas.Series.dt.is_month_start

Series.dt.is_month_start
Logical indicating if first day of month (defined by frequency)

34.3.13.18 pandas.Series.dt.is_month_end

Series.dt.is_month_end
Indicator for whether the date is the last day of the month.

Returns Series or array
For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Indicator for whether the date is the first day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> dates
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]
>>> dates.dt.is_month_end
0   False
1    True
2   False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_end
array([False,  True, False], dtype=bool)
```
34.3.13.19 pandas.Series.dt.is_quarter_start

Series.dt.is_quarter_start
Indicator for whether the date is the first day of a quarter.

Returns is_quarter_start: Series or DatetimeIndex
The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
is_quarter_end Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", ...
...                periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...            is_quarter_start=df.dates.dt.is_quarter_start)
dates    quarter  is_quarter_start
0 2017-03-30     1          False
1 2017-03-31     1          False
2 2017-04-01     2          True
3 2017-04-02     2          False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
               dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_start
array([False, False,  True, False])
```

34.3.13.20 pandas.Series.dt.is_quarter_end

Series.dt.is_quarter_end
Indicator for whether the date is the last day of a quarter.

Returns is_quarter_end: Series or DatetimeIndex
The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
is_quarter_start Similar property indicating the quarter start.
Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", ... periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter, ...
... is_quarter_end=df.dates.dt.is_quarter_end)
```

<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_end</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
```

```
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
               dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_end
```

```
array([False,  True, False, False])
```

34.3.13.21 `pandas.Series.dt.is_year_start`

`Series.dt.is_year_start`

Indicate whether the date is the first day of a year.

**Returns** Series or DatetimeIndex

The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

`is_year_end` Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
```

```
0   2017-12-30
1   2017-12-31
2   2018-01-01
dtype: datetime64[ns]
```

```python
>>> dates.dt.is_year_start
```

```
0   False
1   False
2   True
 dtype: bool
```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
    dtype='datetime64[ns]', freq='D')

>>> idx.is_year_start
array([False, False, True])

34.3.13.22 pandas.Series.dt.is_year_end

Series.dt.is_year_end
Indicate whether the date is the last day of the year.

Returns Series or DatetimeIndex

The same type as the original data with boolean values. Series will have the same
name and index. DatetimeIndex will have the same name.

See also:

is_year_start Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0   2017-12-30
1   2017-12-31
2   2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool

>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
    dtype='datetime64[ns]', freq='D')

>>> idx.is_year_end
array([False, True, False])

34.3.13.23 pandas.Series.dt.is_leap_year

Series.dt.is_leap_year

Boolean indicator if the date belongs to a leap year.
A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

**Returns** Series or ndarray

Booleans indicating if dates belong to a leap year.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
             dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([True, False, False], dtype=bool)

>>> dates = pd.Series(idx)
>>> dates_series
0 2012-12-31
1 2013-12-31
2 2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0  True
1  False
2  False
dtype: bool
```

34.3.13.24 pandas.Series.dt.daysinmonth

Series.dt.daysinmonth

The number of days in the month

34.3.13.25 pandas.Series.dt.days_in_month

Series.dt.days_in_month

The number of days in the month

34.3.13.26 pandas.Series.dt.tz

Series.dt.tz

34.3.13.27 pandas.Series.dt.freq

Series.dt.freq

Datetime Methods

<table>
<thead>
<tr>
<th>Series.dt.to_period(*args, **kwargs)</th>
<th>Cast to PeriodIndex at a particular frequency.</th>
</tr>
</thead>
</table>
### pandas.Series.dt.to_period

**Series.dt.to_period(*args, **kwargs)**  
Cast to PeriodIndex at a particular frequency.

Converts DatetimeIndex to PeriodIndex.

**Parameters freq**: string or Offset, optional

One of pandas’ *offset strings* or an Offset object. Will be inferred by default.

**Returns**

PeriodIndex

**Raises** ValueError

When converting a DatetimeIndex with non-regular values, so that a frequency cannot be inferred.

**See also:**

- pandas.PeriodIndex  Immutable ndarray holding ordinal values
- pandas.DatetimeIndex.to_pydatetime  Return DatetimeIndex as object

#### Examples

```python
>>> df = pd.DataFrame("y": [1,2,3],
...                 index=pd.to_datetime(["2000-03-31 00:00:00",
...                                         "2000-05-31 00:00:00",
...                                         "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(["2000-03", '2000-05', '2000-08'],
             dtype='period[M]', freq='M')
```

Infer the daily frequency
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
dtype='period[D]', freq='D')

34.3.13.29 pandas.Series.dt.to_pydatetime

Series.dt.to_pydatetime()
Return the data as an array of native Python datetime objects
Timezone information is retained if present.

Warning: Python’s datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

Returns numpy.ndarray
object dtype array containing native Python datetime objects.

See also:
datetime.datetime Standard library value for a datetime.

Examples

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
dtype: datetime64[ns]
0 2018-03-10
1 2018-03-11

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

pandas’ nanosecond precision is truncated to microseconds.

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
dtype: datetime64[ns]
0 2018-03-10 00:00:00.
1 2018-03-10 00:00:00.

dtype: datetime64[ns]

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

34.3.13.30 pandas.Series.dt.tz_localize

Series.dt.tz_localize(*args, **kwargs)
Localize tz-naive DatetimeIndex to tz-aware DatetimeIndex.
This method takes a time zone (tz) naive DatetimeIndex object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

**Parameters**
- **tz**: string, pytz.timezone, dateutil.tz.tzfile or None
  
  Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

- **ambiguous**: str {'infer', 'NaT', 'raise'} or bool array, default 'raise'
  
  • 'infer' will attempt to infer fall dst-transition hours based on order
  
  • bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
  
  • 'NaT' will return NaT where there are ambiguous times
  
  • 'raise' will raise an AmbiguousTimeError if there are ambiguous times

- **errors**: {'raise', 'coerce'}, default 'raise'
  
  • 'raise' will raise a NonExistentTimeError if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time)
  
  • 'coerce' will return NaT if the timestamp can not be converted to the specified time zone

New in version 0.19.0.

**Returns**

- **DatetimeIndex**

  Index converted to the specified time zone.

**Raises**

- **TypeError**

  If the DatetimeIndex is tz-aware and tz is not None.

**See also**

- **DatetimeIndex.tz_convert** Convert tz-aware DatetimeIndex from one time zone to another.

**Examples**

```python
tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
tz_aware = tz_naive.tz_localize(tz='US/Eastern')
```

Localize DatetimeIndex in US/Eastern time zone:

```python
tz_aware = tz_naive.tz_localize(tz='US/Eastern')
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):
34.3.13.31 pandas.Series.dt.tz_convert

Series.dt.tz_convert(*args, **kwargs)

Convert tz-aware DatetimeIndex from one time zone to another.

Parameters

tz : string, pytz.timezone, dateutil.tz.tzfile or None

Time zone for time. Corresponding timestamps would be converted to this time zone of the DatetimeIndex. A tz of None will convert to UTC and remove the timezone information.

Returns

normalized [DatetimeIndex]

Raises

TypeError

If DatetimeIndex is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC

DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the tz parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.DatetimeIndex(start='2014-08-01 09:00',
                           freq='H', periods=3, tz='Europe/Berlin')
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the tz=None, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.DatetimeIndex(start='2014-08-01 09:00', freq='H',
                           periods=3, tz='Europe/Berlin')
```
34.3.13.32 pandas.Series.dt.normalize

Series.dt.normalize(*args, **kwargs)
Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The time zones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

Returns DatetimeIndex or Series
The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.
ceil Ceil the datetimes to the specified freq.
round Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.DatetimeIndex(start='2014-08-01 10:00', freq='H',
... periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
'2014-08-01 11:00:00+05:30',
'2014-08-01 12:00:00+05:30'],
dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
'2014-08-01 01:00:00+05:30',
'2014-08-01 02:00:00+05:30'],
dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

34.3.13.33 pandas.Series.dt.strftime

Series.dt.strftime(*args, **kwargs)
Convert to Index using specified date_format.
Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc

**Parameters**

- **date_format**: str
  
  Date format string (e.g. "%Y-%m-%d").

**Returns**

- **Index**: Index of formatted strings

---

### Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"), periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
dtype='object')
```

### 34.3.13.34 pandas.Series.dt.round

**Series.dt.round** (*args, **kwargs*)

Round the data to the specified `freq`.

**Parameters**

- **freq**: str or Offset

  The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.

**Returns**

- **DatetimeIndex, TimedeltaIndex, or Series**: Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

- **ValueError** if the ‘freq‘ cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
dtype='datetime64[ns]', freq='T')
```
Series

```python
>>> pd.Series(rng).dt.round("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

34.3.13.35 pandas.Series.dt.floor

Series.dt.floor(*args, **kwargs)

floor the data to the specified freq.

Parameters

defreq : str or Offset

The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

Returns

DatetimeIndex, TimedeltaIndex, or Series

Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the ‘freq‘ cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0   2018-01-01 11:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```
### 34.3.13.36 pandas.Series.dt.ceil

Series.dt.

#### Parameters
- **freq** : str or Offset

  The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

#### Returns
- DatetimeIndex, TimedeltaIndex, or Series

  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

#### Raises
- **ValueError** if the ‘freq’ cannot be converted.

#### Examples

**Datet imeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
dtype='datetime64[ns]', freq='T')

>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00', '2018-01-01 13:00:00'],
dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

### 34.3.13.37 pandas.Series.dt.month_name

Series.dt.

**Parameters**
- **locale** : string, default None (English locale)

  locale determining the language in which to return the month name

**Returns**
- month_names : Index

  Index of month names

.. versionadded:: 0.23.0
34.3.13.38 pandas.Series.dt.day_name

Series.dt.day_name(*args, **kwargs)
   Return the day names of the DateTimeIndex with specified locale.

   Parameters locale : string, default None (English locale)
      locale determining the language in which to return the day name

   Returns month_names : Index
      Index of day names

   .. versionadded:: 0.23.0

Timedelta Properties

| pandas.Series.dt.days          | Number of days for each element. |
| pandas.Series.dt.seconds       | Number of seconds (>= 0 and less than 1 day) for each element. |
| pandas.Series.dt.milliseconds  | Number of microseconds (>= 0 and less than 1 second) for each element. |
| pandas.Series.dt.nanoseconds   | Number of nanoseconds (>= 0 and less than 1 microsecond) for each element. |
| pandas.Series.dt.components    | Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas. |

34.3.13.39 pandas.Series.dt.days

Series.dt.days
   Number of days for each element.

34.3.13.40 pandas.Series.dt.seconds

Series.dt.seconds
   Number of seconds (>= 0 and less than 1 day) for each element.

34.3.13.41 pandas.Series.dt.milliseconds

Series.dt.milliseconds
   Number of microseconds (>= 0 and less than 1 second) for each element.

34.3.13.42 pandas.Series.dt.nanoseconds

Series.dt.nanoseconds
   Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

34.3.13.43 pandas.Series.dt.components

Series.dt.components
   Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.
ond) of the Timedeltas.

**Returns**

- a DataFrame

**Timedelta Methods**

<table>
<thead>
<tr>
<th><strong>Series.dt.to_pytimedelta()</strong></th>
<th>Return an array of native <code>datetime.timedelta</code> objects.</th>
</tr>
</thead>
<tbody>
<tr>
<td>**Series.dt.total_seconds(***args, <strong>kwargs)</strong></td>
<td>Return total duration of each element expressed in seconds.</td>
</tr>
</tbody>
</table>

### 34.3.13.44 pandas.Series.dt.to_pytimedelta

**Series.dt.to_pytimedelta()**

Return an array of native `datetime.timedelta` objects.

Python’s standard `datetime` library uses a different representation timedelta’s. This method converts a Series of pandas Timedeltas to `datetime.timedelta` format with the same length as the original Series.

**Returns**

- a : `numpy.ndarray`
  
  1D array containing data with `datetime.timedelta` type.

**See also:**

`datetime.timedelta`

**Examples**

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
dtype: timedelta64[ns]
    0  0 days
    1  1 days
    2  2 days
    3  3 days
    4  4 days

>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0),
       datetime.timedelta(1),
       datetime.timedelta(2),
       datetime.timedelta(3),
       datetime.timedelta(4)], dtype=object)
```

### 34.3.13.45 pandas.Series.dt.total_seconds

**Series.dt.total_seconds(***args, **kwargs)**

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaIndex and on Series containing timedelta values under the `.dt` namespace.

**Returns**

- seconds : `Float64Index` or `Series`
When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type float64 whose index is the same as the original.

See also:

datetime.timedelta.total_seconds Standard library version of this method.

TimedeltaIndex.components Return a DataFrame with components of each Timedelta.

Examples

Series

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0 0 days
1 1 days
2 2 days
3 3 days
4 4 days
dtype: timedelta64[ns]

>>> s.dt.total_seconds()
0 0.0
1 86400.0
2 172800.0
3 259200.0
4 345600.0
dtype: float64
```

TimedeltaIndex

```python
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)

>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.00000000003, 345600.0],
               dtype='float64')
```

34.3.14 String handling

Series.str can be used to access the values of the series as strings and apply several methods to it. These can be accessed like Series.str.<function/property>.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.str.capitalize()</td>
<td>Convert strings in the Series/Index to be capitalized.</td>
</tr>
<tr>
<td>Series.str.cat</td>
<td>Concatenate strings in the Series/Index with given separator.</td>
</tr>
<tr>
<td>Series.str.center</td>
<td>Filling left and right side of strings in the Series/Index with an additional character.</td>
</tr>
</tbody>
</table>

Continued on next page
### Series.str.contains(pat[, case, flags, na, ...])
Test if pattern or regex is contained within a string of a Series or Index.

### Series.str.count(pat[, flags])
Count occurrences of pattern in each string of the Series/Index.

### Series.str.decode(encoding[, errors])
Decode character string in the Series/Index using indicated encoding.

### Series.str.encode(encoding[, errors])
Encode character string in the Series/Index using indicated encoding.

### Series.str.endswith(pat[, na])
Test if the end of each string element matches a pattern.

### Series.str.extract(pat[, flags, expand])
For each subject string in the Series, extract groups from the first match of regular expression pat.

### Series.str.extractall(pat[, flags])
For each subject string in the Series, extract groups from all matches of regular expression pat.

### Series.str.find(sub[, start, end])
Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].

### Series.str.findall(pat[, flags])
Find all occurrences of pattern or regular expression in the Series/Index.

### Series.str.get(i)
Extract element from each component at specified position.

### Series.str.index(sub[, start, end])
Return lowest indexes in each strings where the substring is fully contained between [start:end].

### Series.str.join(sep)
Join lists contained as elements in the Series/Index with passed delimiter.

### Series.str.len()
Compute length of each string in the Series/Index.

### Series.str.ljust(width[, fillchar])
Filling right side of strings in the Series/Index with an additional character.

### Series.str.lower()
Convert strings in the Series/Index to lowercase.

### Series.str.lstrip([to_strip])
Strip whitespace (including newlines) from each string in the Series/Index from left side.

### Series.str.match(pat[, case, flags, na, ...])
Determine if each string matches a regular expression.

### Series.str.normalize(form)
Return the Unicode normal form for the strings in the Series/Index.

### Series.str.pad(width[, side, fillchar])
Pad strings in the Series/Index with an additional character to specified side.

### Series.str.partition([pat, expand])
Split the string at the first occurrence of sep, and return 3 elements containing the part before the separator, the separator itself, and the part after the separator.

### Series.str.repeat(repeats)
Duplicate each string in the Series/Index by indicated number of times.

### Series.str.replace(pat, repl[, n, case, ...])
Replace occurrences of pattern/regex in the Series/Index with some other string.

### Series.str.rfind(sub[, start, end])
Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].

### Series.str.rindex(sub[, start, end])
Return highest indexes in each strings where the substring is fully contained between [start:end].

### Series.str.rjust(width[, fillchar])
Filling left side of strings in the Series/Index with an additional character.
### Table 42 – continued from previous page

</tr>
<tr>
<td><code>Series.str.get_dummies([sep])</code></td>
<td>Split each string in the Series by <code>sep</code> and return a frame of dummy/indicator variables.</td>
</tr>
</tbody>
</table>

#### 34.3.14.1 pandas.Series.str.capitalize

Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.

**Returns**

Series/Index of objects
See also:

- **Series.str.lower** Converts all characters to lowercase.
- **Series.str.upper** Converts all characters to uppercase.
- **Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.
- **Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.
- **Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.

**Examples**

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1   CAPITALS
2  this is a sentence
3     SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1   capitals
2  this is a sentence
3     swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1   CAPITALS
2  THIS IS A SENTENCE
3     SWApCASE
dtype: object

>>> s.str.title()
0    Lower
1   Capitals
2  This Is A Sentence
3     Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1   Capitals
2  This is a sentence
3     Swapcase
dtype: object

>>> s.str.swapcase()
0    LOWER
1   capitals
2  THIS IS A SENTENCE
3     sWaPcAsE
dtype: object
```
34.3.14.2 pandas.Series.str.cat

Series.str.cat(others=None, sep=None, na_rep=None, join=None)

Concatenate strings in the Series/Index with given separator.

If others is specified, this function concatenates the Series/Index and elements of others element-wise. If others is not passed, then all values in the Series/Index are concatenated into a single string with a given sep.

Parameters others : Series, Index, DataFrame, np.ndarray or list-like

Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if join is not None.

If others is a list-like that contains a combination of Series, np.ndarray (1-dim) or list-like, then all elements will be unpacked and must satisfy the above criteria individually.

If others is None, the method returns the concatenation of all strings in the calling Series/Index.

sep : string or None, default None

If None, concatenates without any separator.

na_rep : string or None, default None

Representation that is inserted for all missing values:

- If na_rep is None, and others is None, missing values in the Series/Index are omitted from the result.
- If na_rep is None, and others is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

join : {'left', 'right', 'outer', 'inner'}, default None

Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in others (objects without an index need to match the length of the calling Series/Index). If None, alignment is disabled, but this option will be removed in a future version of pandas and replaced with a default of ‘left’. To disable alignment, use .values on any Series/Index/DataFrame in others.

New in version 0.23.0.

Returns concat : str or Series/Index of objects

If others is None, str is returned, otherwise a Series/Index (same type as caller) of objects is returned.

See also:

split Split each string in the Series/Index

Examples

When not passing others, all values are concatenated into a single string:
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'

By default, NA values in the Series are ignored. Using na_rep, they can be given a representation:

>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'

If others is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0 a,A
1 b,B
2 NaN
3 d,D
dtype: object

Missing values will remain missing in the result, but can again be represented using na_rep

>>> s.str.cat(['A', 'B', 'C', 'D'], sep='', na_rep='-')
0 aA
1 bB
2 -,C
3 dD
dtype: object

If sep is not specified, the values are concatenated without separation.

>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0 aA
1 bB
2 -,C
3 dD
dtype: object

Series with different indexes can be aligned before concatenation. The join-keyword works as in other methods.

>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join=None, na_rep='-')
0 ad
1 ba
2 -e
3 dc
dtype: object

>>> s.str.cat(t, join='left', na_rep='-')
0 aa
1 b-
2 -c
3 dd
dtype: object

>>> s.str.cat(t, join='outer', na_rep='-')
0 aa
1 b-
2 -c
3 dd

(continues on next page)
3 dd
dtype: object

>>> s.str.cat(t, join='inner', na_rep='—')
0  aa
1  -c
2 dd
dtype: object

>>> s.str.cat(t, join='right', na_rep='—')
3 dd
0  aa
1  -e
2  -c
dtype: object

For more examples, see here.

34.3.14.3 pandas.Series.str.center

Series.str.center(width, fillchar=' ')  
Filling left and right side of strings in the Series/Index with an additional character. Equivalent to str.center().

Parameters  
width : int  
Minimum width of resulting string; additional characters will be filled with fillchar

fillchar : str  
Additional character for filling, default is whitespace

Returns  
filled [Series/Index of objects]

34.3.14.4 pandas.Series.str.contains

Series.str.contains(pat, case=True, flags=0, na=nan, regex=True)  
Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

Parameters  
pat : str  
Character sequence or regular expression.

case : bool, default True  
If True, case sensitive.

flags : int, default 0 (no flags)  
Flags to pass through to the re module, e.g. re.IGNORECASE.

na : default NaN
Fill value for missing values.

**regex**: bool, default True

If True, assumes the pat is a regular expression.
If False, treats the pat as a literal string.

**Returns** Series or Index of boolean values

A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

**See also:**

*match* analogous, but stricter, relying on re.match instead of re.search

**Examples**

Returning a Series of booleans using only a literal pattern.

```python
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0     False
1      True
2     False
3     False
4    NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```python
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using *case*.

```python
>>> s1.str.contains('oG', case=True, regex=True)
0     False
1      False
2      False
3      False
4    NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN* replaces NaN values with *False*. If Series or Index does not contain NaN values the resultant dtype will be *bool*, otherwise, an *object* dtype.

```python
>>> s1.str.contains('og', na=False, regex=True)
0     False
1      True
2      False
3      False
4      False
dtype: bool
```

Returning ‘house’ and ‘parrot’ within same string.
>>> s1.str.contains('house|parrot', regex=True)
0   False
1   False
2    True
3   False
4    NaN
dtype: object

Ignoring case sensitivity using flags with regex.

>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0   False
1   False
2    True
3   False
4    NaN
dtype: object

Returning any digit using regular expression.

>>> s1.str.contains('\d', regex=True)
0   False
1   False
2    False
3    True
4    NaN
dtype: object

Ensure pat is a not a literal pattern when regex is set to True. Note in the following example one might expect only s2[1] and s2[3] to return True. However, '.0' as a regex matches any character followed by a 0.

>>> s2 = pd.Series(['40','40.0','41','41.0','35'])
>>> s2.str.contains('.0', regex=True)
0    True
1    True
2    False
3    True
4    False
dtype: bool

34.3.14.5 pandas.Series.str.count

Series.str.count(pat, flags=0, **kwargs)

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the Series.

Parameters

pat : str
Valid regular expression.
flags : int, default 0, meaning no flags
Flags for the re module. For a complete list, see here.
**kwargs
For compatibility with other string methods. Not used.

**Returns** counts : Series or Index

Same type as the calling object containing the integer counts.

**See also:**

* re Standard library module for regular expressions.
* str.count Standard library version, without regular expression support.

**Notes**

Some characters need to be escaped when passing in pat. eg. '\$' has a special meaning in regex and must be escaped when finding this literal character.

**Examples**

```python
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape '\$' to find the literal dollar sign.

```python
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0     1
1     0
2     1
3     2
4     2
5     0
dtype: int64
```

This is also available on Index

```python
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

**34.3.14.6 pandas.Series.str.decode**

Series.str.decode( encoding, errors='strict')

Decode character string in the Series/Index using indicated encoding. Equivalent to str.decode() in python2 and bytes.decode() in python3.

**Parameters**

- encoding [str]
errors [str, optional]

Returns

decoded [Series/Index of objects]

34.3.14.7 pandas.Series.str.encode

Series.str.encode (encoding, errors='strict')

Encode character string in the Series/Index using indicated encoding. Equivalent to str.encode().

Parameters

encoding [str]

errors [str, optional]

Returns

coded [Series/Index of objects]

34.3.14.8 pandas.Series.str.endswith

Series.str.endswith (pat, na=nan)

Test if the end of each string element matches a pattern.

Equivalent to str.endswith().

Parameters pat : str

Character sequence. Regular expressions are not accepted.

na : object, default NaN

Object shown if element tested is not a string.

Returns Series or Index of bool

A Series of booleans indicating whether the given pattern matches the end of each string element.

See also:

str.endswith Python standard library string method.

Series.str.startswith Same as endswith, but tests the start of string.

Series.str.contains Tests if string element contains a pattern.

Examples

```python
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0    bat
1    bear
2    caT
3   NaN
dtype: object
```
>>> s.str.endswith('t')
0   True
1  False
2  False
3   NaN
 dtype: object

Specifying `na` to be `False` instead of `NaN`.

```python
>>> s.str.endswith('t', na=False)
0   True
1  False
2  False
3  False
 dtype: bool
```

### 34.3.14.9 pandas.Series.str.extract

`Series.str.extract(pat, flags=0, expand=True)`

For each subject string in the Series, extract groups from the first match of regular expression `pat`.

**Parameters**

- **pat**: string
  
  Regular expression pattern with capturing groups

- **flags**: int, default 0 (no flags)
  
  `re` module flags, e.g. `re.IGNORECASE`

- **expand**: bool, default True
  
  - If True, return DataFrame.
  - If False, return Series/Index/DataFrame.

  New in version 0.18.0.

**Returns**

DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and pat has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

**See also:**

- `extractall` returns all matches (not just the first match)

**Examples**

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.
>>> s = Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'\([ab]\)(\d)')
  0 1
  0 a 1
  1 b 2
  2 NaN NaN

A pattern may contain optional groups.

>>> s.str.extract(r'\([ab]\)?(\d)')
  0 1
  0 a 1
  1 b 2
  2 NaN 3

Named groups will become column names in the result.

>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
  letter  digit
  0    a  1
  1    b  2
  2   NaN  NaN

A pattern with one group will return a DataFrame with one column if expand=True.

>>> s.str.extract(r'\([ab]\)(\d)', expand=True)
  0
  0 1
  1 2
  2 NaN

A pattern with one group will return a Series if expand=False.

>>> s.str.extract(r'\([ab]\)(\d)', expand=False)
  0 1
  1 2
  2 NaN
dtype: object

34.3.14.10 pandas.Series.str.extractall

Series.str.extractall(pat, flags=0)
For each subject string in the Series, extract groups from all matches of regular expression pat. When each
subject string in the Series has exactly one match, extractall(pat).xs(0, level='match') is the same as extract(pat).

New in version 0.18.0.

Parameters pat : string
    Regular expression pattern with capturing groups
flags : int, default 0 (no flags)
    re module flags, e.g. re.IGNORECASE

Returns
    A DataFrame with one row for each match, and one column for each
group. Its rows have a MultiIndex with first levels that come from
the subject Series. The last level is named ‘match’ and indicates
the order in the subject. Any capture group names in regular
expression pat will be used for column names; otherwise capture
group numbers will be used.

See also:

```python
extract returns first match only (not all matches)
```

### Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in
the result.

```python
>>> s = Series(["ala2", "bl", "cl"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
    match
   0  1
   1  2
   2  1
```

Capture group names are used for column names of the result.

```python
>>> s.str.extractall(r"[ab](\P<digit>\d)")
    digit
   match
   0  1
   1  2
   2  1
```

A pattern with two groups will return a DataFrame with two columns.

```python
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
    letter digit
   match
   A  0 a  1
   1 a  2
   B  0 b  1
```

Optional groups that do not match are NaN in the result.

```python
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
    letter digit
   match
   A  0 a  1
   1 a  2
   B  0 b  1
   C  0 NaN  1
```
### 34.3.14.11 pandas.Series.str.find

**Series.str.find(sub, start=0, end=None)**

Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

**Parameters**

- `sub`: str
  - Substring being searched
- `start`: int
  - Left edge index
- `end`: int
  - Right edge index

**Returns**

- `found`: [Series/Index of integer values]

**See also:**

- `rfind` Return highest indexes in each strings

### 34.3.14.12 pandas.Series.str.findall

**Series.str.findall(pat, flags=0, **kwargs)**

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

**Parameters**

- `pat`: string
  - Pattern or regular expression.
- `flags`: int, default 0
  - `re` module flags, e.g. `re.IGNORECASE` (default is 0, which means no flags).

**Returns**

- `Series/Index of lists of strings`
  - All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

**See also:**

- `count` Count occurrences of pattern or regular expression in each string of the Series/Index.
- `extractall` For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.
- `re.findall` The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

**Examples**

```python
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern ‘Monkey’ returns one match:
On the other hand, the search for the pattern ‘MONKEY’ doesn’t return any match:

```python
>>> s.str.findall('MONKEY')
0    []
1    []
2    []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern ‘MONKEY’ ignoring the case:

```python
>>> import re

>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0    []
1    [Monkey]
2    []
dtype: object
```

When the pattern matches more than one string in the Series, all matches are returned:

```python
>>> s.str.findall('on')
0    [on]
1    [on]
2    []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word ‘on’ is shown next:

```python
>>> s.str.findall('on$')
0    [on]
1    []
2    []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```python
>>> s.str.findall('b')
0    []
1    []
2    [b, b]
dtype: object
```

### 34.3.14.13 pandas.Series.str.get

Series.str.get(i)

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

**Parameters**

- **i**: int
Position of element to extract.

Returns

items  [Series/Index of objects]

Examples

```python
>>> s = pd.Series(
    ["String",
     (1, 2, 3),
     ["a", "b", "c"],
     123, -456,
     {1:"Hello", "2":"World"}])
```

```python
>>> s
0       String
1     (1, 2, 3)
2       [a, b, c]
3           123
4          -456
5     {1: 'Hello', '2': 'World'}
```

dtype: object

```python
>>> s.str.get(1)
0   t
1  2
2  b
3  NaN
4  NaN
5  Hello
```

dtype: object

```python
>>> s.str.get(-1)
0   g
1  3
2  c
3  NaN
4  NaN
5  NaN
```

dtype: object

34.3.14.14 pandas.Series.str.index

Series.str.index(sub, start=0, end=None)

Return lowest indexes in each strings where the substring is fully contained between [start:end]. This is the same as str.find except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard str.index.

Parameters

**sub**: str

Substring being searched

**start**: int

Left edge index

**end**: int

34.3. Series 1671
Right edge index

Returns

found [Series/Index of objects]

See also:

rindex Return highest indexes in each strings

34.3.14.15 pandas.Series.str.join

Series.str.join(sep)

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to str.join().

Parameters sep : str

Delimiter to use between list entries.

Returns

Series/Index: object

See also:

str.join Standard library version of this method.

Series.str.split Split strings around given separator/delimiter.

Notes

If any of the lists does not contain string objects the result of the join will be NaN.

Examples

Example with a list that contains non-string elements.

```python
>>> s = pd.Series([[['lion', 'elephant', 'zebra'],
...                   [1.1, 2.2, 3.3]],
...                   [['cat', np.nan, 'dog'],
...                    ['cow', 4.5, 'goat']]
...                   [['duck', ['swan', 'fish'], 'guppy']])
>>> s
0    [lion, elephant, zebra]
1    [1.1, 2.2, 3.3]
2    [cat, nan, dog]
3    [cow, 4.5, goat]
4    [duck, [swan, fish], guppy]
```

dtype: object

Join all lists using an ‘-‘; the lists containing object(s) of types other than str will become a NaN.
>>> s.str.join('-')
0  lion-elephant-zebra
1       NaN
2       NaN
3       NaN
4       NaN
dtype: object

34.3.14.16 pandas.Series.str.len

Series.str.len()
Compute length of each string in the Series/Index.

Returns
lengths [Series/Index of integer values]

34.3.14.17 pandas.Series.str.ljust

Series.str.ljust(width, fillchar=' ')
Filling right side of strings in the Series/Index with an additional character. Equivalent to str.ljust().

Parameters width : int
Minimum width of resulting string; additional characters will be filled with fillchar
fillchar : str
Additional character for filling, default is whitespace

Returns
filled [Series/Index of objects]

34.3.14.18 pandas.Series.str.lower

Series.str.lower()
Convert strings in the Series/Index to lowercase.
Equivalent to str.lower().

Returns
Series/Index of objects

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1  CAPITALS
2  this is a sentence
3   SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1  capitals
2  this is a sentence
3   swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
1  Capitals
2  This Is A Sentence
3  Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1  Capitals
2  This is a sentence
3  Swapcase
dtype: object

>>> s.str.swapcase()
0    LOWER
1  capitals
2  THIS IS A SENTENCE
3  sWaPcAsE
dtype: object
```

34.3.14.19 pandas.Series.str.lstrip

Series.str.lstrip(to_strip=None)

Strip whitespace (including newlines) from each string in the Series/Index from left side. Equivalent to str.lstrip().

Returns

stripped [Series/Index of objects]
34.3.14.20 pandas.Series.str.match

Series.str.match (pat, case=True, flags=0, na=nan, as_indexer=None)
Determine if each string matches a regular expression.

Parameters:
- **pat**: string
  - Character sequence or regular expression
- **case**: boolean, default True
  - If True, case sensitive
- **flags**: int, default 0 (no flags)
  - re module flags, e.g. re.IGNORECASE
- **na** [default NaN, fill value for missing values.]

- **as_indexer**
  - Deprecated since version 0.21.0.

Returns:
- Series/array of boolean values

See also:
- [contains](#) analogous, but less strict, relying on re.search instead of re.match
- [extract](#) extract matched groups

34.3.14.21 pandas.Series.str.normalize

Series.str.normalize (form)
Return the Unicode normal form for the strings in the Series/Index. For more information on the forms, see the unicodedata.normalize().

Parameters:
- **form**: {'NFC', 'NFKC', 'NFD', 'NFKD'}
  - Unicode form

Returns:
- normalized [Series/Index of objects]

34.3.14.22 pandas.Series.str.pad

Series.str.pad (width, side='left', fillchar=' ') Pad strings in the Series/Index with an additional character to specified side.

Parameters:
- **width**: int
  - Minimum width of resulting string; additional characters will be filled with spaces
- **side** [{‘left’, ‘right’, ‘both’}, default ‘left’]
- **fillchar**: str
  - Additional character for filling, default is whitespace
pandas: powerful Python data analysis toolkit, Release 0.23.3

Returns

padded [Series/Index of objects]

34.3.14.23 pandas.Series.str.partition

Series.str.partition (pat=' ', expand=True)
Split the string at the first occurrence of sep, and return 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters pat : string, default whitespace

String to split on.
expand : bool, default True

• If True, return DataFrame/MultiIndex expanding dimensionality.
• If False, return Series/Index.

Returns

split [DataFrame/MultiIndex or Series/Index of objects]

See also:

rpartition Split the string at the last occurrence of sep

Examples

```python
>>> s = Series(['A_B_C', 'D_E_F', 'X'])
0   A_B_C
1   D_E_F
2     X
dtype: object
```

```python
>>> s.str.partition('_')
   0  1  2
0   A _ B_C
1   D _ E_F
2     X
```

```python
>>> s.str.rpartition('_')
   0  1  2
0   A_B _ C
1   D_E _ F
2     X
```

34.3.14.24 pandas.Series.str.repeat

Series.str.repeat (repeats)
Duplicate each string in the Series/Index by indicated number of times.

Parameters repeats : int or array

Same value for all (int) or different value per (array)
Returns

repeated  [Series/Index of objects]

34.3.14.25 pandas.Series.str.replace

Series.str.replace (pat, repl, n=-1, case=None, flags=0, regex=True)
Replace occurrences of pattern/regex in the Series/Index with some other string. Equivalent to str.replace() or re.sub().

Parameters

- pat : string or compiled regex
  
  String can be a character sequence or regular expression.
  
  New in version 0.20.0: pat also accepts a compiled regex.

- repl : string or callable
  
  Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See re.sub().
  
  New in version 0.20.0: repl also accepts a callable.

- n : int, default -1 (all)
  
  Number of replacements to make from start

- case : boolean, default None
  
  - If True, case sensitive (the default if pat is a string)
  
  - Set to False for case insensitive

  - Cannot be set if pat is a compiled regex

- flags : int, default 0 (no flags)
  
  - re module flags, e.g. re.IGNORECASE
  
  - Cannot be set if pat is a compiled regex

- regex : boolean, default True
  
  - If True, assumes the passed-in pattern is a regular expression.

  - If False, treats the pattern as a literal string

  - Cannot be set to False if pat is a compiled regex or repl is a callable.

  New in version 0.23.0.

Returns

replaced  [Series/Index of objects]

Raises

ValueError

- if regex is False and repl is a callable or pat is a compiled regex

- if pat is a compiled regex and case or flags is set

Notes

When pat is a compiled regex, all flags should be included in the compiled regex. Use of case, flags, or regex=False with a compiled regex will raise an error.
Examples

When `pat` is a string and `regex` is True (the default), the given `pat` is compiled as a regex. When `repl` is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0  bao
1  baz
2  NaN
dtype: object
```

When `pat` is a string and `regex` is False, every `pat` is replaced with `repl` as with `str.replace()`:

```python
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0  bao
1  fuz
2  NaN
dtype: object
```

When `repl` is a callable, it is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0  <_sre.SRE_Match object; span=(0, 1), match='f'>oo
1  <_sre.SRE_Match object; span=(0, 1), match='f'>uz
2  NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```python
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0  oof 123
1  rab zab
2  NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```python
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0  tWO
1  bAR
dtype: object
```

Using a compiled regex with flags

```python
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0  foo
1  bar
2  NaN
dtype: object
```
### 34.3.14.26 pandas.Series.str.rfind

`Series.str.rfind(sub, start=0, end=None)`

Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

**Parameters**
- `sub` : str
  Substring being searched
- `start` : int
  Left edge index
- `end` : int
  Right edge index

**Returns**
- `found` : Series/Index of integer values

**See also:**
- `find`  Return lowest indexes in each strings

### 34.3.14.27 pandas.Series.str.rindex

`Series.str.rindex(sub, start=0, end=None)`

Return highest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.rfind` except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard `str.rindex()`.

**Parameters**
- `sub` : str
  Substring being searched
- `start` : int
  Left edge index
- `end` : int
  Right edge index

**Returns**
- `found` : Series/Index of objects

**See also:**
- `index` Return lowest indexes in each strings

### 34.3.14.28 pandas.Series.str.rjust

`Series.str.rjust(width, fillchar=' ')`

Filling left side of strings in the Series/Index with an additional character. Equivalent to `str.rjust()`.

**Parameters**
- `width` : int
  Minimum width of resulting string; additional characters will be filled with `fillchar`
fillchar : str

Additional character for filling, default is whitespace

Returns

filled [Series/Index of objects]

34.3.14.29 pandas.Series.str.rpartition

Series.str.rpartition(pat=' ', expand=True)

Split the string at the last occurrence of sep, and return 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

Parameters pat : string, default whitespace

String to split on.

expand : bool, default True

• If True, return DataFrame/MultiIndex expanding dimensionality.
• If False, return Series/Index.

Returns

split [DataFrame/MultiIndex or Series/Index of objects]

See also:

partition Split the string at the first occurrence of sep

Examples

```python
>>> s = Series(['A_B_C', 'D_E_F', 'X'])
0   A_B_C
1   D_E_F
2     X
dtype: object

>>> s.str.partition('_')
  0   1  2
0   A  _  B_C
1   D  _  E_F
2     X

>>> s.str.rpartition('_')
  0   1  2
0   A_B  _  C
1   D_E  _  F
2     X
```
34.3.14.30 pandas.Series.str.rstrip

Series.str.rstrip(to_strip=None)
Strip whitespace (including newlines) from each string in the Series/Index from right side. Equivalent to str.rstrip().

Returns
stripped [Series/Index of objects]

34.3.14.31 pandas.Series.str.slice

Series.str.slice(start=None, stop=None, step=None)
Slice substrings from each element in the Series/Index

Parameters
start [int or None]
stop [int or None]
step [int or None]

Returns
sliced [Series/Index of objects]

34.3.14.32 pandas.Series.str.slice_replace

Series.str.slice_replace(start=None, stop=None, repl=None)
Replace a positional slice of a string with another value.

Parameters start : int, optional
        Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.
stop : int, optional
        Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.
repl : str, optional
        String for replacement. If not specified (None), the sliced region is replaced with an empty string.

Returns replaced : Series or Index
        Same type as the original object.

See also:

Series.str.slice Just slicing without replacement.

Examples
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0   a
1   ab
2   abc
3   abdc
4   abcde
dtype: object

Specify just `start`, meaning replace `start` until the end of the string with `repl`.

```python
>>> s.str.slice_replace(1, repl='X')
0  aX
1  aX
2  aX
3  aX
4  aX
dtype: object
```

Specify just `stop`, meaning the start of the string to `stop` is replaced with `repl`, and the rest of the string is included.

```python
>>> s.str.slice_replace(stop=2, repl='X')
0  X  
1  X  c
2  X  dc
3  Xdc
4  X  de
dtype: object
```

Specify `start` and `stop`, meaning the slice from `start` to `stop` is replaced with `repl`. Everything before or after `start` and `stop` is included as is.

```python
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0  aX
1  aX
2  aX
3  aXc
4  aXde
dtype: object
```

### 34.3.14.33 pandas.Series.str.split

**Series.str.split** *(pat=None, n=-1, expand=False)*

Split strings around given separator/delimiter.

Split each string in the caller’s values by given pattern, propagating NaN values. Equivalent to `str.split()`.

**Parameters**

- **pat** : str, optional
  
  String or regular expression to split on. If not specified, split on whitespace.

- **n** : int, default -1 (all)
  
  Limit number of splits in output. `None`, 0 and -1 will be interpreted as return all splits.

- **expand** : bool, default False
  
  Expand the splitted strings into separate columns.
• If True, return DataFrame/MultiIndex expanding dimensionality.
• If False, return Series/Index, containing lists of strings.

Returns Series, Index, DataFrame or MultiIndex
Type matches caller unless expand=True (see Notes).

See also:
str.split Standard library version of this method.
Series.str.get_dummies Split each string into dummy variables.
Series.str.partition Split string on a separator, returning the before, separator, and after components.

Notes
The handling of the n keyword depends on the number of found splits:
• If found splits > n, make first n splits only
• If found splits <= n, make all splits
• If for a certain row the number of found splits < n, append None for padding up to n if expand=True
If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples
>>> s = pd.Series(["this is good text", "but this is even better"])

By default, split will return an object of the same size having lists containing the split elements

>>> s.str.split()
0 [this, is, good, text]  
1 [but, this, is, even, better]  
dtype: object

>>> s.str.split("random")
0 [this is good text]  
1 [but this is even better]  
dtype: object

When using expand=True, the split elements will expand out into separate columns.

For Series object, output return type is DataFrame.

>>> s.str.split(expand=True)
   0   1   2   3   4
0 this is good text None
1 but this is even better

>>> s.str.split(" is ", expand=True)
   0   1
0 this good text
1 but this even better

For Index object, output return type is MultiIndex.
>>> i = pd.Index(['ba 100 001', 'ba 101 002', 'ba 102 003'])
>>> i.str.split(expand=True)
MultiIndex(levels=[[0], [0, 1, 2], [0, 1, 2]],
            labels=[[0, 0, 0], [0, 1, 2], [0, 1, 2]])

Parameter `n` can be used to limit the number of splits in the output.

>>> s.str.split("is", n=1)
0    [th, is good text]
1    [but th, is even better]
   dtype: object
>>> s.str.split("is", n=1, expand=True)
   0    1
     th   is good text
     but th is even better

If NaN is present, it is propagated throughout the columns during the split.

>>> s = pd.Series(['this is good text', 'but this is even better', np.nan])
>>> s.str.split(n=3, expand=True)
   0  1  2  3
0  this  is  good  text
1  but  this  is  even  better
2     NaN       NaN       NaN     NaN

34.3.14.34 pandas.Series.str.rsplit

Series.str.rsplit(pat=None, n=-1, expand=False)
Split each string in the Series/Index by the given delimiter string, starting at the end of the string and working to the front. Equivalent to `str.rsplit()`.

Parameters

- **pat**: string, default None
  Separator to split on. If None, splits on whitespace
- **n**: int, default -1 (all)
  None, 0 and -1 will be interpreted as return all splits
- **expand**: bool, default False
  - If True, return DataFrame/MultiIndex expanding dimensionality.
  - If False, return Series/Index.

Returns

split [Series/Index or DataFrame/MultiIndex of objects]

34.3.14.35 pandas.Series.str.startswith

Series.str.startswith(pat, na=nan)
Test if the start of each string element matches a pattern.
Equivalent to `str.startswith()`.

Parameters

- **pat**: str
  Character sequence. Regular expressions are not accepted.
na: object, default NaN
   Object shown if element tested is not a string.

Returns  Series or Index of bool
   A Series of booleans indicating whether the given pattern matches the start of each
   string element.

See also:

str.startswith  Python standard library string method.
Series.str.endswith  Same as startswith, but tests the end of string.
Series.str.contains  Tests if string element contains a pattern.

Examples

```python
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat  
1   Bear 
2    cat  
3     NaN
dtype: object

>>> s.str.startswith('b')
0    True
1   False
2   False
3     NaN
dtype: object

Specifying na to be False instead of NaN.

>>> s.str.startswith('b', na=False)
0    True
1   False
2   False
3   False
dtype: bool
```

34.3.14.36 pandas.Series.str.strip

Series.str.strip(to_strip=None)
   Strip whitespace (including newlines) from each string in the Series/Index from left and right sides. Equivalent
to str.strip().

Returns
   stripped  [Series/Index of objects]
34.3.14.37 pandas.Series.str.swapcase

Series.str.swapcase()

Convert strings in the Series/Index to be swapcased.

Equivalent to str.swapcase().

Returns

Series/Index of objects

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0   lower
1  CAPITALS
2   this is a sentence
3  SwApCaSe
dtype: object

>>> s.str.lower()
0   lower
1  capitals
2   this is a sentence
3  swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
1   Capitals
2  This Is A Sentence
3   Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1   Capitals
(continues on next page)```
34.3.14.38 pandas.Series.str.title

Series.str.title()
Convert strings in the Series/Index to titlecase.
Equivalent to str.title().

Returns
Series/Index of objects

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0  lower
1  CAPITALS
2  this is a sentence
3  SwApCaSe
dtype: object

>>> s.str.lower()
0  lower
1  capitals
2  this is a sentence
3  swapcase
dtype: object

>>> s.str.upper()
0  LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  sWApCaSe
```

(continues on next page)
3 SWAPCASE
dtype: object

```python
>>> s.str.title()
0   Lower
1  Capitals
2 This Is A Sentence
3   Swapcase
dtype: object
```  

```python
>>> s.str.capitalize()
0   Lower
1  Capitals
2 This is a sentence
3   Swapcase
dtype: object
```  

```python
>>> s.str.swapcase()
0   LOWER
1  capitals
2 THIS IS A SENTENCE
3  sWaPcAsE
dtype: object
```  

### 34.3.14.39 pandas.Series.str.translate

**Series.str.translate**(table, deletechars=None)

Map all characters in the string through the given mapping table. Equivalent to standard `str.translate()`. Note that the optional argument `deletechars` is only valid if you are using python 2. For python 3, character deletion should be specified via the table argument.

**Parameters**

- **table**: dict (python 3), str or None (python 2)
  
  In python 3, table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. `str.maketrans()` is a helper function for making translation tables. In python 2, table is either a string of length 256 or None. If the table argument is None, no translation is applied and the operation simply removes the characters in `deletechars`. `string.maketrans()` is a helper function for making translation tables.

- **deletechars**: str, optional (python 2)
  
  A string of characters to delete. This argument is only valid in python 2.

**Returns**

- **translated** [Series/Index of objects]

### 34.3.14.40 pandas.Series.str.upper

**Series.str.upper()**

Convert strings in the Series/Index to uppercase.

Equivalent to `str.upper()`.
Returns

Series/Index of objects

See also:

\textit{Series.str.lower} Converts all characters to lowercase.
\textit{Series.str.upper} Converts all characters to uppercase.
\textit{Series.str.title} Converts first character of each word to uppercase and remaining to lowercase.
\textit{Series.str.capitalize} Converts first character to uppercase and remaining to lowercase.
\textit{Series.str.swapcase} Converts uppercase to lowercase and lowercase to uppercase.

Examples

\begin{verbatim}
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0     lower
1   CAPITALS
2   this is a sentence
3     SwApCaSe
dtype: object

>>> s.str.lower()
0     lower
1   capitals
2   this is a sentence
3   swapcase
dtype: object

>>> s.str.upper()
0   LOWER
1   CAPITALS
2   THIS IS A SENTENCE
3   SWAPCASE
dtype: object

>>> s.str.title()
0  Lower
1  Capitals
2  This Is A Sentence
3    Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1    Capitals
2  This is a sentence
3    Swapcase
dtype: object

>>> s.str.swapcase()
0    LOWER

type: object
\end{verbatim}

34.3.14.41 pandas.Series.str.wrap

Series.str.wrap(width, **kwargs)

Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width. This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

Parameters:
- `width` : int
  Maximum line-width
- `expand_tabs` : bool, optional
  If true, tab characters will be expanded to spaces (default: True)
- `replace_whitespace` : bool, optional
  If true, each whitespace character (as defined by `string.whitespace`) remaining after tab expansion will be replaced by a single space (default: True)
- `drop_whitespace` : bool, optional
  If true, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True)
- `break_long_words` : bool, optional
  If true, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width. (default: True)
- `break_on_hyphens` : bool, optional
  If true, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly inseparable words. (default: True)

Returns:
- `wrapped` [Series/Index of objects]

Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R’s stringr library str_wrap function, use the arguments:

- `expand_tabs = False`
- `replace_whitespace = True`
- `drop_whitespace = True`
- `break_long_words = False`
- `break_on_hyphens = False`
Examples

```
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0    line to be
     wrapped
1    another line
     to be
     wrapped
```

### 34.3.14.42 pandas.Series.str.zfill

`Series.str.zfill(width)`

Filling left side of strings in the Series/Index with 0. Equivalent to `str.zfill()`.

**Parameters**

- `width` : int

**Returns**

- `filled` [Series/Index of objects]

### 34.3.14.43 pandas.Series.str.isalnum

`Series.str.isalnum()`

Check whether all characters in each string in the Series/Index are alphanumeric. Equivalent to `str.isalnum()`.

**Returns**

- `is` [Series/array of boolean values]

### 34.3.14.44 pandas.Series.str.isalpha

`Series.str.isalpha()`

Check whether all characters in each string in the Series/Index are alphabetic. Equivalent to `str.isalpha()`.

**Returns**

- `is` [Series/array of boolean values]

### 34.3.14.45 pandas.Series.str.isdigit

`Series.str.isdigit()`

Check whether all characters in each string in the Series/Index are digits. Equivalent to `str.isdigit()`.

**Returns**

- `is` [Series/array of boolean values]

### 34.3.14.46 pandas.Series.str.isspace

`Series.str.isspace()`

Check whether all characters in each string in the Series/Index are whitespace. Equivalent to `str.isspace()`.

**Returns**

- `is` [Series/array of boolean values]
is  [Series/array of boolean values]

34.3.14.47  pandas.Series.str.islower

Series.str.islower()
Check whether all characters in each string in the Series/Index are lowercase. Equivalent to str.islower().

Returns
is  [Series/array of boolean values]

34.3.14.48  pandas.Series.str.isupper

Series.str.isupper()
Check whether all characters in each string in the Series/Index are uppercase. Equivalent to str.isupper().

Returns
is  [Series/array of boolean values]

34.3.14.49  pandas.Series.str.istitle

Series.str.istitle()
Check whether all characters in each string in the Series/Index are titlecase. Equivalent to str.istitle().

Returns
is  [Series/array of boolean values]

34.3.14.50  pandas.Series.str.isnumeric

Series.str.isnumeric()
Check whether all characters in each string in the Series/Index are numeric. Equivalent to str.isnumeric().

Returns
is  [Series/array of boolean values]

34.3.14.51  pandas.Series.str.isdecimal

Series.str.isdecimal()
Check whether all characters in each string in the Series/Index are decimal. Equivalent to str.isdecimal().

Returns
is  [Series/array of boolean values]

34.3.14.52  pandas.Series.str.get_dummies

Series.str.get_dummies(sep='|')
Split each string in the Series by sep and return a frame of dummy/indicator variables.

Parameters  sep : string, default “|”
        String to split on.
Returns

dummies [DataFrame]

See also:

pandas.get_dummies

Examples

```python
>>> Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1

>>> Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```

### 34.3.15 Categorical

Pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a `Categorical` can be described by a `pandas.api.types.CategoricalDtype`.

```python
api.types.CategoricalDtype([categories, ordered])
```

Type for categorical data with the categories and orderedness

Changed in version 0.21.0.

Parameters:
- `categories`: sequence, optional
  - Must be unique, and must not contain any nulls.
- `ordered`: [bool, default False]

See also:

pandas.Categorical

Notes

This class is useful for specifying the type of a `Categorical` independent of the values. See `CategoricalDtype` for more.
Examples

```python
>>> t = CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0    a
1    b
2    a
3  NaN
dtype: category
Categories (2, object): [b < a]
```

Attributes

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>categories</strong></td>
<td>An <code>Index</code> containing the unique categories allowed.</td>
</tr>
<tr>
<td><strong>ordered</strong></td>
<td>Whether the categories have an ordered relationship</td>
</tr>
</tbody>
</table>

**pandas.api.types.CategoricalDtype.categories**

*CategoricalDtype.categories*

An `Index` containing the unique categories allowed.

**pandas.api.types.CategoricalDtype.ordered**

*CategoricalDtype.ordered*

Whether the categories have an ordered relationship

Methods

None

**api.types.CategoricalDtype.categories**

An `Index` containing the unique categories allowed.

**api.types.CategoricalDtype.ordered**

Whether the categories have an ordered relationship

Categorical data can be stored in a `pandas.Categorical`

```
Categorical(values[, categories, ordered, ...])
```

Represents a categorical variable in classic R / S-plus fashion

### 34.3.15.2 pandas.Categorical

**class pandas.Categorical**

*Represented a categorical variable in classic R / S-plus fashion*

*Categoricals* can only take on only a limited, and usually fixed, number of possible values (categories). In contrast to statistical categorical variables, a *Categorical* might have an order, but numerical operations (additions, divisions, ...) are not possible.
All values of the Categorical are either in categories or np.nan. Assigning values outside of categories will raise a ValueError. Order is defined by the order of the categories, not lexical order of the values.

**Parameters**

- **values**: list-like
  
  The values of the categorical. If categories are given, values not in categories will be replaced with NaN.

- **categories**: Index-like (unique), optional
  
  The unique categories for this categorical. If not given, the categories are assumed to be the unique values of values.

- **ordered**: boolean, (default False)
  
  Whether or not this categorical is treated as a ordered categorical. If not given, the resulting categorical will not be ordered.

- **dtype**: CategoricalDtype
  
  An instance of CategoricalDtype to use for this categorical

New in version 0.21.0.

**Raises**

- **ValueError**
  
  If the categories do not validate.

- **TypeError**
  
  If an explicit ordered=True is given but no categories and the values are not sortable.

**See also:**

- `pandas.api.types.CategoricalDtype` Type for categorical data
- `CategoricalIndex` An Index with an underlying Categorical

**Notes**

See the user guide for more.

**Examples**

```python
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]

>>> pd.Categorical(["a", "b", "c", "a", "b", "c")
[a, b, c, a, b, c]
Categories (3, object): [a, b, c]
```

Ordered Categoricals can be sorted according to the custom order of the categories and can have a min and max value.
```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
                      categories=['c', 'b', 'a'])
>>> c
[a, b, c, a, b, c]
Categories (3, object): [c < b < a]
>>> c.min()
'c'
```

### Attributes

</tbody>
</table>

### pandas.Categorical.categories

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

**Raises** `ValueError`

If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

rename_categories, reorder_categories, add_categories, remove_categories, remove_unused_categories, set_categories

### pandas.Categorical.codes

The category codes of this categorical.

Level codes are an array if integer which are the positions of the real values in the categories array.

There is not setter, use the other categorical methods and the normal item setter to change values in the categorical.

### pandas.Categorical.ordered

Whether the categories have an ordered relationship
pandas.Categorical.dtype

Categorical.dtype
The CategoricalDtype for this instance

Methods

from_codes(codes, categories[, ordered]) Make a Categorical type from codes and categories arrays.

__array__((dtype)) The numpy array interface.

pandas.Categorical.from_codes

classmethod Categorical.from_codes(codes, categories, ordered=False)
Make a Categorical type from codes and categories arrays.

This constructor is useful if you already have codes and categories and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

Parameters codes: array-like, integers
An integer array, where each integer points to a category in categories or -1 for NaN
categories: index-like
The categories for the categorical. Items need to be unique.
ordered: boolean, (default False)
Whether or not this categorical is treated as a ordered categorical. If not given, the resulting categorical will be unordered.

pandas.Categorical.__array__

Categorical.__array__(dtype=None)
The numpy array interface.

Returns values: numpy array
A numpy array of either the specified dtype or, if dtype=None (default), the same dtype as categorical.categories.dtype

The alternative Categorical.from_codes() constructor can be used when you have the categories and integer codes already:

Categorical.from_codes(codes, categories,...)

The dtype information is available on the Categorical
Categorical.dtype
The CategoricalDtype for this instance

Categorical.categories
The categories of this categorical.

Categorical.ordered
Whether the categories have an ordered relationship

Categorical.codes
The category codes of this categorical.

np.asarray(categorical) works by implementing the array interface. Be aware, that this converts the Categorical back to a NumPy array, so categories and order information is not preserved!

Categorical.__array__((dtype)) The numpy array interface.

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use cat = s.astype(dtype) or Series(..., dtype=dtype) where dtype is either

• the string 'category'
• an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, Series.cat can be used to change the categorical data. This accessor is similar to the Series.dt or Series.str and has the following usable methods and properties:

Series.cat.categories
The categories of this categorical.

Series.cat.ordered
Whether the categories have an ordered relationship

Series.cat.codes

34.3.15.3 pandas.Series.cat.categories

Series.cat.categories
The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to categories is a inplace operation!

Raises ValueError
If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:
rename_categories, reorder_categories, add_categories, remove_categories, remove_unused_categories, set_categories

34.3.15.4 pandas.Series.cat.ordered

Series.cat.ordered
Whether the categories have an ordered relationship

34.3.15.5 pandas.Series.cat.codes

Series.cat.codes
### Series.cat.rename_categories

**Series.cat.rename_categories(**

- ***args,**
- ****kwargs)

Renames categories.

**Parameters**

- **new_categories** : list-like, dict-like or callable
  - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
  - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
    - New in version 0.21.0.
  - callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.
    - New in version 0.23.0.

**Warning:** Currently, Series are considered list like. In a future version of pandas they’ll be considered dict-like.

- **inplace** : boolean (default: False)
  - Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

**Returns**

- **cat** : Categorical or None
  - With inplace=False, the new categorical is returned. With inplace=True, there is no return value.

**Raises**

- **ValueError**
  - If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

**See also:**

- reorder_categories,
- add_categories,
- remove_categories,
- remove_unused_categories,
- set_categories

---

### pandas.Series.cat.rename_categories

**Series.cat.rename_categories(**

- ***args,**
- ****kwargs)

Renames categories.

**Parameters**

- **new_categories** : list-like, dict-like or callable
  - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
  - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
    - New in version 0.21.0.
  - callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.
    - New in version 0.23.0.

**Warning:** Currently, Series are considered list like. In a future version of pandas they’ll be considered dict-like.

- **inplace** : boolean (default: False)
  - Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

**Returns**

- **cat** : Categorical or None
  - With inplace=False, the new categorical is returned. With inplace=True, there is no return value.

**Raises**

- **ValueError**
  - If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

**See also:**

- reorder_categories,
- add_categories,
- remove_categories,
- remove_unused_categories,
- set_categories
Examples

```python
>>> c = Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

### 34.3.15.7 pandas.Series.cat.reorder_categories

Series.cat.

`reorder_categories (*args, **kwargs)`

Reorders categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

**Parameters**

`new_categories` : Index-like

The categories in new order.

`ordered` : boolean, optional

Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

`inplace` : boolean (default: False)

Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

`cat` [Categorical with reordered categories or None if inplace.]

**Raises**

ValueError

If the new categories do not contain all old category items or any new ones

**See also:**

`rename_categories`, `add_categories`, `remove_categories`, `remove_unused_categories`, `set_categories`

### 34.3.15.8 pandas.Series.cat.add_categories

Series.cat.

`add_categories (*args, **kwargs)`

Add new categories.

`new_categories` will be included at the last/highest place in the categories and will be unused directly after this call.
Parameters **new_categories** : category or list-like of category

The new categories to be included.

**inplace** : boolean (default: False)

Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Returns

cat [Categorical with new categories added or None if inplace.]

Raises ValueError

If the new categories include old categories or do not validate as categories

See also:

rename_categories, reorder_categories, remove_categories, remove_unused_categories, set_categories

34.3.15.9 pandas.Series.cat.remove_categories

Series.cat.remove_categories(*args, **kwargs)

Removes the specified categories.

**removals** must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters **removals** : category or list of categories

The categories which should be removed.

**inplace** : boolean (default: False)

Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Returns

cat [Categorical with removed categories or None if inplace.]

Raises ValueError

If the removals are not contained in the categories

See also:

rename_categories, reorder_categories, add_categories, remove_unused_categories, set_categories

34.3.15.10 pandas.Series.cat.remove_unused_categories

Series.cat.remove_unused_categories(*args, **kwargs)

Removes categories which are not used.

Parameters **inplace** : boolean (default: False)

Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Returns

cat [Categorical with unused categories dropped or None if inplace.]
See also:

rename_categories, reorder_categories, add_categories, remove_categories, set_categories

34.3.15.11 pandas.Series.cat.set_categories

Series.cat.set_categories(*args, **kwargs)
Sets the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If rename==True, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes on python3, which does not considers a S1 string equal to a single char python string.

**Parameters**

new_categories : Index-like
The categories in new order.

ordered : boolean, (default: False)
Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

rename : boolean (default: False)
Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.

inplace : boolean (default: False)
Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

cat [Categorical with reordered categories or None if inplace.]

Raises ValueError
If new_categories does not validate as categories

See also:

rename_categories, reorder_categories, add_categories, remove_categories, remove_unused_categories

34.3.15.12 pandas.Series.cat.as_ordered

Series.cat.as_ordered(*args, **kwargs)
Sets the Categorical to be ordered

**Parameters**
inplace : boolean (default: False)
Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to True
34.3.15.13 pandas.Series.cat.as_unordered

Series.cat.as_unordered(*args, **kwargs)
Sets the Categorical to be unordered

Parameters inplace : boolean (default: False)
Whether or not to set the ordered attribute inplace or return a copy of this categorical
with ordered set to False

34.3.16 Plotting

Series.plot is both a callable method and a namespace attribute for specific plotting methods of the form
Series.plot.<kind>.

<table>
<thead>
<tr>
<th>Series.plot(kind, ax, figsize, . . . .)</th>
<th>Series plotting accessor and method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.plot.area(**kwds)</td>
<td>Area plot</td>
</tr>
<tr>
<td>Series.plot.bar(**kwds)</td>
<td>Vertical bar plot</td>
</tr>
<tr>
<td>Series.plot.barh(**kwds)</td>
<td>Horizontal bar plot</td>
</tr>
<tr>
<td>Series.plot.box(**kwds)</td>
<td>Boxplot</td>
</tr>
<tr>
<td>Series.plot.density(bw_method, ind)</td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td>Series.plot.hist(bins)</td>
<td>Histogram</td>
</tr>
<tr>
<td>Series.plot.kde(bw_method, ind)</td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td>Series.plot.line(**kwds)</td>
<td>Line plot</td>
</tr>
<tr>
<td>Series.plot.pie(**kwds)</td>
<td>Pie chart</td>
</tr>
</tbody>
</table>

34.3.16.1 pandas.Series.plot.area

Series.plot.area(**kwds)
Area plot

Parameters **kwds : optional
Additional keyword arguments are documented in pandas.Series.plot().

Returns
axes [matplotlib.axes.Axes or numpy.ndarray of them]

34.3.16.2 pandas.Series.plot.bar

Series.plot.bar(**kwds)
Vertical bar plot

Parameters **kwds : optional
Additional keyword arguments are documented in pandas.Series.plot().

Returns
axes [matplotlib.axes.Axes or numpy.ndarray of them]
34.3.16.3 pandas.Series.plot.barh

```python
def barh(**kwds):
    Horizontal bar plot
    Parameters `**kwds` : optional
    Additional keyword arguments are documented in pandas.Series.plot().
    Returns
    axes [matplotlib.axes.Axes or numpy.ndarray of them]
```

34.3.16.4 pandas.Series.plot.box

```python
def box(**kwds):
    Boxplot
    Parameters `**kwds` : optional
    Additional keyword arguments are documented in pandas.Series.plot().
    Returns
    axes [matplotlib.axes.Axes or numpy.ndarray of them]
```

34.3.16.5 pandas.Series.plot.density

```python
def density(bw_method=None, ind=None, **kwds):
    Generate Kernel Density Estimate plot using Gaussian kernels.
    In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.
    Parameters `bw_method` : str, scalar or callable, optional
    The method used to calculate the estimator bandwidth. This can be `scott`, `silverman`, a scalar constant or a callable. If None (default), `scott` is used. See scipy.stats.gaussian_kde for more information.
    `ind` : NumPy array or integer, optional
    Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If `ind` is a NumPy array, the KDE is evaluated at the points passed. If `ind` is an integer, `ind` number of equally spaced points are used.
    `**kwds` : optional
    Additional keyword arguments are documented in pandas.Series.plot().
    Returns
    axes [matplotlib.axes.Axes or numpy.ndarray of them]
```

See also:

- scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.
- DataFrame.plot.kde Generate a KDE plot for a DataFrame.
Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to overfitting, while using a large bandwidth value may result in underfitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
```

```python
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

34.3.16.6 pandas.Series.plot.hist

Series.plot.hist(bins=10, **kwds)

Histogram

**Parameters**

- *bins*: integer, default 10
  - Number of histogram bins to be used

  **kwds**: optional
  - Additional keyword arguments are documented in `pandas.Series.plot()`.

**Returns**

axes [matplotlib.axes.Axes or numpy.ndarray of them]

34.3.16.7 pandas.Series.plot.kde

Series.plot.kde(bw_method=None, ind=None, **kwds)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- *bw_method*: str, scalar or callable, optional
  - The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See `scipy.stats.gaussian_kde` for more information.

- *ind*: NumPy array or integer, optional
  - Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**kwds**: optional
Additional keyword arguments are documented in `pandas.Series.plot()`.

**Returns**

`axes` [matplotlib.axes.Axes or numpy.ndarray of them]

**See also:**

- `scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.
- `Dataframe.plot.kde` Generate a KDE plot for a DataFrame.

**Examples**

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to overfitting, while using a large bandwidth value may result in underfitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
```

```python
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

**34.3.16.8 pandas.Series.plot.line**

Series.plot.line(**kwds)**

Line plot

**Parameters** `**kwds` : optional

Additional keyword arguments are documented in `pandas.Series.plot()`.

**Returns**

`axes` [matplotlib.axes.Axes or numpy.ndarray of them]

**Examples**

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

**34.3.16.9 pandas.Series.plot.pie**

Series.plot.pie(**kwds)**

Pie chart
Parameters `**kwds` : optional

Additional keyword arguments are documented in pandas.Series.plot().

Returns

`axes` [matplotlib.axes.Axes or numpy.ndarray of them]

Series.hist([by, ax, grid, xlabels, ...]) Draw histogram of the input series using matplotlib

34.3.17 Serialization / IO / Conversion

<table>

34.3.18 Sparse

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SparseSeries.to_coo</td>
<td>Create a scipy.sparse.coo_matrix from a SparseSeries with MultiIndex.</td>
</tr>
<tr>
<td>SparseSeries.from_coo</td>
<td>Create a SparseSeries from a scipy.sparse.coo_matrix.</td>
</tr>
</tbody>
</table>

34.3.18.1 pandas.SparseSeries.to_coo

SparseSeries.to_coo(row_levels=(0,), column_levels=(1,), sort_labels=False)
Create a scipy.sparse.coo_matrix from a SparseSeries with MultiIndex.

Use row_levels and column_levels to determine the row and column coordinates respectively. row_levels and column_levels are the names (labels) or numbers of the levels. (row_levels, column_levels) must be a partition of the MultiIndex level names (or numbers).

Parameters

- **row_levels** [tuple/list]
- **column_levels** [tuple/list]
- **sort_labels** : bool, default False
Sort the row and column labels before forming the sparse matrix.

Returns

- y [scipy.sparse.coo_matrix]
- rows [list (row labels)]
- columns [list (column labels)]

Examples

```python
>>> from numpy import nan
>>> s = Series([3.0, nan, 1.0, 3.0, nan, nan])
>>> s.index = MultiIndex.from_tuples([(1, 2, 'a', 0),
                                       (1, 2, 'a', 1),
                                       (1, 1, 'b', 0),
                                       (1, 1, 'b', 1),
                                       (2, 1, 'b', 0),
                                       (2, 1, 'b', 1)],
                          names=['A', 'B', 'C', 'D'])
>>> ss = s.to_sparse()
>>> A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                column_levels=['C', 'D'],
                                sort_labels=True)
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0., 0., 1., 3.],
        [ 3., 0., 0., 0.],
        [ 0., 0., 0., 0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

34.3.18.2 pandas.SparseSeries.from_coo

**classmethod SparseSeries.from_coo(A, dense_index=False)**

Create a SparseSeries from a scipy.sparse.coo_matrix.

**Parameters**

- A [scipy.sparse.coo_matrix]
- dense_index : bool, default False

If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

**Returns**

- s [SparseSeries]
Examples

```python
>>> from scipy import sparse
>>> A = sparse.coo_matrix(((3.0, 1.0, 2.0), ([1, 0, 0], [0, 2, 3])),
                       shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
     with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 3. ,  0. ,  1. ,  2. ],
        [ 3. ,  0. ,  0. ,  0. ],
        [ 0. ,  0. ,  0. ,  0. ]])
>>> ss = SparseSeries.from_coo(A)
>>> ss
0    2    1
   3
1   0    3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

34.4 DataFrame

34.4.1 Constructor

`DataFrame([data, index, columns, dtype, copy])` Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns).

34.4.1.1 pandas.DataFrame

class pandas.DataFrame(data=None, index=None, columns=None, dtype=None, copy=False)
Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns). Arithmetic operations align on both row and column labels. Can be thought of as a dict-like container for Series objects. The primary pandas data structure.

Parameters

- `data` : numpy ndarray (structured or homogeneous), dict, or DataFrame
  - Dict can contain Series, arrays, constants, or list-like objects
  - Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.
- `index` : Index or array-like
  - Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided
- `columns` : Index or array-like
  - Column labels to use for resulting frame. Will default to RangeIndex (0, 1, 2, ..., n) if no column labels are provided
- `dtype` : dtype, default None
Data type to force. Only a single dtype is allowed. If None, infer

```
copy: boolean, default False
```
Copy data from inputs. Only affects DataFrame / 2d ndarray input

**See also:**

*DataFrame.from_records* constructor from tuples, also record arrays

*DataFrame.from_dict* from dicts of Series, arrays, or dicts

*DataFrame.from_items* from sequence of (key, value) pairs

*pandas.read_csv, pandas.read_table, pandas.read_clipboard*

### Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
    col1  col2  
0     1     3  
1     2     4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1  int64
col2  int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
    col1  col2  
col1  int8  int8
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.random.randint(low=0, high=10, size=(5, 5)),
...                     columns=['a', 'b', 'c', 'd', 'e'])
>>> df2
   a  b  c  d  e
0  2  8  8  3  4
1  4  2  9  0  9
2  1  0  7  8  0
3  5  1  7  1  3
4  6  0  2  4  2
```

**Attributes**
### pandas.DataFrame.T

**DataFrame.T**

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property `T` is an accessor to the method `transpose()`.

**Parameters**

- `copy` : bool, default False

  If True, the underlying data is copied. Otherwise (default), no copy is made if possible.

- `*args`, `**kwargs`

  Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

DataFrame

The transposed DataFrame.

**See also:**

- `numpy.transpose` Permute the dimensions of a given array.

<table>
<thead>

<td>Return an int representing the number of elements in this object.</td>
</tr>
<tr>
<td><code>style</code></td>
<td>Property returning a Styler object containing methods for building a styled HTML representation for the DataFrame.</td>
</tr>
<tr>
<td><code>values</code></td>
<td>Return a Numpy representation of the DataFrame.</td>
</tr>
</tbody>
</table>
Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the object dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```python
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0    1    3
1    2    4

>>> df1_transposed = df1.T  # or df1.transpose()
>>> df1_transposed
       0 1
col1  1  2
col2  3  4

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```python
>>> df1.dtypes
   col1  int64
   col2  int64
dtype: object

>>> df1_transposed.dtypes
   0  int64
   1  int64
dtype: object
```

Non-square DataFrame with mixed dtypes

```python
>>> d2 = {'name': ['Alice', 'Bob'],
       ...   'score': [9.5, 8],
       ...   'employed': [False, True],
       ...   'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice  9.5000  False     0
1   Bob  8.0000   True     0

>>> df2_transposed = df2.T  # or df2.transpose()
>>> df2_transposed
    0 1
name Alice Bob
score  9.5  8
employed  False  True
kids      0     0

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the object dtype:

```
```python
>>> df2.dtypes
name    object
score   float64
employed bool
kids    int64
dtype: object
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

**pandas.DataFrame.at**

*DataFrame.at*

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a `DataFrame` or `Series`.

*Raisess* `KeyError`

When label does not exist in `DataFrame`

*See also:*

- `DataFrame.iat`: Access a single value for a row/column pair by integer position
- `DataFrame.loc`: Access a group of rows and columns by label(s)
- `Series.at`: Access a single value using a label

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```
pandas.DataFrame.axes

DataFrame.axes
Return a list representing the axes of the DataFrame.
It has the row axis labels and column axis labels as the only members. They are returned in that order.

Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

pandas.DataFrame.blocks

DataFrame.blocks
Internal property, property synonym for as_blocks()
Deprecated since version 0.21.0.

pandas.DataFrame.columns

DataFrame.columns
The column labels of the DataFrame.

pandas.DataFrame.dtypes

DataFrame.dtypes
Return the dtypes in the DataFrame.
This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

Returns pandas.Series
The data type of each column.

See also:

pandas.DataFrame.ftypes dtype and sparsity information.

Examples

```python
>>> df = pd.DataFrame({'float': [1.0],
...                     'int': [1],
...                     'datetime': [pd.Timestamp('20180310')],
...                     'string': ['foo'])
>>> df.dtypes
float float64
int int64
```
pandas.DataFrame.empty

DataFrame.empty
Indicator whether DataFrame is empty.
True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns bool
If DataFrame is empty, return True, if not return False.

See also:
pandas.Series.dropna, pandas.DataFrame.dropna

Notes
If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples
An example of an actual empty DataFrame. Notice the index is empty:

```python
def_empty = pd.DataFrame({'A' : []})
def_empty
Empty DataFrame
Columns: [A]
Index: []

def_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
df = pd.DataFrame({'A' : [np.nan]})
df
A
0 NaN
df.empty
False
df.dropna().empty
True
```

pandas.DataFrame.ftypes

DataFrame.ftypes
Return the ftypes (indication of sparse/dense and dtype) in DataFrame.
This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

**Returns** pandas.Series

The data type and indication of sparse/dense of each column.

**See also:**

- **pandas.DataFrame.dtypes** Series with just dtype information.
- **pandas.SparseDataFrame** Container for sparse tabular data.

**Notes**

Sparse data should have the same dtypes as its dense representation.

**Examples**

```python
>>> import numpy as np
>>> arr = np.random.RandomState(0).randn(100, 4)
>>> arr[arr < .8] = np.nan
>>> pd.DataFrame(arr).ftypes
0   float64:dense
1   float64:dense
2   float64:dense
3   float64:dense
dtype: object

>>> pd.SparseDataFrame(arr).ftypes
0   float64:sparse
1   float64:sparse
2   float64:sparse
3   float64:sparse
dtype: object
```

**pandas.DataFrame.iat**

DataFrame.iat

Access a single value for a row/column pair by integer position.

Similar to iloc, in that both provide integer-based lookups. Use iat if you only need to get or set a single value in a DataFrame or Series.

**Raises** IndexError

When integer position is out of bounds

**See also:**

- **DataFrame.at** Access a single value for a row/column label pair
- **DataFrame.loc** Access a group of rows and columns by label(s)
- **DataFrame.iloc** Access a group of rows and columns by integer position(s)
Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
        A  B  C
0      0  2  3
1      0  4  1
2    10 20 30

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```python
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```python
>>> df.loc[0].iat[1]
2
```

**pandas.DataFrame.iloc**

*DataFrame.iloc*

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at Selection by Position

**pandas.DataFrame.index**

*DataFrame.index*

The index (row labels) of the DataFrame.
pandas.DataFrame.ix

DataFrame.ix
A primarily label-location based indexer, with integer position fallback.
Warning: Starting in 0.20.0, the .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers.
.ix[] supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.
.ix is the most general indexer and will support any of the inputs in .loc and .iloc. .ix also supports floating point label schemes. .ix is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.
However, when an axis is integer based, ONLY label based access and not positional access is supported. Thus, in such cases, it’s usually better to be explicit and use .iloc or .loc.
See more at Advanced Indexing.

pandas.DataFrame.loc

DataFrame.loc
Access a group of rows and columns by label(s) or a boolean array.
.loc[] is primarily label based, but may also be used with a boolean array.
Allowed inputs are:
• A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and never as an integer position along the index).
• A list or array of labels, e.g. ['a', 'b', 'c'].
• A slice object with labels, e.g. 'a':'f'.

Warning: Note that contrary to usual python slices, both the start and the stop are included

• A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
• A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

See more at Selection by Label

Raises KeyError:
when any items are not found

See also:

DataFrame.at  Access a single value for a row/column label pair
DataFrame.iloc  Access group of rows and columns by integer position(s)
DataFrame.xs   Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
Series.loc     Access group of values using labels
Examples

Getting values

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                    index=['cobra', 'viper', 'sidewinder'],
                    columns=['max_speed', 'shield'])
>>> df
           max_speed  shield
    cobra         1        2
    viper         4        5
    sidewinder    7        8

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using [[]] returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
           max_speed  shield
    viper         4        5
    sidewinder    7        8
```

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc['cobra':'viper', 'max_speed']
    cobra    1
    viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```python
>>> df.loc[[False, False, True]]
           max_speed  shield
    sidewinder    7        8
```

Conditional that returns a boolean Series

```python
>>> df.loc[df['shield'] > 6]
           max_speed  shield
    sidewinder    7        8
```

Conditional that returns a boolean Series with column labels specified

```python
>>> df.loc[df['shield'] > 6, ['max_speed']]
           max_speed
    sidewinder    7
```
Callable that returns a boolean Series

```python
>>> df.loc[lambda df: df['shield'] == 8]
  max_speed  shield
sidewinder    7     8
```

**Setting values**

Set value for all items matching the list of labels

```python
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
  max_speed  shield
  cobra        1     2
  viper        4     50
  sidewinder    7     50
```

Set value for an entire row

```python
>>> df.loc['cobra'] = 10
>>> df
  max_speed  shield
  cobra      10    10
  viper        4     50
  sidewinder    7     50
```

Set value for an entire column

```python
>>> df.loc[:, 'max_speed'] = 30
>>> df
  max_speed  shield
  cobra    30    10
  viper    30     50
  sidewinder 30     50
```

Set value for rows matching callable condition

```python
>>> df.loc[df['shield'] > 35] = 0
>>> df
  max_speed  shield
  cobra    30    10
  viper      0     0
  sidewinder 0      0
```

**Getting values on a DataFrame with an index that has integer labels**

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
   7          1     2
   8          4     5
   9          7     8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.
Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
>>> tuples = [
    ('cobra', 'mark i'), ('cobra', 'mark ii'),
    ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
    ('viper', 'mark ii'), ('viper', 'mark iii')
]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
            [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
    max_speed shield
     cobra mark i     12       2
       mark ii       0       4
   sidewinder mark i    10      20
       mark ii       1       4
     viper mark ii      7       1
       mark iii      16      36

Single label. Note this returns a DataFrame with a single index.

```python
>>> df.loc['cobra']

    max_speed shield
     mark i     12       2
     mark ii       0       4
```

Single index tuple. Note this returns a Series.

```python
>>> df.loc[('cobra', 'mark ii')]

    max_speed
     0
    shield
     4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```python
>>> df.loc[('cobra', 'mark i')]

    max_speed
     12
    shield
     2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```python
>>> df.loc[['cobra', 'mark ii']]

     max_speed shield
    cobra mark ii     0       4
```

Single tuple for the index with a single label for the column
Slice from index tuple to single label

```python
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to index tuple

```python
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
max_speed shield
cobra  mark i  12  2
       mark ii  0  4
sidewinder  mark i  10  20
            mark ii  1  4
viper   mark ii  7  1
        mark iii 16  36
```

**pandas.DataFrame.ndim**

DataFrame.ndim

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

ndarray.ndim

Examples

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

**pandas.DataFrame.shape**

DataFrame.shape

Return a tuple representing the dimensionality of the DataFrame.

See also:

ndarray.shape
Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
... 'col3': [5, 6]})
>>> df.shape
(2, 3)
```

**pandas.DataFrame.size**

Dataframe `size`

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

`ndarray.size`

Examples

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

**pandas.DataFrame.style**

Dataframe `style`

Property returning a Styler object containing methods for building a styled HTML representation for the DataFrame.

See also:

`pandas.io.formats.style.Styler`

**pandas.DataFrame.values**

Dataframe `values`

Return a Numpy representation of the DataFrame.

Only the values in the DataFrame will be returned, the axes labels will be removed.

Returns `numpy.ndarray`

The values of the DataFrame.
See also:

```
pandas.DataFrame.index
```
Retrieve the index labels

```
pandas.DataFrame.columns
```
Retrieving the column names

Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes
(even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if
you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8,
dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64
will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```python
>>> df = pd.DataFrame({'age': [3, 29],
...                     'height': [94, 170],
...                     'weight': [31, 115]})
>>> df
   age  height  weight
0    3      94      31
1   29     170     115
>>> df.dtypes
age     int64
height  int64
weight  int64
dtype: object
>>> df.values
array([[ 3,  94,  31],
       [ 29, 170, 115]], dtype=int64)
```

A DataFrame with mixed type columns (e.g., str/object, int64, float32) results in an ndarray of the broadest
type that accommodates these mixed types (e.g., object).

```python
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                      ('lion', 80.5, 1),
...                      ('monkey', np.nan, None)],
...                    columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed     float64
rank          object
dtype: object
>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion',  80.5,  1],
       ['monkey', nan, None]], dtype=object)
```
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>add(other[, axis, level, fill_value])</code></td>
<td>Addition of dataframe and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td><code>add_prefix(prefix)</code></td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td><code>add_suffix(suffix)</code></td>
<td>Suffix labels with string suffix.</td>
</tr>
<tr>
<td><code>agg(func[, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>aggregate(func[, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>align(other[, join, axis, level, copy, . . .])</code></td>
<td>Align two objects on their axes with the specified join method for each axis Index</td>
</tr>
<tr>
<td><code>all([axis, bool_only, skipna, level])</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>any([axis, bool_only, skipna, level])</code></td>
<td>Return whether any element is True over requested axis.</td>
</tr>
<tr>
<td><code>append(other[, ignore_index, . . .])</code></td>
<td>Append rows of other to the end of this frame, returning a new object.</td>
</tr>
<tr>
<td><code>apply(func[, axis, broadcast, raw, reduce, . . .])</code></td>
<td>Apply a function along an axis of the DataFrame.</td>
</tr>
<tr>
<td><code>applymap(func)</code></td>
<td>Apply a function to a Dataframe elementwise.</td>
</tr>
<tr>
<td><code>as_blocks([copy])</code></td>
<td>(DEPRECATED) Convert the frame to a dict of dtype -&gt; Constructor Types that each has a homogeneous dtype.</td>
</tr>
<tr>
<td><code>as_matrix([columns])</code></td>
<td>(DEPRECATED) Convert the frame to its Numpy-array representation.</td>
</tr>
<tr>
<td><code>asfreq(freq[, method, how, normalize, . . .])</code></td>
<td>Convert TimeSeries to specified frequency.</td>
</tr>
<tr>
<td><code>asof(where[, subset])</code></td>
<td>The last row without any NaN is taken (or the last row without NaN considering only the subset of columns in the case of a DataFrame)</td>
</tr>
<tr>
<td><code>assign(**kwargs)</code></td>
<td>Assign new columns to a DataFrame, returning a new object (a copy) with the new columns added to the original ones.</td>
</tr>
<tr>
<td><code>astype(dtype[, copy, errors])</code></td>
<td>Cast a pandas object to a specified dtype dtype.</td>
</tr>
<tr>
<td><code>at_time(time[, asof])</code></td>
<td>Select values at particular time of day (e.g. 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>between_time(start_time, end_time[, . . .])</code></td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>bfill([axis, inplace, limit, downcast])</code></td>
<td>Synonym for DataFrame.fillna(method='bfill')</td>
</tr>
<tr>
<td><code>bool()</code></td>
<td>Return the bool of a single element PandasObject.</td>
</tr>
<tr>
<td><code>boxplot([column, by, ax, fontsize, rot, . . .])</code></td>
<td>Make a box plot from DataFrame columns.</td>
</tr>
<tr>
<td><code>clip([lower, upper, axis, inplace])</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>clip_lower(threshold[, axis, inplace])</code></td>
<td>Return copy of the input with values below a threshold truncated.</td>
</tr>
<tr>
<td><code>clip_upper(threshold[, axis, inplace])</code></td>
<td>Return copy of input with values above given value(s) truncated.</td>
</tr>
<tr>
<td><code>combine(other, func[, fill_value, overwrite])</code></td>
<td>Add two DataFrame objects and do not propagate NaN values, so if for a (column, time) one frame is missing a value, it will default to the other frame’s value (which might be NaN as well)</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>combine_first(other)</code></td>
<td>Combine two DataFrame objects and default to non-null values in frame calling the method.</td>
</tr>
<tr>
<td><code>compound([axis, skipna, level])</code></td>
<td>Return the compound percentage of the values for the requested axis</td>
</tr>
<tr>
<td><code>consolidate([inplace])</code></td>
<td>(DEPRECATED) Compute NDFrame with “consolidated” internals (data of each dtype grouped together in a single ndarray).</td>
</tr>
<tr>
<td><code>convert_objects([convert_dates, . . . ])</code></td>
<td>(DEPRECATED) Attempt to infer better dtype for object columns.</td>
</tr>
<tr>
<td><code>copy([deep])</code></td>
<td>Make a copy of this object’s indices and data.</td>
</tr>
<tr>
<td><code>corr([method, min_periods])</code></td>
<td>Compute pairwise correlation of columns, excluding NA/null values.</td>
</tr>
<tr>
<td><code>corrwith(other[, axis, drop])</code></td>
<td>Compute pairwise correlation between rows or columns of two DataFrame objects.</td>
</tr>
<tr>
<td><code>count([axis, level, numeric_only])</code></td>
<td>Count non-NA cells for each column or row.</td>
</tr>
<tr>
<td><code>cov([min_periods])</code></td>
<td>Compute pairwise covariance of columns, excluding NA/null values.</td>
</tr>
<tr>
<td><code>cummax([axis, skipna])</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cummin([axis, skipna])</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumprod([axis, skipna])</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumsum([axis, skipna])</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>describe([percentiles, include, exclude])</code></td>
<td>Generates descriptive statistics that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.</td>
</tr>
<tr>
<td><code>diff([periods, axis])</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>div(other[, axis, level, fill_value])</code></td>
<td>Floating division of dataframe and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><code>divide(other[, axis, level, fill_value])</code></td>
<td>Floating division of dataframe and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><code>dot(other)</code></td>
<td>Matrix multiplication with DataFrame or Series objects.</td>
</tr>
<tr>
<td><code>drop([labels, axis, index, columns, level, . . . ])</code></td>
<td>Drop specified labels from rows or columns.</td>
</tr>
<tr>
<td><code>drop_duplicates([subset, keep, inplace])</code></td>
<td>Return DataFrame with duplicate rows removed, optionally only considering certain columns</td>
</tr>
<tr>
<td><code>dropna([axis, how, thresh, subset, inplace])</code></td>
<td>Remove missing values.</td>
</tr>
<tr>
<td><code>duplicated([subset, keep])</code></td>
<td>Return boolean Series denoting duplicate rows, optionally only considering certain columns</td>
</tr>
<tr>
<td><code>eq(other[, axis, level])</code></td>
<td>Wrapper for flexible comparison methods eq</td>
</tr>
<tr>
<td><code>equals(other)</code></td>
<td>Determines if two NDFrame objects contain the same elements.</td>
</tr>
<tr>
<td><code>eval(expr[, inplace])</code></td>
<td>Evaluate a string describing operations on DataFrame columns.</td>
</tr>
<tr>
<td><code>ewm([com, span, halflife, alpha, . . . ])</code></td>
<td>Provides exponential weighted functions</td>
</tr>
<tr>
<td><code>expanding([min_periods, center, axis])</code></td>
<td>Provides expanding transformations.</td>
</tr>
<tr>
<td><code>ffill([axis, inplace, limit, downcast])</code></td>
<td>Synonym for DataFrame.</td>
</tr>
<tr>
<td><code>fillna([value, method, axis, inplace, . . . ])</code></td>
<td>Fill NA/NaN values using the specified method</td>
</tr>
</tbody>

<tr>
<td><code>nsmallest(n, columns[, keep])</code></td>
<td>Get the rows of a DataFrame sorted by the <code>n</code> smallest values of <code>columns</code>.</td>
</tr>
<tr>
<td><code>nunique([axis, dropna])</code></td>
<td>Return Series with number of distinct observations over requested axis.</td>
</tr>
<tr>
<td><code>pct_change([periods, fill_method, limit, freq])</code></td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><code>pipe(func, *args, **kwargs)</code></td>
<td>Apply <code>func(self, *args, **kwargs)</code></td>
</tr>
</tbody>
</table>
Table 61 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>pivot</strong>([index, columns, values])</td>
<td>Return reshaped DataFrame organized by given index / column values.</td>
</tr>
<tr>
<td><strong>pivot_table</strong>([values, index, columns, ...])</td>
<td>Create a spreadsheet-style pivot table as a DataFrame.</td>
</tr>
<tr>
<td><strong>plot</strong></td>
<td>Alias of pandas.plotting._core.FramePlotMethods.</td>
</tr>
<tr>
<td><strong>pop</strong>([item])</td>
<td>Return item and drop from frame.</td>
</tr>
<tr>
<td><strong>pow</strong>(other[, axis, level, fill_value])</td>
<td>Exponential power of dataframe and other, element-wise (binary operator pow).</td>
</tr>
<tr>
<td><strong>prod</strong>([axis, skipna, level, numeric_only, ...])</td>
<td>Return the product of the values for the requested axis.</td>
</tr>
<tr>
<td><strong>product</strong>([axis, skipna, level, numeric_only, ...])</td>
<td>Return the product of the values for the requested axis.</td>
</tr>
<tr>
<td><strong>quantile</strong>([q, axis, numeric_only, interpolation])</td>
<td>Return values at the given quantile over requested axis, a la numpy.percentile.</td>
</tr>
<tr>
<td><strong>query</strong>(expr[, inplace])</td>
<td>Query the columns of a frame with a boolean expression.</td>
</tr>
<tr>
<td><strong>radd</strong>(other[, axis, level, fill_value])</td>
<td>Addition of dataframe and other, element-wise (binary operator radd).</td>
</tr>
<tr>
<td><strong>rank</strong>([axis, method, numeric_only, ...])</td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td><strong>rdiv</strong>(other[, axis, level, fill_value])</td>
<td>Floating division of dataframe and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td><strong>reindex</strong>([labels, index, columns, axis, ...])</td>
<td>Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.</td>
</tr>
<tr>
<td><strong>reindex_axis</strong>([labels[, axis, method, level, ...]])</td>
<td>Conform input object to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.</td>
</tr>
<tr>
<td><strong>rename</strong>([mapper, index, columns, axis, copy, ...])</td>
<td>Alter axes labels.</td>
</tr>
<tr>
<td><strong>rename_axis</strong>(mapper[, axis, copy, inplace])</td>
<td>Alter the name of the index or columns.</td>
</tr>
<tr>
<td><strong>reorder_levels</strong>([order[, axis]])</td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><strong>replace</strong>([to_replace, value, inplace, limit, ...])</td>
<td>Replace values given in to_replace with value.</td>
</tr>
<tr>
<td><strong>resample</strong>(rule[, how, axis, fill_method, ...])</td>
<td>Convenience method for frequency conversion and resampling of time series.</td>
</tr>
<tr>
<td><strong>reset_index</strong>([level, drop, inplace, ...])</td>
<td>For DataFrame with multi-level index, return new DataFrame with labeling information in the columns under the index names, defaulting to ‘level_0’, ‘level_1’, etc.</td>
</tr>
<tr>
<td><strong>rfloordiv</strong>(other[, axis, level, fill_value])</td>
<td>Integer division of dataframe and other, element-wise (binary operator rfloordiv).</td>
</tr>
<tr>
<td><strong>rmod</strong>(other[, axis, level, fill_value])</td>
<td>Modulo of dataframe and other, element-wise (binary operator rmod).</td>
</tr>
<tr>
<td><strong>rmul</strong>(other[, axis, level, fill_value])</td>
<td>Multiplication of dataframe and other, element-wise (binary operator rmul).</td>
</tr>
<tr>
<td><strong>rolling</strong>(window[, min_periods, center, ...])</td>
<td>Provides rolling window calculations.</td>
</tr>
<tr>
<td><strong>round</strong>(decimals)</td>
<td>Round a DataFrame to a variable number of decimal places.</td>
</tr>
<tr>
<td><strong>rpow</strong>(other[, axis, level, fill_value])</td>
<td>Exponential power of dataframe and other, element-wise (binary operator rpow).</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>rsub</code></td>

<td>Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.</td>
</tr>
</tbody>
</table>

pandas.DataFrame.abs

DataFrame.abs()

Return a Series/DataFrame with absolute numeric value of each element.
This function only applies to elements that are all numeric.

**Returns**: `abs`

Series/DataFrame containing the absolute value of each element.

**See also**:  
-numpy:absolute: calculate the absolute value element-wise.

**Notes**

For complex inputs, \(1.2 + 1j\), the absolute value is \(\sqrt{a^2 + b^2}\).

**Examples**

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0   1.10
1   2.00
2   3.33
3   4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0   1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0   1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```python
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
0  5 20 50
(continues on next page)
pandas.DataFrame.add

DataFrame.add(other, axis='columns', level=None, fill_value=None)

Addition of dataframe and other, element-wise (binary operator add).

Equivalent to dataframe + other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
    For Series input, axis to match Series index on
level : int or name
    Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None
    Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.radd

Notes

Mismatched indices will be unioned together

Examples

>>> a = pd.DataFrame([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'],
                  columns=['one'])
>>> a
   one
a  1.0
b  1.0
c  1.0
d  NaN
>>> b = pd.DataFrame(dict(one=[1, np.nan, 1, np.nan],
                        two=[np.nan, 2, np.nan, 2]),
                       index=['a', 'b', 'd', 'e'])
>>> b
   one    two
a  1.0  nan
b  NaN  2.0
c  1.0  nan
d  NaN  2.0

---

### pandas.DataFrame.add_prefix

**DataFrame.add_prefix**(prefix)

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters**

`prefix` : str  
The string to add before each label.

**Returns**

Series or DataFrame  
New Series or DataFrame with updated labels.

**See also:**

*Series.add_suffix*  
Suffix row labels with string *suffix*.

*DataFrame.add_suffix*  
Suffix column labels with string *suffix*.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0  1
1  2
2  3
3  4
dtype: int64

>>> s.add_prefix('item_')
```

<table>
<thead>
<tr>
<th>item_0</th>
</tr>
</thead>
<tbody>
<tr>
<td>item_1</td>
</tr>
<tr>
<td>item_2</td>
</tr>
<tr>
<td>item_3</td>
</tr>
<tr>
<td>dtype: int64</td>
</tr>
</tbody>
</table>

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtype: int64</td>
<td></td>
</tr>
</tbody>
</table>

(continues on next page)
pandas.DataFrame.add_suffix

DataFrame.add_suffix(suffix)

Suffix labels with string suffix.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters  suffix : str

The string to add after each label.

Returns  Series or DataFrame

New Series or DataFrame with updated labels.

See also:

Series.add_prefix Prefix row labels with string prefix.
Dataframe.add_prefix Prefix column labels with string prefix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
  >>> s
0 1
1 2
2 3
3 4
dtype: int64

>>> s.add_suffix('_item')
  0_item  1
  1_item  2
  2_item  3
  3_item  4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
  >>> df
      A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

>>> df.add_suffix('_col')
   A_col  B_col
0    1    3
1    2    4
2    3    5
3    4    6

pandas.DataFrame.agg

DataFrame.agg (func, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.
New in version 0.20.0.

Parameters
- **func**: function, string, dictionary, or list of string/functions
  Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply. For a DataFrame, can pass a dict, if the keys are DataFrame column names.
  Accepted combinations are:
  • string function name.
  • function.
  • list of functions.
  • dict of column names -> functions (or list of functions).

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  • 0 or ‘index’: apply function to each column.
  • 1 or ‘columns’: apply function to each row.

- **args**: Positional arguments to pass to func.

- **kwargs**: Keyword arguments to pass to func.

Returns
- aggregated [DataFrame]

See also:
- DataFrame.apply Perform any type of operations.
- DataFrame.transform Perform transformation type operations.
- pandas.core.groupby.GroupBy Perform operations over groups.
- pandas.core.resample.Resampler Perform operations over resampled bins.
- pandas.core.window.Rolling Perform operations over rolling window.
**pandas.core.window.Expanding** Perform operations over expanding window.

**pandas.core.window.EWM** Perform operation over exponential weighted window.

**Notes**

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (`mean`, `median`, `prod`, `sum`, `std`, `var`), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

`agg` is an alias for `aggregate`. Use the alias.

**Examples**

```python
>>> df = pd.DataFrame([[1, 2, 3],
...                     [4, 5, 6],
...                     [7, 8, 9],
...                     [np.nan, np.nan, np.nan],
...                     columns=['A', 'B', 'C'])

Aggregate these functions over the rows.

```python
df.agg(['sum', 'min'])
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>12.0</td>
<td>15.0</td>
<td>18.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>

Different aggregations per column.

```python
df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>max</td>
<td>NaN</td>
<td>8.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
</tr>
<tr>
<td>sum</td>
<td>12.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Aggregate over the columns.

```python
df.agg("mean", axis="columns")
```

<table>
<thead>
<tr>
<th></th>
<th>2.0</th>
<th>5.0</th>
<th>8.0</th>
<th>NaN</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

dtype: float64

**pandas.DataFrame.aggregate**

DataFrame.aggregate (func, axis=0, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.
**Parameters**

**`func`**: function, string, dictionary, or list of string/functions

Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply. For a DataFrame, can pass a dict, if the keys are DataFrame column names.

Accepted combinations are:
- string function name.
- function.
- list of functions.
- dict of column names -> functions (or list of functions).

**`axis`**: {0 or ‘index’, 1 or ‘columns’}, default 0

- 0 or ‘index’: apply function to each column.
- 1 or ‘columns’: apply function to each row.

**`*args`**

Positional arguments to pass to `func`.

**`**kwargs**`**

Keyword arguments to pass to `func`.

**Returns**

`aggregated` [DataFrame]

**See also:**

*DataFrame.apply*  Perform any type of operations.

*DataFrame.transform*  Perform transformation type operations.

*pandas.core.groupby.GroupBy*  Perform operations over groups.

*pandas.core.resample.Resampler*  Perform operations over resampled bins.

*pandas.core.window.Rolling*  Perform operations over rolling window.

*pandas.core.window.Expanding*  Perform operations over expanding window.

*pandas.core.window.EWM*  Perform operation over exponential weighted window.

**Notes**

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from `numpy` aggregation functions (`mean`, `median`, `prod`, `sum`, `std`, `var`), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

`agg` is an alias for `aggregate`. Use the alias.
Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
... [4, 5, 6],
... [7, 8, 9],
... [np.nan, np.nan, np.nan]],
... columns=['A', 'B', 'C'])

Aggregate these functions over the rows.
```n
```python
>>> df.agg(['sum', 'min'])

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>12.0</td>
<td>15.0</td>
<td>18.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>
```

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>max</td>
<td>NaN</td>
<td>8.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
</tr>
<tr>
<td>sum</td>
<td>12.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```

Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2.0</td>
<td>5.0</td>
<td>8.0</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td>8.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

dtype: float64
```

**pandas.DataFrame.align**

DataFrame.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)

Align two objects on their axes with the specified join method for each axis

**Parameters**

- **other** [DataFrame or Series]
- **join** [['outer', 'inner', 'left', 'right'], default 'outer']
- **axis** : allowed axis of the other object, default None
  
  Align on index (0), columns (1), or both (None)
- **level** : int or level name, default None
  
  Broadcast across a level, matching Index values on the passed MultiIndex level
- **copy** : boolean, default True
  
  Always returns new objects. If copy=False and no reindexing is required then original objects are returned.
- **fill_value** : scalar, default np.NaN
Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**method** [str, default None]

**limit** [int, default None]

**fill_axis** : {0 or ‘index’, 1 or ‘columns’}, default 0

Filling axis, method and limit

**broadcast_axis** : {0 or ‘index’, 1 or ‘columns’}, default None

Broadcast values along this axis, if aligning two objects of different dimensions

**Returns** (left, right) : (DataFrame, type of other)

Aligned objects

**pandas.DataFrame.all**

`DataFrame.all(axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether all elements are True, potentially over an axis.

Returns True if all elements within a series or along a Dataframe axis are non-zero, not-empty or not-False.

**Parameters**

**axis** : {0 or ‘index’, 1 or ‘columns’, None}, default 0

Indicate which axis or axes should be reduced.

• 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.

• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.

• None : reduce all axes, return a scalar.

**skipna** : boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**level** : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**bool_only** : boolean, default None

Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**kwargs** : any, default None

Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

all [Series or DataFrame (if level specified)]

**See also:**

**pandas.Series.all** Return True if all elements are True
pandas: powerful Python data analysis toolkit, Release 0.23.3

**pandas.DataFrame.any**  Return True if one (or more) elements are True

**Examples**

Series

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
```

DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
     col1  col2
0   True   True
1   True   False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
    col1    col2
0   True   True
1  False   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0   True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

**pandas.Dataframe.any**

DataFrame.any (axis=0, bool_only=None, skipna=True, level=None, **kwargs)
Return whether any element is True over requested axis.

Unlike `DataFrame.all()`, this performs an or operation. If any of the values along the specified axis is True, this will return True.

**Parameters**

- **axis**: {0 or ‘index’, 1 or ‘columns’, None}, default 0
  
  Indicate which axis or axes should be reduced.
  
  - 0 / ‘index’: reduce the index, return a Series whose index is the original column labels.
  
  - 1 / ‘columns’: reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

skipna : boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing
into a Series.

bool_only : boolean, default None

Include only boolean columns. If None, will attempt to use everything, then use
only boolean data. Not implemented for Series.

**kwargs : any, default None

Additional keywords have no effect but might be accepted for compatibility with
NumPy.

Returns

any [Series or DataFrame (if level specified)]

See also:

pandas.DataFrame.all Return whether all elements are True.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([True, False]).any()
True
```

DataFrame

Whether each column contains at least one True element (the default).

```python
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
     A  B  C
0   1  0  0
1   2  2  0

>>> df.any()
A   True
B   True
C   False
dtype: bool
```

Aggregating over the columns.

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
     A  B
0  True  1
1  False  2
```
```python
>>> df.any(axis='columns')
0   True
1   True
dtype: bool

>>> df = pd.DataFrame({'A': [True, False], 'B': [1, 0]})
>>> df
   A  B
0  True 1
1  False 0

>>> df.any(axis='columns')
0   True
1   False
dtype: bool

Aggregating over the entire DataFrame with axis=None.
```

```python
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.
```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

**pandas.DataFrame.append**

DataFrame.append(other, ignore_index=False, verify_integrity=False, sort=None)

Append rows of other to the end of this frame, returning a new object. Columns not in this frame are added as new columns.

**Parameters**

- **other** : DataFrame or Series/dict-like object, or list of these
  The data to append.

- **ignore_index** : boolean, default False
  If True, do not use the index labels.

- **verify_integrity** : boolean, default False
  If True, raise ValueError on creating index with duplicates.

- **sort** : boolean, default None
  Sort columns if the columns of self and other are not aligned. The default sorting is deprecated and will change to not-sorting in a future version of pandas. Explicitly pass sort=True to silence the warning and sort. Explicitly pass sort=False to silence the warning and not sort.

New in version 0.23.0.

**Returns**

- appended [DataFrame]

See also:
pandas.concat  General function to concatenate DataFrame, Series or Panel objects

Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

Examples

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
>>> df
   A  B
0  1  2
1  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
>>> df.append(df2)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

With `ignore_index` set to True:

```python
>>> df.append(df2, ignore_index=True)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```python
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4
```

More efficient:

```python
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...    ignore_index=True)
```

**pandas.DataFrame.apply**

```python
DataFrame.apply(func, axis=0, broadcast=None, raw=False, reduce=None, result_type=None, args=(), **kwds)
```

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame’s index (axis=0) or the DataFrame’s columns (axis=1). By default (result_type=None), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the result_type argument.

**Parameters**

- **func**: function
  - Function to apply to each column or row.
- **axis**: {0 or 'index', 1 or 'columns'}, default 0
  - Axis along which the function is applied:
    - 0 or 'index': apply function to each column.
    - 1 or 'columns': apply function to each row.
- **broadcast**: bool, optional
  - Only relevant for aggregation functions:
    - False or None: returns a Series whose length is the length of the index or the number of columns (based on the axis parameter)
    - True: results will be broadcast to the original shape of the frame, the original index and columns will be retained.
  - Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by result_type='broadcast'.
- **raw**: bool, default False
  - False: passes each row or column as a Series to the function.
  - True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.
- **reduce**: bool or None, default None
  - Try to apply reduction procedures. If the DataFrame is empty, `apply` will use reduce to determine whether the result should be a Series or a DataFrame.
  - If reduce=None (the default), `apply`’s return value will be guessed by calling `func` on an empty Series (note: while guessing, exceptions raised by `func` will be ignored). If reduce=True a Series will always be returned, and if reduce=False a DataFrame will always be returned.
  - Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by result_type='reduce'.

34.4. DataFrame 1745
**result_type**: {'expand', 'reduce', 'broadcast', None}, default None

These only act when `axis=1` (columns):

- `expand`: list-like results will be turned into columns.
- `reduce`: returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
- `broadcast`: results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

New in version 0.23.0.

**args**: tuple

Positional arguments to pass to `func` in addition to the array/series.

**kwds**: Additional keyword arguments to pass as keywords arguments to `func`.

**Returns**

- `applied` [Series or DataFrame]

**See also:**

- `DataFrame.applymap`: For elementwise operations
- `DataFrame.aggregate`: only perform aggregating type operations
- `DataFrame.transform`: only perform transforming type operations

**Notes**

In the current implementation apply calls `func` twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first column/row.

**Examples**

```python
>>> df = pd.DataFrame([[4, 9], [4, 9], [4, 9]], columns=['A', 'B'])
```

```python
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as `np.sqrt(df)`):

```python
>>> df.apply(np.sqrt)
   A  B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```
Using a reducing function on either axis

```python
>>> df.apply(np.sum, axis=0)
A  12
B  27
dtype: int64
```

```python
>>> df.apply(np.sum, axis=1)
0  13
1  13
2  13
dtype: int64
```

Returning a list-like will result in a Series

```python
>>> df.apply(lambda x: [1, 2], axis=1)
0  [1, 2]
1  [1, 2]
2  [1, 2]
dtype: object
```

Passing result_type='expand' will expand list-like results to columns of a Dataframe

```python
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   A  B
0  1  2
1  1  2
2  1  2
```

Returning a Series inside the function is similar to passing result_type='expand'. The resulting column names will be the Series index.

```python
>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
     foo  bar
0  1  2
1  1  2
2  1  2
```

Passing result_type='broadcast' will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```python
>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2
```

---

**pandas.DataFrame.applymap**

Dataframe.applymap(func)

Apply a function to a Dataframe elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

**Parameters**

- func : callable
  - Python function, returns a single value from a single value.
Returns DataFrame

Transformed DataFrame.

See also:

Dataframe.apply Apply a function along input axis of DataFrame

Examples

```python
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0      1
0  1.000  2.120
1  3.356  4.567

>>> df.applymap(lambda x: len(str(x)))
   0   1
0  3  4
1  5  5
```

Note that a vectorized version of `func` often exists, which will be much faster. You could square each number elementwise.

```python
>>> df.applymap(lambda x: x**2)
   0      1
0  1.000000  4.494400
1 11.262736 20.857489
```

But it’s better to avoid applymap in that case.

```python
>>> df ** 2
   0      1
0  1.000000  4.494400
1 11.262736 20.857489
```

pandas.DataFrame.as_blocks

DataFrame.as_blocks(copy=True)

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

**NOTE:** the dtypes of the blocks WILL BE PRESERVED HERE (unlike in `as_matrix`)

Parameters

- `copy` [boolean, default True]

Returns

- `values` [a dict of dtype -> Constructor Types]
**pandas.DataFrame.as_matrix**

```
DataFrame.as_matrix(columns=None)
```

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

**Parameters**

- **columns**: list, optional, default: None
  - If None, return all columns, otherwise, returns specified columns.

**Returns**

- **values**: ndarray
  - If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

**See also:**

`pandas.DataFrame.values`

**Notes**

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By numpy.find_common_type convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `.values`.

**pandas.DataFrame.asfreq**

```
DataFrame.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)
```

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

**Parameters**

- **freq**: [DateOffset object, or string]
- **method**: {'backfill'/'bfill', 'pad'/'ffill'}, default None
  - Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
    - 'pad' / 'ffill': propagate last valid observation forward to next valid
    - 'backfill' / 'bfill': use NEXT valid observation to fill
- **how**: {'start', 'end'}, default end
  - For PeriodIndex only, see `PeriodIndex.asfreq`
- **normalize**: bool, default False
Whether to reset output index to midnight

**fill_value: scalar, optional**

Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

**Returns**

converted [type of caller]

**See also:**

*reindex*

**Notes**

To learn more about the frequency strings, please see this link.

**Examples**

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
```

```python
>>> df
          s
2000-01-01 00:00:00  0.0
2000-01-01 00:01:00  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:03:00  3.0
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
          s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
          s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```
Upsample again, providing a method.

```
>>> df.asfreq(freq='30S', method='bfill')  
s
2000-01-01 00:00:00 0.0
2000-01-01 00:00:30 NaN
2000-01-01 00:01:00 NaN
2000-01-01 00:01:30 2.0
2000-01-01 00:02:00 2.0
2000-01-01 00:02:30 3.0
2000-01-01 00:03:00 3.0
```

**pandas.DataFrame.asof**

Data.\(\text{asof}(\text{where}, \text{subset}=\text{None})\)

The last row without any NaN is taken (or the last row without NaN considering only the subset of columns in the case of a DataFrame)

New in version 0.19.0: For DataFrame

If there is no good value, NaN is returned for a Series a Series of NaN values for a DataFrame

**Parameters**

- **where**: [date or array of dates]
- **subset**: string or list of strings, default None
  - if not None use these columns for NaN propagation

**Returns**

- where is scalar
  - value or NaN if input is Series
  - Series if input is DataFrame

**where is Index**: same shape object as input

**See also**

- `merge_asof`

**Notes**

Dates are assumed to be sorted Raises if this is not the case

**pandas.DataFrame.assign**

Data.\(\text{assign}(\text{**kwargs})\)

Assign new columns to a DataFrame, returning a new object (a copy) with the new columns added to the original ones. Existing columns that are re-assigned will be overwritten.

**Parameters**

- **kwargs**: keyword, value pairs
  - keywords are the column names. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn’t check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.
**Returns** df: DataFrame

A new DataFrame with the new columns in addition to all the existing columns.

**Notes**

Assigning multiple columns within the same `assign` is possible. For Python 3.6 and above, later items in `**kwargs` may refer to newly created or modified columns in `df`; items are computed and assigned into `df` in order. For Python 3.5 and below, the order of keyword arguments is not specified, you cannot refer to newly created or modified columns. All items are computed first, and then assigned in alphabetical order.

Changed in version 0.23.0: Keyword argument order is maintained for Python 3.6 and later.

**Examples**

```python
>>> df = pd.DataFrame({'A': range(1, 11), 'B': np.random.randn(10)})
```

Where the value is a callable, evaluated on `df`:

```python
>>> df.assign(ln_A = lambda x: np.log(x.A))
   A        B     ln_A
0  1  0.426905  0.000000
1  2 -0.780949  0.693147
2  3 -0.418711  1.098612
3  4 -0.269708  1.386294
4  5 -0.274002  1.609438
5  6 -0.500792  1.791759
6  7  1.649697  1.945910
7  8 -1.495604  2.079442
8  9  0.549296  2.197225
9 10 -0.758542  2.302585
```

Where the value already exists and is inserted:

```python
>>> newcol = np.log(df['A'])
>>> df.assign(ln_A=newcol)
   A        B     ln_A
0  1  0.426905  0.000000
1  2 -0.780949  0.693147
2  3 -0.418711  1.098612
3  4 -0.269708  1.386294
4  5 -0.274002  1.609438
5  6 -0.500792  1.791759
6  7  1.649697  1.945910
7  8 -1.495604  2.079442
8  9  0.549296  2.197225
9 10 -0.758542  2.302585
```

Where the keyword arguments depend on each other

```python
>>> df = pd.DataFrame({'A': [1, 2, 3]})
```
```python
>>> df.assign(B=df.A, C=lambda x:x['A'] + x['B'])
   A  B  C
0  1  1  2
1  2  2  4
2  3  3  6
```

**pandas.DataFrame.astype**

Dataframe.astype(dtype, copy=True, errors='raise', **kwargs)

Cast a pandas object to a specified dtype `dtype`.

**Parameters**

- **dtype**: data type, or dict of column name -> data type
  
  Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

- **copy**: bool, default True.
  
  Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

- **errors**: {`raise`, `ignore`}, default `raise`.
  
  Control raising of exceptions on invalid data for provided dtype.
  
  - `raise`: allow exceptions to be raised
  
  - `ignore`: suppress exceptions. On error return original object

  New in version 0.20.0.

- **raise_on_error**: raise on invalid input
  
  Deprecated since version 0.20.0: Use `errors` instead

- **kwargs** [keyword arguments to pass on to the constructor]

**Returns**

- **casted** [type of caller]

**See also**

- `pandas.to_datetime` Convert argument to datetime.
- `pandas.to_timedelta` Convert argument to timedelta.
- `pandas.to_numeric` Convert argument to a numeric type.
- `numpy.ndarray.astype` Cast a numpy array to a specified type.

**Examples**
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0   1
1   2
dtype: int32
>>> ser.astype('int64')
0   1
1   2
dtype: int64

Convert to categorical type:

>>> ser.astype('category')
0   1
1   2
dtype: category
Categories (2, int64): [1, 2]

Convert to ordered categorical type with custom ordering:

>>> ser.astype('category', ordered=True, categories=[2, 1])
0   1
1   2
dtype: category
Categories (2, int64): [2 < 1]

Note that using copy=False and changing data on a new pandas object may propagate changes:

>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1
# note that s1[0] has changed too
0   10
1   2
dtype: int64

pandas.DataFrame.at_time

DataFrame.at_time(time, asof=False)
Select values at particular time of day (e.g. 9:30AM).

Parameters
- time [datetime.time or string]

Returns
- values_at_time [type of caller]

Raises
- TypeError
  If the index is not a DatetimeIndex

See also:
- between_time Select values between particular times of the day
- first Select initial periods of time series based on a date offset
last Select final periods of time series based on a date offset

DatetimeIndex.indexer_at_time Get just the index locations for values at particular time of the day

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
     A
2018-04-09 00:00:00 1
2018-04-09 12:00:00 2
2018-04-10 00:00:00 3
2018-04-10 12:00:00 4

>>> ts.at_time('12:00')
     A
2018-04-09 12:00:00 2
2018-04-10 12:00:00 4
```

pandas.DataFrame.between_time

DataFrame.between_time(start_time, end_time, include_start=True, include_end=True) Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting start_time to be later than end_time, you can get the times that are not between the two times.

Parameters

- **start_time** [datetime.time or string]
- **end_time** [datetime.time or string]
- **include_start** [boolean, default True]
- **include_end** [boolean, default True]

Returns

- **values_between_time** [type of caller]

Raises TypeError

If the index is not a DateTimeIndex

See also:

- at_time Select values at a particular time of the day
- first Select initial periods of time series based on a date offset
- last Select final periods of time series based on a date offset

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4
```

```python
>>> ts.between_time('0:15', '0:45')
   A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
```

You get the times that are not between two times by setting `start_time` later than `end_time`:

```python
>>> ts.between_time('0:45', '0:15')
   A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4
```

**pandas.DataFrame.bfill**

DataFrame`\texttt{.bfill}(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for DataFrame`\texttt{.fillna(method='bfill')}\texttt{}`

**pandas.DataFrame.bool**

DataFrame`\texttt{.bool()}`

Return the bool of a single element PandasObject.

This must be a boolean scalar value, either True or False. Raise a ValueError if the PandasObject does not have exactly 1 element, or that element is not boolean

**pandas.DataFrame.boxplot**

DataFrame`\texttt{.boxplot(column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, **kwds)}\texttt{}`

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5 * IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

**Parameters**

- **column**: str or list of str, optional
  - Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.
by : str or array-like, optional

Column in the DataFrame to `pandas.DataFrame.groupby()`. One boxplot will be done per value of columns in by.

ax : object of class matplotlib.axes.Axes, optional

The matplotlib axes to be used by boxplot.

fontsize : float or str

Tick label font size in points or as a string (e.g., large).

rot : int or float, default 0

The rotation angle of labels (in degrees) with respect to the screen coordinate system.

grid : boolean, default True

Setting this to True will show the grid.

figsize : A tuple (width, height) in inches

The size of the figure to create in matplotlib.

layout : tuple (rows, columns), optional

For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

return_type : {'axes', 'dict', 'both'} or None, default 'axes'

The kind of object to return. The default is axes.

• ‘axes’ returns the matplotlib axes the boxplot is drawn on.

• ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.

• ‘both’ returns a namedtuple with the axes and dict.

• when grouping with by, a Series mapping columns to return_type is returned.

If return_type is None, a NumPy array of axes with the same shape as layout is returned.

**kwds

All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

Returns result :

The return type depends on the return_type parameter:

• ‘axes’ : object of class matplotlib.axes.Axes

• ‘dict’ : dict of matplotlib.lines.Line2D objects

• ‘both’ : a namedtuple with structre (ax, lines)

For data grouped with by:

• Series

• array (for return_type = None)

See also:
**Notes**

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

**Examples**

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                   columns=['Col1', 'Col2'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                   columns=['Col1', 'Col2', 'Col3'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

**pandas.DataFrame.clip**

DataFrame.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- `lower` : float or array_like, default None
  Minimum threshold value. All values below this threshold will be set to it.

- `upper` : float or array_like, default None
  Maximum threshold value. All values above this threshold will be set to it.

- `axis` : int or string axis name, optional
  Align object with lower and upper along the given axis.

- `inplace` : boolean, default False
  Whether to perform the operation in place on the data.
  
  New in version 0.21.0.

- `*args`, `**kwargs`
  Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

Series or DataFrame

Same type as calling object with the values outside the clip boundaries replaced

**See also:**

- **clip_lower** Clip values below specified threshold(s).
- **clip_upper** Clip values above specified threshold(s).

**Examples**
```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9    -2
1     -3    -7
2      0     6
3     -1     8
4      5    -5

Clips per column using lower and upper thresholds:

```py
```python
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3    -4
2      0     6
3     -1     6
4      5    -4

Clips using specific lower and upper thresholds per column element:

```py
```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64

```py
```python
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3    -4
2      0     3
3      6     8
4      5     3
```

**pandas.DataFrame.clip_lower**

DataFrame.clip_lower(threshold, axis=None, inplace=False)

Return copy of the input with values below a threshold truncated.

**Parameters**

- **threshold**: numeric or array-like
  
  Minimum value allowed. All values below threshold will be set to this value.
  
  - `float`: every value is compared to threshold.
  
  - array-like: The shape of threshold should match the object it’s compared to. When `self` is a Series, threshold should be the length. When `self` is a DataFrame, threshold should be 2-D and the same shape as `self` for `axis=None`, or 1-D and the same length as the axis being compared.

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0

  Align `self` with threshold along the given axis.
inplace : boolean, default False

Whether to perform the operation in place on the data.

New in version 0.21.0.

Returns

clipped [same type as input]

See also:

Series.clip Return copy of input with values below and above thresholds truncated.

Series.clip_upper Return copy of input with values above threshold truncated.

Examples

Series single threshold clipping:

```python
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip_lower(8)
0    8
1    8
2    8
3    8
4    9
dtype: int64
```

Series clipping element-wise using an array of thresholds. threshold should be the same length as the Series.

```python
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip_lower(elemwise_thresholds)
0    5
1    8
2    7
3    8
4    9
dtype: int64
```

DataFrames can be compared to a scalar.

```python
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
   A  B
0  1  2
1  3  4
2  5  6
>>> df.clip_lower(3)
   A  B
0  3  3
1  3  4
2  5  6
```

Or to an array of values. By default, threshold should be the same shape as the DataFrame.
pandas.DataFrame.clip_lower

DataFrame.clip_lower(threshold, axis=None, inplace=False)

Return copy of input with values above given value(s) truncated.

Parameters

threshold [float or array_like]

axis : int or string axis name, optional

Align object with threshold along the given axis.

inplace : boolean, default False

Whether to perform the operation in place on the data

New in version 0.21.0.

Returns

clipped [same type as input]

See also:

clip

pandas.DataFrame.combine

DataFrame.combine(other, func, fill_value=None, overwrite=True)

Add two DataFrame objects and do not propagate NaN values, so if for a (column, time) one frame is missing a value, it will default to the other frame’s value (which might be NaN as well)

Parameters

other [DataFrame]

func : function

Control how threshold is broadcast with axis. In this case threshold should be the same length as the axis specified by axis.

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>
Function that takes two series as inputs and return a Series or a scalar

fill_value [scalar value]

overwrite : boolean, default True

If True then overwrite values for common keys in the calling frame

Returns

result [DataFrame]

See also:

**DataFrame.combine_first** Combine two DataFrame objects and default to non-null values in frame calling the method

**Examples**

```python
>>> df1 = DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, lambda s1, s2: s1 if s1.sum() < s2.sum() else s2)
    A   B
0  0   3
1  0   3
```

**pandas.DataFrame.combine_first**

Dataframe.combine_first(other)

Combine two DataFrame objects and default to non-null values in frame calling the method. Result index columns will be the union of the respective indexes and columns

Parameters

other [DataFrame]

Returns

combined [DataFrame]

See also:

**DataFrame.combine** Perform series-wise operation on two DataFrames using a given function

**Examples**

df1’s values prioritized, use values from df2 to fill holes:

```python
>>> df1 = pd.DataFrame([[1, np.nan]])
>>> df2 = pd.DataFrame([[3, 4]])
>>> df1.combine_first(df2)
    0  1
0  1  4.0
```
pandas.DataFrame.compound

DataFrame.compound (axis=None, skipna=None, level=None)
Return the compound percentage of the values for the requested axis

Parameters
axis [{index (0), columns (1)}]
skipna : boolean, default True
Exclude NA/null values when computing the result.
level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
compounded [Series or DataFrame (if level specified)]

pandas.DataFrame.consolidate

DataFrame.consolidate (inplace=False)
Compute NDFrame with “consolidated” internals (data of each dtype grouped together in a single ndarray).

Deprecated since version 0.20.0: Consolidate will be an internal implementation only.

pandas.DataFrame.convert_objects

DataFrame.convert_objects (convert_dates=True, convert_numeric=False, convert_timedeltas=True, copy=True)
Attempt to infer better dtype for object columns.

Deprecated since version 0.21.0.

Parameters convert_dates : boolean, default True
If True, convert to date where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.
convert_numeric : boolean, default False
If True, attempt to coerce to numbers (including strings), with unconvertible values becoming NaN.
convert_timedeltas : boolean, default True
If True, convert to timedelta where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.
copy : boolean, default True
If True, return a copy even if no copy is necessary (e.g. no conversion was done). Note: This is meant for internal use, and should not be confused with inplace.
**Returns**

 converted  [same as input object]

**See also:**

* pandas.to_datetime  Convert argument to datetime.
* pandas.to_timedelta  Convert argument to timedelta.
* pandas.to_numeric  Return a fixed frequency timedelta index, with day as the default.

**pandas.DataFrame.copy**

DataFrame.copy(deep=True)

Make a copy of this object’s indices and data.

When deep=True (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When deep=False, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

**Parameters**

 deep : bool, default True

 Make a deep copy, including a copy of the data and the indices. With deep=False neither the indices nor the data are copied.

**Returns**

 copy : Series, DataFrame or Panel

 Object type matches caller.

**Notes**

When deep=True, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to copy.deepcopy in the Standard Library, which recursively copies object data (see examples below).

While Index objects are copied when deep=True, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.

**Examples**

```python
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a  1
b  2
dtype: int64

>>> s_copy = s.copy()
>>> s_copy
a  1
```

(continues on next page)
Shallow copy versus default (deep) copy:

```python
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```python
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```python
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a  3  
b  4
dtype: int64
>>> shallow
a  3  
b  4
dtype: int64
>>> deep
a  1  
b  2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0  [10, 2]
1  [3, 4]
dtype: object
>>> deep
0  [10, 2]
1  [3, 4]
dtype: object
```
**pandas.DataFrame.corr**

DataFrame.corr(method='pearson', min_periods=1)
Compute pairwise correlation of columns, excluding NA/null values

- **Parameters**
  - `method` : {'pearson', 'kendall', 'spearman'}
    - pearson : standard correlation coefficient
    - kendall : Kendall Tau correlation coefficient
    - spearman : Spearman rank correlation
  - `min_periods` : int, optional
    Minimum number of observations required per pair of columns to have a valid result. Currently only available for pearson and spearman correlation

- **Returns**
  - `y` [DataFrame]

**pandas.DataFrame.corrwith**

DataFrame.corrwith(other, axis=0, drop=False)
Compute pairwise correlation between rows or columns of two DataFrame objects.

- **Parameters**
  - `other` [DataFrame, Series]
  - `axis` : {0 or 'index', 1 or 'columns'}, default 0
    0 or 'index' to compute column-wise, 1 or 'columns' for row-wise
  - `drop` : boolean, default False
    Drop missing indices from result, default returns union of all

- **Returns**
  - `correls` [Series]

**pandas.DataFrame.count**

DataFrame.count(axis=0, level=None, numeric_only=False)
Count non-NA cells for each column or row.

- **Parameters**
  - `axis` : {0 or 'index', 1 or 'columns'}, default 0
    If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each row.
  - `level` : int or str, optional
    If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame. A str specifies the level name.
  - `numeric_only` : boolean, default False
Include only float, int or boolean data.

**Returns** Series or DataFrame

For each column/row the number of non-NA/null entries. If level is specified returns a DataFrame.

**See also:**

*Series.count* number of non-NA elements in a Series

*DataFrame.shape* number of DataFrame rows and columns (including NA elements)

*DataFrame.isna* boolean same-sized DataFrame showing places of NA elements

**Examples**

Constructing DataFrame from a dictionary:

```python
>>> df = pd.DataFrame(
    {
        "Person": ["John", "Myla", None, "John", "Myla"],
        "Age": [24., np.nan, 21., 33, 26],
        "Single": [False, True, True, True, False]
    })
```

```
Person  Age  Single
0  John  24.0  False
1  Myla  NaN  True
2  None  21.0  True
3  John  33.0  True
4  Myla  26.0  False
```

Notice the uncounted NA values:

```python
>>> df.count()
Person  4
Age     4
Single  5
dtype: int64
```

Counts for each row:

```python
>>> df.count(axis='columns')
0  3
1  2
2  2
3  3
4  3
dtype: int64
```

Counts for one level of a MultiIndex:

```python
>>> df.set_index(["Person", "Single"]).count(level="Person")
Age
Person
John  2
Myla  1
```
**pandas.DataFrame.cov**

**DataFrame.cov**(min_periods=None)

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

- **min_periods**: int, optional
  - Minimum number of observations required per pair of columns to have a valid result.

**Returns**

**DataFrame**

The covariance matrix of the series of the DataFrame.

**See also:**

- **pandas.Series.cov** compute covariance with another Series
- **pandas.core.window.EWM.cov** exponential weighted sample covariance
- **pandas.core.window.Expanding.cov** expanding sample covariance
- **pandas.core.window.Rolling.cov** rolling sample covariance

**Notes**

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-1.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

**Examples**

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
                    columns=['dogs', 'cats'])
>>> df.cov()
   dogs  cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
                      columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
                  a         b          c         d         e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
                      columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
                  a        b       c
a  0.316741   NaN -0.150812
b   NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

**pandas.DataFrame.cummax**

DataFrame.cummax (axis=None, skipna=True, *args, **kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis : {0 or ‘index’, 1 or ‘columns’}, default 0
   The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna : boolean, default True
   Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs :
   Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

cummax [Series or DataFrame]

See also:

pandas.core.window.Expanding.max Similar functionality but ignores NaN values.

DataFrame.max Return the maximum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.
**DataFrame.cumsum**  Return cumulative sum over DataFrame axis.

**DataFrame.cumprod**  Return cumulative product over DataFrame axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 3, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummax()
   A  B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```
To iterate over columns and find the maximum in each row, use `axis=1`.

```
>>> df.cummax(axis=1)
   A  B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

**pandas.DataFrame.cummin**

`DataFrame.cummin`\(\text{(axis=}\text{None, skipna=\text{True, }*args, **kwargs)}\)\)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

**Parameters**

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna**: boolean, default True
  - Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- ***args, **kwargs**:
  - Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **cummin** [Series or DataFrame]

**See also:**

- `pandas.core.window.Expanding.min` Similar functionality but ignores NaN values.
- `DataFrame.min` Return the minimum over DataFrame axis.
- `DataFrame.cummax` Return cumulative maximum over DataFrame axis.
- `DataFrame.cummin` Return cumulative minimum over DataFrame axis.
- `DataFrame.cumsum` Return cumulative sum over DataFrame axis.
- `DataFrame.cumprod` Return cumulative product over DataFrame axis.

**Examples**

**Series**

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0   2.0
1   NaN
2   5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.
To include NA values in the operation, use `skipna=False`

```python
>>> s.cummin(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
                     [3.0, np.nan],
                     [1.0, 0.0]],
                    columns=list('AB'))
>>> df
       A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummin()
       A   B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```python
>>> df.cummin(axis=1)
       A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

**DataFrame.cumprod**

DataFrame.

```python
DataFrame.cumprod(axis=None, skipna=True, *args, **kwargs)
```

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

**Parameters**

- **axis**: 0 or ‘index’, 1 or ‘columns’, default 0
  
  The index or the name of the axis. 0 is equivalent to None or ‘index’.

---

34.4. DataFrame 1773
skipna : boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs :

Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

cumprod [Series or DataFrame]

See also:

pandas.core.window.Expanding.prod Similar functionality but ignores NaN values.

DataFrame.prod Return the product over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

>>> s = pd.Series([2, np.nan, 5, -1, 0])

>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64

By default, NA values are ignored.

>>> s.cumprod()
0   2.0
1  NaN
2  10.0
3 -10.0
4  -0.0
dtype: float64

To include NA values in the operation, use skipna=False

>>> s.cumprod(skipna=False)
0   2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64

DataFrame
By default, iterates over rows and finds the product in each column. This is equivalent to \texttt{axis=None} or \texttt{axis='index'}.

To iterate over columns and find the product in each row, use \texttt{axis=1}

\begin{verbatim}
>>> df.cumprod(axis=1)
  A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
\end{verbatim}

\texttt{pandas.DataFrame.cumsum}

\texttt{DataFrame.cumsum}(\texttt{axis=None, skipna=True, *args, **kwargs})

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

\begin{itemize}
  \item \textbf{Parameters} \texttt{axis} : \{0 or `index`, 1 or `columns`\}, default 0
    \begin{itemize}
      \item The index or the name of the axis. 0 is equivalent to \texttt{None} or `index`.
    \end{itemize}
  \item \texttt{skipna} : boolean, default True
    \begin{itemize}
      \item Exclude NA/null values. If an entire row/column is NA, the result will be NA.
    \end{itemize}
  \item \texttt{*args, **kwargs} :
    \begin{itemize}
      \item Additional keywords have no effect but might be accepted for compatibility with NumPy.
    \end{itemize}
\end{itemize}

\textbf{Returns}

\texttt{cumsum} [Series or DataFrame]

See also:

\begin{itemize}
  \item \texttt{pandas.core.window.Expanding.sum} Similar functionality but ignores NaN values.
  \item \texttt{DataFrame.sum} Return the sum over DataFrame axis.
  \item \texttt{DataFrame.cummax} Return cumulative maximum over DataFrame axis.
  \item \texttt{DataFrame.cummin} Return cumulative minimum over DataFrame axis.
\end{itemize}
DataFrame.cumsum  Return cumulative sum over DataFrame axis.

DataFrame.cumprod  Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])

>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0  2.0
1  NaN
2  7.0
3  6.0
4  6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumsum(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))

>>> df
   A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'.

```python
>>> df.cumsum()
   A   B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```
To iterate over columns and find the sum in each row, use `axis=1`:

```python
>>> df.cumsum(axis=1)
          A    B
0      2.0  3.0
1      3.0  NaN
2      1.0  1.0
```

### pandas.DataFrame.describe

`DataFrame.describe(percentiles=None, include=None, exclude=None)`

Generates descriptive statistics that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

- `percentiles`: list-like of numbers, optional
  
  The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

- `include`: ‘all’, list-like of dtypes or None (default), optional
  
  A white list of data types to include in the result. Ignored for Series. Here are the options:
  
  - ‘all’: All columns of the input will be included in the output.
  
  - A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`).
  
  To select pandas categorical columns, use 'category'

- `exclude`: list-like of dtypes or None (default), optional,

  A black list of data types to omit from the result. Ignored for Series. Here are the options:

  - A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use 'category'

- None (default): The result will exclude nothing.

**Returns**

- `summary`: Series/DataFrame of summary statistics

**See also:**

- `DataFrame.count`, `DataFrame.max`, `DataFrame.min`, `DataFrame.mean`, `DataFrame.std`, `DataFrame.select_dtypes`
Notes

For numeric data, the result’s index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value’s frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count 4
unique 3
top a
freq 2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([...
... np.datetime64("2000-01-01"),
... np.datetime64("2010-01-01"),
... np.datetime64("2010-01-01")
... ])  
>>> s.describe()
count 3
unique 2
top 2010-01-01 00:00:00
```
Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'object': ['a', 'b', 'c'],
...                    'numeric': [1, 2, 3],
...                    'categorical': pd.Categorical(['d', 'e', 'f'])
...                    })
>>> df.describe()
         numeric
    count   3.0
    mean    2.0
     std    1.0
     min    1.0
    25%    1.5
    50%    2.0
    75%    2.5
    max    3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
     categorical  numeric  object
    count       3  3.0       3
    unique      3  NaN       3
     top       NaN  NaN      NaN
     freq      1  NaN       1
    mean       NaN  2.0  NaN
     std       NaN  1.0  NaN
     min       NaN  1.0  NaN
    25%       NaN  1.5  NaN
    50%       NaN  2.0  NaN
    75%       NaN  2.5  NaN
    max       NaN  3.0  NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
    count   3.0
    mean    2.0
     std    1.0
     min    1.0
    25%    1.5
    50%    2.0
    75%    2.5
    max    3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
         numeric
    count   3.0
```
Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[np.object])
```

<table>
<thead>
<tr>
<th>object</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>3</td>
</tr>
<tr>
<td>unique</td>
<td>3</td>
</tr>
<tr>
<td>top</td>
<td>c</td>
</tr>
<tr>
<td>freq</td>
<td>1</td>
</tr>
</tbody>
</table>

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
```

<table>
<thead>
<tr>
<th>categorical</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>3</td>
</tr>
<tr>
<td>unique</td>
<td>3</td>
</tr>
<tr>
<td>top</td>
<td>f</td>
</tr>
<tr>
<td>freq</td>
<td>1</td>
</tr>
</tbody>
</table>

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
```

<table>
<thead>
<tr>
<th>categorical</th>
<th>object</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>3</td>
</tr>
<tr>
<td>unique</td>
<td>3</td>
</tr>
<tr>
<td>top</td>
<td>f</td>
</tr>
<tr>
<td>freq</td>
<td>1</td>
</tr>
</tbody>
</table>

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.object])
```

<table>
<thead>
<tr>
<th>categorical</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>3</td>
</tr>

<td>NaN</td>
</tr>
<tr>
<td>75%</td>
<td>NaN</td>
</tr>
<tr>
<td>max</td>
<td>NaN</td>
</tr>
</tbody>
</table>

\[
\text{pandas.DataFrame.diff}
\]

\[
\text{DataFrame.diff}(\text{periods}=1, \text{axis}=0)
\]
First discrete difference of element.
Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is the element in the same column of the previous row).

**Parameters**

- **periods**: int, default 1
  
  Periods to shift for calculating difference, accepts negative values.

- **axis**: {0 or 'index', 1 or 'columns'}, default 0
  
  Take difference over rows (0) or columns (1).

**Returns**

- **diffed**: [DataFrame]

**See also:**

- **Series.diff** First discrete difference for a Series.
- **DataFrame.pct_change** Percent change over given number of periods.
- **DataFrame.shift** Shift index by desired number of periods with an optional time freq.

**Examples**

### Difference with previous row

```python
def df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
                      'b': [1, 1, 2, 3, 5, 8],
                      'c': [1, 4, 9, 16, 25, 36]})
>>> df.diff()
```

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>1.0</td>
<td>0.0</td>
<td>3.0</td>
</tr>
<tr>
<td>2</td>
<td>1.0</td>
<td>1.0</td>
<td>5.0</td>
</tr>
<tr>
<td>3</td>
<td>1.0</td>
<td>1.0</td>
<td>7.0</td>
</tr>
<tr>
<td>4</td>
<td>1.0</td>
<td>2.0</td>
<td>9.0</td>
</tr>
<tr>
<td>5</td>
<td>1.0</td>
<td>3.0</td>
<td>11.0</td>
</tr>
</tbody>
</table>

### Difference with previous column

```python
def df.diff(axis=1)
```

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>-1.0</td>
<td>3.0</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>-1.0</td>
<td>7.0</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
<td>-1.0</td>
<td>13.0</td>
</tr>
<tr>
<td>5</td>
<td>NaN</td>
<td>0.0</td>
<td>20.0</td>
</tr>
<tr>
<td>6</td>
<td>NaN</td>
<td>2.0</td>
<td>28.0</td>
</tr>
</tbody>
</table>
Difference with 3rd previous row

```
>>> df.diff(periods=3)
    a   b   c
 0  NaN NaN NaN
 1  NaN NaN NaN
 2  NaN NaN NaN
 3   3   2   15
 4   3   4   21
 5   3   6   27
```

Difference with following row

```
>>> df.diff(periods=-1)
    a   b   c
 0  -1.0  0.0  -3.0
 1  -1.0 -1.0  -5.0
 2  -1.0 -1.0  -7.0
 3  -1.0 -2.0  -9.0
 4  -1.0 -3.0 -11.0
 5   NaN NaN NaN
```

**pandas.DataFrame.div**

DataFrame.div (other, axis='columns', level=None, fill_value=None)

Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series, DataFrame, or constant]
- **axis** : {0, 1, ‘index’, ‘columns’}
  - For Series input, axis to match Series index on
- **level** : int or name
  - Broadcast across a level, matching Index values on the passed MultiIndex level
- **fill_value** : None or float value, default None
  - Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

**Returns**

- **result** [DataFrame]

**See also:**

DataFrame.rtruediv

**Notes**

Mismatched indices will be unioned together
Examples

None

pandas.DataFrame.divide

DataFrame.divide(other, axis='columns', level=None, fill_value=None)

Floating division of dataframe and other, element-wise (binary operator truediv).
Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
   For Series input, axis to match Series index on
level : int or name
   Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None
   Fill existing missing (NaN) values, and any new element needed for successful
   DataFrame alignment, with this value before computation. If data in both corre-
   sponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.rtruediv

Notes

Mismatched indices will be unioned together

Examples

None

pandas.DataFrame.dot

DataFrame.dot(other)

Matrix multiplication with DataFrame or Series objects. Can also be called using self @ other in Python
>= 3.5.

Parameters

other [DataFrame or Series]

Returns
dot_product [DataFrame or Series]

pandas.DataFrame.drop

DataFrame.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Drop specified labels from rows or columns.
Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level.

Parameters

labels : single label or list-like
    Index or column labels to drop.

axis : {0 or ‘index’, 1 or ‘columns’}, default 0
    Whether to drop labels from the index (0 or ‘index’) or columns (1 or ‘columns’).

index, columns : single label or list-like
    Alternative to specifying axis (labels, axis=1 is equivalent to columns=labels).
    New in version 0.21.0.

level : int or level name, optional
    For MultiIndex, level from which the labels will be removed.

inplace : bool, default False
    If True, do operation inplace and return None.

dropped : single label or list-like
    Alternative to specifying index (labels, axis=1 is equivalent to columns=labels).
    New in version 0.21.0.

Raises

KeyError
    If none of the labels are found in the selected axis

See also:

DataFrame.loc  Label-location based indexer for selection by label.

DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing

DataFrame.drop_duplicates Return DataFrame with duplicate rows removed, optionally only considering certain columns

Series.drop Return Series with specified index labels removed.

Examples
### Drop columns

```python
>>> df.drop(['B', 'C'], axis=1)
     A  D
 0  0  3
 1  4  7
 2  8 11
```

```python
>>> df.drop(columns=['B', 'C'])
     A  D
 0  0  3
 1  4  7
 2  8 11
```

### Drop a row by index

```python
>>> df.drop([0, 1])
     big  small
lana  speed 45.0  30.0
      weight  200.0  100.0
      length  1.5  1.0
cow   speed  30.0  20.0
      weight  250.0  150.0
      length  1.5  0.8
falcon speed 320.0 250.0
      weight  1.0  0.8
      length  0.3  0.2
```

### Drop columns and/or rows of MultiIndex DataFrame

```python
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
                             ['speed', 'weight', 'length']],
                      labels=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
                              [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
                    data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
                          [250, 150], [1.5, 0.8], [320, 250],
                          [1, 0.8], [0.3, 0.2]])
>>> df
          big    small
lama  speed 45.0  30.0
        weight  200.0  100.0
        length  1.5  1.0
cow   speed  30.0  20.0
        weight  250.0  150.0
        length  1.5  0.8
falcon speed 320.0 250.0
        weight  1.0  0.8
        length  0.3  0.2
```

```python
>>> df.drop(index='cow', columns='small')
          big
lama  speed 45.0
        weight  200.0
        length  1.5
falcon speed 320.0
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

(continued from previous page)

<table>
<thead>
<tr>
<th>weight</th>
<th>1.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>length</td>
<td>0.3</td>
</tr>
</tbody>
</table>

```python
>>> df.drop(index='length', level=1)
   big   small
lama   speed  45.0  30.0
         weight  200.0  100.0
cow    speed  30.0  20.0
         weight  250.0  150.0
falcon speed  320.0  250.0
         weight  1.0  0.8
```

pandas.DataFrame.drop_duplicates

DataFrame.drop_duplicates(subset=None, keep='first', inplace=False)

Return DataFrame with duplicate rows removed, optionally only considering certain columns

Parameters

subset : column label or sequence of labels, optional

Only consider certain columns for identifying duplicates, by default use all of the columns

keep : {'first', 'last', False}, default 'first'

- first: Drop duplicates except for the first occurrence.
- last: Drop duplicates except for the last occurrence.
- False: Drop all duplicates.

inplace : boolean, default False

Whether to drop duplicates in place or to return a copy

Returns

deduplicated [DataFrame]

pandas.DataFrame.dropna

DataFrame.dropna(axis=0, how='any', thresh=None, subset=None, inplace=False)

Remove missing values.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters

axis : {0 or ‘index’, 1 or ‘columns’}, default 0

Determine if rows or columns which contain missing values are removed.

- 0, or ‘index’: Drop rows which contain missing values.
- 1, or ‘columns’: Drop columns which contain missing value.

Deprecated since version 0.23.0:: Pass tuple or list to drop on multiple axes.

how : {‘any’, ‘all’}, default ‘any’
Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.

- **‘any’**: If any NA values are present, drop that row or column.
- **‘all’**: If all values are NA, drop that row or column.

**thresh**: int, optional

Require that many non-NA values.

**subset**: array-like, optional

Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

**inplace**: bool, default False

If True, do operation inplace and return None.

**Returns** DataFrame

DataFrame with NA entries dropped from it.

**See also:**

DataFrame.isna  Indicate missing values.

DataFrame.notna  Indicate existing (non-missing) values.

DataFrame.fillna  Replace missing values.

Series.dropna  Drop missing values.

Index.dropna  Drop missing indices.

**Examples**

```python
def = pd.DataFrame({'name': ['Alfred', 'Batman', 'Catwoman'],
                   ...
                   'toy': [np.nan, 'Batmobile', 'Bullwhip'],
                   ...
                   'born': [pd.NaT, pd.Timestamp('1940-04-25'),
                            pd.NaT]})
>>> df
    name    toy         born
0  Alfred   NaN        NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip   NaT

Drop the rows where at least one element is missing.

```python
>>> df.dropna()
     name    toy         born
0  Alfred   NaN        NaT
1  Batman  Batmobile  1940-04-25
```

Drop the columns where at least one element is missing.

```python
>>> df.dropna(axis='columns')
    name
0  Alfred
1  Batman
2  Catwoman
```
Drop the rows where all elements are missing.

```python
>>> df.dropna(how='all')
    name     toy     born
0  Alfred   NaN  NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip  NaT
```

Keep only the rows with at least 2 non-NA values.

```python
>>> df.dropna(thresh=2)
    name     toy     born
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip  NaT
```

Define in which columns to look for missing values.

```python
>>> df.dropna(subset=['name', 'born'])
    name     toy     born
1  Batman  Batmobile  1940-04-25
```

Keep the DataFrame with valid entries in the same variable.

```python
>>> df.dropna(inplace=True)
>>> df
    name     toy     born
1  Batman  Batmobile  1940-04-25
```

**pandas.DataFrame.duplicated**

Dataframe.duplicated(subset=None, keep='first')

Return boolean Series denoting duplicate rows, optionally only considering certain columns

**Parameters**

- **subset**: column label or sequence of labels, optional
  
  Only consider certain columns for identifying duplicates, by default use all of the columns

- **keep**: {'first', 'last', False}, default ‘first’
  
  - first: Mark duplicates as True except for the first occurrence.
  - last: Mark duplicates as True except for the last occurrence.
  - False: Mark all duplicates as True.

**Returns**

- **duplicated**: [Series]

**pandas.DataFrame.eq**

Dataframe.eq(other, axis='columns', level=None)

Wrapper for flexible comparison methods eq
pandas.DataFrame.equals

DataFrame.equals(other)
Determines if two NDFrame objects contain the same elements. NaNs in the same location are considered equal.

pandas.DataFrame.eval

DataFrame.eval(expr, inplace=False, **kwargs)
Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows eval to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

Parameters

erp : str
   The expression string to evaluate.

inplace : bool, default False
   If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

New in version 0.18.0.

kwargs : dict
   See the documentation for eval() for complete details on the keyword arguments accepted by query().

Returns
ndarray, scalar, or pandas object
The result of the evaluation.

See also:

DataFrame.query Evaluates a boolean expression to query the columns of a frame.

DataFrame.assign Can evaluate an expression or function to create new values for a column.

pandas.eval Evaluate a Python expression as a string using various backends.

Notes

For more details see the API documentation for eval(). For detailed examples see enhancing performance with eval.

Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1  10
1  2   8
2  3   6
3  4   4
```

(continues on next page)
Assignment is allowed though by default the original DataFrame is not modified.

```python
>>> df.eval('C = A + B')
   A   B   C
0  1  10  11
1  2   8  10
2  3  10   9
3  4   7   8
4  5   4   7
```

Use `inplace=True` to modify the original DataFrame.

```python
>>> df.eval('C = A + B', inplace=True)
```

```
   A   B   C
0  1  10  11
1  2   8  10
2  3  10   9
3  4   7   8
4  5   4   7
```

`pandas.DataFrame.ewm`

Dataframe `ewm (com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0)`

Provides exponential weighted functions

New in version 0.18.0.

**Parameters**

- `com` : float, optional
  Specify decay in terms of center of mass, \( \alpha = 1/(1 + \text{com}), \) for \( \text{com} \geq 0 \)

- `span` : float, optional
  Specify decay in terms of span, \( \alpha = 2/(\text{span} + 1), \) for \( \text{span} \geq 1 \)

- `halflife` : float, optional
  Specify decay in terms of half-life, \( \alpha = 1 - \exp(\log(0.5)/\text{halflife}), \) for \( \text{halflife} > 0 \)
alpha : float, optional
    Specify smoothing factor $\alpha$ directly, $0 < \alpha \leq 1$
    New in version 0.18.0.

min_periods : int, default 0
    Minimum number of observations in window required to have a value (otherwise
    result is NA).

adjust : boolean, default True
    Divide by decaying adjustment factor in beginning periods to account for imbal-
    ance in relative weightings (viewing EWMA as a moving average)

ignore_na : boolean, default False
    Ignore missing values when calculating weights; specify True to reproduce pre-
    0.15.0 behavior

Returns
    a Window sub-classed for the particular operation

See also:

rolling     Provides rolling window calculations
expanding    Provides expanding transformations.

Notes

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship
between the parameters are specified in the parameter descriptions above; see the link at the end of
this section for a detailed explanation.

When adjust is True (default), weighted averages are calculated using weights $(1-\alpha)^{**(n-1)}, (1-
\alpha)^{**(n-2)}, . . . , 1-\alpha, 1$.

When adjust is False, weighted averages are calculated recursively as: weighted_average[0] =
arg[0]; weighted_average[i] = (1-\alpha)*weighted_average[i-1] + \alpha*arg[i].

When ignore_na is False (default), weights are based on absolute positions. For example, the weights of
x and y used in calculating the final weighted average of [x, None, y] are (1-\alpha)**2 and 1 (if adjust is True), and (1-\alpha)**2 and alpha (if adjust is False).

When ignore_na is True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For
example, the weights of x and y used in calculating the final weighted average of [x, None, y] are 1-\alpha
and 1 (if adjust is True), and 1-\alpha and alpha (if adjust is False).

More details can be found at http://pandas.pydata.org/pandas-docs/stable/computation.html#exponentially-weighted-windows

Examples

>>> df = DataFrame({'B': [0, 1, 2, np.nan, 4]})
   B
0  0.0
1  1.0
(continues on next page)
```python
>>> df.ewm(com=0.5).mean()
    B
 0  0.000000
 1  0.750000
 2  1.615385
 3  1.615385
 4  3.670213
```

**pandas.DataFrame.expanding**

DataFrame.expanding(min_periods=1, center=False, axis=0)

Provides expanding transformations.

New in version 0.18.0.

**Parameters**

- `min_periods` : int, default 1
  
  Minimum number of observations in window required to have a value (otherwise result is NA).

- `center` : boolean, default False
  
  Set the labels at the center of the window.

- `axis` [int or string, default 0]

**Returns**

a Window sub-classed for the particular operation

See also:

- `rolling` Provides rolling window calculations
- `ewm` Provides exponential weighted functions

**Notes**

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

**Examples**

```python
>>> df = DataFrame({'B': [0, 1, 2, np.nan, 4]})
     B
 0  0.0
 1  1.0
 2  2.0
 3  NaN
 4  4.0
```
```python
>>> df.expanding(2).sum()
    B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

**pandas.DataFrame.ffill**

DataFrame.ffill (axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna(method='ffill')

**pandas.DataFrame.fillna**

DataFrame.fillna (value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, **kwargs)

Fill NA/NaN values using the specified method

**Parameters**

- **value**: scalar, dict, Series, or DataFrame
  
  Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). (values not in the dict/Series/DataFrame will not be filled). This value cannot be a list.

- **method**: {'backfill', 'bfill', 'pad', 'ffill', None}, default None

  Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

- **axis** [{0 or 'index', 1 or 'columns'}]

- **inplace**: boolean, default False

  If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

- **limit**: int, default None

  If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast**: dict, default is None

  a dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

**Returns**

- **filled** [DataFrame]

See also:
**interpolate** Fill NaN values using interpolation.

**reindex, asfreq**

### Examples

```python
>>> import pandas as pd
>>> import numpy as np

>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                    columns=list('ABCD'))

>>> df
    A    B    C    D
0  NaN  2.0  NaN  0.0
1   3.0  4.0  NaN  1.0
2  NaN  NaN  NaN  5.0
3  NaN  3.0  NaN  4.0

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
    A    B    C    D
0  0.0  2.0  0.0  0.0
1  3.0  4.0  0.0  1.0
2  0.0  0.0  0.0  5.0
3  0.0  3.0  0.0  4.0
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method='ffill')
    A    B    C    D
0  NaN  2.0  NaN  0.0
1  3.0  4.0  NaN  1.0
2  3.0  4.0  NaN  5.0
3  3.0  3.0  NaN  4.0
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
    A    B    C    D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  2.0  1.0
2  0.0  1.0  2.0  5.0
3  0.0  3.0  2.0  4.0
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
    A    B    C    D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  NaN  1.0
2  NaN  1.0  NaN  5.0
3  NaN  3.0  NaN  4.0
```
pandas.DataFrame.filter

DataFrame.filter(items=None, like=None, regex=None, axis=None)
Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

- **items**: list-like
  List of info axis to restrict to (must not all be present)

- **like**: string
  Keep info axis where “arg in col == True”

- **regex**: string (regular expression)
  Keep info axis with re.search(regex, col) == True

- **axis**: int or string axis name
  The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame

Returns

same type as input object

See also:

pandas.DataFrame.loc

Notes

The *items*, *like*, and *regex* parameters are enforced to be mutually exclusive.

*axis* defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df
one  two  three
mouse 1  2  3
rabbit 4  5  6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
one  three
mouse 1  3
rabbit 4  6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
one  three
mouse 1  3
rabbit 4  6
```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
one two three
rabbit 4 5 6

**pandas.DataFrame.first**

*DataFrame.first*(offset)

Convenience method for subsetting initial periods of time series data based on a date offset.

**Parameters**

offset [string, DateOffset, dateutil.relativedelta]

**Returns**

subset [type of caller]

**Raises** TypeError

If the index is not a *DatetimeIndex*

**See also:**

*last* Select final periods of time series based on a date offset

*at_time* Select values at a particular time of the day

*between_time* Select values between particular times of the day

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
   A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calender days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

**pandas.DataFrame.first_valid_index**

*DataFrame.first_valid_index()*

Return index for first non-NA/null value.
Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

pandas.DataFrame.floordiv

DataFrame.floordiv(other, axis='columns', level=None, fill_value=None)

Integer division of dataframe and other, element-wise (binary operator floordiv).

Equivalent to dataframe // other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
For Series input, axis to match Series index on
level : int or name
Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None
Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.rfloordiv

Notes

Mismatched indices will be unioned together

Examples

None

pandas.DataFrame.from_csv

classmethod DataFrame.from_csv(path, header=0, sep=', ', index_col=0, parse_dates=True, encoding=None, tupleize_cols=None, infer_datetime_format=False)

Read CSV file.
Deprecated since version 0.21.0: Use `pandas.read_csv()` instead.

It is preferable to use the more powerful `pandas.read_csv()` for most general purposes, but `from_csv` makes for an easy roundtrip to and from a file (the exact counterpart of `to_csv`), especially with a DataFrame of time series data.

This method only differs from the preferred `pandas.read_csv()` in some defaults:

- `index_col` is 0 instead of `None` (take first column as index by default)
- `parse_dates` is `True` instead of `False` (try parsing the index as datetime by default)

So a `pd.DataFrame.from_csv(path)` can be replaced by `pd.read_csv(path, index_col=0, parse_dates=True)`.

**Parameters**

- `path` [string file path or file handle / StringIO]
- `header` : int, default 0
  Row to use as header (skip prior rows)
- `sep` : string, default `','`
  Field delimiter
- `index_col` : int or sequence, default 0
  Column to use for index. If a sequence is given, a MultiIndex is used. Different default from `read_table`
- `parse_dates` : boolean, default `True`
  Parse dates. Different default from `read_table`
- `tupleize_cols` : boolean, default `False`
  Write multi_index columns as a list of tuples (if `True`) or new (expanded format) if `False`
- `infer_datetime_format` : boolean, default `False`
  If `True` and `parse_dates` is `True` for a column, try to infer the datetime format based on the first datetime string. If the format can be inferred, there often will be a large parsing speed-up.

**Returns**

- `y` [DataFrame]

**See also:**

- `pandas.read_csv`

**pandas.DataFrame.from_dict**

`classmethod` `DataFrame.from_dict`(data, orient='columns', dtype=None, columns=None)

Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing `dtype` specification.

**Parameters**

- `data` : dict
  Of the form `{field : array-like}` or `{field : dict}`.
orient : {'columns', 'index'}, default 'columns'

The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.

dtype : dtype, default None

Data type to force, otherwise infer.

columns : list, default None

Column labels to use when orient='index'. Raises a ValueError if used with orient='columns'.

New in version 0.23.0.

Returns

pandas.DataFrame

See also:

DataFrame.from_records DataFrame from ndarray (structured dtype), list of tuples, dict, or DataFrame

DataFrame DataFrame object creation using constructor

Examples

By default the keys of the dict become the DataFrame columns:

```python
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

Specify orient='index' to create the DataFrame using dictionary keys as rows:

```python
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
   0  1  2  3
row_1 3  2  1  0
row_2 a b c d
```

When using the ‘index’ orientation, the column names can be specified manually:

```python
>>> pd.DataFrame.from_dict(data, orient='index',
... columns=['A', 'B', 'C', 'D'])
   A  B  C  D
row_1 3  2  1  0
row_2 a b c d
```
**pandas.DataFrame.from_items**

**classmethod** `DataFrame.from_items(items, columns=None, orient='columns')`

Construct a dataframe from a list of tuples

Deprecated since version 0.23.0: `from_items` is deprecated and will be removed in a future version. Use `DataFrame.from_dict(dict(items))` instead. `DataFrame.from_dict(OrderedDict(items))` may be used to preserve the key order.

Convert (key, value) pairs to DataFrame. The keys will be the axis index (usually the columns, but depends on the specified orientation). The values should be arrays or Series.

**Parameters**

- **items**: sequence of (key, value) pairs
  
  Values should be arrays or Series.

- **columns**: sequence of column labels, optional
  
  Must be passed if orient='index'.

- **orient**: {'columns', 'index'}, default 'columns'
  
  The “orientation” of the data. If the keys of the input correspond to column labels, pass `columns` (default). Otherwise if the keys correspond to the index, pass `index`.

**Returns**

- **frame** [DataFrame]

**pandas.DataFrame.from_records**

**classmethod** `DataFrame.from_records(data, index=None, exclude=None, columns=None, coerce_float=False, nrows=None)`

Convert structured or record ndarray to DataFrame

**Parameters**

- **data**: ndarray (structured dtype), list of tuples, dict, or DataFrame

- **index**: string, list of fields, array-like
  
  Field of array to use as the index, alternately a specific set of input labels to use

- **exclude**: sequence, default None
  
  Columns or fields to exclude

- **columns**: sequence, default None
  
  Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns)

- **coerce_float**: boolean, default False
  
  Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets

**Returns**

- **df** [DataFrame]
pandas.DataFrame.ge

DataFrame.ge(other, axis='columns', level=None)
Wrapper for flexible comparison methods ge

pandas.DataFrame.get

DataFrame.get(key, default=None)
Get item from object for given key (DataFrame column, Panel slice, etc.). Returns default value if not found.

Parameters
key [object]

Returns
value [type of items contained in object]

pandas.DataFrame.get_dtype_counts

DataFrame.get_dtype_counts()
Return counts of unique dtypes in this object.

Returns dtype: Series
Series with the count of columns with each dtype.

See also:
dtypes Return the dtypes in this object.

Examples

```python
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1   1.0
1   b    2   2.0
2   c    3   3.0

>>> df.get_dtype_counts()
float64 1
int64   1
object  1
dtype: int64
```

pandas.DataFrame.get_ftype_counts

DataFrame.get_ftype_counts()
Return counts of unique ftypes in this object.

Deprecated since version 0.23.0.
This is useful for SparseDataFrame or for DataFrames containing sparse arrays.

**Returns**  
dtype: Series

Series with the count of columns with each type and sparsity (dense/sparse)

**See also:**

**ftypes** Return ftypes (indication of sparse/dense and dtype) in this object.

**Examples**

```python
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0  a    1    1.0
1  b    2    2.0
2  c    3    3.0
```

```python
>>> df.get_fval_counts()
float64:dense 1
int64:dense  1
object:dense 1
dtype: int64
```

**pandas.DataFrame.get_value**

DataFrame.get_value(index, col, takeable=False)  
Quickly retrieve single value at passed column and index

Deprecated since version 0.21.0: Use .at[] or .iat[] accessors instead.

**Parameters**

index [row label]

col [column label]

takeable [interpret the index/col as indexers, default False]

**Returns**

value [scalar value]

**pandas.DataFrame.get_values**

DataFrame.get_values()  
Return an ndarray after converting sparse values to dense.

This is the same as .values for non-sparse data. For sparse data contained in a pandas.SparseArray, the data are first converted to a dense representation.

**Returns**  
numpy.ndarray

Numpy representation of DataFrame

**See also:**
values Numpy representation of DataFrame.

pandas.SparseArray Container for sparse data.

Examples

```python
>>> df = pd.DataFrame({'a': [1, 2], 'b': [True, False], 'c': [1.0, 2.0]})
>>> df
   a     b    c
0  1  True  1.0
1  2  False  2.0

>>> df.get_values()
array([[1, True, 1.0], [2, False, 2.0]], dtype=object)

>>> df = pd.DataFrame({'a': pd.SparseArray([1, None, None]), 'c': [1.0, 2.0, 3.0]})
>>> df
   a     c
0  1.0  1.0
1 NaN  2.0
2 NaN  3.0

>>> df.get_values()
array([[ 1., 1.],
       [nan, 2.],
       [nan, 3.]], dtype=object)
```

pandas.DataFrame.groupby

DataFrame.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=False, observed=False, **kwargs)

Group series using mapper (dict or key function, apply given function to group, return result as series) or by a series of columns.

Parameters by : mapping, function, label, or list of labels

Used to determine the groups for the groupby. If by is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see .align() method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in self. Notice that a tuple is interpreted a (single) key.

axis [int, default 0]

level : int, level name, or sequence of such, default None

If the axis is a MultiIndex (hierarchical), group by a particular level or levels

as_index : boolean, default True

For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. as_index=False is effectively “SQL-style” grouped output
sort : boolean, default True
Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. groupby preserves the order of rows within each group.

group_keys : boolean, default True
When calling apply, add group keys to index to identify pieces

squeeze : boolean, default False
reduce the dimensionality of the return type if possible, otherwise return a consistent type

observed : boolean, default False
This only applies if any of the groupers are Categoricals If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

Returns
GroupBy object

See also:
resample Convenience method for frequency conversion and resampling of time series.

Notes
See the user guide for more.

Examples

DataFrame results

```python
>>> data.groupby(func, axis=0).mean()
>>> data.groupby(['col1', 'col2'])['col3'].mean()
```

DataFrame with hierarchical index

```python
>>> data.groupby(['col1', 'col2']).mean()
```

pandas.DataFrame.gt

DataFrame.gt (other, axis='columns', level=None)
Wrapper for flexible comparison methods gt

pandas.DataFrame.head

DataFrame.head (n=5)
Return the first n rows.
This function returns the first $n$ rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

**Parameters**

- **n**: int, default 5
  
  Number of rows to select.

**Returns**

- **obj_head**: type of caller
  
  The first $n$ rows of the caller object.

**See also:**

- **pandas.DataFrame.tail** Returns the last $n$ rows.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
  ... 'monkey', 'parrot', 'shark', 'whale', 'zebra']})

>>> df
animal
0 alligator
1 bee
2 falcon
3 lion
4 monkey
5 parrot
6 shark
7 whale
8 zebra
```

Viewing the first 5 lines

```python
>>> df.head()
animal
0 alligator
1 bee
2 falcon
3 lion
4 monkey
```

Viewing the first $n$ lines (three in this case)

```python
>>> df.head(3)
animal
0 alligator
1 bee
2 falcon
```

**pandas.DataFrame.hist**

`DataFrame.hist(column=None, by=None, grid=True, xlabels=None, xrot=None, ylabels=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, **kwds)`

Make a histogram of the DataFrame's.
A histogram is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()` on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

**data** : DataFrame
   The pandas object holding the data.

**column** : string or sequence
   If passed, will be used to limit data to a subset of columns.

**by** : object, optional
   If passed, then used to form histograms for separate groups.

**grid** : boolean, default True
   Whether to show axis grid lines.

**xlabelsize** : int, default None
   If specified changes the x-axis label size.

**xrot** : float, default None
   Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.

**ylabelsize** : int, default None
   If specified changes the y-axis label size.

**yrot** : float, default None
   Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.

**ax** : Matplotlib axes object, default None
   The axes to plot the histogram on.

**sharex** : boolean, default True if ax is None else False
   In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

**sharey** : boolean, default False
   In case subplots=True, share y axis and set some y axis labels to invisible.

**figsize** : tuple
   The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.

**layout** : tuple, optional
   Tuple of (rows, columns) for the layout of the histograms.

**bins** : integer or sequence, default 10
   Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

**kwds**
All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

- `axes` [matplotlib.AxesSubplot or numpy.ndarray of them]

See also:

- `matplotlib.pyplot.hist` Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

`pandas.DataFrame.idxmax`

DataFrame. **idxmax**(axis=0, skipna=True)

Return index of first occurrence of maximum over requested axis. NA/null values are excluded.

**Parameters**

- `axis` : {0 or ‘index’, 1 or ‘columns’}, default 0
  
  0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise

- `skipna` : boolean, default True
  
  Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- `idxmax` [Series]

**Raises**

- `ValueError`

  - If the row/column is empty

**See also:**

- `Series.idxmax`

**Notes**

This method is the DataFrame version of `ndarray.argmax`.

`pandas.DataFrame.idxmin`

DataFrame. **idxmin**(axis=0, skipna=True)

Return index of first occurrence of minimum over requested axis. NA/null values are excluded.

**Parameters**

- `axis` : {0 or ‘index’, 1 or ‘columns’}, default 0
  
  0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise
skipna : boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

idxmin [Series]

Raises ValueError

• If the row/column is empty

See also:

Series.idxmin

Notes

This method is the DataFrame version of ndarray.argmin.

pandas.DataFrame.infer_objects

DataFrame.infer_objects ()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

Returns

converted [same type as input object]

See also:

pandas.to_datetime Convert argument to datetime.

pandas.to_timedelta Convert argument to timedelta.

pandas.to_numeric Convert argument to numeric type

Examples

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```python
>>> df.dtypes
A   object
dtype: object
```
pandas.DataFrame.info

DataFrame.info(verbosenone, buf=none, max_cols=none, memory_usage=none, 
null_counts=none)
Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and column dtypes, non-null values and memory usage.

Parameters:
bose : bool, optional
Whether to print the full summary. By default, the setting in pandas.options.display.max_info_columns is followed.

buf : writable buffer, defaults to sys.stdout
Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.

max_cols : int, optional
When to switch from the verbose to the truncated output. If the DataFrame has more than max_cols columns, the truncated output is used. By default, the setting in pandas.options.display.max_info_columns is used.

memory_usage : bool, str, optional
Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the pandas.options.display.memory_usage setting.

True always show memory usage. False never shows memory usage. A value of ‘deep’ is equivalent to “True with deep introspection”. Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

null_counts : bool, optional
Whether to show the non-null counts. By default, this is shown only if the frame is smaller than pandas.options.display.max_info_rows and pandas.options.display.max_info_columns. A value of True always shows the counts, and False never shows the counts.

Returns:
None

This method prints a summary of a DataFrame and returns None.

See also:

DataFrame.describe  Generate descriptive statistics of DataFrame columns.
DataFrame.memory_usage  Memory usage of DataFrame columns.
Examples

```python
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({'int_col': int_values, 'text_col': text_values, ...
...                     'float_col': float_values})
>>> df
   int_col text_col  float_col
0       1     alpha    0.00
1       2      beta    0.25
2       3    gamma    0.50
3       4     delta    0.75
4       5  epsilon    1.00
```

Prints information of all columns:

```python
>>> df.info(verbos=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
int_col 5 non-null int64
text_col 5 non-null object
float_col 5 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```python
>>> df.info(verbos=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```python
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w", encoding="utf-8") as f:
...     f.write(s)
260
```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```python
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({...
...                     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...                     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...                     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
...                 })
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
```

(continues on next page)
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
column_1 1000000 non-null object
column_2 1000000 non-null object
column_3 1000000 non-null object
dtypes: object(3)
memory usage: 22.9+ MB

```
>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
column_1 1000000 non-null object
column_2 1000000 non-null object
column_3 1000000 non-null object
dtypes: object(3)
memory usage: 188.8 MB
```

pandas.DataFrame.insert

DataFrame.insert(loc, column, value, allow_duplicates=False)

Insert column into DataFrame at specified location.

Raises a ValueError if column is already contained in the DataFrame, unless allow_duplicates is set to True.

Parameters

- **loc**: int
  - Insertion index. Must verify 0 <= loc <= len(columns)
- **column**: string, number, or hashable object
  - label of the inserted column
- **value**: [int, Series, or array-like]
- **allow_duplicates**: [bool, optional]

pandas.DataFrame.interpolate

DataFrame.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)

Interpolate values according to different methods.

Please note that only method='linear' is supported for DataFrames/Series with a MultiIndex.

Parameters

- **method**: {'linear', 'time', 'index', 'values', 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'barycentric', 'krogh', 'polynomial', 'spline', 'piecewise_polynomial', 'from_derivatives', 'pchip', 'akima'}
- ‘linear’: ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes. default
• ‘time’: interpolation works on daily and higher resolution data to interpolate
given length of interval

• ‘index’, ‘values’: use the actual numerical values of the index

• ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘barycentric’, ‘polynomial’ is passed to scipy.interpolate.interp1d. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g.
df.interpolate(method=‘polynomial’, order=4). These use the actual numerical
values of the index.

• ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ are all wrap-
pers around the scipy interpolation methods of similar names. These use the
actual numerical values of the index. For more information on their behavior,
see the scipy documentation and tutorial documentation

• ‘from_derivatives’ refers to BPoly.from_derivatives which replaces ‘piece-
wise_polynomial’ interpolation method in scipy 0.18

New in version 0.18.1: Added support for the ‘akima’ method Added interpolate
method ‘from_derivatives’ which replaces ‘piecewise_polynomial’ in scipy 0.18;
backwards-compatible with scipy < 0.18

axis : {0, 1}, default 0
• 0: fill column-by-column
• 1: fill row-by-row

limit : int, default None.
Maximum number of consecutive NaNs to fill. Must be greater than 0.

limit_direction : [{‘forward’, ‘backward’, ‘both’}, default ‘forward’]

limit_area : [{‘inside’, ‘outside’}, default None
• None: (default) no fill restriction
• ‘inside’ Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’ Only fill NaNs outside valid values (extrapolate).

If limit is specified, consecutive NaNs will be filled in this direction.

New in version 0.21.0.

inplace : bool, default False
Update the NDFrame in place if possible.

downcast : optional, ‘infer’ or None, defaults to None
Downcast dtypes if possible.

kwarg : [keyword arguments to pass on to the interpolating function.]

Returns
Series or DataFrame of same shape interpolated at the NaNs

See also:
reindex, replace, fillna
Examples

Filling in NaNs

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s.interpolate()
0   0
1   1
2   2
3   3
dtype: float64
```

**pandas.DataFrame.isin**

DataFrame.isin(values)

Return boolean DataFrame showing whether each element in the DataFrame is contained in values.

**Parameters** values : iterable, Series, DataFrame or dictionary

The result will only be true at a location if all the labels match. If values is a Series, that’s the index. If values is a dictionary, the keys must be the column names, which must match. If values is a DataFrame, then both the index and column labels must match.

**Returns**

DataFrame of booleans

**Examples**

When values is a list:

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': ['a', 'b', 'f']})
>>> df.isin([1, 3, 12, 'a'])
   A  B
0  True  True
1  False False
2  True  False
```

When values is a dict:

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 7, 12]})
>>> df.isin({'A': [1, 3], 'B': [4, 7, 12]})
   A  B
0  True  True # Note that B didn't match the 1 here.
1  False  True
2  True  True
```

When values is a Series or DataFrame:

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': ['a', 'b', 'f']})
>>> other = DataFrame({'A': [1, 3, 3, 2], 'B': ['e', 'f', 'f', 'e']})
>>> df.isin(other)
   A  B
0  True  False
462  0  False
(continues on next page)```
pandas: powerful Python data analysis toolkit, Release 0.23.3

1 False False # Column A in 'other' has a 3, but not at index 1.
2 True True

pandas.DataFrame.isna

DataFrame.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy. NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns DataFrame

Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.isnull alias of isna
DataFrame.notna boolean inverse of isna
DataFrame.dropna omit axes labels with missing values
isna top-level isna

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                      'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                      'name': ['Alfred', 'Batman', ''],
...                      'toy': [None, 'Batmobile', 'Joker']})

>>> df
   age  born      name    toy
0   5.0   NaT  Alfred  None
1  6.0  1939-05-27  Batman  Batmobile
2   NaN  1940-04-25    Joker

>>> df.isna()
   age  born      name    toy
0  False  True    False  True
1  False  False   False  False
2  True  False   False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])

>>> ser
0    5.0
1    6.0
Name: 0, dtype: float64
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

(continued from previous page)

>>> ser.isna()
0    False
1    False
2     True
dtype: bool

**pandas.DataFrame.isnull**

**DataFrame.isnull()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns **DataFrame**

Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

*DataFrame.isnull* alias of isna

*DataFrame.notna* boolean inverse of isna

*DataFrame.dropna* omit axes labels with missing values

*isna* top-level isna

**Examples**

Show which entries in a DataFrame are NA.

>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                              pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})

>>> df
     age   born     name   toy
0   5.0  NaT  Alfred  None
1  6.00 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25  Joker

>>> df.isna()
     age   born     name   toy
0  False    True  False  True
1  False    False  False  False
2  True    False  False  False
Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0   False
1   False
2    True
dtype: bool
```

### pandas.DataFrame.items

Dataframe .items()  
Iterator over (column name, Series) pairs.

See also:

- iterrows Iterate over DataFrame rows as (index, Series) pairs.
- itertuples Iterate over DataFrame rows as namedtuples of the values.

### pandas.DataFrame.iteritems

Dataframe .iteritems()  
Iterator over (column name, Series) pairs.

See also:

- iterrows Iterate over DataFrame rows as (index, Series) pairs.
- itertuples Iterate over DataFrame rows as namedtuples of the values.

### pandas.DataFrame.iterrows

Dataframe .iterrows()  
Iterate over DataFrame rows as (index, Series) pairs.

**Returns**

- it : generator  
  A generator that iterates over the rows of the frame.

See also:

- itertuples Iterate over DataFrame rows as namedtuples of the values.
- iteritems Iterate over (column name, Series) pairs.
Notes

1. Because `iterrows` returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

   ```python
   >>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
   >>> row = next(df.iterrows())[1]
   >>> row
   int    1.0
   float  1.5
   Name: 0, dtype: float64
   >>> print(row['int'].dtype)
   float64
   >>> print(df['int'].dtype)
   int64
   ```

   To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

   **pandas.DataFrame.itertuples**

   `DataFrame.itertuples(index=True, name='Pandas')`

   Iterate over DataFrame rows as namedtuples, with index value as first element of the tuple.

   **Parameters**
   
   - `index` : boolean, default True
     
     If True, return the index as the first element of the tuple.
   
   - `name` : string, default “Pandas”
     
     The name of the returned namedtuples or None to return regular tuples.

   **See also:**

   - `iterrows` Iterate over DataFrame rows as (index, Series) pairs.
   - `iteritems` Iterate over (column name, Series) pairs.

   **Notes**

   The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

   **Examples**

   ```python
   >>> df = pd.DataFrame({
       'col1': [1, 2],
       'col2': [0.1, 0.2]
   }, index=['a', 'b'])
   ```

   ```python
   >>> df
   col1  col2
   a  1  0.1
   ```
pandas: powerful Python data analysis toolkit, Release 0.23.3

(continued from previous page)

```python
>>> b 2 0.2
>>> for row in df.itertuples():
    ...    print(row)
    ...
Pandas(Index='a', col1=1, col2=0.10000000000000001)
Pandas(Index='b', col1=2, col2=0.20000000000000001)
```

**pandas.DataFrame.join**

DataFrame.join(other, on=None, how='left', lsuffix='', rsuffix='', sort=False)

Join columns with other DataFrame either on index or on a key column. Efficiently Join multiple DataFrame objects by index at once by passing a list.

**Parameters**

- **other**: DataFrame, Series with name field set, or list of DataFrame
  
Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame

- **on**: name, tuple/list of names, or array-like
  
Column or index level name(s) in the caller to join on the index in other, otherwise joins index-on-index. If multiple values given, the other DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation

- **how**: {'left', 'right', 'outer', 'inner'}, default: 'left'
  
How to handle the operation of the two objects.

  - left: use calling frame’s index (or column if on is specified)
  - right: use other frame’s index
  - outer: form union of calling frame’s index (or column if on is specified) with other frame’s index, and sort it lexicographically
  - inner: form intersection of calling frame’s index (or column if on is specified) with other frame’s index, preserving the order of the calling’s one

- **lsuffix**: string
  
Suffix to use from left frame’s overlapping columns

- **rsuffix**: string
  
Suffix to use from right frame’s overlapping columns

- **sort**: boolean, default False
  
Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword)

**Returns**

- **joined** [DataFrame]

**See also**

- DataFrame.merge For column(s)-on-columns(s) operations
Notes

on, lsuffix, and rsuffix options are not supported when passing a list of DataFrame objects

Support for specifying index levels as the on parameter was added in version 0.23.0

Examples

```python
>>> caller = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
                          'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```python
>>> caller
   A  key
0  A0  K0
1  A1  K1
2  A2  K2
3  A3  K3
4  A4  K4
5  A5  K5
```

```python
>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
                        'B': ['B0', 'B1', 'B2']})
```

```python
>>> other
   B  key
0  B0  K0
1  B1  K1
2  B2  K2
```

Join DataFrames using their indexes.

```python
>>> caller.join(other, lsuffix='_caller', rsuffix='_other')
      A  key_caller  B  key_other
0  A0   K0Caller  B0    K0Other
1  A1   K1Caller  B1    K1Other
2  A2   K2Caller  B2    K2Other
3   NaN  NaN      NaN   NaN
4   NaN  NaN      NaN   NaN
5   NaN  NaN      NaN   NaN
```

If we want to join using the key columns, we need to set key to be the index in both caller and other. The joined DataFrame will have key as its index.

```python
>>> caller.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```
Another option to join using the key columns is to use the on parameter. DataFrame.join always uses other’s index but we can use any column in the caller. This method preserves the original caller’s index in the result.

```python
>>> caller.join(other.set_index('key'), on='key')

<table>
<thead>
<tr>
<th>A</th>
<th>key</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A0</td>
<td>K0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>K1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>K2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>K3</td>
</tr>
<tr>
<td>4</td>
<td>A4</td>
<td>K4</td>
</tr>
<tr>
<td>5</td>
<td>A5</td>
<td>K5</td>
</tr>
</tbody>
</table>
```

**pandas.DataFrame.keys**

DataFrame.keys()

Get the ‘info axis’ (see Indexing for more)

This is index for Series, columns for DataFrame and major_axis for Panel.

**pandas.DataFrame.kurt**

DataFrame.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1

**Parameters**

- **axis** [{index (0), columns (1)}]
- **skipna** : boolean, default True
  
  Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
- **numeric_only** : boolean, default None
  
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **kurt** [Series or DataFrame (if level specified)]

**pandas.DataFrame.kurtosis**

DataFrame.kurtosis(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1

**Parameters**

- **axis** [{index (0), columns (1)}]
skipna : boolean, default True
    Exclude NA/null values when computing the result.

level : int or level name, default None
    If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing
    into a Series

numeric_only : boolean, default None
    Include only float, int, boolean columns. If None, will attempt to use everything,
    then use only numeric data. Not implemented for Series.

Returns
    kurt [Series or DataFrame (if level specified)]

pandas.DataFrame.last

DataFrame.last(offset)
    Convenience method for subsetting final periods of time series data based on a date offset.

Parameters
    offset [string, DateOffset, dateutil.relativedelta]

Returns
    subset [type of caller]

Raises TypeError
    If the index is not a DatetimeIndex

See also:

first Select initial periods of time series based on a date offset
at_time Select values at a particular time of the day
between_time Select values between particular times of the day

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
   A
2018-04-13  3
2018-04-15  4
```
Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

**pandas.DataFrame.last_valid_index**

Dataframe.`last_valid_index()`
Return index for last non-NA/null value.

**Returns**

scalar [type of index]

**Notes**

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

**pandas.DataFrame.le**

Dataframe.`le(other, axis='columns', level=None)`
Wrapper for flexible comparison methods le

**pandas.DataFrame.lookup**

Dataframe.`lookup(row_labels, col_labels)`
Label-based “fancy indexing” function for DataFrame. Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

**Parameters**

- **row_labels** : sequence
  The row labels to use for lookup
- **col_labels** : sequence
  The column labels to use for lookup

**Notes**

Akin to:

```python
result = []
for row, col in zip(row_labels, col_labels):
    result.append(df.get_value(row, col))
```

**Examples**

- **values** [ndarray] The found values
pandas.DataFrame.lt

DataFrame.lt(other, axis='columns', level=None)
Wrapper for flexible comparison methods lt

pandas.DataFrame.mad

DataFrame.mad(axis=None, skipna=None, level=None)
Return the mean absolute deviation of the values for the requested axis

Parameters
axis [{index (0), columns (1)}]
skipna : boolean, default True
Exclude NA/null values when computing the result.
level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
mad [Series or DataFrame (if level specified)]

pandas.DataFrame.mask

DataFrame.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)
Return an object of same shape as self and whose corresponding entries are from self where cond is False and otherwise are from other.

Parameters cond : boolean NDFrame, array-like, or callable
Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn’t check it).

New in version 0.18.1: A callable can be used as cond.

other : scalar, NDFrame, or callable
Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn’t check it).

New in version 0.18.1: A callable can be used as other.

inplace : boolean, default False
Whether to perform the operation in place on the data
axis [alignment axis if needed, default None]
level [alignment level if needed, default None]
errors: str, {'raise', 'ignore'}, default 'raise'
  • raise: allow exceptions to be raised
  • ignore: suppress exceptions. On error return original object
  Note that currently this parameter won’t affect the results and will always coerce
to a suitable dtype.
try_cast: boolean, default False
  try to cast the result back to the input type (if possible),
raise_on_error: boolean, default True
  Whether to raise on invalid data types (e.g. trying to where on strings)
  Deprecated since version 0.21.0.

Returns

wh [same type as caller]

See also:

Dataframe.where()

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if
cond is False the element is used; otherwise the corresponding element from the DataFrame other
is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2)
is equivalent to np.where(m, df1, df2).

For further details and examples see the mask documentation in Indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0   NaN
1    1.0
2    2.0
3    3.0
4    4.0

>>> s.mask(s > 0)
0    0.0
1   NaN
2   NaN
3   NaN
4   NaN
```
pandas.DataFrame.max

DataFrame.max (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

This method returns the maximum of the values in the object. If you want the index of the maximum, use idxmax. This is the equivalent of the numpy.ndarray method argmax.

Parameters

axis [{index (0), columns (1)}]

skipna : boolean, default True

Exclude NA/null values when computing the result.

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

numeric_only : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

max [Series or DataFrame (if level specified)]
**pandas.DataFrame.mean**

DataFrame.mean(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the mean of the values for the requested axis

**Parameters**

- **axis** [{index (0), columns (1)}]

- **skipna** : boolean, default True

  Exclude NA/null values when computing the result.

- **level** : int or level name, default None

  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

- **numeric_only** : boolean, default None

  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **mean** [Series or DataFrame (if level specified)]

**pandas.DataFrame.median**

DataFrame.median(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the median of the values for the requested axis

**Parameters**

- **axis** [{index (0), columns (1)}]

- **skipna** : boolean, default True

  Exclude NA/null values when computing the result.

- **level** : int or level name, default None

  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

- **numeric_only** : boolean, default None

  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **median** [Series or DataFrame (if level specified)]

**pandas.DataFrame.melt**

DataFrame.melt(id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None)

“Un pivots” a DataFrame from wide format to long format, optionally leaving identifier variables set.
This function is useful to massage a DataFrame into a format where one or more columns are identifier variables \((id\_vars)\), while all other columns, considered measured variables \((value\_vars)\), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

New in version 0.20.0.

**Parameters**

- **frame**  [DataFrame]

  - **id\_vars** : tuple, list, or ndarray, optional
    Column(s) to use as identifier variables.

  - **value\_vars** : tuple, list, or ndarray, optional
    Column(s) to unpivot. If not specified, uses all columns that are not set as \(id\_vars\).

- **var\_name** : scalar
  Name to use for the ‘variable’ column. If None it uses \(frame.columns.name\) or ‘variable’.

- **value\_name** : scalar, default ‘value’
  Name to use for the ‘value’ column.

- **col\_level** : int or string, optional
  If columns are a MultiIndex then use this level to melt.

**See also:**

melt, pivot_table, DataFrame.pivot

**Examples**

```python
>>> import pandas as pd
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                     'B': {0: 1, 1: 3, 2: 5},
...                     'C': {0: 2, 1: 4, 2: 6}})

>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6

>>> df.melt(id_vars=['A'], value_vars=['B'])
     A variable  value
0  a      B     1
1  b      B     3
2  c      B     5

>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
     A variable  value
0  a      B     1
1  b      B     3
2  c      B     5
3  a      C     2
4  b      C     4
5  c      C     6
```
The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> df.melt(id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
      A  myVarname  myValname
0   a         B         1
1   b         B         3
2   c         B         5
```

If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
      A  B  C  D  E  F
0   a  1  2
1   b  3  4
2   c  5  6
```

```python
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
      A  variable  value
0   a  B  E  1
1   b  B  E  3
2   c  B  E  5
```

```python
>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
     (A, D)  variable_0  variable_1  value
0   a B    E        B        E   1
1   b B    E        B        E   3
2   c B    E        B        E   5
```

**pandas.DataFrame.memory_usage**

*DataFrame.memory_usage*(index=True, deep=False)

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of *object* dtype.

This value is displayed in *DataFrame.info* by default. This can be suppressed by setting *pandas.options.display.memory_usage* to False.

**Parameters**

- **index** : bool, default True
  
  Specifies whether to include the memory usage of the DataFrame’s index in returned Series. If *index=True* the memory usage of the index the first item in the output.

- **deep** : bool, default False
  
  If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned values.

**Returns**

- **sizes** : Series
  
  A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

**See also:**

---

1828 Chapter 34. API Reference
**numpy.ndarray.nbytes**  Total bytes consumed by the elements of an ndarray.

**Series.memory_usage**  Bytes consumed by a Series.

**pandas.Categorical**  Memory-efficient array for string values with many repeated values.

**DataFrame.info**  Concise summary of a DataFrame.

### Examples

```python
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000).astype(t))
... for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
   int64  float64  complex128  object  bool
0    1.0     1.0       (1+0j)     1.0      1
1    1.0     1.0       (1+0j)     1.0      1
2    1.0     1.0       (1+0j)     1.0      1
3    1.0     1.0       (1+0j)     1.0      1
4    1.0     1.0       (1+0j)     1.0      1

>>> df.memory_usage()
Index     80
int64  40000
float64 40000
complex128 80000
object  40000
bool  5000
dtype: int64

>>> df.memory_usage(index=False)
int64  40000
float64 40000
complex128 80000
object  40000
bool  5000
dtype: int64

The memory footprint of **object** dtype columns is ignored by default:

```python
>>> df.memory_usage(deep=True)
Index     80
int64  40000
float64 40000
complex128 80000
object  160000
bool  5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```python
>>> df['object'].astype('category').memory_usage(deep=True)
5168
```
pandas.DataFrame.merge

`DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)`

Merge DataFrame objects by performing a database-style join operation by columns or indexes.

If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

Parameters

- **right** [DataFrame]
- **how** : {'left', 'right', 'outer', 'inner'}, default 'inner'
  - left: use only keys from left frame, similar to a SQL left outer join; preserve key order
  - right: use only keys from right frame, similar to a SQL right outer join; preserve key order
  - outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically
  - inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys
- **on** : label or list
  Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.
- **left_on** : label or list, or array-like
  Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.
- **right_on** : label or list, or array-like
  Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.
- **left_index** : boolean, default False
  Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels
- **right_index** : boolean, default False
  Use the index from the right DataFrame as the join key. Same caveats as left_index
- **sort** : boolean, default False
  Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword)
- **suffixes** : 2-length sequence (tuple, list, . . . )
  Suffix to apply to overlapping column names in the left and right side, respectively
**copy** : boolean, default True

If False, do not copy data unnecessarily

**indicator** : boolean or string, default False

If True, adds a column to output DataFrame called “_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left_only” for observations whose merge key only appears in ‘left’ DataFrame, “right_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

**validate** : string, default None

If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

**Returns**  
**merged** : DataFrame

The output type will be the same as ‘left’, if it is a subclass of DataFrame.

**See also:**

*merge_ordered, merge_asof, DataFrame.join*

**Notes**

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0

**Examples**

```python
>>> A
lkey  value
0    foo    1
1    bar    2
2    baz    3
3    foo    4

>>> B
rkey  value
0    foo    5
1    bar    6
2    qux    7
3    bar    8

>>> A.merge(B, left_on='lkey', right_on='rkey', how='outer')
lkey  value_x  rkey  value_y
0    foo      foo    5
1    foo      foo    5
2    bar      bar    6
3    bar      bar    8
4    baz      NaN    NaN
5    NaN      NaN    qux    7
```
pandas.DataFrame.min

DataFrame.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

This method returns the minimum of the values in the object. If you want the index of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

Parameters

- **axis** ([index (0), columns (1)])
- **skipna** : boolean, default True
  Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
- **numeric_only** : boolean, default None
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

- **min** [Series or DataFrame (if level specified)]

pandas.DataFrame.mod

DataFrame.mod(other, axis='columns', level=None, fill_value=None)

Modulo of dataframe and other, element-wise (binary operator mod).

Equivalent to dataframe % other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

- **other** [Series, DataFrame, or constant]
- **axis** : {0, 1, ‘index’, ‘columns’}
  For Series input, axis to match Series index on
- **level** : int or name
  Broadcast across a level, matching Index values on the passed MultiIndex level
- **fill_value** : None or float value, default None
  Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

- **result** [DataFrame]

See also:

DataFrame.rmod
Notes

Mismatched indices will be unioned together

Examples

None

pandas.DataFrame.mode

DataFrame.mode(axis=0, numeric_only=False)

Gets the mode(s) of each element along the axis selected. Adds a row for each mode per label, fills in gaps with nan.

Note that there could be multiple values returned for the selected axis (when more than one item share the maximum frequency), which is the reason why a dataframe is returned. If you want to impute missing values with the mode in a dataframe df, you can just do this: df.fillna(df.mode().iloc[0])

Parameters

axis : {0 or ‘index’, 1 or ‘columns’}, default 0
  • 0 or ‘index’: get mode of each column
  • 1 or ‘columns’: get mode of each row
numeric_only : boolean, default False
  if True, only apply to numeric columns

Returns

modes [DataFrame (sorted)]

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 1, 2, 1, 2, 3]})
>>> df.mode()
   A
0  1
1  2
```

pandas.DataFrame.mul

DataFrame.mul(other, axis='columns', level=None, fill_value=None)

Multiplication of dataframe and other, element-wise (binary operator mul).

Equivalent to dataframe * other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
  For Series input, axis to match Series index on
level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

fill_value : None or float value, default None

Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.rmul

Notes

Mismatched indices will be unioned together

Examples

None

pandas.DataFrame.multiply

Dataframe . multiply (other, axis='columns', level=None, fill_value=None)

Multiplication of dataframe and other, element-wise (binary operator mul).

Equivalent to dataframe * other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}

For Series input, axis to match Series index on
level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

fill_value : None or float value, default None

Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.rmul
Notes

Mismatched indices will be unioned together

Examples

None

**pandas.DataFrame.ne**

`DataFrame.ne(other, axis='columns', level=None)`

Wrapper for flexible comparison methods `ne`

**pandas.DataFrame.nlargest**

`DataFrame.nlargest(n, columns, keep='first')`

Return the first `n` rows ordered by `columns` in descending order.

Return the first `n` rows with the largest values in `columns`, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=False).head(n)`, but more performant.

**Parameters**

- `n : int`
  Number of rows to return.
- `columns : label or list of labels`
  Column label(s) to order by.
- `keep : {'first', 'last'}, default 'first'`
  Where there are duplicate values:
  - `first` : prioritize the first occurrence(s)
  - `last` : prioritize the last occurrence(s)

**Returns**

`DataFrame`

The first `n` rows ordered by the given columns in descending order.

See also:

- `DataFrame.nsmallest` Return the first `n` rows ordered by `columns` in ascending order.
- `DataFrame.sort_values` Sort DataFrame by the values
- `DataFrame.head` Return the first `n` rows without re-ordering.

Notes

This function cannot be used with all column types. For example, when specifying columns with `object` or `category` dtypes, `TypeError` is raised.
pandas: powerful Python data analysis toolkit, Release 0.23.3

Examples
>>> df
...
...
>>> df
a
0
1
1 10
2
8
3 10
4 -1

= pd.DataFrame({'a': [1, 10, 8, 10, -1],
'b': list('abdce'),
'c': [1.0, 2.0, np.nan, 3.0, 4.0]})
b
a
b
d
c
e

c
1.0
2.0
NaN
3.0
4.0

In the following example, we will use nlargest to select the three rows having the largest values in
column “a”.
>>> df.nlargest(3, 'a')
a b
c
1 10 b 2.0
3 10 c 3.0
2
8 d NaN

When using keep='last', ties are resolved in reverse order:
>>> df.nlargest(3, 'a', keep='last')
a b
c
3 10 c 3.0
1 10 b 2.0
2
8 d NaN

To order by the largest values in column “a” and then “c”, we can specify multiple columns like in the
next example.
>>> df.nlargest(3, ['a', 'c'])
a b
c
3 10 c 3.0
1 10 b 2.0
2
8 d NaN

Attempting to use nlargest on non-numeric dtypes will raise a TypeError:
>>> df.nlargest(3, 'b')
Traceback (most recent call last):
TypeError: Column 'b' has dtype object, cannot use method 'nlargest'

pandas.DataFrame.notna
DataFrame.notna()
Detect existing (non-missing) values.
Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to
True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set
pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN,
get mapped to False values.
Returns DataFrame
1836

Chapter 34. API Reference


Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

- `DataFrame.notnull` alias of notna
- `DataFrame.isna` boolean inverse of notna
- `DataFrame.dropna` omit axes labels with missing values
- `notna` top-level notna

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaT],
                              pd.Timestamp('1940-04-25')],
                     'name': ['Alfred', 'Batman', ''],
                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
     age    born     name   toy
0    5.0  NaT   Alfred   None
1    6.0 1939-05-27  Batman  Batmobile
2  NaN  1940-04-25   Joker

>>> df.notna()
       age    born  name   toy
0    True  False  True  False
1    True   True  True   True
2   False   True  True   True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2   NaN
dtype: float64

>>> ser.notna()
0    True
1    True
2   False
dtype: bool
```

**pandas.DataFrame.notnull**

`DataFrame.notnull()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set
pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns DataFrame

Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull alias of notna

DataFrame.isna boolean inverse of notna

DataFrame.dropna omit axes labels with missing values

notna top-level notna

Examples

Show which entries in a DataFrame are not NA.

```python
def = pd.DataFrame({'age': [5, 6, np.NaN],
...           'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                      pd.Timestamp('1940-04-25')],
...           'name': ['Alfred', 'Batman', ''],
...           'toy': [None, 'Batmobile', 'Joker']})

>>> df
   age   born      name    toy
0  5.0   NaT  Alfred   None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25    Joker

>>> df.notna()
   age   born      name    toy
0  True  False  True  False
1  True   True  True   True
2 False   True  True   True
```

Show which entries in a Series are not NA.

```python
ser = pd.Series([5, 6, np.NaN])

>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64

>>> ser.notna()
0  True
1  True
2 False
dtype: bool
```
pandas.DataFrame.nsmallest

DataFrame.nsmallest(n, columns, keep='first')
Get the rows of a DataFrame sorted by the n smallest values of columns.

Parameters
- n : int
  Number of items to retrieve
- columns : list or str
  Column name or names to order by
- keep : {'first', 'last'}, default 'first'
  Where there are duplicate values: - first: take the first occurrence. - last: take the last occurrence.

Returns
- DataFrame

Examples

```python
>>> df = pd.DataFrame({'a': [1, 10, 8, 11, -1],
...                    'b': list('abdce'),
...                    'c': [1.0, 2.0, np.nan, 3.0, 4.0]})
>>> df.nsmallest(3, 'a')
  a  b  c
0  1  a  1
2  8  d  NaN
4 -1  e  4
```

pandas.DataFrame.nunique

DataFrame.nunique(axis=0, dropna=True)
Return Series with number of distinct observations over requested axis.
New in version 0.20.0.

Parameters
- axis : [{0 or 'index', 1 or 'columns'}, default 0]
- dropna : boolean, default True
  Don’t include NaN in the counts.

Returns
- nunique [Series]

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 1, 1]})
>>> df.nunique()
A 3
B 1
```
```python
def.nunique(axis=1)
0 1
1 2
2 2
```

### pandas.DataFrame.pct_change

`DataFrame.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)`

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters**

- `periods` : int, default 1
  - Periods to shift for forming percent change.

- `fill_method` : str, default 'pad'
  - How to handle NAs before computing percent changes.

- `limit` : int, default None
  - The number of consecutive NAs to fill before stopping.

- `freq` : DateOffset, timedelta, or offset alias string, optional
  - Increment to use from time series API (e.g. ‘M’ or BDay()).

- `**kwargs` : Additional keyword arguments are passed into `DataFrame.shift` or `Series.shift`.

**Returns**

- `chg` : Series or DataFrame
  - The same type as the calling object.

**See also:**

- `Series.diff` Compute the difference of two elements in a Series.
- `DataFrame.diff` Compute the difference of two elements in a DataFrame.
- `Series.shift` Shift the index by some number of periods.
- `DataFrame.shift` Shift the index by some number of periods.

**Examples**

### Series

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90  
1  91  
2  85  
```

```python
dtype: int64
```
s.pct_change()
0   NaN
1  0.011111
2 -0.065934
dtype: float64

s.pct_change(periods=2)
0   NaN
1   NaN
2 -0.055556
dtype: float64

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

s = pd.Series([90, 91, None, 85])

s
0   90.0
1   91.0
2   NaN
3   85.0
dtype: float64

s.pct_change(fill_method='ffill')
0   NaN
1  0.011111
2  0.000000
3 -0.065934
dtype: float64

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

df = pd.DataFrame({'FR': [4.0405, 4.0963, 4.3149],
                   'GR': [1.7246, 1.7482, 1.8519],
                   'IT': [804.74, 810.01, 860.13]},

df

FR   GR   IT
1980-01-01 4.0405 1.7246 804.74
1980-02-01 4.0963 1.7482 810.01
1980-03-01 4.3149 1.8519 860.13

df.pct_change()

FR   GR   IT
1980-01-01 NaN  NaN  NaN
1980-02-01 0.013810 0.013684 0.006549
1980-03-01 0.053365 0.059318 0.061876

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

df = pd.DataFrame({'2016': [1769950, 30586265],
                   '2015': [1500923, 40912316]})

(continues on next page)
... '2014': [1371819, 41403351]),
... index=['GOOG', 'APPL'])
>>> df
     2016  2015  2014
GOOG 1769950 1500923 1371819
APPL  30586265 40912316 41403351

>>> df.pct_change(axis='columns')
     2016  2015  2014
GOOG      NaN   -0.152   -0.086
APPL      NaN    0.338    0.012

pandas.DataFrame.pipe

Dataframe.pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs)

Parameters
- func : function
  function to apply to the NDFrame. args, and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the NDFrame.
- args : iterable, optional
  positional arguments passed into func.
- kwargs : mapping, optional
  a dictionary of keyword arguments passed into func.

Returns
- object [the return type of func.]

See also:
pandas.DataFrame.apply, pandas.DataFrame.applymap, pandas.Series.map

Notes

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose f takes its data as arg2:
pandas.DataFrame.pivot

DataFrame.pivot (index=None, columns=None, values=None)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified index / columns to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the User Guide for more on reshaping.

Parameters
  - **index**: string or object, optional
    Column to use to make new frame’s index. If None, uses existing index.
  - **columns**: string or object
    Column to use to make new frame’s columns.
  - **values**: string, object or a list of the previous, optional
    Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

Returns DataFrame

Returns reshaped DataFrame.

Raises ValueError:

When there are any index, columns combinations with multiple values. DataFrame.pivot_table when you need to aggregate.

See also:

- DataFrame.pivot_table generalization of pivot that can handle duplicate values for one index/column pair.
- DataFrame.unstack pivot based on the index values instead of a column.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Examples

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
                           ...
                           'two'],
                   ...
                   'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
                   ...
                   'baz': [1, 2, 3, 4, 5, 6],
```

(continues on next page)
'zoo': ['x', 'y', 'z', 'q', 'w', 't']})

>>> df
  foo  bar  baz  zoo
0   one  A    1   x
1   one  B    2   y
2   one  C    3   z
3   two  A    4   q
4   two  B    5   w
5   two  C    6   t

>>> df.pivot(index='foo', columns='bar', values='baz')
bar     A  B  C
foo
one  1  2  3
two  4  5  6

>>> df.pivot(index='foo', columns='bar')['baz']
bar     A  B  C
foo
one  1  2  3
two  4  5  6

>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
baz  zoo
bar     A  B  C  A  B  C
foo
one  1  2  3   x  y  z
two  4  5  6   q  w  t

A ValueError is raised if there are any duplicates.

>>> df = pd.DataFrame({'foo': ['one', 'one', 'two', 'two'], ...
...                     'bar': ['A', 'A', 'B', 'C'], ...
...                     'baz': [1, 2, 3, 4]})

>>> df
  foo  bar  baz
0   one  A    1
1   one  A    2
2   two  B    3
3   two  C    4

Notice that the first two rows are the same for our index and columns arguments.

>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
  ...
ValueError: Index contains duplicate entries, cannot reshape

**pandas.DataFrame.pivot_table**

DataFrame.pivot_table(values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All')

Create a spreadsheet-style pivot table as a DataFrame. The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.
Parameters

values [column to aggregate, optional]

index : column, Grouper, array, or list of the previous

If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns : column, Grouper, array, or list of the previous

If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc : function, list of functions, dict, default numpy.mean

If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions

fill_value : scalar, default None

Value to replace missing values with

margins : boolean, default False

Add all row / columns (e.g. for subtotal / grand totals)

dropna : boolean, default True

Do not include columns whose entries are all NaN

margins_name : string, default ‘All’

Name of the row / column that will contain the totals when margins is True.

Returns

table [DataFrame]

See also:

DataFrame.pivot pivot without aggregation that can handle non-numeric data

Examples

```python
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo", "bar", "bar", "bar"],
... "B": ["one", "one", "one", "two", "two", "one", "one", "two"],
... "C": ["small", "large", "large", "small", "small", "large"],
... "D": [1, 2, 3, 4, 5, 6, 7]})

>>> df
   A     B     C     D
0   foo   one   small  1
1   foo   one    large  2
2   foo   one    large  2
```

     two  7.0   6.0
  foo  one  4.0   1.0
     two   NaN   6.0

>>> table = pivot_table(df, values='D', index=['A', 'B'],
...                     columns=['C'], aggfunc=np.sum)

>>> table
C    large  small
A B
bar  one  4.0   5.0
     two  7.0   6.0
  foo  one  4.0   1.0
     two   NaN   6.0

>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                    aggfunc={'D': np.mean, 
...                     'E': [min, max, np.mean]})

>>> table
D          E
          mean  max  median  min
A C
bar large  5.500000  16  14.5  13
  small  5.500000  15  14.5  14
  foo large  2.000000  10  9.5   9
  small  2.333333  12  11.0   8

pandas.DataFrame.plot

DataFrame.plot(x=None, y=None, kind='line', ax=None, subplots=False, sharex=None, sharey=False, layout=None, figsize=None, use_index=True, title=None, grid=None, legend=True, style=None, logx=False, logy=False, loglog=False, xticks=None, yticks=None, xlim=None, ylim=None, fontsize=None, colormap=None, table=False, yerr=None, xerr=None, secondary_y=False, sort_columns=False, **kwds)

Make plots of DataFrame using matplotlib / pylab.

New in version 0.17.0: Each plot kind has a corresponding method on the DataFrame.plot accessor: df.plot(kind='line') is equivalent to df.plot.line().

Parameters

data [DataFrame]
x  [label or position, default None]
y : label, position or list of label, positions, default None
   Allows plotting of one column versus another

kind : str
   • ‘line’ : line plot (default)
   • ‘bar’ : vertical bar plot
   • ‘barh’ : horizontal bar plot
   • ‘hist’ : histogram
   • ‘box’ : boxplot
   • ‘kde’ : Kernel Density Estimation plot
   • ‘density’ : same as ‘kde’
   • ‘area’ : area plot
   • ‘pie’ : pie plot
   • ‘scatter’ : scatter plot
   • ‘hexbin’ : hexbin plot

ax  [matplotlib axes object, default None]

subplots : boolean, default False
   Make separate subplots for each column
sharex : boolean, default True if ax is None else False
   In case subplots=True, share x axis and set some x axis labels to invisible; defaults
to True if ax is None otherwise False if an ax is passed in; Be aware, that passing
in both an ax and sharex=True will alter all x axis labels for all axis in a figure!
sharey : boolean, default False
   In case subplots=True, share y axis and set some y axis labels to invisible

layout : tuple (optional)
   (rows, columns) for the layout of subplots

figsize  [a tuple (width, height) in inches]

use_index : boolean, default True
   Use index as ticks for x axis

title : string or list
   Title to use for the plot. If a string is passed, print the string at the top of the
   figure. If a list is passed and subplots is True, print each item in the list above the
   corresponding subplot.

grid : boolean, default None (matlab style default)
   Axis grid lines

legend : False/True/’reverse’
Place legend on axis subplots

**style** : list or dict
  matplotlib line style per column

**logx** : boolean, default False
  Use log scaling on x axis

**logy** : boolean, default False
  Use log scaling on y axis

**loglog** : boolean, default False
  Use log scaling on both x and y axes

**xticks** : sequence
  Values to use for the xticks

**yticks** : sequence
  Values to use for the yticks

**xlim** [2-tuple/list]

**ylim** [2-tuple/list]

**rot** : int, default None
  Rotation for ticks (xticks for vertical, yticks for horizontal plots)

**fontsize** : int, default None
  Font size for xticks and yticks

**colormap** : str or matplotlib colormap object, default None
  Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** : boolean, optional
  If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots)

**position** : float
  Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**table** : boolean, Series or DataFrame, default False
  If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** : DataFrame, Series, array-like, dict and str
  See *Plotting with Error Bars* for detail.

**xerr** [same types as yerr.]

**stacked** : boolean, default False in line and bar plots, and True in area plot. If True, create stacked plot.
sort_columns : boolean, default False
    Sort column names to determine plot ordering

secondary_y : boolean or sequence, default False
    Whether to plot on the secondary y-axis If a list/tuple, which columns to plot on secondary y-axis

mark_right : boolean, default True
    When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend

**kwds** : keywords
    Options to pass to matplotlib plotting method

Returns
    axes [matplotlib.axes.Axes or numpy.ndarray of them]

Notes

• See matplotlib documentation online for more on this subject

• If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

• If kind = ‘scatter’ and the argument c is the name of a dataframe column, the values of that column are used to color each point.

• If kind = ‘hexbin’, you can control the size of the bins with the gridsize argument. By default, a histogram of the counts around each (x, y) point is computed. You can specify alternative aggregations by passing values to the C and reduce_C_function arguments. C specifies the value at each (x, y) point and reduce_C_function is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std).

pandas.DataFrame.pop

DataFrame.pop(item)
    Return item and drop from frame. Raise KeyError if not found.

Parameters item : str
    Column label to be popped

Returns
    popped [Series]

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
                     ('parrot', 'bird', 24.0),
                     ('lion', 'mammal', 80.5),
                     ('monkey', 'mammal', np.nan)],
                    columns=('name', 'class', 'max_speed'))
```

(continues on next page)
>>> df
   name   class  max_speed
0  falcon   bird     389.0
1  parrot   bird     24.0
2    lion  mammal     80.5
3   monkey  mammal      NaN

>>> df.pop('class')
0   bird
1   bird
2  mammal
3  mammal
Name: class, dtype: object

>>> df
   name  max_speed
0  falcon     389.0
1  parrot     24.0
2    lion     80.5
3   monkey      NaN

pandas.DataFrame.pow

DataFrame.pow(other, axis='columns', level=None, fill_value=None)

Exponential power of dataframe and other, element-wise (binary operator pow).
Equivalent to dataframe ** other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
    For Series input, axis to match Series index on
level : int or name
    Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None
    Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.rpow

Notes

Mismatched indices will be unioned together
Examples

None

pandas.DataFrame.prod

DataFrame.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values for the requested axis

Parameters

axis [[index (0), columns (1)]]

skipna : boolean, default True

Include only numeric data. Not implemented for Series.

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing
into a Series

numeric_only : boolean, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing
into a Series

min_count : int, default 0

The required number of valid values to perform the operation. If fewer than
min_count non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of
an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

Returns

prod [Series or DataFrame (if level specified)]

Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the min_count parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```
pandas.DataFrame.product

DataFrame.product (axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)
Return the product of the values for the requested axis

Parameters
axis [[index (0), columns (1)]]
skipna : boolean, default True
   Exclude NA/null values when computing the result.
level : int or level name, default None
   If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
numeric_only : boolean, default None
   Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
min_count : int, default 0
   The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

Returns
prod [Series or DataFrame (if level specified)]

Examples
By default, the product of an empty or all-NA Series is 1
>>> pd.Series([]).prod()
1.0

This can be controlled with the min_count parameter
>>> pd.Series([]).prod(min_count=1)
nan

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

>>> pd.Series([np.nan]).prod()
1.0

>>> pd.Series([np.nan]).prod(min_count=1)
nan
pandas: powerful Python data analysis toolkit, Release 0.23.3

pandas.DataFrame.quantile

DataFrame.quantile(q=0.5, axis=0, numeric_only=True, interpolation='linear')

Return values at the given quantile over requested axis, a la numpy.percentile.

**Parameters**: q : float or array-like, default 0.5 (50% quantile)

- 0 <= q <= 1, the quantile(s) to compute

axis : {0, 1, ‘index’, ‘columns’} (default 0)

- 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise

numeric_only : boolean, default True

- If False, the quantile of datetime and timedelta data will be computed as well

- New in version 0.18.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:

- linear: \( i + (j - i) \times \text{fraction} \), where fraction is the fractional part of the index surrounded by i and j.

- lower: i.

- higher: j.

- nearest: i or j whichever is nearest.

- midpoint: \( (i + j) / 2 \).

**Returns**: quantiles : Series or DataFrame

- If q is an array, a DataFrame will be returned where the index is q, the columns are the columns of self, and the values are the quantiles.

- If q is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.

**See also**:

pandas.core.window.Rolling.quantile

**Examples**

```python
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
                      columns=['a', 'b'])
>>> df.quantile(.1)
da  1.3
b  3.7
dtype: float64
>>> df.quantile([.1, .5])
da  b
0.1 1.3 3.7
0.5 2.5 55.0
```

Specifying **numeric_only=False** will also compute the quantile of datetime and timedelta data.
```python
>>> df = pd.DataFrame({'A': [1, 2],
                     'B': [pd.Timestamp('2010'),
                          pd.Timestamp('2011')],
                     'C': [pd.Timedelta('1 days'),
                          pd.Timedelta('2 days')]})
>>> df.quantile(0.5, numeric_only=False)
   A    1.5
   B 2010-07-02 12:00:00
   C   1 days 12:00:00
Name: 0.5, dtype: object
```

### pandas.DataFrame.query

`DataFrame.query(expr, inplace=False, **kwargs)`

Query the columns of a frame with a boolean expression.

**Parameters**

- **expr**: string
  
  The query string to evaluate. You can refer to variables in the environment by prefixing them with an ‘@’ character like `@a + b`.

- **inplace**: bool
  
  Whether the query should modify the data in place or return a modified copy

  New in version 0.18.0.

- **kwargs**: dict
  
  See the documentation for `pandas.eval()` for complete details on the keyword arguments accepted by `DataFrame.query()`.

**Returns**

- `q` [DataFrame]

**See also:**

`pandas.eval`, `DataFrame.eval`

**Notes**

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level `pandas.eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the `&` and `|` (bitwise) operators have the precedence of their boolean cousins, `and` and `or`. This is syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`. This enforces the same semantics as evaluation in Python space. Likewise, you can pass `engine='python'` to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using numexpr as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of
the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the `query` documentation in `indexing`.

**Examples**

```python
>>> from numpy.random import randn
>>> from pandas import DataFrame

>>> df = pd.DataFrame(randn(10, 2), columns=list('ab'))
>>> df.query('a > b')
>>> df[df.a > df.b]  # same result as the previous expression
```

### pandas.DataFrame.radd

DataFrame.radd(other, axis='columns', level=None, fill_value=None)

Addition of dataframe and other, element-wise (binary operator radd).

Equivalent to other + dataframe, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series, DataFrame, or constant]
- **axis** [0, 1, ‘index’, ‘columns’]
  - For Series input, axis to match Series index on
- **level** int or name
  - Broadcast across a level, matching Index values on the passed MultiIndex level
- **fill_value** : None or float value, default None
  - Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

**Returns**

- **result** [DataFrame]

**See also:**

- DataFrame.add

**Notes**

Mismatched indices will be unioned together

**Examples**
```python
>>> a = pd.DataFrame([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'],
                   columns=['one'])
>>> a
   one
a  1.0
b  1.0
c  1.0
d  NaN

>>> b = pd.DataFrame(dict(one=[1, np.nan, 1, np.nan],
                         two=[np.nan, 2, np.nan, 2]),
                    index=['a', 'b', 'd', 'e'])
>>> b
   one    two
a  1.0  NaN
b  NaN  2.0
d  1.0  NaN
e  NaN  2.0

>>> a.add(b, fill_value=0)
   one    two
a  2.0  NaN
b  1.0  2.0
c  1.0  NaN
d  1.0  NaN
e  NaN  2.0

pandas.DataFrame.rank

DataFrame.rank(axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)

Compute numerical data ranks (1 through n) along axis. Equal values are assigned a rank that is the
average of the ranks of those values

Parameters axis : {0 or 'index', 1 or 'columns'}, default 0
                   index to direct ranking
method : {'average', 'min', 'max', 'first', 'dense'}
         • average: average rank of group
         • min: lowest rank in group
         • max: highest rank in group
         • first: ranks assigned in order they appear in the array
         • dense: like 'min', but rank always increases by 1 between groups
numeric_only : boolean, default None
               Include only float, int, boolean data. Valid only for DataFrame or Panel objects
na_option : {'keep', 'top', 'bottom'}
            • keep: leave NA values where they are
            • top: smallest rank if ascending
            • bottom: smallest rank if descending
ascending : boolean, default True
False for ranks by high (1) to low (N)

**pct** : boolean, default False
Computes percentage rank of data

**Returns**

**ranks** [same type as caller]

### pandas.DataFrame.rdiv

- **DataFrame.rdiv**(other, axis='columns', level=None, fill_value=None)
  - Floating division of dataframe and other, element-wise (binary operator `rtruediv`).
  - Equivalent to `other / dataframe`, but with support to substitute a fill_value for missing data in one of the inputs.

**Parameters**

- **other** [Series, DataFrame, or constant]
- **axis** : {0, 1, ‘index’, ‘columns’}
  - For Series input, axis to match Series index on
- **level** : int or name
  - Broadcast across a level, matching Index values on the passed MultiIndex level
- **fill_value** : None or float value, default None
  - Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

**Returns**

**result** [DataFrame]

See also:

**Notes**

Mismatched indices will be unioned together

**Examples**

None

### pandas.DataFrame.reindex

- **DataFrame.reindex**(labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill_value=nan, limit=None, tolerance=None)
  - Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False
Parameters

**labels**: array-like, optional

New labels / index to conform the axis specified by ‘axis’ to.

**index, columns**: array-like, optional (should be specified using keywords)

New labels / index to conform to. Preferably an Index object to avoid duplicating data

**axis**: int or str, optional

Axis to target. Can be either the axis name (‘index’, ‘columns’) or number (0, 1).

**method**: {None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}, optional

Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- default: don’t fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy**: boolean, default True

Return a new object, even if the passed indexes are the same

**level**: int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

**fill_value**: scalar, default np.NaN

Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**limit**: int, default None

Maximum number of consecutive elements to forward or backward fill

**tolerance**: optional

Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \min(|\text{index}[\text{indexer}] - \text{target}|) \leq \text{tolerance} \). Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

**Returns**

reindexed [DataFrame]

**Examples**

**DataFrame.reindex** supports two calling conventions

- (index=index_labels, columns=column_labels, ...)
We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
    ... 'http_status': [200, 200, 404, 404, 301],
    ... 'response_time': [0.04, 0.02, 0.07, 0.08, 1.0],
    ...}, index=index)
>>> df
http_status  response_time
Firefox         200         0.04
Chrome          200         0.02
Safari      404         0.07
IE10           404         0.08
Konqueror        301        1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index= ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10', 'Chrome']
>>> df.reindex(new_index)
http_status  response_time
Safari        404.0        0.07
Iceweasel       NaN          NaN
Comodo Dragon   NaN          NaN
IE10           404.0        0.08
Chrome          200.0        0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
http_status  response_time
Safari         404         0.07
Iceweasel       0          0.00
Comodo Dragon   0          0.00
IE10           404         0.08
Chrome          200        0.02
```

```python
>>> df.reindex(new_index, fill_value='missing')
http_status  response_time
Safari        404         0.07
Iceweasel    missing    missing
Comodo Dragon missing    missing
IE10           404         0.08
Chrome          200        0.02
```

We can also reindex the columns.

```python
>>> df.reindex(columns=['http_status', 'user_agent'])
http_status  user_agent
Firefox        200          NaN
Chrome        200          NaN
```

(continues on next page)
Or we can use “axis-style” keyword arguments

```py
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
   http_status  user_agent
Firefox  200          NaN
Chrome  200          NaN
Safari  404          NaN
IE10    404          NaN
Konqueror  301      NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```py
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({'prices': [100, 101, np.nan, 100, 89, 88]},
...                     index=date_index)
>>> df2
         prices
2010-01-01  100
2010-01-02  101
2010-01-03  NaN
2010-01-04  100
2010-01-05  89
2010-01-06  88
```

Suppose we decide to expand the dataframe to cover a wider date range.

```py
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
         prices
2009-12-29  NaN
2009-12-30  NaN
2009-12-31  NaN
2010-01-01  100
2010-01-02  101
2010-01-03  NaN
2010-01-04  100
2010-01-05  89
2010-01-06  88
2010-01-07  NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with `NaN`. If desired, we can fill in the missing values using one of several options.

For example, to backpropagate the last valid value to fill the `NaN` values, pass `bfill` as an argument to the `method` keyword.

```py
>>> df2.reindex(date_index2, method='bfill')
         prices
2009-12-29  100
2009-12-30  100
2009-12-31  100
2010-01-01  100
```

(continues on next page)
Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method. See the user guide for more.

**pandas.DataFrame.reindex_axis**

DataFrame.reindex_axis(labels, axis=0, method=None, level=None, copy=True, limit=None, fill_value=np.nan)  
Conform input object to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False

**Parameters**  
labels : array-like  
New labels / index to conform to. Preferably an Index object to avoid duplicating data

axis [[0 or ‘index’, 1 or ‘columns’]]

Method to use for filling holes in reindexed DataFrame:
• default: don’t fill gaps
• pad / ffill: propagate last valid observation forward to next valid
• backfill / bfill: use next valid observation to fill gap
• nearest: use nearest valid observations to fill gap

copy : boolean, default True  
Return a new object, even if the passed indexes are the same

level : int or name  
Broadcast across a level, matching Index values on the passed MultiIndex level

limit : int, default None  
Maximum number of consecutive elements to forward or backward fill

tolerance : optional  
Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list,
tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

**Returns**

reindexed [DataFrame]

**See also:**

reindex, reindex_like

**Examples**

```python
>>> df.reindex_axis(['A', 'B', 'C'], axis=1)
```

### pandas.DataFrame.reindex_like

**DataFrame.reindex_like** *(other, method=None, copy=True, limit=None, tolerance=None)*

Return an object with matching indices to myself.

**Parameters**

- **other** [Object]
- **method** [string or None]
- **copy** [boolean, default True]
- **limit** : int, default None
  
  Maximum number of consecutive labels to fill for inexact matches.
- **tolerance** : optional
  
  Maximum distance between labels of the other object and this object for inexact matches. Can be list-like.

New in version 0.21.0: (list-like tolerance)

**Returns**

reindexed [same as input]

**Notes**

Like calling s.reindex(index=other.index, columns=other.columns, method=...)

### pandas.DataFrame.rename

**DataFrame.rename** *(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False, level=None)*

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

See the user guide for more.
Parameters `mapper, index, columns` : dict-like or function, optional

dict-like or functions transformations to apply to that axis’ values. Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and `columns`.

`axis` : int or str, optional

Axis to target with `mapper`. Can be either the axis name (‘index’, ‘columns’) or number (0, 1). The default is ‘index’.

`copy` : boolean, default True

Also copy underlying data

`inplace` : boolean, default False

Whether to return a new DataFrame. If True then value of copy is ignored.

`level` : int or level name, default None

In case of a MultiIndex, only rename labels in the specified level.

Returns

`renamed` [DataFrame]

See also:

`pandas.DataFrame.rename_axis`

Examples

DataFrame.rename supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

We highly recommend using keyword arguments to clarify your intent.

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(index=str, columns={"A": "a", "B": "c"})
   a  c
0  1  4
1  2  5
2  3  6
```

```python
>>> df.rename(index=str, columns={"A": "a", "C": "c"})
   a  b
0  1  4
1  2  5
2  3  6
```

Using axis-style parameters

```python
>>> df.rename(str.lower, axis='columns')
   a  b
0  1  4
1  2  5
2  3  6
```
>>> df.rename({1: 2, 2: 4}, axis='index')

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.rename_axis**

DataFrame.rename_axis(mapper, axis=0, copy=True, inplace=False)

Alter the name of the index or columns.

**Parameters**

- **mapper**: scalar, list-like, optional
  - Value to set as the axis name attribute.

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - The index or the name of the axis.

- **copy**: boolean, default True
  - Also copy underlying data.

- **inplace**: boolean, default False
  - Modifies the object directly, instead of creating a new Series or DataFrame.

**Returns**

renamed : Series, DataFrame, or None

The same type as the caller or None if inplace is True.

**See also**

- pandas.Series.rename Alter Series index labels or name
- pandas.DataFrame.rename Alter DataFrame index labels or name
- pandas.Index.rename Set new names on index

**Notes**

Prior to version 0.21.0, rename_axis could also be used to change the axis labels by passing a mapping or scalar. This behavior is deprecated and will be removed in a future version. Use rename instead.

**Examples**

**Series**

```python
>>> s = pd.Series([1, 2, 3])
>>> s.rename_axis("foo")
foo
<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
```

**Dataframe**

```python
```
```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})
>>> df.rename_axis('foo')
   A  B
foo
  0 1 4
  1 2 5
  2 3 6

>>> df.rename_axis('bar', axis='columns')
   bar  A  B
   0 1 4
   1 2 5
   2 3 6
```

**pandas.DataFrame.reorder_levels**

Dataframe.reorder_levels(order, axis=0)

Rearranges index levels using input order. May not drop or duplicate levels.

- **Parameters**
  - `order`: list of int or list of str
    List representing new level order. Reference level by number (position) or by key (label).
  - `axis`: int
    Where to reorder levels.

- **Returns**
  - type of caller (new object)

**pandas.DataFrame.replace**

Dataframe.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')

Replace values given in `to_replace` with `value`.

Values of the DataFrame are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

- **Parameters**
  - `to_replace`: str, regex, list, dict, Series, int, float, or None
    How to find the values that will be replaced.
    - numeric, str or regex:
      - numeric: numeric values equal to `to_replace` will be replaced with `value`
      - str: string exactly matching `to_replace` will be replaced with `value`
      - regex: regexs matching `to_replace` will be replaced with `value`
    - list of str, regex, or numeric:
      - First, if `to_replace` and `value` are both lists, they must be the same length.
      - Second, if regex=True then all of the strings in both lists will be interpreted as regexs otherwise they will match directly. This doesn’t matter
much for value since there are only a few possible substitution regexes you can use.

- str, regex and numeric rules apply as above.

• dict:

  - Dicts can be used to specify different replacement values for different existing values. For example, \{'a\': 'b', 'y': 'z'\} replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the value parameter should be None.

  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, \{'a\': 1, 'b': 'z'\} looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in value. The value parameter should not be None in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.

  - For a DataFrame nested dictionaries, e.g., \{'a': {'b': np.nan}\}, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The value parameter should be None to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) cannot be regular expressions.

• None:

  - This means that the regex argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If value is also None then this must be a nested dictionary or Series.

See the examples section for examples of each of these.

value : scalar, dict, list, str, regex, default None

Value to replace any values matching to_replace with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace : boolean, default False

If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit : int, default None

Maximum size gap to forward or backward fill.

regex : bool or same types as to_replace, default False

Whether to interpret to_replace and/or value as regular expressions. If this is True then to_replace must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case to_replace must be None.

method : \{'pad’, ‘ffill’, ‘bfill’, None\}

The method to use when for replacement, when to_replace is a scalar, list or tuple and value is None.

Changed in version 0.23.0: Added to DataFrame.

Returns DataFrame
Object after replacement.

Raises `AssertionError`

- If `regex` is not a `bool` and `to_replace` is not `None`.

Type`Error`

- If `to_replace` is a `dict` and `value` is not a `list, dict, ndarray, or Series`
- If `to_replace` is `None` and `regex` is not compilable into a regular expression or is a list, `dict, ndarray, or Series`
- When replacing multiple `bool` or `datetime64` objects and the arguments to `to_replace` does not match the type of the value being replaced

Value`Error`

- If a `list` or an `ndarray` is passed to `to_replace` and `value` but they are not the same length.

See also:

`DataFrame.fillna` Fill NA values
`DataFrame.where` Replace values based on boolean condition
`Series.str.replace` Simple string replacement.

Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.
- This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the `to_replace` value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar ‘to_replace‘ and ‘value’

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0   5
1   1
2   2
3   3
4   4
dtype: int64
```
```python
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
... 'B': [5, 6, 7, 8, 9],
... 'C': ['a', 'b', 'c', 'd', 'e']})
```

```
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

**List-like ‘to_replace’**

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0  0
1  3
2  3
3  3
4  4
dtype: int64
```

**dict-like ‘to_replace’**

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0  100  5  a
1  100  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0  100  100  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

---

1868 Chapter 34. API Reference
Regular expression ‘to_replace’

```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1   foo new
2  bait xyz
```

```python
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1   foo new
2  bait xyz
```

```python
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1   foo new
2  bait xyz
```

```python
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1   new new
2  bait xyz
```

Note that when replacing multiple bool or datetime64 objects, the data types in the to_replace parameter must match the data type of the value being replaced:

```python
>>> df = pd.DataFrame({'A': [True, False, True],
                     'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False})  # raises
Traceback (most recent call last):
  ...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a TypeError because one of the dict keys is not of the correct type for replacement.

Compare the behavior of s.replace({"a": None}) and s.replace('a', None) to understand the peculiarities of the to_replace parameter:
When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the value parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0    10
1    None
2    None
3     b
4    None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default 'pad') to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad'):

```python
>>> s.replace('a', None)
0   10
1  10
2  10
3     b
4     b
dtype: object
```

### pandas.DataFrame.resample

DataFrame.resample(rule, how=None, axis=0, fill_method=None, closed=None, label=None, convention='start', kind=None, loffset=None, limit=None, base=0, on=None, level=None)

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or pass datetime-like values to the on or level keyword.

**Parameters**

- `rule` : string
  
  the offset string or object representing target conversion

- `axis` : [int, optional, default 0]

- `closed` : {'right', 'left'}
  
  Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

- `label` : {'right', 'left'}
  
  Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

- `convention` : {'start', 'end', 's', 'e'}
  
  For PeriodIndex only, controls whether to use the start or end of `rule`

---

1870 Chapter 34. API Reference
kind: {'timestamp', 'period'}, optional
    Pass 'timestamp' to convert the resulting index to a DateTimeIndex or 'period' to convert it to a PeriodIndex. By default the input representation is retained.

loffset : timedelta
    Adjust the resampled time labels

base : int, default 0
    For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0

on : string, optional
    For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.
    New in version 0.19.0.

level : string or int, optional
    For a MultiIndex, level (name or number) to use for resampling. Level must be datetime-like.
    New in version 0.19.0.

Returns

Resampler object

See also:

groupby  Group by mapping, function, label, or list of labels.

Notes

See the user guide for more.

To learn more about the offset strings, please see this link.

Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
```
(continues on next page)
Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket **2000-01-01 00:03:00** contains the value 3, but the summed value in the resampled bucket with the label **2000-01-01 00:03:00** does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5]  # select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the **pad** method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the **bfill** method.
Pass a custom function via `apply`

```python
>>> def custom_resampler(array_like):
...     return np.sum(array_like)+5
```  
```python
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00     8
2000-01-01 00:03:00    17
2000-01-01 00:06:00    26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of `rule`.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01', freq='A', periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
```

Resample by month using 'start' `convention`. Values are assigned to the first month of the period.

```python
>>> s.resample('M', convention='start').asfreq().head()
2012-01  1.0
2012-02  NaN
2012-03  NaN
2012-04  NaN
2012-05  NaN
Freq: M, dtype: float64
```

Resample by month using 'end' `convention`. Values are assigned to the last month of the period.

```python
>>> s.resample('M', convention='end').asfreq()
2012-12  1.0
2013-01  NaN
2013-02  NaN
2013-03  NaN
2013-04  NaN
2013-05  NaN
2013-06  NaN
2013-07  NaN
2013-08  NaN
2013-09  NaN
2013-10  NaN
2013-11  NaN
2013-12  2.0
Freq: M, dtype: float64
```
For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> df = pd.DataFrame(data=9*[range(4)], columns=['a', 'b', 'c', 'd'])
>>> df['time'] = pd.date_range('1/1/2000', periods=9, freq='T')
>>> df.resample('3T', on='time').sum()
   a   b   c   d
time
2000-01-01 00:00:00 0   3   6   9
2000-01-01 00:03:00 0   3   6   9
2000-01-01 00:06:00 0   3   6   9
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on level the resampling needs to take place.

```python
>>> time = pd.date_range('1/1/2000', periods=5, freq='T')
>>> df2 = pd.DataFrame(data=10*[range(4)],
                      columns=['a', 'b', 'c', 'd'],
                      index=pd.MultiIndex.from_product([time, [1, 2]])
                     )
>>> df2.resample('3T', level=0).sum()
   a   b   c   d
2000-01-01 00:00:00 0   6  12  18
2000-01-01 00:03:00 0   4   8  12
```

### pandas.DataFrame.reset_index

DataFrame. **reset_index**(level=None, drop=False, inplace=False, col_level=0, col_fill="")

For DataFrame with multi-level index, return new DataFrame with labeling information in the columns under the index names, defaulting to ‘level_0’, ‘level_1’, etc. if any are None. For a standard index, the index name will be used (if set), otherwise a default ‘index’ or ‘level_0’ (if ‘index’ is already taken) will be used.

**Parameters**

- **level** : int, str, tuple, or list, default None
  
  Only remove the given levels from the index. Removes all levels by default

- **drop** : boolean, default False
  
  Do not try to insert index into dataframe columns. This resets the index to the default integer index.

- **inplace** : boolean, default False
  
  Modify the DataFrame in place (do not create a new object)

- **col_level** : int or str, default 0
  
  If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.

- **col_fill** : object, default 
  
  If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

**Returns**

- **resetted** [DataFrame]
Examples

```python
>>> df = pd.DataFrame([('bird', 389.0),
...                   ('bird', 24.0),
...                   ('mammal', 80.5),
...                   ('mammal', np.nan)],
...                   index=['falcon', 'parrot', 'lion', 'monkey'],
...                   columns=('class', 'max_speed'))
>>> df
   class  max_speed
falcon    bird    389.0
parrot    bird     24.0
lion      mammal   80.5
monkey    mammal   NaN

When we reset the index, the old index is added as a column, and a new sequential index is used:

```python
>>> df.reset_index()
   index    class  max_speed
0   falcon    bird    389.0
1   parrot    bird     24.0
2   lion      mammal   80.5
3   monkey    mammal   NaN

We can use the drop parameter to avoid the old index being added as a column:

```python
>>> df.reset_index(drop=True)
   class  max_speed
0    bird    389.0
1    bird     24.0
2  mammal    80.5
3  mammal     NaN

You can also use reset_index with MultiIndex.

```python
>>> index = pd.MultiIndex.from_tuples([('bird', 'falcon'),
...                                          ('bird', 'parrot'),
...                                          ('mammal', 'lion'),
...                                          ('mammal', 'monkey')],
...                                          names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples([('speed', 'max'),
...                                          ('species', 'type')])
>>> df = pd.DataFrame([(389.0, 'fly'),
...                     ( 24.0, 'fly'),
...                     ( 80.5, 'run'),
...                     (np.nan, 'jump')],
...                     index=index,
...                     columns=columns)
>>> df
    speed  species   max  type
  class name
bird  falcon  389.0    fly
  parrot  24.0    fly
mammal  lion  80.5    run
  monkey  NaN    jump

If the index has multiple levels, we can reset a subset of them:
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> df.reset_index(level='class')
   class  speed  species
      max   type
    name
      falcon   bird   389.0   fly
       parrot   bird    24.0   fly
        lion  mammal    80.5   run
      monkey  mammal   NaN    jump
```

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```python
>>> df.reset_index(level='class', col_level=1)
   speed  species
      class  max   type
    name
      falcon   bird   389.0   fly
       parrot   bird    24.0   fly
        lion  mammal    80.5   run
      monkey  mammal   NaN    jump
```

When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='species')
      species  speed  species
         class   max   type
    name
      falcon   bird   389.0   fly
       parrot   bird    24.0   fly
        lion  mammal    80.5   run
      monkey  mammal   NaN    jump
```

If we specify a nonexistent level for `col_fill`, it is created:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='genus')
      genus  speed  species
         class   max   type
    name
      falcon   bird   389.0   fly
       parrot   bird    24.0   fly
        lion  mammal    80.5   run
      monkey  mammal   NaN    jump
```

**pandas.DataFrame.rfloordiv**

`DataFrame.rfloordiv(other, axis='columns', level=None, fill_value=None)`

Integer division of dataframe and other, element-wise (binary operator `rfloordiv`).

Equivalent to `other // dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- `other` [Series, DataFrame, or constant]
- `axis` [0, 1, ‘index’, ‘columns’]

  For Series input, axis to match Series index on
level : int or name
  Broadcast across a level, matching Index values on the passed MultiIndex level

fill_value : None or float value, default None
  Fill existing missing (NaN) values, and any new element needed for successful
  DataFrame alignment, with this value before computation. If data in both corre-
  sponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.floordiv

Notes

Mismatched indices will be unioned together

Examples

None

pandas.DataFrame.rmod

DataFrame.rmod(other, axis='columns', level=None, fill_value=None)
Modulo of dataframe and other, element-wise (binary operator rmod).
Equivalent to other % dataframe, but with support to substitute a fill_value for missing data in one
of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
  For Series input, axis to match Series index on
level : int or name
  Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None
  Fill existing missing (NaN) values, and any new element needed for successful
  DataFrame alignment, with this value before computation. If data in both corre-
  sponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.mod
Notes

Mismatched indices will be unioned together

Examples

None

pandas.DataFrame.rmul

Dataframe.rmul(other, axis=‘columns’, level=None, fill_value=None)

Multiplication of dataframe and other, element-wise (binary operator rmul).
Equivalent to other * dataframe, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
For Series input, axis to match Series index on
level : int or name
Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None
Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

result [DataFrame]

See also:

DataFrame.mul

Notes

Mismatched indices will be unioned together

Examples

None

pandas.DataFrame.rolling

Dataframe.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)

Provides rolling window calculations.
New in version 0.18.0.

**Parameters**

- `window`: int, or offset
  
  Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.
  
  If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. This is new in 0.19.0

- `min_periods`: int, default None
  
  Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, this will default to 1.

- `center`: boolean, default False
  
  Set the labels at the center of the window.

- `win_type`: string, default None
  
  Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

- `on`: string, optional
  
  For a DataFrame, column on which to calculate the rolling window, rather than the index

- `closed`: string, default None
  
  Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. For offset-based windows, it defaults to ‘right’. For fixed windows, defaults to ‘both’. Remaining cases not implemented for fixed windows.

  New in version 0.20.0.

- `axis`: [int or string, default 0]

**Returns**

- a Window or Rolling sub-classed for the particular operation

**See also:**

- `expanding`: Provides expanding transformations.
- `ewm`: Provides exponential weighted functions

**Notes**

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see this link.

The recognized `win_types` are:

- `boxcar`
- `triang`
- `blackman`
• hamming
• bartlett
• parzen
• bohman
• blackmanharris
• nuttall
• barthann
• kaiser (needs beta)
• gaussian (needs std)
• general_gaussian (needs power, width)
• slepian (needs width).

If win_type=None all points are evenly weighted. To learn more about different window types see scipy.signal window functions.

**Examples**

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

Rolling sum with a window length of 2, using the 'triang' window type.
```n
```python
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  1.0
2  2.5
3  NaN
4  NaN

Rolling sum with a window length of 2, min_periods defaults to the window length.

```python
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN

Same as above, but explicitly set the min_periods
```
A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4],
...                    'A': [np.nan, 2, np.nan, np.nan, np.nan]},
...                    index=[pd.Timestamp('20130101 09:00:00'),
...                          pd.Timestamp('20130101 09:00:02'),
...                          pd.Timestamp('20130101 09:00:03'),
...                          pd.Timestamp('20130101 09:00:05'),
...                          pd.Timestamp('20130101 09:00:06')])
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```python
>>> df.rolling('2s').sum()  
B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

**pandas.DataFrame.round**

DataFrame.round(*decimals=0, **kwargs*)

Round a DataFrame to a variable number of decimal places.

**Parameters**

- **decimals**: int, dict, Series
  
  Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if decimals is a dict-like, or in the index if decimals is a Series. Any columns not included in decimals will be left as is. Elements of decimals which are not columns of the input will be ignored.

**Returns**

DataFrame object

**See also**

numpy.around, Series.round
Examples

```python
>>> df = pd.DataFrame(np.random.random([3, 3]),
                    columns=['A', 'B', 'C'], index=['first', 'second', 'third'])
>>> df
A    B    C
first 0.028208 0.992815 0.173891
second 0.038683 0.645646 0.577595
third 0.877076 0.149370 0.491027
>>> df.round(2)
A  B  C
first 0.03 0.99 0.17
second 0.04 0.65 0.58
third 0.88 0.15 0.49
>>> df.round({'A': 1, 'C': 2})
A   B   C
first 0.0  1.0 0.17
second 0.0  1.0 0.58
third 0.9  1.0 0.49
>>> decimals = pd.Series([1, 0, 2], index=['A', 'B', 'C'])
>>> df.round(decimals)
A   B   C
first 0.0  1.0 0.17
second 0.0  1.0 0.58
third 0.9  1.0 0.49
```

`pandas.DataFrame.rpow`

DataFrame.rpow(other, axis='columns', level=None, fill_value=None)

Exponential power of dataframe and other, element-wise (binary operator rpow).

Equivalent to `other ** dataframe`, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]

axis : {0, 1, ‘index’, ‘columns’}

For Series input, axis to match Series index on

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

fill_value : None or float value, default None

Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

`DataFrame.pow`
Notes

Mismatched indices will be unioned together

Examples

None

```
pandas.DataFrame.rsub

DataFrame.rsub(other, axis='columns', level=None, fill_value=None)
Subtraction of dataframe and other, element-wise (binary operator rsub).
Equivalent to other - dataframe, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
For Series input, axis to match Series index on
level : int or name
Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None
Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:
DataFrame.sub
```

Notes

Mismatched indices will be unioned together

Examples

```
>>> a = pd.DataFrame([2, 1, 1, np.nan], index=['a', 'b', 'c', 'd'],
                   columns=['one'])
...                      
>>> a
    one
  a  2.0
  b  1.0
  c  1.0
  d  NaN

(continues on next page)
>>> b = pd.DataFrame(dict(one=[1, np.nan, 1, np.nan],
...                        two=[3, 2, np.nan, 2]),
...                        index=['a', 'b', 'd', 'e'])
>>> b
    one  two
a 1.0  3.0
b NaN  2.0
d 1.0  NaN
e NaN  2.0

>>> a.sub(b, fill_value=0)
    one   two
a 1.0  -3.0
b 1.0  -2.0
c 1.0   NaN
d -1.0  NaN
e   NaN -2.0

pandas.DataFrame.rtruediv

DataFrame.rtruediv(other, axis='columns', level=None, fill_value=None)

Floating division of dataframe and other, element-wise (binary operator rtruediv).

Equivalent to other / dataframe, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]

axis : {0, 1, ‘index’, ‘columns’}

For Series input, axis to match Series index on

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

fill_value : None or float value, default None

Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.truediv

Notes

Mismatched indices will be unioned together
Examples

None

pandas.DataFrame.sample

DataFrame.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

Parameters

- **n**: int, optional
  Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.

- **frac**: float, optional
  Fraction of axis items to return. Cannot be used with n.

- **replace**: boolean, optional
  Sample with or without replacement. Default = False.

- **weights**: str or ndarray-like, optional
  Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. inf and -inf values not allowed.

- **random_state**: int or numpy.random.RandomState, optional
  Seed for the random number generator (if int), or numpy RandomState object.

- **axis**: int or string, optional
  Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames, 1 for Panels).

Returns

A new object of same type as caller.

Examples

Generate an example Series and DataFrame:

```python
>>> s = pd.Series(np.random.randn(50))
>>> s.head()
0  -0.038497
1   1.820773
2  -0.972766
3  -1.598270
```

(continues on next page)
Next extract a random sample from both of these objects...

3 random elements from the Series:

```
>>> s.sample(n=3)
27    -0.994689
55    -1.049016
67    -0.224565
dtype: float64
```

And a random 10% of the DataFrame with replacement:

```
>>> df.sample(frac=0.1, replace=True)
   A          B          C          D
35  1.981780  0.142106  1.817165  -0.290805
49 -1.336199 -0.448634 -0.789640  0.217116
40  0.823173 -0.078816  1.009536  1.015108
15  1.421154 -0.055301 -1.922594  0.019696
  6 -0.148339  0.832938  1.787600 -1.383767
```

You can use random state for reproducibility:

```
>>> df.sample(random_state=1)
    A          B          C          D
37 -2.027662  0.103611  0.237496  -0.165867
43 -0.259323 -0.583426  1.516140  -0.479118
12 -1.686325 -0.579510  0.985195  -0.460286
  8  1.167946  0.429082  1.215742  -1.636041
  9  1.197475 -0.864188  1.554031  -1.505264
```

---

**DataFrame.select**

DataFrame.select (crit, axis=0)

Return data corresponding to axis labels matching criteria

Deprecated since version 0.21.0: Use df.loc[df.index.map(crit)] to select via labels

Parameters  
crit : function
  
  To be called on each index (label). Should return True or False

  axis [int]

Returns

  selection [type of caller]
pandas.DataFrame.select_dtypes

DataFrame.select_dtypes(include=None, exclude=None)

Return a subset of the DataFrame’s columns based on the column dtypes.

Parameters

- **include, exclude**: scalar or list-like

  A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

Returns

- **subset**: DataFrame

  The subset of the frame including the dtypes in include and excluding the dtypes in exclude.

Raises

- **ValueError**

  - If both of include and exclude are empty
  - If include and exclude have overlapping elements
  - If any kind of string dtype is passed in.

Notes

- To select all numeric types, use np.number or 'number'
- To select strings you must use the object dtype, but note that this will return all object dtype columns
- See the numpy dtype hierarchy
- To select datetimes, use np.datetime64, 'datetime' or 'datetime64'
- To select timedeltas, use np.timedelta64, 'timedelta' or 'timedelta64'
- To select Pandas categorical dtypes, use 'category'
- To select Pandas datetimetz dtypes, use 'datetimetz' (new in 0.20.0) or 'datetime64[ns, tz]'

Examples

```python
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
   a   b  c
0  1  True  1.0
1  2  False  2.0
2  1  True  1.0
3  2  False  2.0
4  1  True  1.0
5  2  False  2.0

>>> df.select_dtypes(include='bool')
   b
0  True
```
1 False
2 True
3 False
4 True
5 False

```python
>>> df.select_dtypes(include=['float64'])
c
0 1.0
1 2.0
2 1.0
3 2.0
4 1.0
5 2.0

>>> df.select_dtypes(exclude=['int'])
 b c
0 True 1.0
1 False 2.0
2 True 1.0
3 False 2.0
4 True 1.0
5 False 2.0
```

**pandas.DataFrame.sem**

DataFrame.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased standard error of the mean over requested axis. Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- **axis**: {index (0), columns (1)}
- **skipna**: boolean, default True
  
  Exclude NA/null values. If an entire row/column is NA, the result will be NA
- **level**: int or level name, default None

  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
- **ddof**: int, default 1

  Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only**: boolean, default None

  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **sem**: [Series or DataFrame (if level specified)]
**pandas.DataFrame.set_axis**

DataFrame.set_axis (labels, axis=0, inplace=None)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now `labels` and `axis`, consistent with the rest of pandas API. Previously, the `axis` and `labels` arguments were respectively the first and second positional arguments.

**Parameters**

- **labels**: list-like, Index
  - The values for the new index.

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

- **inplace**: boolean, default None
  - Whether to return a new `%{klass}s instance.

**Warning**: inplace=None currently falls back to True, but in a future version, will default to False. Use inplace=True explicitly rather than relying on the default.

**Returns**

- **renamed**: `%{klass}s or None
  - An object of same type as caller if inplace=False, None otherwise.

**See also:**

* pandas.DataFrame.rename_axis: Alter the name of the index or columns.

**Examples**

**Series**

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0  1
1  2
2  3
dtype: int64
```

```python
>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a  1
b  2
c  3
dtype: int64
```

The original object is not modified.

```python
>>> s
0  1
1  2
```
2 3
dtype: int64

**DataFrame**

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```python
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>b</td>
<td>2</td>
</tr>
<tr>
<td>c</td>
<td>3</td>
</tr>
</tbody>
</table>

Change the column labels.

```python
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
```

<table>
<thead>
<tr>
<th>I</th>
<th>II</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Now, update the labels inplace.

```python
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
```

<table>
<thead>
<tr>
<th>i</th>
<th>ii</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.set_index**

`DataFrame.set_index(keys, drop=True, append=False, inplace=False, verify_integrity=False)`

Set the DataFrame index (row labels) using one or more existing columns. By default yields a new object.

**Parameters**

- **keys** [column label or list of column labels / arrays]
- **drop** : boolean, default True
  Delete columns to be used as the new index
- **append** : boolean, default False
  Whether to append columns to existing index
- **inplace** : boolean, default False
  Modify the DataFrame in place (do not create a new object)
- **verify_integrity** : boolean, default False
  Check the new index for duplicates. Otherwise defer the check until necessary.

**Returns**
dataframe [DataFrame]

Examples

```python
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
    ... 'year': [2012, 2014, 2013, 2014],
    ... 'sale': [55, 40, 84, 31]})

   month  sale  year
0    1    55  2012
1    4    40  2014
2    7    84  2013
3   10    31  2014

Set the index to become the ‘month’ column:

```python
>>> df.set_index('month')

   sale  year
month
1    55  2012
4    40  2014
7    84  2013
10   31  2014

Create a multi-index using columns ‘year’ and ‘month’:

```python
>>> df.set_index(['year', 'month'])

   sale
year month
2012   1    55
2014   4    40
2013   7    84
2014  10    31

Create a multi-index using a set of values and a column:

```python
>>> df.set_index(([1, 2, 3, 4], 'year'))

   month  sale
year
1  2012   1    55
2  2014   4    40
3  2013   7    84
4  2014  10    31
```

pandas.DataFrame.set_value

DataFrame.set_value(index, col, value, takeable=False)

Put single value at passed column and index

Deprecated since version 0.21.0: Use .at[] or .iat[] accessors instead.

Parameters

- **index** [row label]
- **col** [column label]
- **value** [scalar value]
**pandas.DataFrame.shift**

Dataframe.shift(periods=1, freq=None, axis=0)

Shift index by desired number of periods with an optional time freq

**Parameters**

- **periods**: int
  Number of periods to move, can be positive or negative

- **freq**: DateOffset, timedelta, or time rule string, optional
  Increment to use from the tseries module or time rule (e.g. ‘EOM’). See Notes.

- **axis**: [0 or ‘index’, 1 or ‘columns’]

**Returns**

- **shifted**: [DataFrame]

**Notes**

If freq is specified then the index values are shifted but the data is not realigned. That is, use freq if you would like to extend the index when shifting and preserve the original data.

**pandas.DataFrame.skew**

Dataframe.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased skew over requested axis Normalized by N-1

**Parameters**

- **axis**: [index (0), columns (1)]

- **skipna**: boolean, default True
  Exclude NA/null values when computing the result.

- **level**: int or level name, default None
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

- **numeric_only**: boolean, default None
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **skew**: [Series or DataFrame (if level specified)]
**pandas.DataFrame.slice_shift**

DataFrame.slice_shift(periods=1, axis=0)

Equivalent to shift without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

**Parameters**
- **periods** : int
  Number of periods to move, can be positive or negative

**Returns**
- **shifted** [same type as caller]

**Notes**

While the slice_shift is faster than shift, you may pay for it later during alignment.

**pandas.DataFrame.sort_index**

DataFrame.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, by=None)

Sort object by labels (along an axis)

**Parameters**
- **axis** [index, columns to direct sorting]
- **level** : int or level name or list of ints or list of level names
  if not None, sort on values in specified index level(s)
- **ascending** : boolean, default True
  Sort ascending vs. descending
- **inplace** : bool, default False
  if True, perform operation in-place
- **kind** : {'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'
  Choice of sorting algorithm. See also ndarray.np.sort for more information.
  mergesort is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** : {'first', 'last'}, default 'last'
  first puts NaNs at the beginning, last puts NaNs at the end. Not implemented for MultiIndex.
- **sort_remaining** : bool, default True
  if true and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level

**Returns**
- **sorted_obj** [DataFrame]
pandas.DataFrame.sort_values

DataFrame.sort_values(by, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last')

Sort by the values along either axis

Parameters

by : str or list of str
    Name or list of names to sort by.
    • if `axis` is 0 or 'index' then `by` may contain index levels and/or column labels
    • if `axis` is 1 or 'columns' then `by` may contain column levels and/or index labels

    Changed in version 0.23.0: Allow specifying index or column level names.

axis : {0 or 'index', 1 or 'columns'}, default 0
    Axis to be sorted

ascending : bool or list of bool, default True
    Sort ascending vs. descending. Specify list for multiple sort orders. If this is a
    list of bools, must match the length of the by.

inplace : bool, default False
    if True, perform operation in-place

kind : {'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'
    Choice of sorting algorithm. See also ndarray.np.sort for more information.
    mergesort is the only stable algorithm. For DataFrames, this option is only ap-
    plied when sorting on a single column or label.

na_position : {'first', 'last'}, default 'last'
    first puts NaNs at the beginning, last puts NaNs at the end

Returns

sorted_obj [DataFrame]

Examples

```python
>>> df = pd.DataFrame({
...     'col1' : ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2' : [2, 1, 9, 8, 7, 4],
...     'col3' : [0, 1, 9, 4, 2, 3],
... })
```
```python
>>> df
  col1  col2  col3
0   A     2     0
1   A     1     1
2   B     9     9
3   NaN   8     4
4   D     7     2
5   C     4     3
```

Sort by col1
>>> df.sort_values(by=['col1'])
col1  col2  col3
0    A    2    0
1    A    1    1
2    B    9    9
5    C    4    3
4    D    7    2
3   NaN    8    4

Sort by multiple columns

>>> df.sort_values(by=['col1', 'col2'])
col1  col2  col3
1    A    1    1
0    A    2    0
2    B    9    9
5    C    4    3
4    D    7    2
3   NaN    8    4

Sort Descending

>>> df.sort_values(by='col1', ascending=False)
col1  col2  col3
4    D    7    2
5    C    4    3
2    B    9    9
0    A    2    0
1    A    1    1
3   NaN    8    4

Putting NAs first

>>> df.sort_values(by='col1', ascending=False, na_position='first')
col1  col2  col3
3   NaN    8    4
4    D    7    2
5    C    4    3
2    B    9    9
0    A    2    0
1    A    1    1

pandas.DataFrame.sortlevel

DataFrame.sortlevel (level=0, axis=0, ascending=True, inplace=False, sort_remaining=True)
Sort multilevel index by chosen axis and primary level. Data will be lexicographically sorted by the chosen level followed by the other levels (in order).
Depreciated since version 0.20.0: Use DataFrame.sort_index()

Parameters

level [int]
axis [{0 or ‘index’, 1 or ‘columns’}, default 0]
ascending [boolean, default True]
inplace : boolean, default False
    Sort the DataFrame without creating a new instance

sort_remaining : boolean, default True
    Sort by the other levels too.

Returns
    sorted [DataFrame]

See also:
    DataFrame.sort_index

pandas.DataFrame.squeeze

DataFrame.squeeze(axis=None)
    Squeeze length 1 dimensions.

Parameters axis : None, integer or string axis name, optional
    The axis to squeeze if 1-sized.

New in version 0.20.0.

Returns
    scalar if 1-sized, else original object

pandas.DataFrame.stack

DataFrame.stack(level=-1, dropna=True)
    Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

The new index levels are sorted.

Parameters level : int, str, list, default -1
    Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

dropna : bool, default True
    Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

Returns DataFrame or Series
    Stacked dataframe or series.

See also:
*DataFrame.unstack* Unstack prescribed level(s) from index axis onto column axis.

*DataFrame.pivot* Reshape dataframe from long format to wide format.

*DataFrame.pivot_table* Create a spreadsheet-style pivot table as a DataFrame.

**Notes**

The function is named by analogy with a collection of books being re-organised from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

**Examples**

**Single level columns**

```python
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
    index=['cat', 'dog'],
    columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```python
>>> df_single_level_cols
   weight  height
cat       0      1
dog       2      3
```

```python
>>> df_single_level_cols.stack()
   weight
cat     0
   height
   cat 1
   dog 2
```

dtype: int64

**Multi level columns: simple case**

```python
>>> multicoll = pd.MultiIndex.from_tuples([('weight', 'kg'),
                                           ('weight', 'pounds')])
```

```python
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
                                       index=['cat', 'dog'],
                                       columns=multicoll)
```

Stacking a dataframe with a multi-level column axis:

```python
>>> df_multi_level_cols1
   weight
   kg  pounds
cat  1      2
dog  2      4
```

```python
>>> df_multi_level_cols1.stack()
   weight
   kg
   cat 1
   pounds 2
   dog 2
   pounds 4
```

**Missing values**
It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked
dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```
>>> df_multi_level_cols2

Weight  Height
      kg    m
Cat  1.0  2.0
Dog  3.0  4.0
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```
>>> df_multi_level_cols2.stack(0)

Height  Weight
     kg    m
Cat NaN  2.0
     weight 1.0 NaN
Dog NaN  4.0
     weight 3.0 NaN
```

Dropping missing values

Note that rows where all values are missing are dropped by default but this behaviour can be controlled
via the dropna keyword parameter:

```
>>> df_multi_level_cols3

Weight  Height
      kg    m
Cat NaN  1.0
Dog  2.0  3.0
```

```
>>> df_multi_level_cols3.stack(dropna=False)

Height  Weight
     kg    m
Cat NaN NaN
     m 1.0 NaN
Dog kg NaN
     m 2.0
```
m 3.0 NaN
>>>

def_multi_level_cols3.stack(dropna=True)

<table>
<thead>
<tr>
<th></th>
<th>height</th>
<th>weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat m</td>
<td>1.0</td>
<td>NaN</td>
</tr>
<tr>
<td>dog kg</td>
<td>NaN</td>
<td>2.0</td>
</tr>
<tr>
<td></td>
<td>3.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

pandas.DataFrame.std

DataFrame.std (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

axis [{index (0), columns (1)}]
skipna : boolean, default True
Exclude NA/null values. If an entire row/column is NA, the result will be NA
level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
ddof : int, default 1
Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

std [Series or DataFrame (if level specified)]

pandas.DataFrame.sub

DataFrame.sub (other, axis=‘columns’, level=None, fill_value=None)
Subtraction of dataframe and other, element-wise (binary operator sub).
Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}
For Series input, axis to match Series index on
level : int or name
Broadcast across a level, matching Index values on the passed MultiIndex level
fill_value : None or float value, default None

Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

result [DataFrame]

See also:

DataFrame.rsub

Notes

Mismatched indices will be unioned together

Examples

```python
>>> a = pd.DataFrame([2, 1, 1, np.nan], index=['a', 'b', 'c', 'd'],
...                  columns=['one'])
>>> a
   one
a  2.0
b  1.0
c  1.0
d  NaN
```
```
>>> b = pd.DataFrame(dict(one=[1, np.nan, 1, np.nan],
...                        two=[3, 2, np.nan, 2]),
...                  index=['a', 'b', 'd', 'e'])
>>> b
   one  two
a  1.0  3.0
b  NaN  2.0
d  1.0  NaN
e  NaN  2.0
```
```
>>> a.sub(b, fill_value=0)
   one  two
a  1.0 -3.0
b  1.0 -2.0
c  1.0  NaN
d -1.0  NaN
e  NaN -2.0
```

pandas.DataFrame.subtract

DataFrame.subtract(other, axis='columns', level=None, fill_value=None)

Subtraction of dataframe and other, element-wise (binary operator sub).

Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs.

Parameters

other [Series, DataFrame, or constant]
axis : {0, 1, ‘index’, ‘columns’}

For Series input, axis to match Series index on

level : int or name

Broadcast across a level, matching Index values on the passed MultiIndex level

fill_value : None or float value, default None

Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing

Returns

result [DataFrame]

See also:

DataFrame.rsub

Notes

Mismatched indices will be unioned together

Examples

```python
>>> a = pd.DataFrame([2, 1, 1, np.nan], index=['a', 'b', 'c', 'd'],
...                  columns=['one'])
>>> a
   one
a 2.0
b 1.0
c 1.0
d NaN

>>> b = pd.DataFrame(dict(one=[1, np.nan, 1, np.nan],
...                        two=[3, 2, np.nan, 2]),
...                   index=['a', 'b', 'd', 'e'])
>>> b
   one  two
a  1.0  3.0
b  NaN  2.0
d  1.0  NaN
e  NaN  2.0

>>> a.sub(b, fill_value=0)
   one  two
a  1.0 -3.0
b  1.0 -2.0
c  1.0  NaN
d -1.0  NaN
e  NaN -2.0
```
pandas.DataFrame.sum

DataFrame.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the sum of the values for the requested axis

Parameters
axis [{index (0), columns (1)}]
skipna : boolean, default True
Exclude NA/null values when computing the result.
level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
min_count : int, default 0
The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

Returns
sum [Series or DataFrame (if level specified)]

Examples
By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([]).sum()  # min_count=0 is the default
0.0
```

This can be controlled with the min_count parameter. For example, if you’d like the sum of an empty series to be NaN, pass min_count=1.

```python
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0
```

```python
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```
pandas.DataFrame.swapaxes

DataFrame.swapaxes(axis1, axis2, copy=True)
Interchange axes and swap values axes appropriately

Returns
y [same as input]

pandas.DataFrame.swaplevel

DataFrame.swaplevel(i=-2, j=-1, axis=0)
Swap levels i and j in a MultiIndex on a particular axis

Parameters i, j : int, string (can be mixed)
Level of index to be swapped. Can pass level name as string.

Returns
swapped [type of caller (new object)]

.. versionchanged:: 0.18.1
The indexes i and j are now optional, and default to the two innermost levels of
the index.

pandas.DataFrame.tail

DataFrame.tail(n=5)
Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data,
for example, after sorting or appending rows.

Parameters n : int, default 5
Number of rows to select.

Returns type of caller
The last n rows of the caller object.

See also:
pandas.DataFrame.head The first n rows of the caller object.

Examples

>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
... 'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1       bee
2     falcon
3        lion
(continues on next page)
Viewing the last 5 lines

```python
>>> df.tail()
   animal
4   monkey
5   parrot
6   shark
7   whale
8   zebra
```

Viewing the last $n$ lines (three in this case)

```python
>>> df.tail(3)
   animal
6   shark
7   whale
8   zebra
```

### pandas.DataFrame.take

Dataframe.take(indices, axis=0, convert=None, is_copy=True, **kwargs)

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- **indices**: array-like
  - An array of ints indicating which positions to take.
- **axis**: {0 or ‘index’, 1 or ‘columns’, None}, default 0
  - The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- **convert**: bool, default True
  - Whether to convert negative indices into positive ones. For example, -1 would map to the len(axis) − 1. The conversions are similar to the behavior of indexing a regular Python list.
  
  Deprecated since version 0.21.0: In the future, negative indices will always be converted.
- **is_copy**: bool, default True
  - Whether to return a copy of the original object or not.

**Returns**

- **taken**: type of caller

For compatibility with numpy.take(). Has no effect on the output.
An array-like containing the elements taken from the object.

See also:

- **Dataframe.loc** Select a subset of a DataFrame by labels.
- **Dataframe.iloc** Select a subset of a DataFrame by positions.
- **numpy.take** Take elements from an array along an axis.

### Examples

```python
def = pd.DataFrame(
    [(falcon', 'bird', 389.0),
     ('parrot', 'bird', 24.0),
     ('lion', 'mammal', 80.5),
     ('monkey', 'mammal', np.nan),
     columns=['name', 'class', 'max_speed'],
     index=[0, 2, 3, 1])
```

Take elements at positions 0 and 3 along the axis 0 (default).

```
>>> df.take([0, 3])
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
```

---

**pandas.DataFrame.to_clipboard**

```python
DataFrame.to_clipboard(excel=True, sep=None, **kwargs)
```

Copy object to the system clipboard.
Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel** : bool, default True
  - True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
  - False, write a string representation of the object to the clipboard.

- **sep** : str, default '\t'
  - Field delimiter.

- ****kwargs
  - These parameters will be passed to DataFrame.to_csv.

**See also:**

- **DataFrame.to_csv** Write a DataFrame to a comma-separated values (csv) file.
- **read_clipboard** Read text from clipboard and pass to read_table.

**Notes**

Requirements for your platform.

- Linux : xclip, or xsel (with gtk or PyQt4 modules)
- Windows : none
- OS X : none

**Examples**

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword *index* and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```
DataFrame.to_csv

DataFrame.to_csv(path_or_buf=None, sep=’,’, na_rep=’’, float_format=None, columns=None, header=True, index=True, index_label=None, mode=’w’, encoding=None, compression=None, quoting=None, quotechar=’”’, line_terminator=’
’, chunksize=None, tupleize_cols=None, date_format=None, doublequote=True, escapechar=None, decimal=’.’)

Write DataFrame to a comma-separated values (csv) file

**Parameters**

- **path_or_buf**: string or file handle, default None
  - File path or object, if None is provided the result is returned as a string.
  - **sep**: character, default ‘’
    - Field delimiter for the output file.
  - **na_rep**: string, default ‘’
    - Missing data representation
  - **float_format**: string, default None
    - Format string for floating point numbers
  - **columns**: sequence, optional
    - Columns to write
  - **header**: boolean or list of string, default True
    - Write out the column names. If a list of strings is given it is assumed to be aliases for the column names
  - **index**: boolean, default True
    - Write row names (index)
  - **index_label**: string or sequence, or False, default None
    - Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex. If False do not print fields for index names. Use index_label=False for easier importing in R
  - **mode**: str
    - Python write mode, default ‘w’
  - **encoding**: string, optional
    - A string representing the encoding to use in the output file, defaults to ‘ascii’ on Python 2 and ‘utf-8’ on Python 3.
  - **compression**: string, optional
    - A string representing the compression to use in the output file. Allowed values are ‘gzip’, ‘bz2’, ‘zip’, ‘xz’. This input is only used when the first argument is a filename.
  - **line_terminator**: string, default ‘\n’
    - The newline character or character sequence to use in the output file
  - **quoting**: optional constant from csv module
defaults to csv.QUOTE_MINIMAL. If you have set a float_format then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric

quotechar: string (length 1), default “”
character used to quote fields

doublequote: boolean, default True
Control quoting of quotechar inside a field

escapechar: string (length 1), default None
character used to escape sep and quotechar when appropriate

chunksize: int or None
rows to write at a time

tupleize_cols: boolean, default False
Deprecated since version 0.21.0: This argument will be removed and will always write each row of the multi-index as a separate row in the CSV file.
Write MultiIndex columns as a list of tuples (if True) or in the new, expanded format, where each MultiIndex column is a row in the CSV (if False).

date_format: string, default None
Format string for datetime objects

decimal: string, default ‘.’
Character recognized as decimal separator. E.g. use ‘,’ for European data

pandas.DataFrame.to_dense

DataFrame.to_dense()
Return dense representation of NDFrame (as opposed to sparse)

pandas.DataFrame.to_dict

DataFrame.to_dict(orient='dict', into=<class 'dict'>)
Convert the DataFrame to a dictionary.
The type of the key-value pairs can be customized with the parameters (see below).

Parameters orient: str {'dict', 'list', 'series', 'split', 'records', 'index'}
Determines the type of the values of the dictionary.
  • ‘dict’ (default): dict like {column -> {index -> value}}
  • ‘list’: dict like {column -> [values]}
  • ‘series’: dict like {column -> Series(values)}
  • ‘split’: dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  • ‘records’: list like [{column -> value}, ..., {column -> value}]
  • ‘index’: dict like {index -> {column -> value}}
Abbreviations are allowed. *s* indicates *series* and *sp* indicates *split.*

**into** : class, default dict

The collections.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

**Returns**

result  [collections.Mapping like {column -> {index -> value}}]

See also:

*DataFrame.from_dict* create a DataFrame from a dictionary

*DataFrame.to_json* convert a DataFrame to JSON format

**Examples**

```python
>>> df = pd.DataFrame({'col1': [1, 2],
...                    'col2': [0.5, 0.75]},
...                   index=['a', 'b'])
>>> df
col1  col2
a    1    0.50
b    2    0.75

>>> df.to_dict()
{'col1': {'a': 1, 'b': 2}, 'col2': {'a': 0.5, 'b': 0.75}}

You can specify the return orientation.

```python
>>> df.to_dict('series')
{'col1': a 1
 b 2
   Name: col1, dtype: int64,
 'col2': a 0.50
 b 0.75
   Name: col2, dtype: float64}

>>> df.to_dict('split')
{'index': ['a', 'b'], 'columns': ['col1', 'col2'],
 'data': [[1.0, 0.5], [2.0, 0.75]]}

>>> df.to_dict('records')
[['col1': 1.0, 'col2': 0.5], ['col1': 2.0, 'col2': 0.75]]

>>> df.to_dict('index')
{'a': {'col1': 1.0, 'col2': 0.5}, 'b': {'col1': 2.0, 'col2': 0.75}}

You can also specify the mapping type.

```python
>>> from collections import OrderedDict, defaultdict

>>> df.to_dict(into=OrderedDict)
OrderedDict(
'col1': OrderedDict([('a', 1), ('b', 2)]),
'col2': OrderedDict([('a', 0.5), ('b', 0.75)]))
```
If you want a `defaultdict`, you need to initialize it:

```python
>>> dd = defaultdict(list)
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1.0, 'col2': 0.5}),
 defaultdict(<class 'list'>, {'col1': 2.0, 'col2': 0.75})]
```

### pandas.DataFrame.to_excel

DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)

Write DataFrame to an excel sheet

**Parameters**

- **excel_writer**: string or ExcelWriter object
  - File path or existing ExcelWriter
- **sheet_name**: string, default ‘Sheet1’
  - Name of sheet which will contain DataFrame
- **na_rep**: string, default ”
  - Missing data representation
- **float_format**: string, default None
  - Format string for floating point numbers
- **columns**: sequence, optional
  - Columns to write
- **header**: boolean or list of string, default True
  - Write out the column names. If a list of strings is given it is assumed to be aliases for the column names
- **index**: boolean, default True
  - Write row names (index)
- **index_label**: string or sequence, default None
  - Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow**: 
  - upper left cell row to dump data frame
- **startcol**: 
  - upper left cell column to dump data frame
- **engine**: string, default None
  - write engine to use - you can also set this via the options io.excel.xlsx.writer, io.excel.xls.writer, and io.excel.xlsm.writer.
- **merge_cells**: boolean, default True
Write MultiIndex and Hierarchical Rows as merged cells.

**encoding**: string, default None

encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

**inf_rep**: string, default ‘inf’

Representation for infinity (there is no native representation for infinity in Excel)

**freeze_panes**: tuple of integer (length 2), default None

Specifies the one-based bottommost row and rightmost column that is to be frozen

New in version 0.20.0.

**Notes**

If passing an existing ExcelWriter object, then the sheet will be added to the existing workbook. This can be used to save different DataFrames to one workbook:

```python
>>> writer = pd.ExcelWriter('output.xlsx')
>>> df1.to_excel(writer,'Sheet1')
>>> df2.to_excel(writer, 'Sheet2')
>>> writer.save()
```

For compatibility with to_csv, to_excel serializes lists and dicts to strings before writing.

**pandas.DataFrame.to_feather**

DataFrame.to_feather(

write out the binary feather-format for DataFrames

New in version 0.20.0.

**Parameters**

- **fname**: str
  
  string file path

**pandas.DataFrame.to_gbq**

DataFrame.to_gbq(

Write a DataFrame to a Google BigQuery table.

This function requires the pandas-gbq package.

Authentication to the Google BigQuery service is via OAuth 2.0.

- If private_key is provided, the library loads the JSON service account credentials and uses those to authenticate.
- If no private_key is provided, the library tries application default credentials.
- If application default credentials are not found or cannot be used with BigQuery, the library authenticates with user account credentials. In this case, you will be asked to grant permissions for product name ‘pandas GBQ’.
Parameters  

**destination_table**: str

Name of table to be written, in the form ‘dataset.tablename’.

**project_id**: str

Google BigQuery Account project ID.

**chunksize**: int, optional

Number of rows to be inserted in each chunk from the dataframe. Set to None to load the whole dataframe at once.

**reauth**: bool, default False

Force Google BigQuery to reauthenticate the user. This is useful if multiple accounts are used.

**if_exists**: str, default ‘fail’

Behavior when the destination table exists. Value can be one of:

- **fail**: If table exists, do nothing.
- **replace**: If table exists, drop it, recreate it, and insert data.
- **append**: If table exists, insert data. Create if does not exist.

**private_key**: str, optional

Service account private key in JSON format. Can be file path or string contents. This is useful for remote server authentication (e.g. Jupyter/IPython notebook on remote host).

**auth_local_webserver**: bool, default False

Use the local webserver flow instead of the console flow when getting user credentials.

*New in version 0.2.0 of pandas-gbq.*

**table_schema**: list of dicts, optional

List of BigQuery table fields to which according DataFrame columns conform to, e.g. [{‘name’: ‘col1’, ‘type’: ‘STRING’}, ...]. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

*New in version 0.3.1 of pandas-gbq.*

**verbose**: boolean, deprecated

*Deprecated in Pandas-GBQ 0.4.0.* Use the logging module to adjust verbosity instead.

See also:

- `pandas_gbq.to_gbq` This function in the pandas-gbq library.
- `pandas.read_gbq` Read a DataFrame from Google BigQuery.
**DataFrame.to_hdf**

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.

For more information see the user guide.

**Parameters**

- **path_or_buf**: str or pandas.HDFStore
  - File path or HDFStore object.

- **key**: str
  - Identifier for the group in the store.

- **mode**: {'a', 'w', 'r+'}, default 'a'
  - Mode to open file:
    - 'w': write, a new file is created (an existing file with the same name would be deleted).
    - 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
    - 'r+': similar to 'a', but the file must already exist.

- **format**: {'fixed', 'table'}, default 'fixed'
  - Possible values:
    - 'table': Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

- **append**: bool, default False
  - For Table formats, append the input data to the existing.

- **data_columns**: list of columns or True, optional
  - List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via Data Columns. Applicable only to format='table'.

- **complevel**: {0-9}, optional
  - Specifies a compression level for data. A value of 0 disables compression.

- **complib**: {'zlib', 'lz4', 'bzip2', 'blosc'}, default 'zlib'
  - Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.
fletcher32 : bool, default False
If applying compression use the fletcher32 checksum.

dropna : bool, default False
If true, ALL nan rows will not be written to store.

errors : str, default ‘strict’
Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

See also:

DataFrame.read_hdf  Read from HDF file.
DataFrame.to_parquet Write a DataFrame to the binary parquet format.
DataFrame.to_sql  Write to a sql table.
DataFrame.to_feather  Write out feather-format for DataFrames.
DataFrame.to_csv  Write out to a csv file.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
   A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
  0  1
  1  2
  2  3
  3  4
dtype: int64
```

Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```
pandas.DataFrame.to_html

DataFrame.to_html(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, bold_rows=True, classes=None, escape=True, max_rows=None, max_cols=None, show_dimensions=False, notebook=False, decimal='.', border=None, table_id=None)

Render a DataFrame as an HTML table.

to_html-specific options:

bold_rows   [boolean, default True] Make the row labels bold in the output
classes     [str or list or tuple, default None] CSS class(es) to apply to the resulting html table
escape      [boolean, default True] Convert the characters <, >, and & to HTML-safe sequences.
max_rows    [int, optional] Maximum number of rows to show before truncating. If None, show all.
max_cols    [int, optional] Maximum number of columns to show before truncating. If None, show all.
decimal     [string, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe

Parameters

buf : StringIO-like, optional
    buffer to write to
columns : sequence, optional
    the subset of columns to write; default None writes all columns
col_space : int, optional
    the minimum width of each column
header : bool, optional
    whether to print column labels, default True
index : bool, optional
    whether to print index (row) labels, default True
na_rep : string, optional
    string representation of NaN to use, default ‘NaN’
formatters : list or dict of one-parameter functions, optional
    formatter functions to apply to columns’ elements by position or name, default None. The result of each function must be a unicode string. List must be of length equal to the number of columns.
float_format : one-parameter function, optional
formatter function to apply to columns’ elements if they are floats, default None. The result of this function must be a unicode string.

sparsify : bool, optional
Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row, default True

index_names : bool, optional
Prints the names of the indexes, default True

line_width : int, optional
Width to wrap a line in characters, default no wrap

table_id : str, optional
id for the <table> element create by to_html
New in version 0.23.0.

justify : str, default None
How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are

• left
• right
• center
• justify
• justify-all
• start
• end
• inherit
• match-parent
• initial
• unset

Returns

formatted [string (or unicode, depending on data and options)]

pandas.DataFrame.to_json

DataFrame.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10,
force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression=None, index=True)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters path_or_buf : string or file handle, optional
File path or object. If not specified, the result is returned as a string.
orient : string

Indication of expected JSON string format.

- Series
  - default is ‘index’
  - allowed values are: {'split', 'records', 'index'}
- DataFrame
  - default is ‘columns’
  - allowed values are: {'split', 'records', 'index', 'columns', 'values'}

- The format of the JSON string
  - ‘split’: dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - ‘records’: list like [{column -> value}, . . . , {column -> value}]}
  - ‘index’: dict like {index -> {column -> value}}
  - ‘columns’: dict like {column -> {index -> value}}
  - ‘values’: just the values array
  - ‘table’: dict like {'schema': {schema}, 'data': {data}} describing the data, and the data component is like orient='records'.

Changed in version 0.20.0.

date_format : {None, ‘epoch’, ‘iso’}

Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision : int, default 10

The number of decimal places to use when encoding floating point values.

force_ascii : boolean, default True

Force encoded string to be ASCII.

date_unit : string, default ‘ms’ (milliseconds)

The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler : callable, default None

Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines : boolean, default False

If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

New in version 0.19.0.

A string representing the compression to use in the output file, only used when the first argument is a filename.

New in version 0.21.0.

**index**: boolean, default True

Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

New in version 0.23.0.

See also:

*pandas.read_json*

**Examples**

```python
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                    index=['row 1', 'row 2'],
...                    columns=['col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns": ["col 1", "col 2"],
  "index": ["row 1", "row 2"],
  "data": ["a", "b"], ["c", "d"]}'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> df.to_json(orient='records')
'["col 1":"a", "col 2":"b"],
["col 1":"c", "col 2":"d"]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a", "col 2":"b"},
  "row 2":{"col 1":"c", "col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a", "row 2":"c"},
  "col 2":{"row 1":"b", "row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> df.to_json(orient='values')
'[["a", "b"], ["c", "d"]]
```

Encoding with Table Schema

```python
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
  {"name": "col 1", "type": "string"},
  {"name": "col 2", "type": "string"}],
  "primaryKey": "index",
  "pandas_version": "0.20.0"},
  "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
    {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

1918 Chapter 34. API Reference
pandas: powerful Python data analysis toolkit, Release 0.23.3

pandas.DataFrame.to_latex

```
DataFrame.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparse=False, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=False)
```

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires `\usepackage{booktabs}.

Changed in version 0.20.2: Added to Series

to_latex-specific options:

- **bold_rows** [boolean, default False] Make the row labels bold in the output
- **column_format** [str, default None] The columns format as specified in LaTeX table format e.g. ‘rc’ for 3 columns
- **longtable** [boolean, default will be read from the pandas config module] Default: False. Use a longtable environment instead of tabular. Requires adding a `\usepackage{longtable}` to your LaTeX preamble.
- **escape** [boolean, default will be read from the pandas config module] Default: True. When set to False prevents from escaping latex special characters in column names.
- **encoding** [str, default None] A string representing the encoding to use in the output file, defaults to ‘ascii’ on Python 2 and ‘utf-8’ on Python 3.
- **decimal** [string, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

New in version 0.18.0.

- **multicolumn** [boolean, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

New in version 0.20.0.

- **multicolumn_format** [str, default ‘l’] The alignment for multicolumns, similar to column_format. The default will be read from the config module.

New in version 0.20.0.

- **multirow** [boolean, default False] Use multirow to enhance MultiIndex rows. Requires adding a `\usepackage{multirow}` to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

New in version 0.20.0.

pandas.DataFrame.to_msgpack

```
DataFrame.to_msgpack(path_or_buf=None, encoding='utf-8', **kwargs)
```

msgpack (serialize) object to input file path

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

- **path** : string File path, buffer-like, or None

if None, return generated string

- **append** : boolean whether to append to an existing msgpack

(default is False)
```python
compress : type of compressor (zlib or blosc), default to None (no compression)
```

**pandas.DataFrame.to_panel**

```python
DataFrame.to_panel()
```
Transform long (stacked) format (DataFrame) into wide (3D, Panel) format.
Deprecated since version 0.20.0.
Currently the index of the DataFrame must be a 2-level MultiIndex. This may be generalized later

**Returns**

- **panel** [Panel]

**pandas.DataFrame.to_parquet**

```python
DataFrame.to_parquet(fname, engine='auto', compression='snappy', **kwargs)
```
Write a DataFrame to the binary parquet format.
New in version 0.21.0.
This function writes the dataframe as a parquet file. You can choose different parquet backends, and have the option of compression. See the [user guide](https://pandas.pydata.org/pandas-docs/stable/user_guide/io.html) for more details.

**Parameters**

- **fname** : str
  String file path.

- **engine** : {'auto', 'pyarrow', 'fastparquet'}, default 'auto'
  Parquet library to use. If 'auto', then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try 'pyarrow', falling back to 'fastparquet' if 'pyarrow' is unavailable.

- **compression** : {'snappy', 'gzip', 'brotli', None}, default 'snappy'
  Name of the compression to use. Use `None` for no compression.

- **kwargs**
  Additional arguments passed to the parquet library. See pandas io for more details.

**See also:**

**Notes**

This function requires either the fastparquet or pyarrow library.
Examples

```python
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip', compression='gzip')
>>> pd.read_parquet('df.parquet.gzip')
coll   col2
0    1   3
1    2   4
```

pandas.DataFrame.to_period

DataFrame.to_period(freq=None, axis=0, copy=True)
Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed)

Parameters

- freq [string, default]
- axis : {0 or ‘index’, 1 or ‘columns’}, default 0
  The axis to convert (the index by default)
- copy : boolean, default True
  If False then underlying input data is not copied

Returns

- ts [TimeSeries with PeriodIndex]

pandas.DataFrame.to_pickle

DataFrame.to_pickle(path, compression='infer', protocol=4)
Pickle (serialize) object to file.

Parameters

- path : str
  File path where the pickled object will be stored.
- compression : {'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default ‘infer’
  A string representing the compression to use in the output file. By default, infers from the file extension in specified path.
  New in version 0.20.0.
- protocol : int
  Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [R15] paragraph 12.1.2). The possible values for this parameter depend on the version of Python. For Python 2.x, possible values are 0, 1, 2. For Python>=3.0, 3 is a valid value. For Python >= 3.4, 4 is a valid value. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.
  New in version 0.21.0.

See also:
**read_pickle**  Load pickled pandas object (or any object) from file.

**DataFrame.to_hdf**  Write DataFrame to an HDF5 file.

**DataFrame.to_sql**  Write DataFrame to a SQL database.

**DataFrame.to_parquet**  Write a DataFrame to the binary parquet format.

**Examples**

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> original_df.to_pickle("./dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> import os
>>> os.remove("./dummy.pkl")
```

**pandas.DataFrame.to_records**

```
DataFrame.to_records(index=True, convert_datetime64=None)
```

Convert DataFrame to a NumPy record array.

Index will be put in the `index` field of the record array if requested.

**Parameters**

- **index**: boolean, default True
  - Include index in resulting record array, stored in `index` field.

- **convert_datetime64**: boolean, default None
  - Deprecated since version 0.23.0.
  - Whether to convert the index to datetime.datetime if it is a DatetimeIndex.

**Returns**

- **y** [numpy.recarray]

**See also:**

- **DataFrame.from_records**  convert structured or record ndarray to DataFrame.
- **numpy.recarray**  ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
                   index=['a', 'b'])
>>> df
   A  B
a  1  0.5
b  2  0.75
>>> df.to_records()
rec.array([(b'a', 1, 0.5), (b'b', 2, 0.75)],
          dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The index can be excluded from the record array:

```python
>>> df.to_records(index=False)
rec.array([(1, 0.5), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])
```

By default, timestamps are converted to `datetime.datetime`

```python
>>> df.index = pd.date_range('2018-01-01 09:00', periods=2, freq='min')
>>> df
   A     B
2018-01-01 09:00:00  1  0.5
2018-01-01 09:01:00  2  0.75
>>> df.to_records()
rec.array([(pd.Timestamp('2018-01-01 09:00:00'), 1, 0.5),
            (pd.Timestamp('2018-01-01 09:01:00'), 2, 0.75)],
            dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The timestamp conversion can be disabled so NumPy’s `datetime64` data type is used instead:

```python
>>> df.to_records(convert_datetime64=False)
rec.array([(pd.to_datetime('2018-01-01T09:00:00.000000000'), 1, 0.5),
            (pd.to_datetime('2018-01-01T09:01:00.000000000'), 2, 0.75)],
            dtype=[('index', '<M8[ns]'), ('A', '<i8'), ('B', '<f8')])
```

`pandas.DataFrame.to_sparse`

`DataFrame.to_sparse` *(fill_value=None, kind='block')*
Convert to SparseDataFrame

Parameters

- **fill_value** [float, default NaN]
- **kind** [‘block’, ‘integer’]

Returns

- **y** [SparseDataFrame]
pandas.DataFrame.to_stata

DataFrame.to_stata(fname, convert_dates=None, write_index=True, encoding='latin-1', byteorder=None, time_stamp=None, data_label=None, variable_labels=None, version=114, convert_strl=None)

Export Stata binary dta files.

**Parameters**

- **fname** : path (string), buffer or path object
  - String, path object (pathlib.Path or py._path.local.LocalPath) or object implementing a binary write() functions. If using a buffer then the buffer will not be automatically closed after the file data has been written.

- **convert_dates** : dict
  - Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises NotImplementedError if a datetime column has timezone information.

- **write_index** : bool
  - Write the index to Stata dataset.

- **encoding** : str
  - Default is latin-1. Unicode is not supported.

- **byteorder** : str
  - Can be “>”, “<”, “little”, or “big”. default is sys.byteorder.

- **time_stamp** : datetime
  - A datetime to use as file creation date. Default is the current time.

- **data_label** : str
  - A label for the data set. Must be 80 characters or smaller.

- **variable_labels** : dict
  - Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

New in version 0.19.0.

- **version** : {114, 117}
  - Version to use in the output dta file. Version 114 can be used read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 114 limits string variables to 244 characters or fewer while 117 allows strings with lengths up to 2,000,000 characters.

New in version 0.23.0.

- **convert_strl** : list, optional
  - List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

New in version 0.23.0.

**Raises** NotImplementeError
• If datetimes contain timezone information
• Column dtype is not representable in Stata

ValueError
• Columns listed in convert_dates are neither datetime64[ns] or datetime
• Column listed in convert_dates is not in DataFrame
• Categorical label contains more than 32,000 characters

New in version 0.19.0.

See also:

pandas.read_stata  Import Stata data files
pandas.io.stata.StataWriter  low-level writer for Stata data files
pandas.io.stata.StataWriter117  low-level writer for version 117 files

Examples

```python
>>> data.to_stata('./data_file.dta')
```

Or with dates

```python
>>> data.to_stata('./date_data_file.dta', {2 : 'tw'})
```

Alternatively you can create an instance of the StataWriter class

```python
>>> writer = StataWriter('./data_file.dta', data)
```

```python
>>> writer.write_file()
```

With dates:

```python
>>> writer = StataWriter('./date_data_file.dta', data, {2 : 'tw'})
```

```python
>>> writer.write_file()
```

**pandas.DataFrame.to_string**

DataFrame.to_string  Render a DataFrame to a console-friendly tabular output.

**Parameters**

- **buf** : StringIO-like, optional
  
  buffer to write to

- **columns** : sequence, optional
  
  the subset of columns to write; default None writes all columns

- **col_space** : int, optional
  
  the minimum width of each column
header : bool, optional
Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names

index : bool, optional
whether to print index (row) labels, default True

na_rep : string, optional
string representation of NaN to use, default ‘NaN’

formatters : list or dict of one-parameter functions, optional
formatter functions to apply to columns’ elements by position or name, default None. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format : one-parameter function, optional
formatter function to apply to columns’ elements if they are floats, default None. The result of this function must be a unicode string.

sparsify : bool, optional
Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row, default True

index_names : bool, optional
Prints the names of the indexes, default True

line_width : int, optional
Width to wrap a line in characters, default no wrap

table_id : str, optional
id for the <table> element create by to_html
New in version 0.23.0.

justify : str, default None
How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are
• left
• right
• center
• justify
• justify-all
• start
• end
• inherit
• match-parent
• initial
• unset
Returns

formatted [string (or unicode, depending on data and options)]

pandas.DataFrame.to_timestamp

DataFrame.to_timestamp(freq=None, how='start', axis=0, copy=True)
Cast to DatetimeIndex of timestamps, at beginning of period

Parameters

freq : string, default frequency of PeriodIndex
    Desired frequency

how : {'s', 'e', 'start', 'end'}
    Convention for converting period to timestamp; start of period vs. end

axis : {0 or 'index', 1 or 'columns'}, default 0
    The axis to convert (the index by default)

copy : boolean, default True
    If false then underlying input data is not copied

Returns

df [DataFrame with DatetimeIndex]

pandas.DataFrame.to_xarray

DataFrame.to_xarray()
Return an xarray object from the pandas object.

Returns

a DataArray for a Series

a Dataset for a DataFrame

a DataArray for higher dims

Notes

See the xarray docs

Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2],
                     'B': ['foo', 'bar', 'foo'],
                     'C': np.arange(4.,7)})

>>> df
       A  B   C
0  foo  1  4.0
1  bar  1  5.0
2  foo  2  6.0
```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (index: 3)
Coordinates:
  * index (index) int64 0 1 2
Data variables:
  A (index) int64 1 1 2
  B (index) object 'foo' 'bar' 'foo'
  C (index) float64 4.0 5.0 6.0

>>> df = pd.DataFrame({'A': [1, 1, 2],
                     'B': ['foo', 'bar', 'foo'],
                     'C': np.arange(4., 7, 1).set_index(['B', 'A'])})

>>> df
   C
B  A
foo 1 4.0
bar 1 5.0
foo 2 6.0

>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (A: 2, B: 2)
Coordinates:
  * B (B) object 'bar' 'foo'
  * A (A) int64 1 2
Data variables:
  C (B, A) float64 5.0 nan 4.0 6.0

>>> p = pd.Panel(np.arange(24).reshape(4, 3, 2),
                items=list('ABCD'),
                major_axis=pd.date_range('20130101', periods=3),
                minor_axis=['first', 'second'])

>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 2 (minor_axis)
Items axis: A to D
Major_axis axis: 2013-01-01 00:00:00 to 2013-01-03 00:00:00
Minor_axis axis: first to second

>>> p.to_xarray()
<xarray.DataArray (items: 4, major_axis: 3, minor_axis: 2)>
array([[[ 0, 1],
        [ 2, 3],
        [ 4, 5]],
       [[ 6, 7],
        [ 8, 9],
        [10, 11]],
       [[12, 13],
        [14, 15],
        [16, 17]],
       [[18, 19],
        [20, 21],
        [22, 23]]])
Coordinates:
pandas.DataFrame.transform

DataFrame.transform(func, *args, **kwargs)

Call function producing a like-indexed NDFrame and return a NDFrame with the transformed values

New in version 0.20.0.

Parameters

func : callable, string, dictionary, or list of string/callables

To apply to column

Accepted Combinations are:

• string function name
• function
• list of functions
• dict of column names -> functions (or list of functions)

Returns

transformed [NDFrame]

See also:
pandas.NDFrame.aggregate, pandas.NDFrame.apply

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                    index=pd.date_range('1/1/2000', periods=10))
df.iloc[3:7] = np.nan

>>> df.transform(lambda x: (x - x.mean()) / x.std())
   A       B       C
2000-01-01  0.579457  1.236184  0.123424
2000-01-02  0.370357 -0.605875 -1.231325
2000-01-03  1.455756 -0.277446  0.288967
2000-01-04  NaN      NaN      NaN
2000-01-05  NaN      NaN      NaN
2000-01-06  NaN      NaN      NaN
2000-01-07  NaN      NaN      NaN
2000-01-08 -0.498658  1.274522  1.642524
2000-01-09 -0.540524 -1.012676 -0.828968
2000-01-10 -1.366388 -0.614710  0.005378
```
pandas.DataFrame.transpose

DataFrame.transpose(*args, **kwargs)
Transpose index and columns.
Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property $T$ is an accessor to the method transpose().

Parameters:
- copy : bool, default False
  If True, the underlying data is copied. Otherwise (default), no copy is made if possible.
- *args, **kwargs
  Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns:
- DataFrame
  The transposed DataFrame.

See also:
- numpy.transpose
  Permute the dimensions of a given array.

Notes
Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the object dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```python
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0    1    3
1    2    4
```

```python
>>> df1_transposed = df1.T  # or df1.transpose()
>>> df1_transposed
   0  1
   col1  1  2
   col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```python
>>> df1.dtypes
col1   int64
col2   int64
dtype: object
```

```python
>>> df1_transposed.dtypes
```

(continues on next page)
Non-square DataFrame with mixed dtypes

```python
>>> d2 = {'name': ['Alice', 'Bob'],
...      'score': [9.5, 8],
...      'employed': [False, True],
...      'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5       False   0
1    Bob    8.0        True   0
```

```python
>>> df2_transposed = df2.T  # or df2.transpose()
>>> df2_transposed
   0  1
name Alice Bob
score    9.5    8
employed False True
kids     0      0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the `object` dtype:

```python
>>> df2.dtypes
    name    object
    score  float64
    employed  bool
    kids    int64
dtype: object
>>> df2_transposed.dtypes
   0  1
   object  object
```

**pandas.DataFrame.truediv**

`DataFrame.truediv(other, axis='columns', level=None, fill_value=None)`

Floating division of dataframe and other, element-wise (binary operator `truediv`).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

- `other` [Series, DataFrame, or constant]
- `axis` : {0, 1, ‘index’, ‘columns’}
  
  For Series input, axis to match Series index on
- `level` : int or name
  
  Broadcast across a level, matching Index values on the passed MultiIndex level
- `fill_value` : None or float value, default None
Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

result [DataFrame]

**See also:**

`DataFrame.rtruediv`

**Notes**

Mismatched indices will be unioned together

**Examples**

None

`pandas.DataFrame.truncate`

`DataFrame.truncate(before=None, after=None, axis=None, copy=True)`

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- **before** : date, string, int
  - Truncate all rows before this index value.
- **after** : date, string, int
  - Truncate all rows after this index value.
- **axis** : {0 or ‘index’, 1 or ‘columns’}, optional
  - Axis to truncate. Truncates the index (rows) by default.
- **copy** : boolean, default is True,
  - Return a copy of the truncated section.

**Returns**  

The truncated Series or DataFrame.

**See also:**

- `DataFrame.loc`  Select a subset of a DataFrame by label.
- `DataFrame.iloc`  Select a subset of a DataFrame by position.

**Notes**

If the index being truncated contains only datetime values, `before` and `after` may be specified as strings instead of Timestamps.
Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                    index=[1, 2, 3, 4, 5])

>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o

>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n

The columns of a DataFrame can be truncated.

```python
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```  

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
2  b
3  c
4  d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')

>>> df = pd.DataFrame(index=dates, data={'A': 1})

>>> df.tail()
   A
2016-01-31 23:59:56    1
2016-01-31 23:59:57    1
2016-01-31 23:59:58    1
2016-01-31 23:59:59    1
2016-02-01 00:00:00    1

```python
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...              after=pd.Timestamp('2016-01-10')).tail()
   A
2016-01-09 23:59:56    1
2016-01-09 23:59:57    1
2016-01-09 23:59:58    1
```
Because the index is a DatetimeIndex containing only dates, we can specify before and after as strings. They will be coerced to Timestamps before truncation.

```python
>>> df.truncate('2016-01-05', '2016-01-10').tail()
A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```python
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

**pandas.DataFrame.tshift**

`DataFrame.tshift (periods=1, freq=None, axis=0)`  
Shift the time index, using the index’s frequency if available.

**Parameters**

- **periods**: int  
  Number of periods to move, can be positive or negative

- **freq**: DateOffset, timedelta, or time rule string, default None  
  Increment to use from the tseries module or time rule (e.g. ‘EOM’)

- **axis**: int or basestring  
  Corresponds to the axis that contains the Index

**Returns**

- shifted [NDFrame]

**Notes**

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

**pandas.DataFrame.tz_convert**

`DataFrame.tz_convert (tz, axis=0, level=None, copy=True)`  
Convert tz-aware axis to target time zone.
Parameters

tz [string or pytz.timezone object]
axis [the axis to convert]
level : int, str, default None
If axis ia a MultiIndex, convert a specific level. Otherwise must be None
copy : boolean, default True
Also make a copy of the underlying data

Raises TypeError
If the axis is tz-naive.

pandas.DataFrame.tz_localize

DataFrame.tz_localize (tz, axis=0, level=None, copy=True, ambiguous='raise')
Localize tz-naive TimeSeries to target time zone.

Parameters

tz [string or pytz.timezone object]
axis [the axis to localize]
level : int, str, default None
If axis ia a MultiIndex, localize a specific level. Otherwise must be None
copy : boolean, default True
Also make a copy of the underlying data
ambiguous : ‘infer’, bool-ndarray, ‘NaT’, default ‘raise’
• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

Raises TypeError
If the TimeSeries is tz-aware and tz is not None.

pandas.DataFrame.unstack

DataFrame.unstack (level=-1, fill_value=None)
Pivot a level of the (necessarily hierarchical) index labels, returning a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels. If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex). The level involved will automatically get sorted.

Parameters level : int, string, or list of these, default -1 (last level)

Level(s) of index to unstack, can pass level name
fill_value : replace NaN with this value if the unstack produces missing values

New in version 0.18.0.

Returns

unstacked [DataFrame or Series]

See also:

DataFrame.pivot Pivot a table based on column values.

DataFrame.stack Pivot a level of the column labels (inverse operation from unstack).

Examples

```python
def MultIndex.from_tuples([('one', 'a'), ('one', 'b'), ('two', 'a'), ('two', 'b')])
def Series(np.arange(1.0, 5.0), index=index)
>>> s
  one  a  1.0
  b  2.0
  two a  3.0
  b  4.0
dtype: float64

>>> s.unstack(level=-1)
a b
one 1.0 2.0
two 3.0 4.0

>>> s.unstack(level=0)
one two
  a  1.0  3.0
  b  2.0  4.0

>>> df = s.unstack(level=0)
>>> df.unstack()
Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

**join**: ['left'], default 'left'

Only left join is implemented, keeping the index and columns of the original object.

**overwrite**: bool, default True

How to handle non-NA values for overlapping keys:

- True: overwrite original DataFrame’s values with values from other.
- False: only update values that are NA in the original DataFrame.

**filter_func**: callable(1d-array) -> boolean 1d-array, optional

Can choose to replace values other than NA. Return True for values that should be updated.

**raise_conflict**: bool, default False

If True, will raise a ValueError if the DataFrame and other both contain non-NA data in the same place.

**Raises** ValueError

When raise_conflict is True and there’s overlapping non-NA data.

**See also**:

- `dict.update` Similar method for dictionaries.
- `DataFrame.merge` For column(s)-on-columns(s) operations.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame’s length does not increase as a result of the update, only values at matching index/column labels are updated.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'], 'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B
0  a  d
1  b  e
2  c  f
```

(continues on next page)
For Series, it's name attribute must be set.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
                     'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A  B
0  a  d
1  b  y
2  c  e
```

If `other` contains NaNs the corresponding values are not updated in the original dataframe.

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
                     'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A  B
0 1  4.0
1 2 500.0
2 3  6.0
```

**pandas.DataFrame.var**

DataFrame.var (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- `axis` ([index (0), columns (1)])
- `skipna` : boolean, default True
  
  Exclude NA/null values. If an entire row/column is NA, the result will be NA
- `level` : int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
- `ddof` : int, default 1
Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric_only** : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

**var** [Series or DataFrame (if level specified)]

### pandas.DataFrame.where

**DataFrame.where**

```python
DataFrame.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)
```

Return an object of same shape as self and whose corresponding entries are from self where `cond` is True and otherwise are from `other`.

**Parameters**

**cond** : boolean NDFrame, array-like, or callable

Where `cond` is True, keep the original value. Where False, replace with corresponding value from `other`. If `cond` is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn’t check it).

New in version 0.18.1: A callable can be used as cond.

**other** : scalar, NDFrame, or callable

Entries where `cond` is False are replaced with corresponding value from `other`. If other is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn’t check it).

New in version 0.18.1: A callable can be used as other.

**inplace** : boolean, default False

Whether to perform the operation in place on the data

**axis** [alignment axis if needed, default None]

**level** [alignment level if needed, default None]

**errors** : str, `{‘raise’, ‘ignore’}`, default ‘raise’

- `raise`: allow exceptions to be raised
- `ignore`: suppress exceptions. On error return original object

Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

**try_cast** : boolean, default False

try to cast the result back to the input type (if possible),

**raise_on_error** : boolean, default True

Whether to raise on invalid data types (e.g. trying to where on strings)

Deprecated since version 0.21.0.
Returns

wh  [same type as caller]

See also:

Dataframe.mask()

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is True the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for Dataframe.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the where documentation in indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
   0   NaN
   1   1.0
   2   2.0
   3   3.0
   4   4.0

>>> s.mask(s > 0)
   0  0.0
   1  NaN
   2  NaN
   3  NaN
   4  NaN

>>> s.where(s > 1, 10)
   0  10.0
   1  10.0
   2   2.0
   3   3.0
   4   4.0

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
       A    B
0  0  -1  NaN
1 -2   3  NaN
2 -4  -5  NaN
3  6  -7  NaN
4 -8   9  NaN

>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True True
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

```
1 True True
2 True True
3 True True
4 True True
>>> df.where(m, -df) == df.mask(~m, -df)
    A  B
0 True True
1 True True
2 True True
3 True True
4 True True
```

**pandas.DataFrame.xs**

`DataFrame.xs(key, axis=0, level=None, drop_level=True)`

Returns a cross-section (row(s) or column(s)) from the Series/DataFrame. Defaults to cross-section on the rows (axis=0).

**Parameters**

- `key`: object
  - Some label contained in the index, or partially in a MultiIndex

- `axis`: int, default 0
  - Axis to retrieve cross-section on

- `level`: object, defaults to first n levels (n=1 or len(key))
  - In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.

- `drop_level`: boolean, default True
  - If False, returns object with same levels as self.

**Returns**

- `xs` [Series or DataFrame]

**Notes**

`xs` is only for getting, not setting values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of `xs` functionality, see `MultiIndex Slicers`

**Examples**

```
>>> df
    A  B  C
a 4  5  2
b 4  0  9
c 9  7  3
>>> df.xs('a')
    A  B
a 4
```
```python
>>> df.xs('C', axis=1)
Name: C
a 2
b 9
c 3
```

```python
>>> df
A  B  C  D
first  second  third
bar   one   1  4  1  8  9
two   1  7  5  5  0
baz   one   1  6  6  8  0
two   2  5  3  5  3
```

```python
>>> df.xs(('baz', 'three'))
A  B  C  D
third
2  5  3  5  3
```

```python
>>> df.xs(('baz', 2), level=[0, 'third'])
A  B  C  D
second
three 5 3 5 3
```

### 34.4.2 Attributes and underlying data

#### Axes

<table>

<td><code>DataFrame.aggregate(func[, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>DataFrame.transform(func, *args, **kwargs)</code></td>
<td>Call function producing a like-indexed NDFrame and return a NDFrame with the transformed values.</td>
</tr>
<tr>
<td><code>DataFrame.groupby([by, axis, level, ...])</code></td>
<td>Group series using mapper (dict or key function, apply given function to group, return result as series) or by a series of columns.</td>
</tr>
<tr>
<td><code>DataFrame.rolling(window[, min_periods, ...])</code></td>
<td>Provides rolling window calculations.</td>
</tr>
<tr>
<td><code>DataFrame.expanding([min_periods, center, axis])</code></td>
<td>Provides expanding transformations.</td>
</tr>
<tr>
<td><code>DataFrame.ewm([com, span, halflife, alpha, ...])</code></td>
<td>Provides exponential weighted functions</td>
</tr>
</tbody>
</table>

### 34.4.7 Computations / Descriptive Stats

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>DataFrame.all([axis, bool_only, skipna, level])</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>DataFrame.any([axis, bool_only, skipna, level])</code></td>
<td>Return whether any element is True over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.clip([lower, upper, axis, inplace])</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>DataFrame.clip_lower(threshold[, axis, inplace])</code></td>
<td>Return copy of the input with values below a threshold truncated.</td>
</tr>
</tbody>

<td>Assign new columns to a DataFrame, returning a new object (a copy) with the new columns added to the original ones.</td>
</tr>
<tr>
<td>DataFrame.join(other[, on, how, lsuffix, ...])</td>
<td>Join columns with other DataFrame either on index or on a key column.</td>
</tr>
<tr>
<td>DataFrame.merge(right[, how, on, left_on, ...])</td>
<td>Merge DataFrame objects by performing a database-style join operation by columns or indexes.</td>
</tr>
<tr>
<td>DataFrame.update(other[, join, overwrite, ...])</td>
<td>Modify in place using non-NA values from another DataFrame.</td>
</tr>
</tbody>
</table>

### 34.4.12 Time series-related

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.asfreq(freq[, method, how, ...])</td>
<td>Convert TimeSeries to specified frequency.</td>
</tr>
<tr>
<td>DataFrame.asof(where[, subset])</td>
<td>The last row without any NaN is taken (or the last row without NaN considering only the subset of columns in the case of a DataFrame)</td>
</tr>
<tr>
<td>DataFrame.shift([periods, freq, axis])</td>
<td>Shift index by desired number of periods with an optional time freq</td>
</tr>
<tr>
<td>DataFrame.slice_shift([periods, axis])</td>
<td>Equivalent to shift without copying data.</td>
</tr>
<tr>
<td>DataFrame.tshift([periods, freq, axis])</td>
<td>Shift the time index, using the index’s frequency if available.</td>
</tr>
<tr>
<td>DataFrame.first_valid_index()</td>
<td>Return index for first non-NA/null value.</td>
</tr>
<tr>
<td>DataFrame.last_valid_index()</td>
<td>Return index for last non-NA/null value.</td>
</tr>
<tr>
<td>DataFrame.resample(rule[, how, axis, ...])</td>
<td>Convenience method for frequency conversion and resampling of time series.</td>
</tr>
<tr>
<td>DataFrame.to_period([freq, axis, copy])</td>
<td>Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed)</td>
</tr>
<tr>
<td>DataFrame.to_timestamp([freq, how, axis, copy])</td>
<td>Cast to DatetimeIndex of timestamps, at beginning of period.</td>
</tr>
<tr>
<td>DataFrame.tz_convert(tz[, axis, level, copy])</td>
<td>Convert tz-aware axis to target time zone.</td>
</tr>
<tr>
<td>DataFrame.tz_localize(tz[, axis, level, ...])</td>
<td>Localize tz-naive TimeSeries to target time zone.</td>
</tr>
</tbody>
</table>

### 34.4.13 Plotting

DataFrame.plot is both a callable method and a namespace attribute for specific plotting methods of the form DataFrame.plot.<kind>.

DataFrame.plot([x, y, kind, ax, ...]) | DataFrame plotting accessor and method |
DataFrame.plot.area([x, y])
Area plot

Parameters:
- x, y : label or position, optional
  Coordinates for each point.
- **kwds : optional
  Additional keyword arguments are documented in pandas.DataFrame.plot().

Returns:
axes : matplotlib.axes.Axes or numpy.ndarray of them

34.4.13.2 pandas.DataFrame.plot.bar

DataFrame.plot.bar([x, y], **kwds)
Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters:
- x : label or position, optional
  Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y : label or position, optional
  Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **kwds : optional
  Additional keyword arguments are documented in pandas.DataFrame.plot().

Returns:
axes : matplotlib.axes.Axes or numpy.ndarray of them
An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

- `pandas.DataFrame.plot.barh` Horizontal bar plot.
- `pandas.DataFrame.plot` Make plots of a DataFrame.
- `matplotlib.pyplot.bar` Make a bar plot with matplotlib.

Examples

Basic plot.

```python
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

34.4.13.3 pandas.DataFrame.plot.barh

`DataFrame.plot.barh(x=None, y=None, **kwds)` Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- `x`: label or position, default DataFrame.index
  - Column to be used for categories.
- `y`: label or position, default All numeric columns in dataframe
Columns to be plotted from the DataFrame.

**kwds**
Keyword arguments to pass on to `pandas.DataFrame.plot()`.

Returns

```
axes [matplotlib.axes.Axes or numpy.ndarray of them.]
```

See also:

`pandas.DataFrame.plot.bar` Vertical bar plot.

`pandas.DataFrame.plot` Make plots of DataFrame using matplotlib.

`matplotlib.axes.Axes.bar` Plot a vertical bar plot using matplotlib.

Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...     'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...     'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...     'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
34.4.13.4 pandas.DataFrame.plot.box

DataFrame.plot.box(by=None, **kwds)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by : string or sequence

Column in the DataFrame to group by.

**kwds : optional

Additional keywords are documented in pandas.DataFrame.plot().

Returns

axes [matplotlib.axes.Axes or numpy.ndarray of them]

See also:

pandas.DataFrame.boxplot Another method to draw a box plot.
pandas.Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

34.4.13.5 pandas.DataFrame.plot.density

DataFrame.plot.density(bw_method=None, ind=None, **kwds)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method : str, scalar or callable, optional

The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

ind : NumPy array or integer, optional
Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwsds :** optional

Additional keyword arguments are documented in `pandas.DataFrame.plot()`.

**Returns**

`axes` [matplotlib.axes.Axes or numpy.ndarray of them]

**See also:**

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

`Series.plot.kde` Generate a KDE plot for a Series.

**Examples**

Given several Series of points randomly sampled from unknown distributions, estimate their PDFs using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
```

```python
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to overfitting, while using a large bandwidth value may result in underfitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

```python
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the ind parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

34.4.13.6 pandas.DataFrame.plot.hexbin

`DataFrame.plot.hexbin(x, y, C=None, reduce_C_function=None, gridsize=None, **kwsds)`

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of x versus y. If C is None (the default), this is a histogram of the number of occurrences of the observations at (x[i], y[i]).

If C is specified, specifies values at given coordinates (x[i], y[i]). These values are accumulated for each hexagonal bin and then reduced according to reduce_C_function, having as default the NumPy's mean function (numpy.mean()). (If C is specified, it must also be a 1-D sequence of the same length as x and y, or a column label.)

**Parameters**

- `x` : int or str
The column label or position for x points.

\( y \): int or str

The column label or position for y points.

\( C \): int or str, optional

The column label or position for the value of \((x, y)\) point.

**reduce_C_function**: callable, default \( \text{np.mean} \)

Function of one argument that reduces all the values in a bin to a single number (e.g. \( \text{np.mean}, \text{np.max}, \text{np.sum}, \text{np.std} \)).

\( \text{gridsize} \): int or tuple of (int, int), default 100

The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, \( \text{gridsize} \) can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.

**kwds**

Additional keyword arguments are documented in \( \text{pandas.DataFrame.plot()} \).

Returns \( \text{matplotlib.AxesSubplot} \)

The \( \text{matplotlib} \) \( \text{Axes} \) on which the hexbin is plotted.

See also:

\( \text{DataFrame.plot} \) Make plots of a DataFrame.

\( \text{matplotlib.pyplot.hexbin} \) hexagonal binning plot using \( \text{matplotlib} \), the \( \text{matplotlib} \) function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```python
>>> n = 10000
>>> df = pd.DataFrame({
... 'x': np.random.randn(n),
... 'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses \( C \) and \( \text{np.sum} \) as **reduce_C_function**. Note that ‘observations’ values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the **reduce_C_function**.

```python
>>> n = 500
>>> df = pd.DataFrame(
... {'coord_x': np.random.uniform(-3, 3, size=n),
... 'coord_y': np.random.uniform(30, 50, size=n),
... 'observations': np.random.randint(1,5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
... y='coord_y',
... C='observations',
... reduce_C_function=np.sum,
... (continues on next page)
```
... gridsize=10, 
... cmap="viridis")

34.4.13.7 pandas.DataFrame.plot.hist

DataFrame.plot.hist(by=None, bins=10, **kwds)
Draw one histogram of the DataFrame's columns.
A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame's Series are in a similar scale.

Parameters
by : str or sequence, optional
   Column in the DataFrame to group by.
bins : int, default 10
   Number of histogram bins to be used.
**kwds
   Additional keyword arguments are documented in pandas.DataFrame.plot().

Returns
axes [matplotlib.AxesSubplot histogram.]

See also:
DataFrame.hist Draw histograms per DataFrame's Series.
Series.hist Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(
... np.random.randint(1, 7, 6000),
... columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

34.4.13.8 pandas.DataFrame.plot.kde

DataFrame.plot.kde(bw_method=None, ind=None, **kwds)
Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwith determination.

Parameters
bw_method : str, scalar or callable, optional
The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See `scipy.stats.gaussian_kde` for more information.

ind : NumPy array or integer, optional

Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwds : optional

Additional keyword arguments are documented in `pandas.DataFrame.plot`.

Returns

axes [matplotlib.axes.Axes or numpy.ndarray of them]

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

`Series.plot.kde` Generate a KDE plot for a Series.

Examples

Given several Series of points randomly sampled from unknown distributions, estimate their PDFs using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> df = pd.DataFrame(
...     ...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     ...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
...     ...)
...)
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to overfitting, while using a large bandwidth value may result in underfitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

34.4.13.9 pandas.DataFrame.plot.line

DataFrame.plot.line(x=None, y=None, **kwds)

Plot DataFrame columns as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

Parameters x : int or str, optional
Columns to use for the horizontal axis. Either the location or the label of the columns to be used. By default, it will use the DataFrame indices.

**y**: int, str, or list of them, optional

The values to be plotted. Either the location or the label of the columns to be used. By default, it will use the remaining DataFrame numeric columns.

**kwds**: keyword arguments to pass on to pandas.DataFrame.plot().

Returns **axes**: matplotlib.axes.Axes or numpy.ndarray

Returns an ndarray when subplots=True.

See also:

matplotlib.pyplot.plot Plot y versus x as lines and/or markers.

Examples

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900],
```

```python
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```

34.4.13.10 pandas.DataFrame.plot.pie

DataFrame.plot.pie (y=None, **kwds)

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps matplotlib.pyplot.pie() for the specified column. If no column reference is passed and subplots=True a pie plot is drawn for each numerical column independently.

**Parameters**

**y**: int or label, optional

Label or position of the column to plot. If not provided, subplots=True argument must be passed.

**kwds**: keyword arguments to pass on to pandas.DataFrame.plot().

Returns **axes**: matplotlib.axes.Axes or np.ndarray of them.
A NumPy array is returned when `subplots` is True.

See also:

- `Series.plot.pie` Generate a pie plot for a Series.
- `DataFrame.plot` Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
                    'radius': [2439.7, 6051.8, 6378.1]},
                    index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
>>> plot = df.plot.pie(subplots=True, figsize=(6, 3))
```

### 34.4.13.11 pandas.DataFrame.plot.scatter

`DataFrame.plot.scatter(x, y, s=None, c=None, **kwds)`  
Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

**Parameters**

- **x**: int or str  
  The column name or column position to be used as horizontal coordinates for each point.

- **y**: int or str  
  The column name or column position to be used as vertical coordinates for each point.

- **s**: scalar or array_like, optional  
  The size of each point. Possible values are:
  - A single scalar so all points have the same size.
  - A sequence of scalars, which will be used for each point’s size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

- **c**: str, int or array_like, optional  
  The color of each point. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point’s color recursively. For instance ['green', 'yellow'] all points will be filled in green or yellow, alternatively.
• A column name or position whose values will be used to color the marker points according to a colormap.

**kwds
Keyword arguments to pass on to pandas.DataFrame.plot().

Returns

axes [matplotlib.axes.Axes or numpy.ndarray of them]

See also:

matplotlib.pyplot.scatter scatter plot using multiple input data formats.

Examples

Let’s see how to draw a scatter plot using coordinates from the values in a DataFrame’s columns.

```python
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
... [6.4, 3.2, 1], [5.9, 3.0, 2]],
... columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
... y='width',
... c='DarkBlue')
```

And now with the color determined by a column as well.

```python
>>> ax2 = df.plot.scatter(x='length',
... y='width',
... c='species',
... colormap='viridis')
```

Dataframe.boxplot([column, by, ax, . . . ]) Make a box plot from DataFrame columns.

Dataframe.hist([column, by, grid, . . . ]) Make a histogram of the DataFrame’s.

34.4.14 Serialization / IO / Conversion

Dataframe.from_csv(path[, header, sep, . . . ]) (DEPRECATED) Read CSV file.

Dataframe.from_dict(data[, orient, dtype, . . . ]) Construct DataFrame from dict of array-like or dicts.

Dataframe.from_items(items[, columns, orient]) (DEPRECATED) Construct a dataframe from a list of tuples

Dataframe.from_records(data[, index, . . . ]) Convert structured or record ndarray to DataFrame

Dataframe.info([verbose, buf, max_cols, . . . ]) Print a concise summary of a DataFrame.

Dataframe.to_parquet(fname[, engine, . . . ]) Write a DataFrame to the binary parquet format.

Dataframe.to_pickle(path[, compression, . . . ]) Pickle (serialize) object to file.

Dataframe.to_csv([path_or_buf, sep, na_rep, . . . ]) Write DataFrame to a comma-separated values (csv) file

Dataframe.to_hdf(path_or_buf, key, **kwargs) Write the contained data to an HDF5 file using HDFStore.

Dataframe.to_sql(name, con[, schema, . . . ]) Write records stored in a DataFrame to a SQL database.

Dataframe.to_dict([orient, into]) Convert the DataFrame to a dictionary.

Dataframe.to_excel(excel_writer[, . . . ]) Write DataFrame to an excel sheet

Continued on next page
Table 77 – continued from previous page

*DataFrame.to_json*([path_or_buf, orient, ...]) Convert the object to a JSON string.

*DataFrame.to_html*([buf, columns, col_space, ...]) Render a DataFrame as an HTML table.

*DataFrame.to_feather*(fname) write out the binary feather-format for DataFrames

*DataFrame.to_latex*([buf, columns, ...]) Render an object to a tabular environment table.

*DataFrame.to_stata*(fname[, convert_dates, ...]) Export Stata binary dta files.

*DataFrame.to_msgpack*([path_or_buf, encoding]) msgpack (serialize) object to input file path

*DataFrame.to_gbq*(destination_table, project_id) Write a DataFrame to a Google BigQuery table.

*DataFrame.to_records*([index, convert_datetime64]) Convert DataFrame to a NumPy record array.

*DataFrame.to_sparse*([fill_value, kind]) Convert to SparseDataFrame

*DataFrame.to_dense*() Return dense representation of NDFrame (as opposed to sparse)

*DataFrame.to_string*([buf, columns, ...]) Render a DataFrame to a console-friendly tabular output.

*DataFrame.to_clipboard*([excel, sep]) Copy object to the system clipboard.

*DataFrame.style* Property returning a Styler object containing methods for building a styled HTML representation of the DataFrame.

34.4.15 Sparse

*SparseDataFrame.to_coo*() Return the contents of the frame as a sparse SciPy COO matrix.

34.4.15.1 pandas.SparseDataFrame.to_coo

SparseDataFrame.to_coo() Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.20.0.

**Returns** coo_matrix : scipy.sparse.spmatrix

If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

**Notes**

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find_common_type convention, mixing int64 and and uint64 will result in a float64 dtype.
34.5 Panel

34.5.1 Constructor

```
Panel([data, items, major_axis, minor_axis, ...])  (DEPRECATED) Represents wide format panel data, stored as 3-dimensional array
```

34.5.1.1 pandas.Panel

class pandas Panel(data=None, items=None, major_axis=None, minor_axis=None, copy=False, dtype=None)

Represents wide format panel data, stored as 3-dimensional array

Deprecated since version 0.20.0: The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the `to_frame()` method or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion.

**Parameters**

- **data**: ndarray (items x major x minor), or dict of DataFrames
- **items**: [Index or array-like] axis=0
- **major_axis**: [Index or array-like] axis=1
- **minor_axis**: [Index or array-like] axis=2
- **dtype**: [dtype, default None] Data type to force, otherwise infer
- **copy**: [boolean, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input

**Attributes**

- **at**: Access a single value for a row/column label pair.
- **axes**: Return index label(s) of the internal NDFrame
- **blocks**: (DEPRECATED) Internal property, property synonym for `as_blocks()`
- **dtypes**: Return the dtypes in the DataFrame.
- **empty**: Indicator whether DataFrame is empty.
- **ftypes**: Return the ftypes (indication of sparse/dense and dtype) in DataFrame.
- **iat**: Access a single value for a row/column pair by integer position.
- **iloc**: Purely integer-location based indexing for selection by position.
- **items**: A primarily label-location based indexer, with integer position fallback.
- **loc**: Access a group of rows and columns by label(s) or a boolean array.
- **major_axis**: 
- **minor_axis**: 

Continued on next page
### pandas.Panel.at

#### Panel.at
Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**  
`KeyError`  
When label does not exist in DataFrame

**See also:**

- `DataFrame.iat`  Access a single value for a row/column pair by integer position
- `DataFrame.loc`  Access a group of rows and columns by label(s)
- `Series.at`  Access a single value using a label

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```n

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```n

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```n
pandas.Panel.axes

Panel.axes
Return index label(s) of the internal NDFrame

pandas.Panel.blocks

Panel.blocks
Internal property, property synonym for as_blocks()
Depreciated since version 0.21.0.

pandas.Panel.dtypes

Panel.dtypes
Return the dtypes in the DataFrame.
This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

Returns pandas.Series
The data type of each column.

See also:
pandas.DataFrame.ftypes dtype and sparsity information.

Examples

```python
gf = pd.DataFrame({'float': [1.0],
...                     'int': [1],
...                     'datetime': [pd.Timestamp('20180310')],
...                     'string': ['foo']})
gf.dtypes
float float64
int int64
datetime datetime64[ns]
string object
dtype: object
```

pandas.Panel.empty

Panel.empty
Indicator whether DataFrame is empty.
True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns bool
If DataFrame is empty, return True, if not return False.

See also:
pandas.Series.dropna, pandas.DataFrame.dropna
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

**pandas.Panel.ftypes**

Panel.ftypes

Return the ftypes (indication of sparse/dense and dtype) in DataFrame.

This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

Returns pandas.Series

The data type and indication of sparse/dense of each column.

See also:

- **pandas.DataFrame.dtypes** Series with just dtype information.
- **pandas.SparseDataFrame** Container for sparse tabular data.

Notes

Sparse data should have the same dtypes as its dense representation.
Examples

```python
>>> import numpy as np
>>> arr = np.random.RandomState(0).randn(100, 4)
>>> arr[arr < .8] = np.nan
>>> pd.DataFrame(arr).dtypes
0 float64:dense
1 float64:dense
2 float64:dense
3 float64:dense
dtype: object
```

```python
>>> pd.SparseDataFrame(arr).dtypes
0 float64:sparse
1 float64:sparse
2 float64:sparse
3 float64:sparse
dtype: object
```

Pandas.Panel.iat

Panel.iat

Access a single value for a row/column pair by integer position.

Similar to iloc, in that both provide integer-based lookups. Use iat if you only need to get or set a
single value in a DataFrame or Series.

Raises IndexError

When integer position is out of bounds

See also:

DataFrame.at Access a single value for a row/column label pair
DataFrame.loc Access a group of rows and columns by label(s)
DataFrame.iloc Access a group of rows and columns by integer position(s)

Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                      columns=['A', 'B', 'C'])
>>> df
    A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10

Get value within a series

```python
>>> df.loc[0].iat[1]
2
```

**pandas.Panel.iloc**

**Panel.iloc**

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. `[4, 3, 0]`.
- A slice object with ints, e.g. `1:7`.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except `slice` indexers which allow out-of-bounds indexing (this conforms with python/numpy `slice` semantics).

See more at *Selection by Position*

**pandas.Panel.items**

**Panel.items**

**pandas.Panel.ix**

**Panel.ix**

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers.

`.ix[]` supports mixed integer and label based access. It is primarily label based, but will fall back to integerpositional access unless the corresponding axis is of integer type.

`.ix` is the most general indexer and will support any of the inputs in `.loc` and `.iloc`. .ix also supports floating point label schemes. .ix is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, ONLY label based access and not positional access is supported. Thus, in such cases, it’s usually better to be explicit and use .iloc or .loc.

See more at *Advanced Indexing*.
pandas.Panel.loc

Panel.loc
Access a group of rows and columns by label(s) or a boolean array.
.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and never as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, both the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

**Raises** KeyError:

when any items are not found

**See also:**

- **DataFrame.at** Access a single value for a row/column label pair
- **DataFrame.iloc** Access group of rows and columns by integer position(s)
- **DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- **Series.loc** Access group of values using labels

**Examples**

**Getting values**

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...    index=['cobra', 'viper', 'sidewinder'],
...    columns=['max_speed', 'shield'])
>>> df
     max_speed  shield
  cobra         1       2
  viper         4       5
  sidewinder    7       8
```

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
max_speed  4
shield    5
Name: viper, dtype: int64
```
List of labels. Note using `[]` returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
max_speed  shield
viper      4      5
sidewinder 7      8
```

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc['cobra':'viper', 'max_speed']
cobra 1
viper 4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```python
>>> df.loc[[False, False, True]]
max_speed  shield
sidewinder 7      8
```

Conditional that returns a boolean Series

```python
>>> df.loc[df['shield'] > 6]
max_speed  shield
sidewinder 7      8
```

Conditional that returns a boolean Series with column labels specified

```python
>>> df.loc[df['shield'] > 6, ['max_speed']]
max_speed
sidewinder 7
```

Callable that returns a boolean Series

```python
>>> df.loc[lambda df: df['shield'] == 8]
max_speed  shield
sidewinder 7      8
```

**Setting values**

Set value for all items matching the list of labels

```python
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
```

```python
>>> df
max_speed  shield
cobra      1      2
viper      4      50
sidewinder 7      50
```

Set value for an entire row
Set value for an entire column

```python
>>> df.loc[:, 'max_speed'] = 30
>>> df
   max_speed  shield
  cobra      30     10
  viper      30      50
  sidewinder 30      50
```

Set value for rows matching callable condition

```python
>>> df.loc[df['shield'] > 35] = 0
>>> df
   max_speed  shield
  cobra      30     10
  viper       0      0
  sidewinder  0      0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                     index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
  7           1     2
  8           4     5
  9           7     8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc[7:9]
   max_speed  shield
  7           1     2
  8           4     5
  9           7     8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
>>> tuples = [
            ('cobra', 'mark i'), ('cobra', 'mark ii'),
            ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
            ('viper', 'mark ii'), ('viper', 'mark iii')
        ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
            [1, 4], [7, 1], [16, 36]]
```
```python
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
    max_speed  shield
cobra     mark i   12     2
         mark ii   0      4
sidewinder     mark i 10    20
         mark ii   1      4
viper     mark ii   7      1
         mark iii  16    36
```

Single label. Note this returns a DataFrame with a single index.

```python
>>> df.loc['cobra']
    max_speed  shield
mark i     12     2
mark ii    0      4
```

Single index tuple. Note this returns a Series.

```python
>>> df.loc[('cobra', 'mark ii')]
max_speed     0
shield       4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```python
>>> df.loc['cobra', 'mark i']
max_speed     12
shield       2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[]` returns a DataFrame.

```python
>>> df.loc[('cobra', 'mark ii')]  
    max_speed  shield
cobra mark ii 0     4
```

Single tuple for the index with a single label for the column

```python
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```python
>>> df.loc[('cobra', 'mark i'):'viper']
    max_speed  shield
cobra     mark i   12     2
         mark ii   0      4
sidewinder     mark i 10    20
         mark ii   1      4
viper     mark ii   7      1
         mark iii  16    36
```

Slice from index tuple to index tuple
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
max_speed  shield
    cobra     mark i  12   2
          mark ii  0   4
   sidewinder mark i  10  20
          mark ii  1   4
     viper     mark ii  7   1
```

`pandas.Panel.major_axis`

`Panel.major_axis`

`pandas.Panel.minor_axis`

`Panel.minor_axis`

`pandas.Panel.ndim`

`Panel.ndim`

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

ndarray.ndim

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

`pandas.Panel.shape`

`Panel.shape`

Return a tuple of axis dimensions

`pandas.Panel.size`

`Panel.size`

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.
See also:

ndarray.size

Examples

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

**pandas.Panel.values**

*Panel.values*

Return a Numpy representation of the DataFrame.

Only the values in the DataFrame will be returned, the axes labels will be removed.

**Returns** numpy.ndarray

The values of the DataFrame.

See also:

`pandas.DataFrame.index` Retrieve the index labels

`pandas.DataFrame.columns` Retrieving the column names

Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

E.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```python
>>> df = pd.DataFrame({'age': [3, 29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df.dtypes
(continues on next page)
```
A DataFrame with mixed type columns (e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```python
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
                     ('lion', 80.5, 1),
                     ('monkey', np.nan, None)],
                     columns=['name', 'max_speed', 'rank'])
```

```python
>>> df2.dtypes
name    object
max_speed  float64
rank     object
dtype: object
```

```python
>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)
```

**Methods**

- `abs()`  
  Return a Series/DataFrame with absolute numeric value of each element.

- `add(other[, axis])`  
  Addition of series and other, element-wise (binary operator `add`).

- `add_prefix(prefix)`  
  Prefix labels with string `prefix`.

- `add_suffix(suffix)`  
  Suffix labels with string `suffix`.

- `align(other, **kwargs)`  
  Align two objects on their axes with the specified join method for each axis Index.

- `all([axis, bool_only, skipna, level])`  
  Return whether all elements are True, potentially over an axis.

- `any([axis, bool_only, skipna, level])`  
  Return whether any element is True over requested axis.

- `apply(func[, axis])`  
  Applies function along axis (or axes) of the Panel.

- `as_blocks([copy])`  
  (DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

- `as_matrix([copy])`  
  Convert the frame to its Numpy-array representation.

- `asfreq(freq[, method, how, normalize, ...])`  
  Convert TimeSeries to specified frequency.

- `asof(where[, subset])`  
  The last row without any NaN is taken (or the last row without NaN considering only the subset of columns in the case of a DataFrame).

### pandas.Panel.abs

**Panel.abs()**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns **abs**

Series/DataFrame containing the absolute value of each element.

See also:

- `numpy.absolute` calculate the absolute value element-wise.

### Notes

For complex inputs, `1.2 + 1j`, the absolute value is $\sqrt{a^2 + b^2}$.

### Examples

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.
```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4  10  100
1  5  20  50
2  6  30 -30
3  7  40 -50

>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
0  4  10  100
1  5  20  50
2  6  30 -30
3  7  40 -50
```

**pandas.Panel.add**

Panel.add(other, axis=0)

Addition of series and other, element-wise (binary operator add). Equivalent to panel + other.

Parameters

- **other** [DataFrame or Panel]
- **axis** : [items, major_axis, minor_axis]

Axis to broadcast over

Returns

Panel

See also:

Panel.radd

**pandas.Panel.add_prefix**

Panel.add_prefix(prefix)

Prefix labels with string prefix.
For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters**  
*prefix*: str  
The string to add before each label.

**Returns**  
Series or DataFrame  
New Series or DataFrame with updated labels.

**See also:**  
*Series.add_suffix*  
Suffix row labels with string *suffix*.

*DataFrame.add_suffix*  
Suffix column labels with string *suffix*.

**Examples**

```python
taxprint
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0 1
1 2
2 3
3 4
dtype: int64

>>> s.add_prefix('item_')
item_0 1
item_1 2
item_2 3
item_3 4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0 1 3
1 2 4
2 3 5
3 4 6

>>> df.add_prefix('col_')
   col_A  col_B
0   1    3
1   2    4
2   3    5
3   4    6
```

**pandas.Panel.add_suffix**

Panel.add_suffix(*suffix*)  
Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**  
*suffix*: str
The string to add after each label.

**Returns**  
Series or DataFrame

New Series or DataFrame with updated labels.

**See also:**

*Series.add_prefix*  
Prefix row labels with string *prefix*.

*DataFrame.add_prefix*  
Prefix column labels with string *prefix*.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_suffix('_item')
0_item  1
1_item  2
2_item  3
3_item  4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_suffix('_col')
   A_col  B_col
0      1      3
1      2      4
2      3      5
3      4      6
```

**pandas.Panel.align**

Panel.{align}(other, **kwargs)

Align two objects on their axes with the specified join method for each axis

**Parameters**

- **other**  
  [DataFrame or Series]

- **join**  
  [{'outer', 'inner', 'left', 'right'}, default 'outer']

- **axis**  
  allowed axis of the other object, default None
Align on index (0), columns (1), or both (None)

**level**: int or level name, default None

Broadcast across a level, matching Index values on the passed MultiIndex level

**copy**: boolean, default True

Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

**fill_value**: scalar, default np.NaN

Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**method** [str, default None]

**limit** [int, default None]

**fill_axis**: int or labels for object, default 0

Filling axis, method and limit

**broadcast_axis**: int or labels for object, default None

Broadcast values along this axis, if aligning two objects of different dimensions

**Returns** (left, right): (NDFrame, type of other)

Aligned objects

**pandas.Panel.all**

Panel.all *(axis=0, bool_only=None, skipna=True, level=None, **kwargs)*

Return whether all elements are True, potentially over an axis.

Returns True if all elements within a series or along a Dataframe axis are non-zero, not-empty or not-False.

**Parameters**

- **axis**: {0 or ‘index’, 1 or ‘columns’, None}, default 0
  - Indicate which axis or axes should be reduced.
    - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
    - 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
    - None : reduce all axes, return a scalar.

- **skipna**: boolean, default True
  - Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- **level**: int or level name, default None
  - If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

- **bool_only**: boolean, default None
  - Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.
**kwargs: any, default None

Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

- `all` [DataFrame or Panel (if level specified)]

See also:

- `pandas.Series.all` Return True if all elements are True
- `pandas.DataFrame.any` Return True if one (or more) elements are True

Examples

Series

```python
>>> pd.Series([True, True]).all()
True
```
```python
>>> pd.Series([True, False]).all()
False
```

DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
col1  col2
0    True  True
1    True  False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
coll   True
col2   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0    True
1    False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

`pandas.Panel.any`

Panel.any (axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether any element is True over requested axis.
Unlike DataFrame.all(), this performs an or operation. If any of the values along the specified axis is True, this will return True.

**Parameters**

- **axis**: {0 or 'index', 1 or 'columns', None}, default 0
  Indicate which axis or axes should be reduced.
  - 0 / 'index': reduce the index, return a Series whose index is the original column labels.
  - 1 / 'columns': reduce the columns, return a Series whose index is the original index.
  - None: reduce all axes, return a scalar.

- **skipna**: boolean, default True
  Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- **level**: int or level name, default None
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

- **bool_only**: boolean, default None
  Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

- **kwargs**: any, default None
  Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **any**: [DataFrame or Panel (if level specified)]

See also:

- **pandas.DataFrame.all** Return whether all elements are True.

**Examples**

**Series**

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([True, False]).any()
True
```

**DataFrame**

Whether each column contains at least one True element (the default).

```python
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```
Aggregating over the columns.

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True 1
1  False 2
```

```python
>>> df.any(axis='columns')
0  True
1  True
dtype: bool
```

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True 1
1  False 0
```

```python
>>> df.any(axis='columns')
0  True
1  False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```python
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```python
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

**pandas.Panel.apply**

Panel.apply(func, axis='major', **kwargs)

Applies function along axis (or axes) of the Panel

**Parameters**

<table>
<thead>
<tr>
<th>func</th>
<th>function</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Function to apply to each combination of ‘other’ axes e.g. if axis = ‘items’, the combination of major_axis/minor_axis will each be passed as a Series; if axis = (‘items’, ‘major’), DataFrames of items &amp; major axis will be passed</td>
</tr>
<tr>
<td>axis</td>
<td>(‘items’, ‘minor’, ‘major’), or {0, 1, 2}, or a tuple with two axes</td>
</tr>
</tbody>
</table>

Additional keyword arguments will be passed as keywords to the function
Returns

result [Panel, DataFrame, or Series]

Examples

Returns a Panel with the square root of each element

```python
>>> p = pd.Panel(np.random.rand(4,3,2))
>>> p.apply(np.sqrt)
```

Equivalent to p.sum(1), returning a DataFrame

```python
>>> p.apply(lambda x: x.sum(), axis=1)
```

Equivalent to previous:

```python
>>> p.apply(lambda x: x.sum(), axis='major')
```

Return the shapes of each DataFrame over axis 2 (i.e the shapes of items x major), as a Series

```python
>>> p.apply(lambda x: x.shape, axis=(0,1))
```

pandas.Panel.as_blocks

Panel.as_blocks (copy=True)
Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in as_matrix)

Parameters

- copy [boolean, default True]

Returns

- values [a dict of dtype -> Constructor Types]

pandas.Panel.as_matrix

Panel.as_matrix()
Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use DataFrame.values() instead.

Parameters columns: list, optional, default:None
If None, return all columns, otherwise, returns specified columns.

Returns values : ndarray
If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

See also:

pandas.DataFrame.values
Notes

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By numpy.find_common_type convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use ‘.values’.

pandas.Panel.asfreq

Panel.asfreq(freq=None, method=None, how=None, normalize=False, fill_value=None)

Convert TimeSeries to specified frequency. Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. resample is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset object, or string]

method : {'backfill'/'bfill', 'pad'/'ffill'}, default None

Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

• 'pad' / 'ffill': propagate last valid observation forward to next valid
• 'backfill' / 'bfill': use NEXT valid observation to fill

how : {'start', 'end'}, default end

For PeriodIndex only, see PeriodIndex.asfreq

normalize : bool, default False

Whether to reset output index to midnight

fill_value: scalar, optional

Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

Returns

converted [type of caller]

See also:

reindex

Notes

To learn more about the frequency strings, please see this link.
Examples

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
   s
2000-01-01 00:00:00  0.0
2000-01-01 00:01:00  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:03:00  3.0
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
   s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
   s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```

Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')
   s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  2.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  3.0
2000-01-01 00:03:00  3.0
```

**pandas.Panel.asof**

Panel.asof(where, subset=None)

The last row without any NaN is taken (or the last row without NaN considering only the subset of columns in the case of a DataFrame)

New in version 0.19.0: For DataFrame
If there is no good value, NaN is returned for a Series a Series of NaN values for a DataFrame

**Parameters**

- **where** [date or array of dates]
- **subset** : string or list of strings, default None
  if not None use these columns for NaN propagation

**Returns**

- **where is scalar**
  - value or NaN if input is Series
  - Series if input is DataFrame

**where is Index: same shape object as input**

**See also:**

merge_asof

**Notes**

Dates are assumed to be sorted Raises if this is not the case

### pandas.Panel.astype

**Panel.astype**(dtype, copy=True, errors='raise', **kwargs)

Cast a pandas object to a specified dtype dtype.

**Parameters**

dtype : data type, or dict of column name -> data type

Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

copy : bool, default True.

Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

ersors : {'raise', 'ignore'}, default 'raise'.

Control raising of exceptions on invalid data for provided dtype.

- **raise**: allow exceptions to be raised
- **ignore**: suppress exceptions. On error return original object

New in version 0.20.0.

raise_on_error : raise on invalid input

Deprecated since version 0.20.0: Use errors instead

kwarg**s** [keyword arguments to pass on to the constructor]

**Returns**

casted [type of caller]
See also:

- **pandas.to_datetime** Convert argument to datetime.
- **pandas.to_timedelta** Convert argument to timedelta.
- **pandas.to_numeric** Convert argument to a numeric type.
- **numpy.ndarray.astype** Cast a numpy array to a specified type.

**Examples**

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0 1
1 2
dtype: int32
>>> ser.astype('int64')
0 1
1 2
dtype: int64
```

Convert to categorical type:

```python
>>> ser.astype('category')
0 1
1 2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> ser.astype('category', ordered=True, categories=[2, 1])
0 1
1 2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1
# note that s1[0] has changed too
0 10
1 2
dtype: int64
```

**pandas.Panel.at_time**

Panel.at_time(time, asof=False)
Select values at particular time of day (e.g. 9:30AM).

**Parameters**

- **time** [datetime.time or string]
Returns

values_at_time  [type of caller]

Raises TypeError

If the index is not a `DatetimeIndex`

See also:

between_time  Select values between particular times of the day
first  Select initial periods of time series based on a date offset
last  Select final periods of time series based on a date offset

`DatetimeIndex.indexer_at_time`  Get just the index locations for values at particular time of the day

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4

>>> ts.at_time('12:00')
   A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

pandas.Panel.between_time

`Panel.between_time` *(start_time, end_time, include_start=True, include_end=True)*

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

- **start_time**  [datetime.time or string]
- **end_time**  [datetime.time or string]
- **include_start**  [boolean, default True]
- **include_end**  [boolean, default True]

Returns

values_between_time  [type of caller]

Raises TypeError

If the index is not a `DatetimeIndex`
See also:

**at_time** Select values at a particular time of the day

**first** Select initial periods of time series based on a date offset

**last** Select final periods of time series based on a date offset

**DatetimeIndex.indexer_between_time** Get just the index locations for values between particular times of the day

### Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4

>>> ts.between_time('0:15', '0:45')
   A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3

You get the times that are not between two times by setting `start_time` later than `end_time`:

```python
>>> ts.between_time('0:45', '0:15')
   A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4
```
Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- **lower**: float or array_like, default None
  - Minimum threshold value. All values below this threshold will be set to it.
  - **upper**: float or array_like, default None
  - Maximum threshold value. All values above this threshold will be set to it.
  - **axis**: int or string axis name, optional
  - Align object with lower and upper along the given axis.
- **inplace**: boolean, default False
  - Whether to perform the operation in place on the data.
  - New in version 0.21.0.
- ***args**, ****kwargs**
  - Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

- Series or DataFrame
  - Same type as calling object with the values outside the clip boundaries replaced

**See also:**

- **clip_lower** Clip values below specified threshold(s).
- **clip_upper** Clip values above specified threshold(s).

**Examples**

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
   col_0  col_1
0      6     -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2    1
3    6
4    3
dtype: int64
```

```python
>>> df.clip(t, t + 4, axis=0)
       col_0  col_1
0        6     2
1       -3    -4
2        0     3
3        6     8
4        5     3
```

**pandas.Panel.clip_lower**

Panel.clip_lower(threshold, axis=None, inplace=False)

Return copy of the input with values below a threshold truncated.

**Parameters**

- **threshold**: numeric or array-like
  
  Minimum value allowed. All values below threshold will be set to this value.
  
  - float: every value is compared to threshold.
  
  - array-like: The shape of threshold should match the object it’s compared to. When self is a Series, threshold should be the length. When self is a DataFrame, threshold should be 2-D and the same shape as self for axis=None, or 1-D and the same length as the axis being compared.

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  
  Align self with threshold along the given axis.

- **inplace**: boolean, default False
  
  Whether to perform the operation in place on the data.

**Returns**

clipped [same type as input]

**See also:**

- Series.clip Return copy of input with values below and above thresholds truncated.
- Series.clip_upper Return copy of input with values above threshold truncated.

**Examples**

Series single threshold clipping:
Series clipping element-wise using an array of thresholds. \textit{threshold} should be the same length as the Series.

DataFrames can be compared to a scalar.

Or to an array of values. By default, \textit{threshold} should be the same shape as the DataFrame.

Control how \textit{threshold} is broadcast with \textit{axis}. In this case \textit{threshold} should be the same length as the axis specified by \textit{axis}.
pandas.Panel.clip_upper

Panel.clip_upper(threshold, axis=None, inplace=False)
Return copy of input with values above given value(s) truncated.

Parameters
   threshold [float or array_like]
   axis : int or string axis name, optional
      Align object with threshold along the given axis.
   inplace : boolean, default False
      Whether to perform the operation in place on the data
      New in version 0.21.0.

Returns
   clipped [same type as input]

See also:
   clip

pandas.Panel.compound

Panel.compound(axis=None, skipna=None, level=None)
Return the compound percentage of the values for the requested axis

Parameters
   axis [[items (0), major_axis (1), minor_axis (2)]
   skipna : boolean, default True
      Exclude NA/null values when computing the result.
   level : int or level name, default None
      If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing
      into a DataFrame
   numeric_only : boolean, default None
      Include only float, int, boolean columns. If None, will attempt to use everything,
      then use only numeric data. Not implemented for Series.

Returns
   compounded [DataFrame or Panel (if level specified)]
pandas.Panel.conform

Panel.conform(frame, axis='items')
Conform input DataFrame to align with chosen axis pair.

Parameters

frame [DataFrame]
axis : {'items', 'major', 'minor'}
    Axis the input corresponds to. E.g., if axis='major', then the frame’s columns
    would be items, and the index would be values of the minor axis

Returns

DataFrame

pandas.Panel.consolidate

Panel.consolidate(inplace=False)
Compute NDFrame with “consolidated” internals (data of each dtype grouped together in a single ndarray).

Deprecated since version 0.20.0: Consolidate will be an internal implementation only.

pandas.Panel.convert_objects

Panel.convert_objects(convert_dates=True, convert_numeric=False, convert_timedeltas=True, copy=True)
Attempt to infer better dtype for object columns.

Deprecated since version 0.21.0.

Parameters convert_dates : boolean, default True
    If True, convert to date where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.

convert_numeric : boolean, default False
    If True, attempt to coerce to numbers (including strings), with unconvertible values becoming NaN.

convert_timedeltas : boolean, default True
    If True, convert to timedelta where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.

copy : boolean, default True
    If True, return a copy even if no copy is necessary (e.g. no conversion was done).
    Note: This is meant for internal use, and should not be confused with inplace.

Returns

converted [same as input object]

See also:

pandas.to_datetime Convert argument to datetime.
pandas.to_timedelta  Convert argument to timedelta.
pandas.to_numeric  Return a fixed frequency timedelta index, with day as the default.

pandas.Panel.copy

Panel.copy (deep=True)
Make a copy of this object’s indices and data.

When deep=True (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When deep=False, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters deep : bool, default True
Make a deep copy, including a copy of the data and the indices. With deep=False neither the indices nor the data are copied.

Returns copy : Series, DataFrame or Panel
Object type matches caller.

Notes

When deep=True, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to copy.deepcopy in the Standard Library, which recursively copies object data (see examples below).

While Index objects are copied when deep=True, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```python
>>> s = pd.Series([1, 2], index=["a", "b")
>>> s
a  1
b  2
dtype: int64

>>> s_copy = s.copy()
>>> s_copy
a  1
b  2
dtype: int64

Shallow copy versus default (deep) copy:
```
Shallow copy shares data and index with original.

```python
global s
shallow = s

>>> s is shallow
False

>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```python
global s
deep = s

>>> s is deep
False

>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
s[0] = 3
shallow[1] = 4

>>> s
a 3
b 4
dtype: int64

>>> shallow
a 3
b 4
dtype: int64

>>> s[0] = 10

>>> s
0 [10, 2]
1 [3, 4]
dtype: object

>>> shallow
a 3
b 4
dtype: int64
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
s[0] = 3
shallow[1] = 4

>>> s
a 3
b 4
dtype: int64

>>> shallow
a 3
b 4
dtype: int64

>>> s[0] = 10

>>> s
0 [10, 2]
1 [3, 4]
dtype: object

>>> shallow
a 3
b 4
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
s = pd.Series([[1, 2], [3, 4]])
data = s.copy()

>>> s[0][0] = 10

>>> s
0 [10, 2]
1 [3, 4]
dtype: object

>>> data
0 [10, 2]
1 [3, 4]
dtype: object
```

---

**pandas.Panel.count**

`Panel.count(axis='major')`

Return number of observations over requested axis.

**Parameters**

- `axis` (`{'items', 'major', 'minor'}` or `0, 1, 2`)

**Returns**

- `count` (`DataFrame`)
**pandas.Panel.cummax**

Panel.cummax(\(axis=\)None, skipna=True, *args, **kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

**Parameters**

**axis**: {0 or ‘index’, 1 or ‘columns’}, default 0

The index or the name of the axis. 0 is equivalent to None or ‘index’.

**skipna**: boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

cummax [DataFrame or Panel]

**See also:**

**pandas.core.window.Expanding.max** Similar functionality but ignores NaN values.

**Panel.max** Return the maximum over Panel axis.

**Panel.cummax** Return cumulative maximum over Panel axis.

**Panel.cummin** Return cumulative minimum over Panel axis.

**Panel.cumsum** Return cumulative sum over Panel axis.

**Panel.cumprod** Return cumulative product over Panel axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
0    2.0
1   NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use skipna=False
```python
>>> s.cummax(skipna=False)
0   2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0], ... [3.0, np.nan], ... [1.0, 0.0]], columns=list('AB'))
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummax()
    A   B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```python
>>> df.cummax(axis=1)
    A   B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

### pandas.Panel.cummin

**Panel.cummin** *(axis=None, skipna=True, *args, **kwargs)*

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

**Parameters**

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  
The index or the name of the axis. 0 is equivalent to None or ‘index’.

- **skipna** : boolean, default True
  
Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- *args, **kwargs*
  
Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**
cummin [DataFrame or Panel]

See also:

pandas.core.window.Expanding.min Similar functionality but ignores NaN values.
Panel.min Return the minimum over Panel axis.
Panel.cummax Return cumulative maximum over Panel axis.
Panel.cummin Return cumulative minimum over Panel axis.
Panel.cumsum Return cumulative sum over Panel axis.
Panel.cumprod Return cumulative product over Panel axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0   2.0
1   NaN
2   5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0   2.0
1   NaN
2   2.0
3  -1.0
4  -1.0
dtype: float64
```

To include NA values in the operation, use skipna=False

```python
>>> s.cummin(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
```

(continues on next page)
By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummin()
   A  B
0 2.0 1.0
1 2.0 NaN
2 1.0 0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```python
>>> df.cummin(axis=1)
   A  B
0 2.0 1.0
1 3.0 NaN
2 1.0 0.0
```

### pandas.Panel.cumprod

```
Panel.cumprod (axis=None, skipna=True, *args, **kwargs)  
```

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

- **Parameters axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - The index or the name of the axis. 0 is equivalent to None or ‘index’.
  - **skipna**: boolean, default True
    - Exclude NA/null values. If an entire row/column is NA, the result will be NA.
  - **args**, **kwargs**:
    - Additional keywords have no effect but might be accepted for compatibility with NumPy.

- **Returns**
  - `cumprod` [DataFrame or Panel]

- **See also**

  - `pandas.core.window.Expanding.prod` Similar functionality but ignores NaN values.
  - `Panel.prod` Return the product over Panel axis.
  - `Panel.cummax` Return cumulative maximum over Panel axis.
  - `Panel.cummin` Return cumulative minimum over Panel axis.
  - `Panel.cumsum` Return cumulative sum over Panel axis.
  - `Panel.cumprod` Return cumulative product over Panel axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])

>>> s
0    2.0
1     NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))

>>> df
   A   B
0  2.0  1.0
1  3.0   NaN
2  1.0   0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumprod()
   A   B
0  2.0  1.0
1  6.0   NaN
2  6.0   0.0
```

To iterate over columns and find the product in each row, use `axis=1`
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> df.cumprod(axis=1)
   A   B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

**pandas.Panel.cumsum**

```
pandas.Panel.cumsum(axis=None, skipna=True, *args, **kwargs)
```

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters
----------

axis : {0 or ‘index’, 1 or ‘columns’}, default 0

The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna : boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs :

Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns
-------

cumsum [DataFrame or Panel]

See also:
---------

pandas.core.window.Expanding.cumsum Similar functionality but ignores NaN values.

Panel.cummax Return cumulative maximum over Panel axis.

Panel.cummin Return cumulative minimum over Panel axis.

Panel.cumsum Return cumulative sum over Panel axis.

Panel.cumprod Return cumulative product over Panel axis.

Examples
--------

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
```

```python
>>> s
0   2.0
1  NaN
2   5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.
To include NA values in the operation, use `skipna=False`

```python
>>> s.cumsum(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame(
    [[2.0, 1.0],
     [3.0, np.nan],
     [1.0, 0.0]],
    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumsum()
   A  B
0  2.0  3.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```python
>>> df.cumsum(axis=1)
   A  B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

**pandas.Panel.describe**

Panel . describe ( percentiles=None , include=None , exclude=None )

Generates descriptive statistics that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

- **Parameters** percentiles : list-like of numbers, optional
The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

**include**: `all`, list-like of dtypes or None (default), optional

A white list of data types to include in the result. Ignored for Series. Here are the options:

- `'all'`: All columns of the input will be included in the output.
- A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`

- None (default): The result will include all numeric columns.

**exclude**: list-like of dtypes or None (default), optional,

A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`

- None (default): The result will exclude nothing.

**Returns**

summary: Series/DataFrame of summary statistics

**See also:**

`DataFrame.count`, `DataFrame.max`, `DataFrame.min`, `DataFrame.mean`, `DataFrame.std`, `DataFrame.select_dtypes`

**Notes**

For numeric data, the result’s index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value’s frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`. 
Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count   3.0
mean    2.0
std     1.0
min     1.0
25%     1.5
50%     2.0
75%     2.5
max     3.0
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count   4
unique   3
top     a
freq    2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([np.datetime64('2000-01-01'),
...                 np.datetime64('2010-01-01'),
...                 np.datetime64('2010-01-01')])
>>> s.describe()
count   3
unique   2
top  2010-01-01 00:00:00
freq    2
first  2000-01-01 00:00:00
last  2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({
...                      'object': ['a', 'b', 'c'],
...                      'numeric': [1, 2, 3],
...                      'categorical': pd.Categorical(['d', 'e', 'f'])
...                      })
>>> df.describe()
numeric
   count   3.0
   mean    2.0
   std     1.0
   min     1.0
   25%     1.5
   50%     2.0
   75%     2.5
   max     3.0
```
Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
categorical    numeric    object
count           3          3.0          3
unique          3          NaN          3
top             f          NaN          c
freq            1          NaN          1
mean            NaN         2.0          NaN
std             NaN         1.0          NaN
min             NaN         1.0          NaN
25%             NaN         1.5          NaN
50%             NaN         2.0          NaN
75%             NaN         2.5          NaN
max             NaN         3.0          NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
categorical
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[np.object])
object
count 3
unique 3
top c
freq 1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
categorical
count 3
unique 3
```
Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
   categorical  object
       count     3    3
       unique     3    3
        top   f    c
       freq     1    1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.object])
   categorical  numeric
       count     3    3.0
       unique     3    NaN
        top   f    NaN
       freq     1    NaN
        mean     NaN   2.0
        std     NaN   1.0
       min     NaN   1.0
      25%     NaN   1.5
      50%     NaN   2.0
      75%     NaN   2.5
      max     NaN   3.0
```

**pandas.Panel.div**

Panel.div(other, axis=0)

Floating division of series and other, element-wise (binary operator truediv). Equivalent to panel / other.

**Parameters**

- **other** [DataFrame or Panel]
- **axis** : {items, major_axis, minor_axis}

  Axis to broadcast over

**Returns**

Panel

See also:

- Panel.rtruediv

**pandas.Panel.divide**

Panel.divide(other, axis=0)

Floating division of series and other, element-wise (binary operator truediv). Equivalent to panel / other.

**Parameters**
other  [DataFrame or Panel]
axis : [items, major_axis, minor_axis]
    Axis to broadcast over

Returns
Panel

See also:
Panel.rtruediv

pandas.Panel.dropna

Panel.dropna (axis=0, how='any', inplace=False)
Drop 2D from panel, holding passed axis constant

Parameters axis : int, default 0
    Axis to hold constant. E.g. axis=1 will drop major_axis entries having a certain amount of NA data
how : {'all', 'any'}, default 'any'
    'any': one or more values are NA in the DataFrame along the axis. For 'all' they all must be.
inplace : bool, default False
    If True, do operation inplace and return None.

Returns
    dropped [Panel]

pandas.Panel.eq

Panel.eq (other, axis=None)
Wrapper for comparison method eq

pandas.Panel.equals

Panel.equals (other)
Determines if two NDFrame objects contain the same elements. NaNs in the same location are considered equal.

pandas.Panel.ffill

Panel.ffill (axis=None, inplace=False, limit=None, downcast=None)
Synonym for DataFrame.fillna(method='ffill')
pandas.Panel.fillna

Panel.fillna(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, **kwargs)

Fill NA/NaN values using the specified method

**Parameters**

- **value**: scalar, dict, Series, or DataFrame
  - Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). (values not in the dict/Series/DataFrame will not be filled). This value cannot be a list.

- **method**: {'backfill', 'bfill', 'pad', 'ffill', None}, default None
  - Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

- **axis** [{0, 1, 2, ‘items’, ‘major_axis’, ‘minor_axis’}]

- **inplace**: boolean, default False
  - If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

- **limit**: int, default None
  - If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast**: dict, default is None
  - a dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

**Returns**

- **filled** [Panel]

See also:

- **interpolate** Fill NaN values using interpolation.
- **reindex, asfreq**

**Examples**

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                     columns=list('ABCD'))
>>> df
A  B  C  D
--- --- --- ---
NaN  2 NaN  0
3  4 NaN  1
NaN NaN NaN  5
NaN  3 NaN  4
```

(continues on next page)
Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
   A  B  C  D
0  0.0 2.0 0.0 0
1  3.0 4.0 0.0 1
2  0.0 0.0 0.0 5
3  0.0 3.0 0.0 4
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method='ffill')
   A  B  C  D
0  NaN 2.0 NaN 0
1  3.0 4.0 NaN 1
2  3.0 4.0 NaN 5
3  3.0 3.0 NaN 4
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 2.0 1
2  0.0 1.0 2.0 5
3  0.0 3.0 2.0 4
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 NaN 1
2  NaN 1.0 NaN 5
3  NaN 3.0 NaN 4
```

**pandas.Panel.filter**

Panel.filter(items=None, like=None, regex=None, axis=None)

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items** : list-like
  List of info axis to restrict to (must not all be present)
- **like** : string
  Keep info axis where “arg in col == True”
**regex**: string (regular expression)
 Keep info axis with re.search(regex, col) == True

**axis**: int or string axis name
 The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame

**Returns**

same type as input object

**See also:**

*pandas.DataFrame.loc*

**Notes**

The **items**, **like**, and **regex** parameters are enforced to be mutually exclusive.

**axis** defaults to the info axis that is used when indexing with [].

**Examples**

```python
>>> df
one  two  three
mouse 1  2  3
rabbit 4  5  6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
one  three
mouse 1  3
rabbit 4  6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
one  three
mouse 1  3
rabbit 4  6

>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
one  two  three
rabbit 4  5  6
```

**pandas.Panel.first**

**Panel.first** *(offset)*

Convenience method for subsetting initial periods of time series data based on a date offset.

**Parameters**

**offset** [string, DateOffset, dateutil.relativedelta]
Returns

  subset [type of caller]

Raises  TypeError

  If the index is not a DatetimeIndex

See also:

  last  Select final periods of time series based on a date offset

  at_time  Select values at a particular time of the day

  between_time  Select values between particular times of the day

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
   A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.Panel.first_valid_index

Panel.first_valid_index()  
Return index for first non-NA/null value.

Returns

  scalar [type of index]

Notes

  If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

pandas.Panel.floordiv

Panel.floordiv(other, axis=0)  
Integer division of series and other, element-wise (binary operator floordiv). Equivalent to panel // other.
Parameters

other  [DataFrame or Panel]

axis : {items, major_axis, minor_axis}

Axis to broadcast over

Returns

Panel

See also:

Panel.rfloordiv

pandas.Panel.fromDict

classmethod Panel.fromDict (data, intersect=False, orient='items', dtype=None)

Construct Panel from dict of DataFrame objects

Parameters data : dict

{ field : DataFrame }

intersect : boolean

Intersect indexes of input DataFrames

orient : {'items', 'minor'}, default 'items'

The “orientation” of the data. If the keys of the passed dict should be the items of
the result panel, pass ‘items’ (default). Otherwise if the columns of the values of
the passed DataFrame objects should be the items (which in the case of mixed-
dtype data you should do), instead pass ‘minor’

dtype : dtype, default None

Data type to force, otherwise infer

Returns

Panel

pandas.Panel.from_dict

classmethod Panel.from_dict (data, intersect=False, orient='items', dtype=None)

Construct Panel from dict of DataFrame objects

Parameters data : dict

{ field : DataFrame }

intersect : boolean

Intersect indexes of input DataFrames

orient : {'items', 'minor'}, default 'items'

The “orientation” of the data. If the keys of the passed dict should be the items of
the result panel, pass ‘items’ (default). Otherwise if the columns of the values of
the passed DataFrame objects should be the items (which in the case of mixed-
dtype data you should do), instead pass ‘minor’
**Panel**

**Panel.ge**

Panel.ge(other, axis=None)

Wrapper for comparison method ge

**Panel.get**

Panel.get(key, default=None)

Get item from object for given key (DataFrame column, Panel slice, etc.). Returns default value if not found.

**Parameters**

<table>
<thead>
<tr>
<th>key</th>
<th>[object]</th>
</tr>
</thead>
</table>

**Returns**

<table>
<thead>
<tr>
<th>value</th>
<th>[type of items contained in object]</th>
</tr>
</thead>
</table>

**Panel.get_dtype_counts**

Panel.get_dtype_counts()

Return counts of unique dtypes in this object.

<table>
<thead>
<tr>
<th>dtype</th>
<th>Series</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series with the count of columns with each dtype.</td>
<td></td>
</tr>
</tbody>
</table>

**See also:**

dtypes Return the dtypes in this object.

**Examples**

```python
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
    str  int  float
0    a   1   1.0
1    b   2   2.0
2    c   3   3.0

>>> df.get_dtype_counts()
float64     1
int64       1
object      1
dtype: int64
```
pandas.Panel.get_ftype_counts

Panel.get_ftype_counts()  
Return counts of unique ftypes in this object.  
Depreciated since version 0.23.0.  
This is useful for SparseDataFrame or for DataFrames containing sparse arrays.  

Returns dtype: Series  
Series with the count of columns with each type and sparsity (dense/sparse)  

See also:  
ftypes Return ftypes (indication of sparse/dense and dtype) in this object.  

Examples

```python
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
    str  int  float
0    a    1   1.0
1    b    2   2.0
2    c    3   3.0

>>> df.get_ftype_counts()
float64:dense  1
int64:dense  1
object:dense  1
dtype: int64
```

pandas.Panel.get_value

Panel.get_value(*args, **kwargs)  
Quickly retrieve single value at (item, major, minor) location  
Depreciated since version 0.21.0.  
Please use .at[] or .iat[] accessors.  

Parameters

item [item label (panel item)]  
major [major axis label (panel item row)]  
minor [minor axis label (panel item column)]  
takeable [interpret the passed labels as indexers, default False]  

Returns

value [scalar value]
pandas: powerful Python data analysis toolkit, Release 0.23.3

pandas.Panel.get_values
Panel.get_values()
Return an ndarray after converting sparse values to dense.
This is the same as .values for non-sparse data. For sparse data contained in a pandas.SparseArray,
the data are first converted to a dense representation.
Returns numpy.ndarray
Numpy representation of DataFrame
See also:
values Numpy representation of DataFrame.
pandas.SparseArray Container for sparse data.
Examples
>>> df = pd.DataFrame({'a': [1, 2], 'b': [True, False],
...
'c': [1.0, 2.0]})
>>> df
a
b
c
0 1
True 1.0
1 2 False 2.0
>>> df.get_values()
array([[1, True, 1.0], [2, False, 2.0]], dtype=object)
>>> df = pd.DataFrame({"a": pd.SparseArray([1, None, None]),
...
"c": [1.0, 2.0, 3.0]})
>>> df
a
c
0 1.0 1.0
1 NaN 2.0
2 NaN 3.0
>>> df.get_values()
array([[ 1., 1.],
[nan, 2.],
[nan, 3.]])

pandas.Panel.groupby
Panel.groupby(function, axis=’major’)
Group data on given axis, returning GroupBy object
Parameters function : callable
Mapping function for chosen access
axis [{‘major’, ‘minor’, ‘items’}, default ‘major’]
Returns
2020

Chapter 34. API Reference


pandas: powerful Python data analysis toolkit, Release 0.23.3

grouped PanelGroupBy

pandas.Panel.gt

Panel.gt(other, axis=None)  
Wrapper for comparison method gt

pandas.Panel.head

Panel.head(n=5)  
Return the first n rows.
This function returns the first n rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

Parameters n : int, default 5  
Number of rows to select.

Returns obj_head : type of caller  
The first n rows of the caller object.

See also:

pandas.DataFrame.tail Returns the last n rows.

Examples

>>> df = pd.DataFrame({'animal':['alligator', 'bee', 'falcon', 'lion', ...  
                      'monkey', 'parrot', 'shark', 'whale', 'zebra']})

Viewing the first 5 lines

>>> df.head()

animal
0  alligator
1   bee
2  falcon
3   lion
4 monkey
5  parrot
6   shark
7  whale
8  zebra

Viewing the first n lines (three in this case)
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
df = pd.DataFrame({'A': ['a', 1, 2, 3]})
df = df.iloc[1:]
df
```

```
A  1  2  3
1  1
2  2
3  3
```

```python
df.dtypes
A  object
dtype: object
```

```python
df.infer_objects().dtypes
A  int64
dtype: object
```

pandas.Panel.infer_objects

Panel.infer_objects()  
Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

Returns
- **converted**: [same type as input object]

See also:
- `pandas.to_datetime` Convert argument to datetime.
- `pandas.to_timedelta` Convert argument to timedelta.
- `pandas.to_numeric` Convert argument to numeric type

Examples

```python
def df = pd.DataFrame({'A': ['a', 1, 2, 3]})
def df = df.iloc[1:]
def df
```

```
A  1  2  3
1  1
2  2
3  3
```

```python
df.dtypes
A  object
dtype: object
```

```python
df.infer_objects().dtypes
A  int64
dtype: object
```

pandas.Panel.interpolate

Panel.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)

Interpolate values according to different methods.

Please note that only method='linear' is supported for DataFrames/Series with a MultiIndex.

Parameters:
- **method**: ['linear', 'time', 'index', 'values', 'nearest', 'zero', 'polynomial', 'backfill', 'bfill', 'pad', 'ffill']
`'linear'`, `'quadratic'`, `'cubic'`, `'barycentric'`, `'krogh'`, `'polynomial'`, `'spline'`,
`'piecewise_polynomial'`, `'from_derivatives'`, `'pchip'`, `'akima'`)

- `'linear'`: ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes. default
- `'time'`: interpolation works on daily and higher resolution data to interpolate given length of interval
- `'index'`, `'values'`: use the actual numerical values of the index
- `'nearest'`, `'zero'`, `'slinear'`, `'quadratic'`, `'cubic'`, `'barycentric'`, `'polynomial'` is passed to `scipy.interpolate.interp1d`. Both `'polynomial'` and `'spline'` require that you also specify an `order` (int), e.g. `df.interpolate(method='polynomial', order=4)`. These use the actual numerical values of the index.
- `'krogh'`, `'piecewise_polynomial'`, `'spline'`, `'pchip'` and `'akima'` are all wrappers around the scipy interpolation methods of similar names. These use the actual numerical values of the index. For more information on their behavior, see the scipy documentation and tutorial documentation
- `'from_derivatives'` refers to `BPoly.from_derivatives` which replaces `piecewise_polynomial` interpolation method in scipy 0.18

New in version 0.18.1: Added support for the `'akima'` method Added interpolate method `'from_derivatives'` which replaces `'piecewise_polynomial'` in scipy 0.18; backwards-compatible with scipy < 0.18

[axis]: `{0, 1}`, default 0
- 0: fill column-by-column
- 1: fill row-by-row

[limit]: int, default None.
Maximum number of consecutive NaNs to fill. Must be greater than 0.

[limit_direction]: [{`'forward'`, `'backward'`, `'both'`}, default `'forward'`]

[limit_area]: {'inside', `'outside'`}, default None
- None: (default) no fill restriction
- `'inside'` Only fill NaNs surrounded by valid values (interpolate).
- `'outside'` Only fill NaNs outside valid values (extrapolate).

If limit is specified, consecutive NaNs will be filled in this direction.

New in version 0.21.0.

[inplace]: bool, default False
Update the NDFrame in place if possible.

downcast : optional, `infer` or None, defaults to None
Downcast dtypes if possible.

kwags [keyword arguments to pass on to the interpolating function.]
**Returns**

Series or DataFrame of same shape interpolated at the NaNs

**See also:**

*reindex, replace, fillna*

**Examples**

Filling in NaNs

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s.interpolate()
0    0
1    1
2    2
3    3
dtype: float64
```

**pandas.Panel.isna**

Panel.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy. NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

**Returns**  NDFrame

Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

**See also:**

*NDFrame.isnull* alias of isna

*NDFrame.notna* boolean inverse of isna

*NDFrame.dropna* omit axes labels with missing values

*isna* top-level isna

**Examples**

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.nan], ...
... 'born': [pd.NaT, pd.Timestamp('1939-05-27'), ...
... pd.Timestamp('1940-04-25')], ...
... 'name': ['Alfred', 'Batman', ''], ...
... 'toy': [None, 'Batmobile', 'Joker']})
>>> df
age  born    name     toy
0    5    1939-05-27  Alfred  None
1    6    1940-04-25  Batman  Batmobile
```

(continues on next page)
Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
1  False
2  True
dtype: bool
```

**pandas.Panel.isnull**

`Panel.isnull()`  
Detect missing values.  

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or `numpy.Nan`, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**  
NDFrame  
Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

**See also:**

- `NDFrame.isnull` alias of `isna`
- `NDFrame.notna` boolean inverse of `isna`
- `NDFrame.dropna` omit axes labels with missing values
- `isna` top-level `isna`

**Examples**

Show which entries in a DataFrame are NA.
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''),
...                    'toy': [None, 'Batmobile', 'Joker']})

>>> df
   age     born     name    toy
0    5.0  NaT     Alfred   None
1    6.0 1939-05-27 Batman  Batmobile
2   NaN  1940-04-25   Joker

>>> df.isna()
   age    born    name    toy
0  False   True  False  True
1  False  False  False   False
2  True  False  False  False

Show which entries in a Series are NA.

>>> ser = pd.Series([5, 6, np.NaN])

>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64

>>> ser.isna()
0  False
1  False
2  True
dtype: bool

pandas.Panel.iteritems

Panel.iteritems()
Iterate over (label, values) on info axis
This is index for Series, columns for DataFrame, major_axis for Panel, and so on.

pandas.Panel.join

Panel.join(other, how='left', lsuffix='', rsuffix='')
Join items with other Panel either on major and minor axes column

Parameters  other : Panel or list of Panels

Index should be similar to one of the columns in this one

how : {'left', 'right', 'outer', 'inner'}

How to handle indexes of the two objects. Default: 'left' for joining on index,
None otherwise * left: use calling frame’s index * right: use input frame’s index
* outer: form union of indexes * inner: use intersection of indexes

lsuffix : string
Suffix to use from left frame’s overlapping columns

rsuffix : string

Suffix to use from right frame’s overlapping columns

Returns

joined  [Panel]

pandas.Panel.keys

Panel.Keys()

Get the ‘info axis’ (see Indexing for more)

This is index for Series, columns for DataFrame and major_axis for Panel.

pandas.Panel.kurt

Panel.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1

Parameters

axis [{items (0), major_axis (1), minor_axis (2)}]

skipna : boolean, default True

Exclude NA/null values when computing the result.

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

numeric_only : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

kurt  [DataFrame or Panel (if level specified)]

pandas.Panel.kurtosis

Panel.kurtosis(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1

Parameters

axis [{items (0), major_axis (1), minor_axis (2)}]

skipna : boolean, default True

Exclude NA/null values when computing the result.

level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

**numeric_only** : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **kurt** [DataFrame or Panel (if level specified)]

### pandas.Panel.last

**Panel.last(offset)**

Convenience method for subsetting final periods of time series data based on a date offset.

#### Parameters

- **offset** [string, DateOffset, dateutil.relativedelta]

#### Returns

- **subset** [type of caller]

#### Raises **TypeError**

If the index is not a `DatetimeIndex`

**See also:**

- **first** Select initial periods of time series based on a date offset
- **at_time** Select values at a particular time of the day
- **between_time** Select values between particular times of the day

### Examples

```python
gap
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
  A
2018-04-09 1
2018-04-11 2
2018-04-13 3
2018-04-15 4

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
    A
2018-04-13 3
2018-04-15 4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.
**pandas.Panel.last_valid_index**

Panel.last_valid_index()  
Return index for last non-NA/null value.  

Returns  
scalar [type of index]

Notes  
If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

**pandas.Panel.le**

Panel.le( other, axis=None)  
Wrapper for comparison method le

**pandas.Panel.lt**

Panel.lt( other, axis=None)  
Wrapper for comparison method lt

**pandas.Panel.mad**

Panel.mad( axis=None, skipna=None, level=None)  
Return the mean absolute deviation of the values for the requested axis  

Parameters  
axis [{items (0), major_axis (1), minor_axis (2)}]  
skipna : boolean, default True  
Exclude NA/null values when computing the result.  
level : int or level name, default None  
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame  
numeric_only : boolean, default None  
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns  
mad [DataFrame or Panel (if level specified)]

**pandas.Panel.major_xs**

Panel.major_xs( key)  
Return slice of panel along major axis
Parameters key : object
    Major axis label

Returns y : DataFrame
    index -> minor axis, columns -> items

Notes

major_xs is only for getting, not setting values.

MultiIndex Slicers is a generic way to get/set values on any level or levels and is a superset of major_xs functionality, see MultiIndex Slicers

pandas.Panel.mask

Panel.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)

Return an object of same shape as self and whose corresponding entries are from self where cond is False and otherwise are from other.

Parameters cond : boolean NDFrame, array-like, or callable
    Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn’t check it).
    New in version 0.18.1: A callable can be used as cond.

other : scalar, NDFrame, or callable
    Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn’t check it).
    New in version 0.18.1: A callable can be used as other.

inplace : boolean, default False
    Whether to perform the operation in place on the data

axis [alignment axis if needed, default None]

level [alignment level if needed, default None]

errors : str, {‘raise’, ‘ignore’}, default ‘raise’
    - raise : allow exceptions to be raised
    - ignore : suppress exceptions. On error return original object
    Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

try_cast : boolean, default False
    try to cast the result back to the input type (if possible),

raise_on_error : boolean, default True
Whether to raise on invalid data types (e.g. trying to where on strings)

Deprecated since version 0.21.0.

Returns

wh [same type as caller]

See also:

DataFrame.where()

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is False the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the mask documentation in indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0  NaN
1  1.0
2  2.0
3  3.0
4  4.0

>>> s.mask(s > 0)
0   0.0

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True True
1  True True
2  True True
3  True True
4  True True

>>> df.where(m, -df) == df.mask(~m, -df)
   A    B
0  True True
1  True True
2  True True
3  True True
4  True True
```

**pandas Panel.max**

```
Panel.max (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
```

This method returns the maximum of the values in the object. If you want the index of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

**Parameters**

- `axis` [{items (0), major_axis (1), minor_axis (2)}]
- `skipna` : boolean, default True
  Exclude NA/null values when computing the result.
- `level` : int or level name, default None
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame
- `numeric_only` : boolean, default None
  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- `max` [DataFrame or Panel (if level specified)]

**pandas Panel.mean**

```
Panel.mean (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
```

Return the mean of the values for the requested axis

**Parameters**

- `axis` [{items (0), major_axis (1), minor_axis (2)}]
- `skipna` : boolean, default True
  Exclude NA/null values when computing the result.
- `level` : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

**numeric_only** : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

**mean** [DataFrame or Panel (if level specified)]

---

**pandas.Panel.median**

*Panel.median*(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the median of the values for the requested axis

**Parameters**

- **axis** [[items (0), major_axis (1), minor_axis (2)]]
- **skipna** : boolean, default True
  
  Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

  **numeric_only** : boolean, default None

  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

**median** [DataFrame or Panel (if level specified)]

---

**pandas.Panel.min**

*Panel.min*(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

This method returns the minimum of the values in the object. If you want the index of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

**Parameters**

- **axis** [[items (0), major_axis (1), minor_axis (2)]]
- **skipna** : boolean, default True
  
  Exclude NA/null values when computing the result.
- **level** : int or level name, default None
  
  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

  **numeric_only** : boolean, default None

  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
Returns

\texttt{\textcolor{blue}{\textbf{min}}} [\textcolor{blue}{\textbf{DataFrame or Panel (if level specified)}}]

\textbf{pandas.Panel.minor_xs}

\texttt{Panel.minor_xs(key)}

Return slice of panel along minor axis.

\textbf{Parameters}

- \texttt{key} : object

\textbf{Returns}

- \texttt{y} : DataFrame

  index -> major axis, columns -> items

\textbf{Notes}

\texttt{minor_xs} is only for getting, not setting values.

MultiIndex Slicers is a generic way to get/set values on any level or levels and is a superset of \texttt{minor_xs} functionality, see \textit{MultiIndex Slicers}

\textbf{pandas.Panel.mod}

\texttt{Panel.mod(other, axis=0)}

Modulo of series and other, element-wise (binary operator \texttt{mod}). Equivalent to \texttt{panel \% other}.

\textbf{Parameters}

- \texttt{other} [\textcolor{blue}{\textbf{DataFrame or Panel}}]

- \texttt{axis} : \{\textcolor{blue}{\textbf{items, major_axis, minor_axis}}

  Axis to broadcast over

\textbf{Returns}

\texttt{Panel}

\textbf{See also:}

\texttt{Panel.rmod}

\textbf{pandas.Panel.mul}

\texttt{Panel.mul(other, axis=0)}

Multiplication of series and other, element-wise (binary operator \texttt{mul}). Equivalent to \texttt{panel * other}.

\textbf{Parameters}

- \texttt{other} [\textcolor{blue}{\textbf{DataFrame or Panel}}]

- \texttt{axis} : \{\textcolor{blue}{\textbf{items, major_axis, minor_axis}}

  Axis to broadcast over

\textbf{Returns}
Panel

See also:

Panel.rmul

pandas.Panel.multiply

Panel.multiply(other, axis=0)
Multplication of series and other, element-wise (binary operator \textit{mul}). Equivalent to \texttt{panel * other}.

Parameters

\textbf{other} [DataFrame or Panel]
\textbf{axis} : \{items, major_axis, minor_axis\}
Axis to broadcast over

Returns

Panel

See also:

Panel.rmul

pandas.Panel.ne

Panel.ne(other, axis=None)
Wrapper for comparison method \texttt{ne}

pandas.Panel.notna

Panel.notna()
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

NDFrame
Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

See also:

NDFrame.notnull alias of notna
NDFrame.isna boolean inverse of notna
NDFrame.dropna omit axes labels with missing values
notna top-level notna
Examples

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
```

```python
>>> df
   age  born      name  toy
0  5.0   NaT    Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25   Joker       
```

```python
>>> df.notna()
   age  born      name  toy
0  True  False    True  False
1  True   True    True  True
2  False  True    True  True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
```

```python
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.notna()
0  True
1  True
2  False
dtype: bool
```

**pandas.Panel.notnull**

Panel.notnull()  
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns NDFrame  
Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

See also:

- NDFrame.notnull alias of notna
- NDFrame.isna boolean inverse of notna
**NDFrame.dropna**  omit axes labels with missing values

**notna**  top-level notna

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                            pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
```

```python
>>> df
   age      born        name   toy
0   5.0        NaT     Alfred   None
1   6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25    Joker
```

```python
>>> df.notna()
   age  born  name   toy
0  True  False  True  False
1  True   True  True   True
2False  True  True   True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
```

```python
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.notna()
0  True
1  True
2False
dtype: bool
```

**pandas.Panel.pct_change**

Panel.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters**

- **periods** : int, default 1
  
  Periods to shift for forming percent change.

- **fill_method** : str, default ‘pad’
  
  How to handle NAs before computing percent changes.

- **limit** : int, default None
The number of consecutive NAs to fill before stopping.

freq : DateOffset, timedelta, or offset alias string, optional
  Increment to use from time series API (e.g. ‘M’ or BDay()).

**kwargs
  Additional keyword arguments are passed into DataFrame.shift or Series.shift.

Returns chg : Series or DataFrame
  The same type as the calling object.

See also:

Series.diff Compute the difference of two elements in a Series.

Dataframe.diff Compute the difference of two elements in a DataFrame.

Series.shift Shift the index by some number of periods.

Dataframe.shift Shift the index by some number of periods.

Examples

Series

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64

>>> s.pct_change()
0   NaN
1  0.011111
2 -0.065934
dtype: float64

>>> s.pct_change(periods=2)
0   NaN
1   NaN
2 -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0  90.0
1  91.0
2  NaN
3  85.0
```

```
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> s.pct_change(fill_method='ffill')
0  NaN
1  0.011111
2  0.000000
3 -0.065934
dtype: float64
```

**DataFrame**

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame({
... 'FR': [4.0405, 4.0963, 4.3149],
... 'GR': [1.7246, 1.7482, 1.8519],
... 'IT': [804.74, 810.01, 860.13],
... index=['1980-01-01', '1980-02-01', '1980-03-01'])
```

```python
>>> df
   FR     GR     IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13
```

```python
>>> df.pct_change()
   FR     GR     IT
1980-01-01 NaN   NaN   NaN
1980-02-01 0.013810 0.013684 0.006549
1980-03-01 0.053365 0.059318 0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```python
>>> df = pd.DataFrame({
... '2016': [1769950, 30586265],
... '2015': [1500923, 40912316],
... '2014': [1371819, 41403351],
... index=['GOOG', 'APPL'])
```

```python
>>> df
   2016  2015  2014
GOOG  1769950 1500923 1371819
APPL  30586265 40912316 41403351
```

```python
>>> df.pct_change(axis='columns')
   2016  2015  2014
GOOG  NaN -0.151997 -0.086016
APPL  NaN  0.337604  0.012002
```

**pandas.Panel.pipe**

Panel.pipe(func, *args, **kwargs)

Apply func(self, *args, **kwargs)

**Parameters**

- **func**: function
  - function to apply to the NDFrame. args, and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where
**data_keyword** is a string indicating the keyword of callable that expects the NDFrame.

**args** : iterable, optional
   positional arguments passed into func.

**kwargs** : mapping, optional
   a dictionary of keyword arguments passed into func.

**Returns**

   **object** [the return type of func.]

**See also:**

*pandas.DataFrame.apply, pandas.DataFrame.applymap, pandas.Series.map*

**Notes**

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose f takes its data as arg2:

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, 'arg2'), arg1=a, arg3=c)
... )
```

**pandas.Panel.pop**

Panel.pop(item)
   Return item and drop from frame. Raise KeyError if not found.

**Parameters**

   **item** : str
   Column label to be popped

**Returns**

   **popped** [Series]

**Examples**
```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
                     ('parrot', 'bird', 24.0),
                     ('lion', 'mammal', 80.5),
                     ('monkey', 'mammal', np.nan)],
                    columns=('name', 'class', 'max_speed'))
>>> df
   name   class  max_speed
0  falcon    bird     389.0
1  parrot    bird      24.0
2    lion  mammal      80.5
3 monkey  mammal        NaN

>>> df.pop('class')
0   bird
1   bird
2  mammal
3  mammal
Name: class, dtype: object

>>> df
   name  max_speed
0  falcon     389.0
1  parrot     24.0
2    lion      80.5
3 monkey       NaN

pandas.Panel.pow

Panel.pow(other, axis=0)

Exponential power of series and other, element-wise (binary operator pow). Equivalent to panel ** other.

Parameters

other [DataFrame or Panel]
axis : {items, major_axis, minor_axis}

Axis to broadcast over

Returns

Panel

See also:

Panel.rpow

pandas.Panel.prod

Panel.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values for the requested axis

Parameters

axis [[items (0), major_axis (1), minor_axis (2)]]

skipna : boolean, default True
Exclude NA/null values when computing the result.

**level**: int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

**numeric_only**: boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min_count**: int, default 0

The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**Returns**

**prod** [DataFrame or Panel (if level specified)]

**Examples**

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the min_count parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.Panel.product**

Panel.product (axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values for the requested axis

**Parameters**

**axis** [[items (0), major_axis (1), minor_axis (2)]]

**skipna** : boolean, default True

Exclude NA/null values when computing the result.

**level** : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

**numeric_only**: boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min_count**: int, default 0

The required number of valid values to perform the operation. If fewer than \( \text{min\_count} \) non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**Returns**

**prod**: [DataFrame or Panel (if level specified)]

**Examples**

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the **min_count** parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the **skipna** parameter, **min_count** handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.Panel.add**

Panel.add(other, axis=0)

Addition of series and other, element-wise (binary operator \( \text{radd} \)). Equivalent to \( \text{other} + \text{panel} \).

**Parameters**

other [DataFrame or Panel]

axis : [items, major_axis, minor_axis]

Axis to broadcast over

**Returns**

Panel

See also:

Panel.add
pandas.Panel.rank

Panel.rank(axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)

Compute numerical data ranks (1 through n) along axis. Equal values are assigned a rank that is the average of the ranks of those values

Parameters
- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - index to direct ranking
- **method**: {'average', 'min', 'max', 'first', 'dense'}
  - average: average rank of group
  - min: lowest rank in group
  - max: highest rank in group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups
- **numeric_only**: boolean, default None
  - Include only float, int, boolean data. Valid only for DataFrame or Panel objects
- **na_option**: {'keep', ‘top’, ‘bottom’}
  - keep: leave NA values where they are
  - top: smallest rank if ascending
  - bottom: smallest rank if descending
- **ascending**: boolean, default True
  - False for ranks by high (1) to low (N)
- **pct**: boolean, default False
  - Computes percentage rank of data

Returns
- **ranks** [same type as caller]

pandas.Panel.rdiv

Panel.rdiv(other, axis=0)

Floating division of series and other, element-wise (binary operator rtruediv). Equivalent to other / panel.

Parameters
- **other** [DataFrame or Panel]
- **axis**: {items, major_axis, minor_axis}
  - Axis to broadcast over

Returns
- **Panel**
See also:

*Panel.truediv*

**pandas.Panel.reindex**

Panel.reindex(*args, **kwargs)

Conform Panel to new index with optional filling logic, placing NA/NaN in locations having no value in
the previous index. A new object is produced unless the new index is equivalent to the current one and
*copy=False*

**Parameters**  *items, major_axis, minor_axis*: array-like, optional (should be specified using
keywords)

  - New labels / index to conform to. Preferably an Index object to avoid duplicating data

**method**: {None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}, optional

  - method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
    - default: don’t fill gaps
    - pad / ffill: propagate last valid observation forward to next valid
    - backfill / bfill: use next valid observation to fill gap
    - nearest: use nearest valid observations to fill gap

**copy**: boolean, default True

  - Return a new object, even if the passed indexes are the same

**level**: int or name

  - Broadcast across a level, matching Index values on the passed MultiIndex level

**fill_value**: scalar, default np.NaN

  - Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**limit**: int, default None

  - Maximum number of consecutive elements to forward or backward fill

**tolerance**: optional

  - Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.

  - Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

  - New in version 0.21.0: (list-like tolerance)

**Returns**

**reindexed** [Panel]
Examples

DataFrame.reindex supports two calling conventions

• (index=index_labels, columns=column_labels, ...)
• (labels, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
gindex = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
gdf = pd.DataFrame(
  ...  'http_status': [200, 200, 404, 404, 301],
  ...  'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]),
  ...  index=index)
gdf
```

```
http_status  response_time
Firefox       200  0.04
Chrome        200  0.02
Safari        404  0.07
IE10          404  0.08
Konqueror     301  1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
gnew_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10', 'Chrome']
gdf.reindex(new_index)
```

```
http_status  response_time
Safari       404.0  0.07
Iceweasel    NaN   NaN
Comodo Dragon NaN   NaN
IE10         404.0  0.08
Chrome       200.0  0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```python
gdf.reindex(new_index, fill_value=0)
```

```
http_status  response_time
Safari       404  0.07
Iceweasel    0   0.00
Comodo Dragon 0   0.00
IE10         404  0.08
Chrome       200  0.02
```

```python
gdf.reindex(new_index, fill_value='missing')
```

```
http_status  response_time
Safari       404  0.07
Iceweasel    missing  missing
Comodo Dragon missing  missing
IE10         404  0.08
Chrome       200  0.02
```

We can also reindex the columns.
Or we can use “axis-style” keyword arguments.

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

Suppose we decide to expand the dataframe to cover a wider date range.

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to backpropagate the last valid value to fill the NaN values, pass `bfill` as an argument to the method keyword.
Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the [user guide](https://pandas.pydata.org/pandas-docs/stable/user_guide.html) for more.

### pandas.Panel.reindex_axis

Panel.reindex_axis(labels, axis=0, method=None, level=None, copy=True, limit=None, fill_value=nan)

Conform input object to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

**Parameters**

- **labels**: array-like
  - New labels / index to conform to. Preferably an Index object to avoid duplicating data.

- **axis**: [0, 1, 2, ‘items’, ‘major_axis’, ‘minor_axis’]

- **method**: {None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}, optional
  - Method to use for filling holes in reindexed DataFrame:
    - default: don’t fill gaps
    - pad / ffill: propagate last valid observation forward to next valid
    - backfill / bfill: use next valid observation to fill gap
    - nearest: use nearest valid observations to fill gap

- **copy**: boolean, default True
  - Return a new object, even if the passed indexes are the same.

- **level**: int or name
  - Broadcast across a level, matching Index values on the passed MultiIndex level.

- **limit**: int, default None
  - Maximum number of consecutive elements to forward or backward fill.

- **tolerance**: optional
Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs(index[indexer] - target)} \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

Returns

reindexed [Panel]

See also:

reindex, reindex_like

Examples

```python
>>> df.reindex_axis(['A', 'B', 'C'], axis=1)
```

**pandas.Panel.reindex_like**

Panel.reindex_like(other=None, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices to myself.

Parameters

other [Object]

method [string or None]

copy [boolean, default True]

limit : int, default None

Maximum number of consecutive labels to fill for inexact matches.

tolerance : optional

Maximum distance between labels of the other object and this object for inexact matches. Can be list-like.

New in version 0.21.0: (list-like tolerance)

Returns

reindexed [same as input]

Notes

Like calling s.reindex(index=other.index, columns=other.columns, method=...)
pandas.Panel.rename

Panel.rename(items=None, major_axis=None, minor_axis=None, **kwargs)
Alter axes input function or functions. Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error. Alternatively, change Series.name with a scalar value (Series only).

Parameters  
items, major_axis, minor_axis : scalar, list-like, dict-like or function, optional
    Scalar or list-like will alter the Series.name attribute, and raise on DataFrame or Panel. dict-like or functions are transformations to apply to that axis’ values

copy : boolean, default True
    Also copy underlying data

inplace : boolean, default False
    Whether to return a new Panel. If True then value of copy is ignored.

level : int or level name, default None
    In case of a MultiIndex, only rename labels in the specified level.

Returns
renamed [Panel (new object)]

See also:
pandas.NDFrame.rename_axis

Examples

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0 1
1 2
2 3
dtype: int64
>>> s.rename("my_name")  # scalar, changes Series.name
0 1
1 2
2 3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2)  # function, changes labels
0 1
1 2
4 3
dtype: int64
>>> s.rename({1: 3, 2: 5})  # mapping, changes labels
0 1
3 2
5 3
dtype: int64
```

Since DataFrame doesn’t have a .name attribute, only mapping-type arguments are allowed.
pandas: powerful Python data analysis toolkit, Release 0.23.3

>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(2)
Traceback (most recent call last):
...
TypeError: 'int' object is not callable

DataFrame.rename supports two calling conventions
• (index=index_mapper, columns=columns_mapper, ...)
• (mapper, axis={'index', 'columns'}, ...)
We highly recommend using keyword arguments to clarify your intent.
>>> df.rename(index=str, columns={"A": "a", "B": "c"})
a c
0 1 4
1 2 5
2 3 6
>>> df.rename(index=str, columns={"A": "a", "C": "c"})
a B
0 1 4
1 2 5
2 3 6

Using axis-style parameters
>>> df.rename(str.lower, axis='columns')
a b
0 1 4
1 2 5
2 3 6
>>> df.rename({1: 2, 2: 4}, axis='index')
A B
0 1 4
2 2 5
4 3 6

See the user guide for more.
pandas.Panel.rename_axis
Panel.rename_axis(mapper, axis=0, copy=True, inplace=False)
Alter the name of the index or columns.
Parameters mapper : scalar, list-like, optional
Value to set as the axis name attribute.
axis : {0 or ‘index’, 1 or ‘columns’}, default 0
The index or the name of the axis.
copy : boolean, default True
Also copy underlying data.

34.5. Panel

2051


inplace : boolean, default False

Modifies the object directly, instead of creating a new Series or DataFrame.

Returns renamed : Series, DataFrame, or None

The same type as the caller or None if inplace is True.

See also:

pandas.Series.rename  Alter Series index labels or name
pandas.DataFrame.rename  Alter DataFrame index labels or name
pandas.Index.rename  Set new names on index

Notes

Prior to version 0.21.0, rename_axis could also be used to change the axis labels by passing a mapping or scalar. This behavior is deprecated and will be removed in a future version. Use rename instead.

Examples

Series

```python
>>> s = pd.Series([1, 2, 3])
>>> s.rename_axis("foo")
foo
0 1
1 2
2 3
dtype: int64
```

DataFrame

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})

```

```python
>>> df.rename_axis("foo")
A  B
foo
0 1 4
1 2 5
2 3 6
```

```python
>>> df.rename_axis("bar", axis="columns")
bar  A  B
0 1 4
1 2 5
2 3 6
```

pandas.Panel.replace

Panel.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')

Replace values given in to_replace with value.
Values of the NDFrame are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

**Parameters**

- `to_replace`: str, regex, list, dict, Series, int, float, or None
  
  How to find the values that will be replaced.
  
  - numeric, str or regex:
    
    - numeric: numeric values equal to `to_replace` will be replaced with `value`
    
    - str: string exactly matching `to_replace` will be replaced with `value`
    
    - regex: regexs matching `to_replace` will be replaced with `value`
  
  - list of str, regex, or numeric:
    
    - First, if `to_replace` and `value` are both lists, they **must** be the same length.
    
    - Second, if `regex=True` then all of the strings in both lists will be interpreted as regexs otherwise they will match directly. This doesn’t matter much for `value` since there are only a few possible substitution regexes you can use.
    
    - str, regex and numeric rules apply as above.
  
  - dict:
    
    - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the `value` parameter should be `None`.
    
    - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in `value`. The `value` parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
    
    - For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The `value` parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
    
  - None:
    
    - This means that the regex argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If `value` is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

- `value`: scalar, dict, list, str, regex, default `None`
  
  Value to replace any values matching `to_replace` with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

- `inplace`: boolean, default `False`
If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

**limit** : int, default None

Maximum size gap to forward or backward fill.

**regex** : bool or same types as `to_replace`, default False

Whether to interpret `to_replace` and/or `value` as regular expressions. If this is True then `to_replace` must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case `to_replace` must be None.

**method** : \{‘pad’, ‘ffill’, ‘bfill’, None\}

The method to use when for replacement, when `to_replace` is a scalar, list or tuple and `value` is None.

Changed in version 0.23.0: Added to DataFrame.

**Returns** NDFrame

Object after replacement.

**Raises** `AssertionError`

- If `regex` is not a bool and `to_replace` is not None.

**TypeError**

- If `to_replace` is a dict and `value` is not a list, dict, ndarray, or Series
- If `to_replace` is None and `regex` is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple bool or datetime64 objects and the arguments to `to_replace` does not match the type of the value being replaced

**ValueError**

- If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

**See also:**

NDFrame.fillna Fill NA values

NDFrame.where Replace values based on boolean condition

Series.str.replace Simple string replacement.

**Notes**

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.
- This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
• When dict is used as the to_replace value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar ‘to_replace‘ and ‘value‘

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
... 'B': [5, 6, 7, 8, 9],
... 'C': ['a', 'b', 'c', 'd', 'e']})
```

```python
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

List-like ‘to_replace‘

```python
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```python
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```python
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

dict-like ‘to_replace‘
```python
>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100  6  b
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4 400  9  e
```

### Regular expression `to_replace`

```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
                    'B': ['abc', 'bar', 'xyz']})
```

```python
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0 new abc
1 foo new
2 bait xyz
```

```python
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0 new abc
1 foo bar
2 bait xyz
```

```python
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0 new abc
1 foo new
2 bait xyz
```

```python
>>> df.replace(regex={r'^ba.$': 'new', 'foo':'xyz'})
   A  B
0 new abc
1 xyz new
2 bait xyz
```

```python
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0 new abc
```

(continues on next page)
Note that when replacing multiple bool or datetime64 objects, the data types in the to_replace parameter must match the data type of the value being replaced:

```python
>>> df = pd.DataFrame({'A': [True, False, True],
...                     'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False})  # raises
Traceback (most recent call last):
... TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a TypeError because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the to_replace parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
When one uses a dict as the to_replace value, it is like the value(s) in the dict are equal to the value parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0 10
1 None
2 None
3 b
4 None
dtype: object
```

When value=None and to_replace is a scalar, list or tuple, replace uses the method parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad'):

```python
>>> s.replace('a', None)
0 10
1 10
2 10
3 b
4 b
dtype: object
```

**pandas.Panel.resample**

`pandas.Panel.resample` convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or pass datetime-like values to the on or level keyword.

**Parameters**

- **rule**: string
the offset string or object representing target conversion

axis  [int, optional, default 0]

closed : {'right', 'left'}
    Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

label : {'right', 'left'}
    Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

convention : {'start', 'end', 's', 'e'}
    For PeriodIndex only, controls whether to use the start or end of rule

kind: {'timestamp', 'period'}, optional
    Pass ‘timestamp’ to convert the resulting index to a DateTimeIndex or ‘period’ to convert it to a PeriodIndex. By default the input representation is retained.

loffset : timedelta
    Adjust the resampled time labels

base : int, default 0
    For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0

on : string, optional
    For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

New in version 0.19.0.

level : string or int, optional
    For a MultiIndex, level (name or number) to use for resampling. Level must be datetime-like.

New in version 0.19.0.

Returns

Resampler object

See also:

groupby  Group by mapping, function, label, or list of labels.

Notes

See the user guide for more.

To learn more about the offset strings, please see this link.
Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5] #select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```
Upsample the series into 30 second bins and fill the NaN values using the \texttt{pad} method.

\begin{verbatim}
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   0
2000-01-01 00:01:00   1
2000-01-01 00:01:30   1
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
\end{verbatim}

Upsample the series into 30 second bins and fill the NaN values using the \texttt{bfill} method.

\begin{verbatim}
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   1
2000-01-01 00:01:00   1
2000-01-01 00:01:30   2
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
\end{verbatim}

Pass a custom function via \texttt{apply}

\begin{verbatim}
>>> def custom_resampler(array_like):
...     return np.sum(array_like)+5

>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00   8
2000-01-01 00:03:00  17
2000-01-01 00:06:00  26
Freq: 3T, dtype: int64
\end{verbatim}

For a Series with a PeriodIndex, the keyword \textit{convention} can be used to control whether to use the start or end of \textit{rule}.

\begin{verbatim}
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
            freq='A',
            periods=2))

>>> s
2012   1
2013   2
Freq: A-DEC, dtype: int64

Resample by month using \texttt{start} \textit{convention}. Values are assigned to the first month of the period.

\begin{verbatim}
>>> s.resample('M', convention='start').asfreq().head()
2012-01  1.0
2012-02  NaN
2012-03  NaN
2012-04  NaN
2012-05  NaN
Freq: M, dtype: float64
\end{verbatim}

Resample by month using \texttt{end} \textit{convention}. Values are assigned to the last month of the period.

\begin{verbatim}
>>> s.resample('M', convention='end').asfreq()
2012-12  1.0
2013-01  NaN
(continues on next page)
\end{verbatim}
For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> df = pd.DataFrame(data=9*[range(4)], columns=['a', 'b', 'c', 'd'])
>>> df['time'] = pd.date_range('1/1/2000', periods=9, freq='T')
>>> df.resample('3T', on='time').sum()
   a    b    c    d
time
2000-01-01 00:00:00    0    3    6    9
2000-01-01 00:03:00    0    3    6    9
2000-01-01 00:06:00    0    3    6    9
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on level the resampling needs to take place.

```python
>>> time = pd.date_range('1/1/2000', periods=5, freq='T')
>>> df2 = pd.DataFrame(data=10*[range(4)], columns=['a', 'b', 'c', 'd'],
                        index=pd.MultiIndex.from_product([time, [1, 2]])
                    )
>>> df2.resample('3T', level=0).sum()
   a    b    c    d
2000-01-01 00:00:00    0    6   12   18
2000-01-01 00:03:00    0    4    8   12
```

**pandas.Panel.rfloordiv**

Panel.rfloordiv(other, axis=0)

Integer division of series and other, element-wise (binary operator rfloordiv). Equivalent to other // panel.

Parameters

- **other** [DataFrame or Panel]
- **axis** : [items, major_axis, minor_axis]

  Axis to broadcast over

Returns

Panel

See also:
**Panel.floordiv**

**pandas.Panel.rmod**

```
Panel.rmod(other, axis=0)
```

Modulo of series and other, element-wise (binary operator \texttt{rmod}). Equivalent to \texttt{other \% panel}.

**Parameters**

- **other** [DataFrame or Panel]
- **axis** : \{\texttt{items, major_axis, minor_axis}\}
  
  Axis to broadcast over

**Returns**

Panel

**See also:**

Panel.mod

**pandas.Panel.rmul**

```
Panel.rmul(other, axis=0)
```

Multiplication of series and other, element-wise (binary operator \texttt{rmul}). Equivalent to \texttt{other \* panel}.

**Parameters**

- **other** [DataFrame or Panel]
- **axis** : \{\texttt{items, major_axis, minor_axis}\}
  
  Axis to broadcast over

**Returns**

Panel

**See also:**

Panel.mul

**pandas.Panel.round**

```
Panel.round(decimals=0, *args, **kwargs)
```

Round each value in Panel to a specified number of decimal places.

New in version 0.18.0.

**Parameters**

- **decimals** : int
  
  Number of decimal places to round to (default: 0). If decimals is negative, it specifies the number of positions to the left of the decimal point.

**Returns**

Panel object
See also:

numpy.around

**pandas.Panel.rpow**

Panel.rpow(other, axis=0)
Exponential power of series and other, element-wise (binary operator rpow). Equivalent to other ** panel.

Parameters

- other [DataFrame or Panel]
- axis : [items, major_axis, minor_axis]
  
  Axis to broadcast over

Returns

Panel

See also:

Panel.pow

**pandas.Panel.rsub**

Panel.rsub(other, axis=0)
Subtraction of series and other, element-wise (binary operator rsub). Equivalent to other - panel.

Parameters

- other [DataFrame or Panel]
- axis : [items, major_axis, minor_axis]
  
  Axis to broadcast over

Returns

Panel

See also:

Panel.sub

**pandas.Panel.rtruediv**

Panel.rtruediv(other, axis=0)
Floating division of series and other, element-wise (binary operator rtruediv). Equivalent to other / panel.

Parameters

- other [DataFrame or Panel]
- axis : [items, major_axis, minor_axis]
  
  Axis to broadcast over

Returns
Panel

See also:

Panel.truediv

pandas.Panel.sample

Panel.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

Parameters:

- **n**: int, optional
  Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.

- **frac**: float, optional
  Fraction of axis items to return. Cannot be used with n.

- **replace**: boolean, optional
  Sample with or without replacement. Default = False.

- **weights**: str or ndarray-like, optional
  Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. inf and -inf values not allowed.

- **random_state**: int or numpy.random.RandomState, optional
  Seed for the random number generator (if int), or numpy RandomState object.

- **axis**: int or string, optional
  Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames, 1 for Panels).

Returns:

A new object of same type as caller.

Examples

Generate an example Series and DataFrame:

```python
>>> s = pd.Series(np.random.randn(50))
>>> s.head()
0   -0.038497
1    1.820773
2   -0.972766
3   -1.598270
4   -0.150278
```

(continues on next page)
Next extract a random sample from both of these objects...

3 random elements from the Series:

```python
3 random elements from the Series:
```

```
>>> s.sample(n=3)
27 -0.994689
55 -1.049016
67 -0.224565
dtype: float64
```

And a random 10% of the DataFrame with replacement:

```python
And a random 10% of the DataFrame with replacement:
```

```
>>> df.sample(frac=0.1, replace=True)
A   B   C   D
35  1.981780 0.142106 1.817165 -0.290805
49 -1.336199 -0.448634 -0.789640 0.217116
40  0.823173 -0.078816 1.009536 1.015108
15  1.421154 -0.055301 -1.922594 -0.019696
   -0.148339 0.832938 1.787600 -1.383767
dtype: float64
```

You can use random state for reproducibility:

```python
You can use random state for reproducibility:
```

```
>>> df.sample(random_state=1)
A   B   C   D
37 -2.027662 0.103611 0.237496 -0.165867
43 -0.259323 -0.583426 1.516140 -0.479118
12 -1.686325 -0.579510 0.985195 -0.460286
  1.167946 0.429082 1.215742 -1.636041
  1.197475 -0.864188 1.554031 -1.505264
dtype: float64
```

### pandas.Panel.select

**Panel.select** *(crit, axis=0)*

Return data corresponding to axis labels matching criteria

Deprecated since version 0.21.0: Use df.loc[df.index.map(crit)] to select via labels

**Parameters**

- **crit**: function
  
  To be called on each index (label). Should return True or False

- **axis**: int

**Returns**

- **selection**: type of caller
Panel.sem

Panel.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{items (0), major_axis (1), minor_axis (2)}]

skipna : boolean, default True

Exclude NA/null values. If an entire row/column is NA, the result will be NA

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

ddof : int, default 1

Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

sem [DataFrame or Panel (if level specified)]

Panel.set_axis

Panel.set_axis(labels, axis=0, inplace=None)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now labels and axis, consistent with the rest of pandas API. Previously, the axis and labels arguments were respectively the first and second positional arguments.

Parameters labels : list-like, Index

The values for the new index.

axis : {0 or ‘index’, 1 or ‘columns’}, default 0

The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace : boolean, default None

Whether to return a new %(klass)s instance.

Warning: inplace=None currently falls back to True, but in a future version, will default to False. Use inplace=True explicitly rather than relying on the default.

Returns renamed : %(klass)s or None
An object of same type as caller if inplace=False, None otherwise.

See also:

`pandas.DataFrame.rename_axis` Alter the name of the index or columns.

Examples

Series

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```python
>>> s.set_axis(["a", "b", "c"], axis=0, inplace=False)
a    1
b    2
c    3
dtype: int64
```

The original object is not modified.

```python
>>> s
0    1
1    2
2    3
dtype: int64
```

DataFrame

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```python
>>> df.set_axis(["a", "b", "c"], axis=\'index\', inplace=False)  
A    B
a    1  4
b    2  5
c    3  6
```

Change the column labels.

```python
>>> df.set_axis(["I", "II"], axis=\'columns\', inplace=False)  
I    II
0    1  4
1    2  5
2    3  6
```

Now, update the labels inplace.

```python
>>> df.set_axis(["i", "ii"], axis=\'columns\', inplace=True)  
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.3

Pandas.Panel.set_value

Panel.set_value(*args, **kwargs)
Quickly set single value at (item, major, minor) location
Deprecated since version 0.21.0.
Please use .at[] or .iat[] accessors.

Parameters
- item [item label (panel item)]
- major [major axis label (panel item row)]
- minor [minor axis label (panel item column)]
- value [scalar]
- takeable [interpret the passed labels as indexers, default False]

Returns panel : Panel
If label combo is contained, will be reference to calling Panel, otherwise a new object

Pandas.Panel.shift

Panel.shift(periods=1, freq=None, axis='major')
Shift index by desired number of periods with an optional time freq. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original. This is different from the behavior of DataFrame.shift()

Parameters periods : int
Number of periods to move, can be positive or negative
freq [DateOffset, timedelta, or time rule string, optional]
axis [{‘items’, ‘major’, ‘minor’} or {0, 1, 2}]

Returns
shifted [Panel]

Pandas.Panel.skew

Panel.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased skew over requested axis Normalized by N-1

Parameters
axis [{‘items (0), major_axis (1), minor_axis (2)}]
skipna : boolean, default True

Exclude NA/null values when computing the result.

level : int or level name, default None

If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

numeric_only : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

skew [DataFrame or Panel (if level specified)]

pandas.Panel.slice_shift

Panel.slice_shift(periods=1, axis=0)

Equivalent to shift without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Parameters periods : int

Number of periods to move, can be positive or negative

Returns

shifted [same type as caller]

Notes

While the slice_shift is faster than shift, you may pay for it later during alignment.

pandas.Panel.sort_index

Panel.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True)

Sort object by labels (along an axis)

Parameters

axis [axes to direct sorting]

level : int or level name or list of ints or list of level names

if not None, sort on values in specified index level(s)

ascending : boolean, default True

Sort ascending vs. descending

inplace : bool, default False

if True, perform operation in-place

kind : {'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'
Choice of sorting algorithm. See also `ndarray.np.sort` for more information. `mergesort` is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

`na_position` : {'first', 'last'}, default 'last'

- first puts NaNs at the beginning, last puts NaNs at the end. Not implemented for MultiIndex.

`sort_remaining` : bool, default True

- if true and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level

Returns

- `sorted_obj` [NDFrame]

**pandas.Panel.sort_values**

```python
Panel.sort_values(by=None, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last')
```

NOT IMPLEMENTED: do not call this method, as sorting values is not supported for Panel objects and will raise an error.

**pandas.Panel.squeeze**

```python
Panel.squeeze(axis=None)
```

Squeeze length 1 dimensions.

- **Parameters axis**: None, integer or string axis name, optional
  - The axis to squeeze if 1-sized.
  - New in version 0.20.0.

Returns

- scalar if 1-sized, else original object

**pandas.Panel.std**

```python
Panel.std(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
```

Return sample standard deviation over requested axis.

- Normalized by N-1 by default. This can be changed using the `ddof` argument

**Parameters**

- **axis** [items (0), major_axis (1), minor_axis (2)]
- **skipna** : boolean, default True
  - Exclude NA/null values. If an entire row/column is NA, the result will be NA
- **level** : int or level name, default None
  - If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame
- **ddof** : int, default 1
Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric_only** : boolean, default None

Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

std [DataFrame or Panel (if level specified)]

---

**pandas.Panel.sub**

Panel.sub(\textit{other, axis=0})

Subtraction of series and other, element-wise (binary operator sub). Equivalent to \texttt{panel - other}.

**Parameters**

\textit{other} [DataFrame or Panel]
\textit{axis} : \{items, major_axis, minor_axis\}

Axis to broadcast over

**Returns**

Panel

**See also:**

Panel.rsub

---

**pandas.Panel.subtract**

Panel.subtract(\textit{other, axis=0})

Subtraction of series and other, element-wise (binary operator sub). Equivalent to \texttt{panel - other}.

**Parameters**

\textit{other} [DataFrame or Panel]
\textit{axis} : \{items, major_axis, minor_axis\}

Axis to broadcast over

**Returns**

Panel

**See also:**

Panel.rsub

---

**pandas.Panel.sum**

Panel.sum(\textit{axis=\texttt{None}}, \textit{skipna=\texttt{None}}, \textit{level=\texttt{None}}, \textit{numeric_only=\texttt{None}}, \textit{min_count=0}, **\texttt{kwargs})

Return the sum of the values for the requested axis

**Parameters**

\textit{axis} \{\{\texttt{items (0), major_axis (1), minor_axis (2)}\}\}
skipna : boolean, default True
    Exclude NA/null values when computing the result.

level : int or level name, default None
    If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing
    into a DataFrame

numeric_only : boolean, default None
    Include only float, int, boolean columns. If None, will attempt to use everything,
    then use only numeric data. Not implemented for Series.

min_count : int, default 0
    The required number of valid values to perform the operation. If fewer than
    min_count non-NA values are present the result will be NA.

    New in version 0.22.0: Added with the default being 0. This means the sum of
    an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

Returns

sum [DataFrame or Panel (if level specified)]

Examples

By default, the sum of an empty or all-NA Series is 0.

```
  >>> pd.Series([]).sum()  # min_count=0 is the default
  0.0
```

This can be controlled with the min_count parameter. For example, if you’d like the sum of an empty
series to be NaN, pass min_count=1.

```
  >>> pd.Series([]).sum(min_count=1)
  nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```
  >>> pd.Series([np.nan]).sum()
  0.0
```

```
  >>> pd.Series([np.nan]).sum(min_count=1)
  nan
```

pandas.Panel.swapaxes

Panel.swapaxes (axis1, axis2, copy=True)
    Interchange axes and swap values axes appropriately

Returns

y [same as input]
**pandas.Panel.swaplevel**

*pandas.Panel.swaplevel*(i=-2, j=-1, axis=0)

Swap levels i and j in a MultiIndex on a particular axis

**Parameters** i, j : int, string (can be mixed)

  Level of index to be swapped. Can pass level name as string.

**Returns**

  swapped [type of caller (new object)]

  .. versionchanged:: 0.18.1

  The indexes i and j are now optional, and default to the two innermost levels of the index.

**pandas.Panel.tail**

*pandas.Panel.tail*(n=5)

Return the last n rows.

  This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

**Parameters** n : int, default 5

  Number of rows to select.

**Returns** type of caller

  The last n rows of the caller object.

**See also:**

**pandas.DataFrame.head** The first n rows of the caller object.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...   'monkey', 'parrot', 'shark', 'whale', 'zebra']})

>>> df
animal    
0  alligator
1     bee
2  falcon
3    lion
4  monkey
5   parrot
6   shark
7  whale
8  zebra
```

Viewing the last 5 lines
>>> df.tail()
    animal
   4  monkey
   5  parrot
   6  shark
   7   whale
   8  zebra

Viewing the last \( n \) lines (three in this case)

>>> df.tail(3)
    animal
     6  shark
     7   whale
     8  zebra

**pandas.Panel.take**

Panel.take(\( indices, axis=0, convert=None, is_copy=True, **kwargs \))

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- **indices** : array-like
  An array of ints indicating which positions to take.

- **axis** : \{0 or ‘index’, 1 or ‘columns’, None\}, default 0
  The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

- **convert** : bool, default True
  Whether to convert negative indices into positive ones. For example, \(-1\) would map to the \( \text{len(axis)} - 1 \). The conversions are similar to the behavior of indexing a regular Python list.

  Deprecated since version 0.21.0: In the future, negative indices will always be converted.

- **is_copy** : bool, default True
  Whether to return a copy of the original object or not.

- **kwargs**
  For compatibility with \( \text{numpy.take()} \). Has no effect on the output.

**Returns**

- **taken** : type of caller
  An array-like containing the elements taken from the object.

*See also:

- **DataFrame.loc** Select a subset of a DataFrame by labels.
- **DataFrame.iloc** Select a subset of a DataFrame by positions.
- **numpy.take** Take elements from an array along an axis.
Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=['name', 'class', 'max_speed'],
...                     index=[0, 2, 3, 1])
>>> df
name    class   max_speed
0  falcon  bird     389.0
2  parrot  bird     24.0
3  lion    mammal   80.5
1  monkey  mammal   NaN

Take elements at positions 0 and 3 along the axis 0 (default).
Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's
because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
name    class   max_speed
0  falcon  bird     389.0
1  monkey  mammal   NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
>>> df.take([1, 2], axis=1)
class   max_speed
0  bird     389.0
2  bird     24.0
3  mammal   80.5
1  mammal   NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just
like with Python lists.

```python
>>> df.take([-1, -2])
name    class   max_speed
1  monkey  mammal   NaN
3  lion    mammal   80.5
```

pandas.Panel.to_clipboard

Panel.to_clipboard(excel=True, sep=None, **kwargs)
Copy object to the system clipboard.
Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters excel : bool, default True
- True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
- False, write a string representation of the object to the clipboard.

sep : str, default ' \t '
Field delimiter.

**kwargs

These parameters will be passed to DataFrame.to_csv.

See also:

DataFrame.to_csv  Write a DataFrame to a comma-separated values (csv) file.

read_clipboard  Read text from clipboard and pass to read_table.

Notes

Requirements for your platform.

- Linux : 
xclip, or xsel (with gtk or PyQt4 modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword index and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

pandas.Panel.to_dense

Panel.to_dense()

Return dense representation of NDFrame (as opposed to sparse)

pandas.Panel.to_excel

Panel.to_excel(path, na_rep='", engine=None, **kwargs)

Write each DataFrame in Panel to a separate excel sheet

Parameters path : string or ExcelWriter object

File path or existing ExcelWriter

na_rep : string, default ""
Missing data representation

**engine** : string, default None

Write engine to use - you can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

**Other Parameters**

**float_format** : string, default None

Format string for floating point numbers

**cols** : sequence, optional

Columns to write

**header** : boolean or list of string, default True

Write out column names. If a list of string is given it is assumed to be aliases for the column names

**index** : boolean, default True

Write row names (index)

**index_label** : string or sequence, default None

Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**startrow** [upper left cell row to dump data frame]

**startcol** [upper left cell column to dump data frame]

**Notes**

Keyword arguments (and na_rep) are passed to the `to_excel` method for each DataFrame written.

**pandas.Panel.to_frame**

Panel.to_frame(filter_observations=True)

Transform wide format into long (stacked) format as DataFrame whose columns are the Panel’s items and whose index is a MultiIndex formed of the Panel’s major and minor axes.

**Parameters**

**filter_observations** : boolean, default True

Drop (major, minor) pairs without a complete set of observations across all the items

**Returns**

y [DataFrame]

**pandas.Panel.to_hdf**

Panel.to_hdf(path_or_buf, key, **kwargs)

Write the contained data to an HDF5 file using HDFStore.
Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.

For more information see the user guide.

**Parameters**

- `path_or_buf` : str or pandas.HDFStore
  - File path or HDFStore object.

- `key` : str
  - Identifier for the group in the store.

- `mode` : {'a', 'w', 'r+'}, default ‘a’
  - Mode to open file:
    - ‘w’: write, a new file is created (an existing file with the same name would be deleted).
    - ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
    - ‘r+’: similar to ‘a’, but the file must already exist.

- `format` : {'fixed', 'table'}, default ‘fixed’
  - Possible values:
    - ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

- `append` : bool, default False
  - For Table formats, append the input data to the existing.

- `data_columns` : list of columns or True, optional
  - List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via Data Columns. Applicable only to format=‘table’.

- `complevel` : {0-9}, optional
  - Specifies a compression level for data. A value of 0 disables compression.

- `complib` : {'zlib', 'lz4', 'bzip2', 'blosc'}, default ‘zlib’
  - Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: ‘blosc:blosclz’): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.

- `fletcher32` : bool, default False
  - If applying compression use the fletcher32 checksum.

- `dropna` : bool, default False
If true, ALL nan rows will not be written to store.

**errors**: str, default ‘strict’

Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

See also:

**DataFrame.read_hdf** Read from HDF file.

**DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to_sql** Write to a sql table.

**DataFrame.to_feather** Write out feather-format for DataFrames.

**DataFrame.to_csv** Write out to a csv file.

**Examples**

```python
df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                 index=['a', 'b', 'c'])
df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```python
s = pd.Series([1, 2, 3, 4])
s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A  B
a 1 4
b 2 5
c 3 6

>>> pd.read_hdf('data.h5', 's')
0 1
1 2
2 3
3 4
dtype: int64
```

Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```

**pandas.Panel.to_json**

Panel.to_json(*path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression=None, index=True*)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.
Parameters path_or_buf : string or file handle, optional

File path or object. If not specified, the result is returned as a string.

orient: string

Indication of expected JSON string format.

- Series
  - default is ‘index’
  - allowed values are: {'split','records','index’}
- DataFrame
  - default is ‘columns’
  - allowed values are: {'split','records','index',‘columns’,’values’}
- The format of the JSON string
  - ‘split’ : dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
  - ‘records’ : list like [{column -> value}, . . . , {column -> value}]
  - ‘index’ : dict like {index -> {column -> value}}
  - ‘columns’ : dict like {column -> {index -> value}}
  - ‘values’ : just the values array
  - ‘table’ : dict like {‘schema’: {schema}, ‘data’: {data}} describing the data, and the data component is like orient='records'.

  Changed in version 0.20.0.

date_format: {None, ‘epoch’, ‘iso’}

Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision: int, default 10

The number of decimal places to use when encoding floating point values.

force_ascii: boolean, default True

Force encoded string to be ASCII.

date_unit: string, default ‘ms’ (milliseconds)

The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler: callable, default None

Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines: boolean, default False
If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

New in version 0.19.0.

A string representing the compression to use in the output file, only used when the first argument is a filename.

New in version 0.21.0.

**index**: boolean, default True

Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

New in version 0.23.0.

See also:

*pandas.read_json*

Examples

```python
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
                   index=['row 1', 'row 2'],
                   columns=['col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns": ["col 1", "col 2"],
  "index": ["row 1", "row 2"],
  "data": [["a", "b"], ["c", "d"]]}'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"},{"col 1":"c","col 2":"d"}]
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> df.to_json(orient='values')
'[["a","b"],["c","d"]]'
```

Encoding with Table Schema

```python
>>> df.to_json(orient='table')
'{"schema": {"fields": [["name": "index", "type": "string"],
  ["name": "col 1", "type": "string"],
  ["name": "col 2", "type": "string"],
  ["name": "row 1", "type": "string"],
  ["name": "row 2", "type": "string"],
  ["name": "col 1", "type": "string"],
  ["name": "col 2", "type": "string"],
  ["name": "row 1", "type": "string"],
  ["name": "row 2", "type": "string"]]}
```

(continues on next page)
Panel.to_latex(buf=None, columns=None, col_space=None, header=True, index=True,
na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True,
bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None,
decimal='.', multicolumn=True, multicolumn_format=None, multirow=False)

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires \usepackage{booktabs}.

Changed in version 0.20.2: Added to Series

to_latex-specific options:

bold_rows [boolean, default False] Make the row labels bold in the output

column_format [str, default None] The columns format as specified in LaTeX table format e.g 'rc' for 3 columns

longtable [boolean, default will be read from the pandas config module] Default: False. Use a longtable environment instead of tabular. Requires adding a \usepackage{longtable} to your LaTeX preamble.

escape [boolean, default will be read from the pandas config module] Default: True. When set to False prevents from escaping latex special characters in column names.

encoding [str, default None] A string representing the encoding to use in the output file, defaults to ‘ascii’ on Python 2 and ‘utf-8’ on Python 3.

decimal [string, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

New in version 0.18.0.

multicolumn [boolean, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

New in version 0.20.0.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to column_format. The default will be read from the config module.

New in version 0.20.0.

multirow [boolean, default False] Use multirow to enhance MultiIndex rows. Requires adding a \usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

New in version 0.20.0.
pandas.Panel.to_msgpack

Panel.to_msgpack(path_or_buf=None, encoding='utf-8', **kwargs)
msgpack (serialize) object to input file path

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

Parameters path : string
File path, buffer-like, or None
if None, return generated string

append : boolean whether to append to an existing msgpack
(default is False)

compress : type of compressor (zlib or blosc), default to None (no
compression)

pandas.Panel.to_pickle

Panel.to_pickle(path, compression='infer', protocol=4)
Pickle (serialize) object to file.

Parameters path : str
File path where the pickled object will be stored.

compression : {'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'
A string representing the compression to use in the output file. By default, infers from the file extension in specified path.
New in version 0.20.0.

protocol : int
Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [R21] paragraph 12.1.2). The possible values for this parameter depend on the version of Python. For Python 2.x, possible values are 0, 1, 2. For Python>=3.0, 3 is a valid value. For Python >= 3.4, 4 is a valid value. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.
New in version 0.21.0.

See also:

read_pickle  Load pickled pandas object (or any object) from file.
DataFrame.to_hdf  Write DataFrame to an HDF5 file.
DataFrame.to_sql  Write DataFrame to a SQL database.
DataFrame.to_parquet  Write a DataFrame to the binary parquet format.

Examples
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9
>>> original_df.to_pickle("./dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> import os
>>> os.remove("./dummy.pkl")

pandas.Panel.to_sparse

Panel.to_sparse(*args, **kwargs)

    NOT IMPLEMENTED: do not call this method, as sparsifying is not supported for Panel objects and will raise an error.

    Convert to SparsePanel

pandas.Panel.to_sql

Panel.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None)

    Write records stored in a DataFrame to a SQL database.

    Databases supported by SQLAlchemy [R22] are supported. Tables can be newly created, appended to, or overwritten.

    Parameters name : string

        Name of SQL table.

    con : sqlalchemy.engine.Engine or sqlite3.Connection

        Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

    schema : string, optional

        Specify the schema (if database flavor supports this). If None, use default schema.

    if_exists : {'fail', 'replace', 'append'}, default 'fail'

        How to behave if the table already exists.

        * fail: Raise a ValueError.
• replace: Drop the table before inserting new values.
• append: Insert new values to the existing table.

index : boolean, default True
Write DataFrame index as a column. Uses index_label as the column name in the table.

index_label : string or sequence, default None
Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize : int, optional
Rows will be written in batches of this size at a time. By default, all rows will be written at once.

dtype : dict, optional
Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

Raises ValueError
When the table already exists and if_exists is 'fail' (the default).

See also:
pandas.read_sql read a DataFrame from a table

References
[R22], [R23]

Examples
Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite:///\', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
      name
0  User 1
1  User 2
2  User 3

>>> df.to_sql('users', con=engine)

>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```
Overwrite the table with just df1.

```python
>>> df1.to_sql('users', con=engine, if_exists='replace',
             index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
            dtype={"A": Integer()})
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

### pandas.Panel.to_xarray

**Panel.to_xarray()**

Return an xarray object from the pandas object.

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>a DataArray for a Series</td>
</tr>
<tr>
<td>a Dataset for a DataFrame</td>
</tr>
<tr>
<td>a DataArray for higher dims</td>
</tr>
</tbody>
</table>

**Notes**

See the xarray docs

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 1, 2],
                     'B': ['foo', 'bar', 'foo'],
                     'C': [0, 0, 0]})
```
>>> df
   A  B  C
0 1  foo  4.0
1 1  bar  5.0
2 2  foo  6.0

>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (index: 3)
Coordinates:
  * index (index) int64 0 1 2
Data variables:
   A (index) int64 1 1 2
   B (index) object 'foo' 'bar' 'foo'
   C (index) float64 4.0 5.0 6.0

>>> df = pd.DataFrame({'A': [1, 1, 2],
                    'B': ['foo', 'bar', 'foo'],
                    'C': np.arange(4.,7)})
.set_index(['B','A'])

>>> df
   B   A  C
foo 1  4.0
bar 1  5.0
foo 2  6.0

>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (A: 2, B: 2)
Coordinates:
  * B (B) object 'bar' 'foo'
  * A (A) int64 1 2
Data variables:
   C (B, A) float64 5.0 nan 4.0 6.0

>>> p = pd.Panel(np.arange(24).reshape(4,3,2),
               items=list('ABCD'),
               major_axis=pd.date_range('20130101', periods=3),
               minor_axis=['first', 'second'])

>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 2 (minor_axis)
Items axis: A to D
Major_axis axis: 2013-01-01 00:00:00 to 2013-01-03 00:00:00
Minor_axis axis: first to second

>>> p.to_xarray()
<xarray.DataArray (items: 4, major_axis: 3, minor_axis: 2)>
array([[ 0,  1],
       [ 2,  3],
       [ 4,  5],
       [ 6,  7],

       [10, 11],
       [12, 13],
       [14, 15],
       [16, 17],
       [18, 19],
       [20, 21],
       [22, 23]])

(continues on next page)
[10, 11]),
[[12, 13],
 [14, 15],
 [16, 17]],
[[18, 19],
 [20, 21],
 [22, 23]])
Coordinates:
 * items (items) object 'A' 'B' 'C' 'D'
 * major_axis (major_axis) datetime64[ns] 2013-01-01 2013-01-02 2013-01-03
   → # noqa
 * minor_axis (minor_axis) object 'first' 'second'

pandas.Panel.transpose

Panel.transpose(*args, **kwargs)
Permute the dimensions of the Panel

Parameters

args [three positional arguments: each one of]
{0, 1, 2, ‘items’, ‘major_axis’, ‘minor_axis’}

copy [boolean, default False] Make a copy of the underlying data. Mixed-dtype
data will always result in a copy

Returns

y [same as input]

Examples

>>> p.transpose(2, 0, 1)
>>> p.transpose(2, 0, 1, copy=True)

pandas.Panel.truediv

Panel.truediv(other, axis=0)
Floating division of series and other, element-wise (binary operator truediv). Equivalent to panel /
other.

Parameters

other [DataFrame or Panel]

axis : {items, major_axis, minor_axis}
   Axis to broadcast over

Returns

Panel
See also:

Panel.rtruediv

pandas.Panel.truncate

Panel.truncate(before=None, after=None, axis=None, copy=True)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

before : date, string, int
    Truncate all rows before this index value.

after : date, string, int
    Truncate all rows after this index value.

axis : {0 or 'index', 1 or 'columns'}, optional
    Axis to truncate. Truncates the index (rows) by default.

copy : boolean, default is True,
    Return a copy of the truncated section.

Returns

type of caller

The truncated Series or DataFrame.

See also:

DataFrame.loc  Select a subset of a DataFrame by label.

DataFrame.iloc  Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, before and after may be specified as strings instead of Timestamps.

Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
... 'B': ['f', 'g', 'h', 'i', 'j'],
... 'C': ['k', 'l', 'm', 'n', 'o'],
... 'index': [1, 2, 3, 4, 5])
>>> df
   A  B  C
0  a  f  k
1  b  g  l
2  c  h  m
3  d  i  n
4  e  j  o
```
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n

The columns of a DataFrame can be truncated.

>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j

For Series, only rows can be truncated.

>>> df['A'].truncate(before=2, after=4)
   2  b
   3  c
   4  d
Name: A, dtype: object

The index values in truncate can be datetimes or string dates.

```python
dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
df = pd.DataFrame(index=dates, data={'A': 1})
df.head()
   A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```python
>>> df.truncate(before=pd.Timestamp('2016-01-05'),...after=pd.Timestamp('2016-01-10')).tail()
   A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a DatetimeIndex containing only dates, we can specify before and after as strings. They will be coerced to Timestamps before truncation.

```python
>>> df.truncate('2016-01-05', '2016-01-10').tail()
   A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that truncate assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.
>>> df.loc['2016-01-05':'2016-01-10',:].tail()
    A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1

pandas.Panel.tshift

Panel.tshift(periods=1, freq=None, axis='major')
Shift the time index, using the index’s frequency if available.

Parameters
periods : int
    Number of periods to move, can be positive or negative
freq : DateOffset, timedelta, or time rule string, default None
    Increment to use from the tseries module or time rule (e.g. ‘EOM’)
axis : int or basestring
    Corresponds to the axis that contains the Index

Returns
shifted [NDFrame]

Notes
If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.Panel.tz_convert

Panel.tz_convert(tz, axis=0, level=None, copy=True)
Convert tz-aware axis to target time zone.

Parameters
tz [string or pytz.timezone object]
axis [the axis to convert]
level : int, str, default None
    If axis ia a MultiIndex, convert a specific level. Otherwise must be None
copy : boolean, default True
    Also make a copy of the underlying data

Raises
TypeError
    If the axis is tz-naive.
pandas.Panel.tz_localize

Panel.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise')
Localize tz-naive TimeSeries to target time zone.

Parameters
- **tz** [string or pytz.timezone object]
- **axis** [the axis to localize]
- **level**: int, str, default None
  If axis ia a MultiIndex, localize a specific level. Otherwise must be None
- **copy**: boolean, default True
  Also make a copy of the underlying data
- **ambiguous**: ‘infer’, bool-ndarray, ‘NaT’, default ‘raise’
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

Raises TypeError
If the TimeSeries is tz-aware and tz is not None.

pandas.Panel.update

Panel.update(other, join='left', overwrite=True, filter_func=None, raise_conflict=False)
Modify Panel in place using non-NA values from passed Panel, or object coercible to Panel. Aligns on items

Parameters
- **other** [Panel, or object coercible to Panel]
- **join**: How to join individual DataFrames
  - {‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’
- **overwrite**: boolean, default True
  If True then overwrite values for common keys in the calling panel
- **filter_func**: callable(1d-array) -> 1d-array<boolean>, default None
  Can choose to replace values other than NA. Return True for values that should be updated
- **raise_conflict**: bool
  If True, will raise an error if a DataFrame and other both contain data in the same place.
pandas.Panel.var

Panel.var (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
Return unbiased variance over requested axis.
Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{items (0), major_axis (1), minor_axis (2)}]
skipna : boolean, default True
Exclude NA/null values. If an entire row/column is NA, the result will be NA
level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing
into a DataFrame
ddof : int, default 1
Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N
represents the number of elements.
numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything,
then use only numeric data. Not implemented for Series.

Returns

var [DataFrame or Panel (if level specified)]

pandas.Panel.where

Panel.where (cond, other=nan, inplace=False, axis=None, level=None, errors='raise',
try_cast=False, raise_on_error=None)
Return an object of same shape as self and whose corresponding entries are from self where cond is True
and otherwise are from other.

Parameters cond : boolean NDFrame, array-like, or callable
Where cond is True, keep the original value. Where False, replace with corre-
sponding value from other. If cond is callable, it is computed on the NDFrame
and should return boolean NDFrame or array. The callable must not change input
NDFrame (though pandas doesn’t check it).
New in version 0.18.1: A callable can be used as cond.
other : scalar, NDFrame, or callable
Entries where cond is False are replaced with corresponding value from other.
If other is callable, it is computed on the NDFrame and should return scalar or
NDFrame. The callable must not change input NDFrame (though pandas doesn’t
check it).
New in version 0.18.1: A callable can be used as other.
inplace : boolean, default False
Whether to perform the operation in place on the data
axis [alignment axis if needed, default None]
level [alignment level if needed, default None]

errors: str, {'raise', ‘ignore’}, default ‘raise’
  • raise: allow exceptions to be raised
  • ignore: suppress exceptions. On error return original object
  Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

try_cast : boolean, default False
  try to cast the result back to the input type (if possible),

raise_on_error : boolean, default True
  Whether to raise on invalid data types (e.g. trying to where on strings)
  Deprecated since version 0.21.0.

Returns
wh [same type as caller]

See also:
DataFrame.mask()

Notes
The where method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is True the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the where documentation in indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
```

```python
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> s.where(s > 1, 10)
0    10.0
1    10.0
2     2.0
3     3.0
4     4.0
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A   B
0  0  -1
1  1   3
2  2 - 5
3  3  -7
4  4  -9
```

```python
>>> df.where(m, -df) == np.where(m, df, -df)
   A   B
0  True True
1  True True
2  True True
3  True True
4  True True
```

```python
>>> df.where(m, -df) == df.mask(~m, -df)
   A   B
0  True True
1  True True
2  True True
3  True True
4  True True
```

### pandas.Panel.xs

Panel.xs(key, axis=1)
Return slice of panel along selected axis

**Parameters**
  
  **key**: object

  Label

  **axis** [('items', 'major', 'minor'), default 1/'major']

**Returns**

  `y` [ndim(self)-1]

**Notes**

xs is only for getting, not setting values.

MultiIndex Slicers is a generic way to get/set values on any level or levels and is a superset of xs functionality, see [MultiIndex Slicers](#)
34.5.2 Attributes and underlying data

Aaxes

• items: axis 0; each item corresponds to a DataFrame contained inside
• major_axis: axis 1; the index (rows) of each of the DataFrames
• minor_axis: axis 2; the columns of each of the DataFrames

Panel.values
Return a Numpy representation of the DataFrame.

Panel.axes
Return index label(s) of the internal NDFrame

Panel.ndim
Return an int representing the number of axes / array dimensions.

Panel.size
Return an int representing the number of elements in this object.

Panel.shape
Return a tuple of axis dimensions

Panel.dtypes
Return the dtypes in the DataFrame.

Panel.ftypes
Return the ftypes (indication of sparse/dense and dtype) in DataFrame.

Panel.get_dtype_counts()
Return counts of unique dtypes in this object.

Panel.get_ftype_counts()
(DEPRECATED) Return counts of unique ftypes in this object.

34.5.3 Conversion

Panel.astype(dtype[, copy, errors])
Cast a pandas object to a specified dtype dtype.

Panel.copy([deep])
Make a copy of this object’s indices and data.

Panel.isna()
Detect missing values.

Panel.notna()
Detect existing (non-missing) values.

34.5.4 Getting and setting

Panel.get_value(*args, **kwargs)
(DEPRECATED) Quickly retrieve single value at (item, major, minor) location

Panel.set_value(*args, **kwargs)
(DEPRECATED) Quickly set single value at (item, major, minor) location

34.5.5 Indexing, iteration, slicing

Panel.at
Access a single value for a row/column label pair.

Panel.iat
Access a single value for a row/column pair by integer position.
Panel.loc
Access a group of rows and columns by label(s) or a boolean array.

Panel.iloc
Purely integer-location based indexing for selection by position.

Panel.__iter__
Iterate over info axis

Panel.iteritems()
Iterate over (label, values) on info axis

Panel.pop(item)
Return item and drop from frame.

Panel.xs(key[, axis])
Return slice of panel along selected axis

Panel.major_xs(key)
Return slice of panel along major axis

Panel.minor_xs(key)
Return slice of panel along minor axis

34.5.5.1 pandas.Panel.__iter__

Panel.__iter__()
Iterate over info axis

For more information on .at, .iat, .loc, and .iloc, see the indexing documentation.

34.5.6 Binary operator functions

Panel.add(other[, axis])
Addition of series and other, element-wise (binary operator add).

Panel.sub(other[, axis])
Subtraction of series and other, element-wise (binary operator sub).

Panel.mul(other[, axis])
Multiplication of series and other, element-wise (binary operator mul).

Panel.div(other[, axis])
Floating division of series and other, element-wise (binary operator truediv).

Panel.truediv(other[, axis])
Floating division of series and other, element-wise (binary operator truediv).

Panel.floordiv(other[, axis])
Integer division of series and other, element-wise (binary operator floordiv).

Panel.mod(other[, axis])
Modulo of series and other, element-wise (binary operator mod).

Panel.pow(other[, axis])
Exponential power of series and other, element-wise (binary operator pow).

Panel.radd(other[, axis])
Addition of series and other, element-wise (binary operator radd).

Panel.rsub(other[, axis])
Subtraction of series and other, element-wise (binary operator rsub).

Panel.rmul(other[, axis])
Multiplication of series and other, element-wise (binary operator rmul).

Panel.rdiv(other[, axis])
Floating division of series and other, element-wise (binary operator rtruediv).

Panel.rtruediv(other[, axis])
Floating division of series and other, element-wise (binary operator rtruediv).

Panel.rfloordiv(other[, axis])
Integer division of series and other, element-wise (binary operator rfloordiv).

Panel.rmod(other[, axis])
Modulo of series and other, element-wise (binary operator rmod).

<tr>
<td><code>Panel.skew</code></td>
<td>Return unbiased skew over requested axis Normalized by N-1</td>
</tr>
<tr>
<td><code>Panel.sum</code></td>
<td>Return the sum of the values for the requested axis</td>
</tr>
<tr>
<td><code>Panel.std</code></td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td><code>Panel.var</code></td>
<td>Return unbiased variance over requested axis.</td>
</tr>
</tbody>
</table>
34.5.9 Reindexing / Selection / Label manipulation

- `Panel.add_prefix(prefix)`  
  Prefix labels with string `prefix`.

- `Panel.add_suffix(suffix)`  
  Suffix labels with string `suffix`.

- `Panel.drop([labels, axis, index, columns, ...])`  
  Determines if two NDFrame objects contain the same elements.

- `Panel.equals(other)`  
  Subset rows or columns of dataframe according to labels in the specified index.

- `Panel.first(offset)`  
  Convenience method for subsetting initial periods of time series data based on a date offset.

- `Panel.last(offset)`  
  Convenience method for subsetting final periods of time series data based on a date offset.

- `Panel.reindex(*args, **kwargs)`  
  Conform Panel to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.

- `Panel.reindex_axis(labels[, axis, method, ...])`  
  Conform input object to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.

- `Panel.reindex_like(other[, method, copy, ...])`  
  Return an object with matching indices to myself.

- `Panel.rename([items, major_axis, minor_axis])`  
  Alter axes input function or functions.

- `Panel.sample([n, frac, replace, weights, ...])`  
  Return a random sample of items from an axis of object.

- `Panel.select(crit[, axis])`  
  (DEPRECATED) Return data corresponding to axis labels matching criteria.

- `Panel.take(indices[, axis, convert, is_copy])`  
  Return the elements in the given positional indices along an axis.

- `Panel.truncate([before, after, axis, copy])`  
  Truncate a Series or DataFrame before and after some index value.

34.5.9.1 pandas.Panel.drop

- `Panel.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')`

34.5.10 Missing data handling

- `Panel.dropna([axis, how, inplace])`  
  Drop 2D from panel, holding passed axis constant

34.5.11 Reshaping, sorting, transposing

- `Panel.sort_index([axis, level, ascending, ...])`  
  Sort object by labels (along an axis)

- `Panel.swaplevel([i, j, axis])`  
  Swap levels i and j in a MultiIndex on a particular axis

- `Panel.transpose(*args, **kwargs)`  
  Permute the dimensions of the Panel

- `Panel.swapaxes(axis1, axis2[, copy])`  
  Interchange axes and swap values axes appropriately

- `Panel.conform(frame[, axis])`  
  Conform input DataFrame to align with chosen axis pair.
### 34.5.12 Combining / joining / merging

- **Panel.join**(other[, how, lsuffix, rsuffix])
  Join items with other Panel either on major and minor axes column
- **Panel.update**(other[, join, overwrite, ...])
  Modify Panel in place using non-NA values from passed Panel, or object coercible to Panel.

### 34.5.13 Time series-related

- **Panel.asfreq**(freq[, method, how, normalize, ...])
  Convert TimeSeries to specified frequency.
- **Panel.shift**([periods, freq, axis])
  Shift index by desired number of periods with an optional time freq.
- **Panel.resample**(rule[, how, axis, ...])
  Convenience method for frequency conversion and resampling of time series.
- **Panel.tz_convert**(tz[, axis, level, copy])
  Convert tz-aware axis to target time zone.
- **Panel.tz_localize**(tz[, axis, level, copy, ...])
  Localize tz-naive TimeSeries to target time zone.

### 34.5.14 Serialization / IO / Conversion

- **Panel.from_dict**(data[, intersect, orient, dtype])
  Construct Panel from dict of DataFrame objects
- **Panel.to_pickle**(path[, compression, protocol])
  Pickle (serialize) object to file.
- **Panel.to_excel**(path[, na_rep, engine])
  Write each DataFrame in Panel to a separate excel sheet
- **Panel.to_hdf**(path_or_buf, key, **kwargs)
  Write the contained data to an HDF5 file using HDFStore.
- **Panel.to_sparse**(args, **kwargs)
  NOT IMPLEMENTED: do not call this method, as sparsifying is not supported for Panel objects and will raise an error.
- **Panel.to_frame**([filter_observations])
  Transform wide format into long (stacked) format as DataFrame whose columns are the Panel’s items and whose index is a MultiIndex formed of the Panel’s major and minor axes.
- **Panel.to_clipboard**(excel, sep)
  Copy object to the system clipboard.

### 34.6 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

- **Index**
  Immutable ndarray implementing an ordered, sliceable set.

### 34.6.1 pandas.Index

**class** pandas.Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects

**Parameters**
data  [array-like (1-dimensional)]

dtype : NumPy dtype (default: object)

    If dtype is None, we find the dtype that best fits the data. If an actual dtype is
    provided, we coerce to that dtype if it’s safe. Otherwise, an error will be raised.

copy : bool

    Make a copy of input ndarray

name : object

    Name to be stored in the index

tupleize_cols : bool (default: True)

    When True, attempt to create a MultiIndex if possible

See also:

   RangeIndex  Index implementing a monotonic integer range
   CategoricalIndex  Index of Categoricals.
   MultiIndex  A multi-level, or hierarchical, Index
   IntervalIndex  an Index of Intervals.

   DatetimeIndex, TimedeltaIndex, PeriodIndex, Int64Index, UInt64Index,
   Float64Index

Notes

An Index instance can only contain hashable objects

Examples

>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')

>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')

Attributes

<tr>
<td>values</td>
<td>return the underlying data as an ndarray</td>
</tr>
</tbody>
</table>

34.6.1.1 pandas.Index.T

Index.T
   return the transpose, which is by definition self

34.6.1.2 pandas.Index.base

Index.base
   return the base object if the memory of the underlying data is shared

34.6.1.3 pandas.Index.data

Index.data
   return the data pointer of the underlying data

34.6.1.4 pandas.Index.dtype

Index.dtype
   return the dtype object of the underlying data

34.6.1.5 pandas.Index.dtype_str

Index.dtype_str
   return the dtype str of the underlying data

34.6.1.6 pandas.Index.flags

Index.flags
34.6.1.7 pandas.Index.hasnans

Index. hasnans
  return if I have any nans; enables various perf speedups

34.6.1.8 pandas.Index.inferred_type

Index. inferred_type
  return a string of the type inferred from the values

34.6.1.9 pandas.Index.is_monotonic

Index. is_monotonic
  alias for is_monotonic_increasing (deprecated)

34.6.1.10 pandas.Index.is_monotonic_decreasing

Index. is_monotonic_decreasing
  return if the index is monotonic decreasing (only equal or decreasing) values.

Examples

```python
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```

34.6.1.11 pandas.Index.is_monotonic_increasing

Index. is_monotonic_increasing
  return if the index is monotonic increasing (only equal or increasing) values.

Examples

```python
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

34.6.1.12 pandas.Index.is_unique

Index. is_unique
  return if the index has unique values
34.6.1.13 pandas.Index.itemsize

Index.itemsize
return the size of the dtype of the item of the underlying data

34.6.1.14 pandas.Index.nbytes

Index.nbytes
return the number of bytes in the underlying data

34.6.1.15 pandas.Index.ndim

Index.ndim
return the number of dimensions of the underlying data, by definition 1

34.6.1.16 pandas.Index.shape

Index.shape
return a tuple of the shape of the underlying data

34.6.1.17 pandas.Index.size

Index.size
return the number of elements in the underlying data

34.6.1.18 pandas.Index.strides

Index.strides
return the strides of the underlying data

34.6.1.19 pandas.Index.values

Index.values
return the underlying data as an ndarray

<table>

Table 97 – continued from previous page
34.6.1.20 pandas.Index.all

Index.all(*args, **kwargs)

Return whether all elements are True.

Parameters

*args

These parameters will be passed to numpy.all.

**kwargs

These parameters will be passed to numpy.all.

Returns

all : bool or array_like (if axis is specified)

A single element array_like may be converted to bool.

See also:

pandas.Index.any Return whether any element in an Index is True.
pandas.Series.any Return whether any element in a Series is True.
pandas.Series.all Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all

True, because nonzero integers are considered True.

>>> pd.Index([1, 2, 3]).all()
True

False, because 0 is considered False.

>>> pd.Index([0, 1, 2]).all()
False

any

True, because 1 is considered True.

>>> pd.Index([0, 0, 1]).any()
True

False, because 0 is considered False.

>>> pd.Index([0, 0, 0]).any()
False
34.6.1.21 pandas.Index.any

Index\texttt{.any}(*\texttt{args}, **\texttt{kwargs})

Return whether any element is True.

Parameters
*\texttt{args}

These parameters will be passed to numpy.any.

**\texttt{kwargs}

These parameters will be passed to numpy.any.

Returns \texttt{any} : bool or array_like (if axis is specified)

A single element array_like may be converted to bool.

See also:

\texttt{pandas.Index.all} Return whether all elements are True.

\texttt{pandas.Series.all} Return whether all elements are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

```python
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True
```

```python
>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

34.6.1.22 pandas.Index.append

Index\texttt{.append}(\texttt{other})

Append a collection of Index options together

Parameters

\texttt{other} [Index or list/tuple of indices]

Returns

\texttt{appended} [Index]

34.6.1.23 pandas.Index.argmax

Index\texttt{.argmax}(\texttt{axis=None})

return a ndarray of the maximum argument indexer
See also:

numpy.ndarray.argmin

34.6.1.24 pandas.Index.argmin

Index.argmin(\(axis=None\))
return a ndarray of the minimum argument indexer
See also:

numpy.ndarray.argmin

34.6.1.25 pandas.Index.argsort

Index.argsort(*args, **kwargs)
Return the integer indices that would sort the index.

Parameters

*args
Passed to numpy.ndarray.argsort.

**kwargs
Passed to numpy.ndarray.argsort.

Returns

numpy.ndarray
Integer indices that would sort the index if used as an indexer.

See also:

numpy.argsort Similar method for NumPy arrays.

Index.sort_values Return sorted copy of Index.

Examples

```python
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')

>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])

>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

34.6.1.26 pandas.Index.asof

Index.asof(label)
For a sorted index, return the most recent label up to and including the passed label. Return NaN if not found.

See also:
get_loc  asof is a thin wrapper around get_loc with method='pad'

34.6.1.27 pandas.Index.asof_locs

Index.asof_locs(where, mask)
    where : array of timestamps
    mask  : array of booleans where data is not NA

34.6.1.28 pandas.Index.astype

Index.astype(dtype, copy=True)
    Create an Index with values cast to dtypes. The class of a new Index is determined by dtype. When conversion is impossible, a ValueError exception is raised.
    Parameters
    dtype [numpy dtypes or pandas type]
    copy  : bool, default True
        By default, astype always returns a newly allocated object. If copy is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.
        New in version 0.19.0.

34.6.1.29 pandas.Index.contains

Index.contains(key)
    return a boolean if this key is IN the index
    Parameters
    key  [object]
    Returns
    boolean

34.6.1.30 pandas.Index.copy

Index.copy(name=None, deep=False, dtype=None, **kwargs)
    Make a copy of this object. Name and dtype sets those attributes on the new object.
    Parameters
    name  [string, optional]
    deep  [boolean, default False]
    dtype [numpy dtypes or pandas type]
    Returns
    copy  [Index]
Notes

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to deepcopy.

34.6.1.31 pandas.Index.delete

`Index.delete(loc)`  
Make new Index with passed location(-s) deleted  

Returns  

`new_index` [Index]

34.6.1.32 pandas.Index.difference

`Index.difference(other)`  
Return a new Index with elements from the index that are not in `other`.  
This is the set difference of two Index objects. It’s sorted if sorting is possible.  

Parameters  

`other` [Index or array-like]  

Returns  

`difference` [Index]

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
```

34.6.1.33 pandas.Index.drop

`Index.drop(labels, errors='raise')`  
Make new Index with passed list of labels deleted  

Parameters  

`labels` [array-like]  

`errors`: {'ignore', 'raise'}, default 'raise'  
If 'ignore', suppress error and existing labels are dropped.  

Returns  

`dropped` [Index]  

Raises KeyError  
If not all of the labels are found in the selected axis
34.6.1.34 pandas.Index.drop_duplicates

Index.drop_duplicates(keep='first')
Return Index with duplicate values removed.

Parameters keep : {'first', 'last', False}, default ‘first’
   • ‘first’ : Drop duplicates except for the first occurrence.
   • ‘last’ : Drop duplicates except for the last occurrence.
   • False : Drop all duplicates.

Returns
deduplicated [Index]

See also:
Series.drop_duplicates equivalent method on Series
DataFrame.drop_duplicates equivalent method on DataFrame
Index.duplicated related method on Index, indicating duplicate Index values.

Examples

Generate an pandas.Index with duplicate values.

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The keep parameter controls which duplicate values are removed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```python
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value ‘last’ keeps the last occurrence for each set of duplicated entries.

```python
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value False discards all sets of duplicated entries.

```python
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

34.6.1.35 pandas.Index.dropna

Index.dropna (how='any')
Return Index without NA/NaN values

Parameters how : {'any', ‘all’}, default ‘any’
   If the Index is a MultiIndex, drop the value when any or all levels are NaN.

Returns
valid [Index]
### 34.6.1.36 pandas.Index.duplicated

`Index.duplicated(keep='first')`

Indicate duplicate index values.

Duplicated values are indicated as `True` values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

**Parameters**

`keep` : {‘first’, ‘last’, False}, default ‘first’  
The value or values in a set of duplicates to mark as missing.  
  - ‘first’ : Mark duplicates as `True` except for the first occurrence.  
  - ‘last’ : Mark duplicates as `True` except for the last occurrence.  
  - False : Mark all duplicates as `True`.

**Returns**

`numpy.ndarray`

See also:

- `pandas.Series.duplicated` Equivalent method on pandas.Series
- `pandas.DataFrame.duplicated` Equivalent method on pandas.DataFrame
- `pandas.Index.drop_duplicates` Remove duplicate values from Index

**Examples**

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False, True, False, True])
```

which is equivalent to

```python
>>> idx.duplicated(keep='first')
array([False, False, True, False, True])
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> idx.duplicated(keep='last')
array([ True, False, True, False, False])
```

By setting keep on False, all duplicates are True:

```python
>>> idx.duplicated(keep=False)
array([ True, False, True, False, True])
```

### 34.6.1.37 pandas.Index.equals

`Index.equals(other)`  
Determines if two Index objects contain the same elements.
## 34.6.1.38 pandas.Index.factorize

`Index.factorize(sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

### Parameters

- **sort**: boolean, default False
  - Sort `uniques` and shuffle `labels` to maintain the relationship.
- **na_sentinel**: int, default -1
  - Value to mark “not found”.

### Returns

- **labels**: ndarray
  - An integer ndarray that’s an indexer into `uniques`. `uniques.take(labels)` will have the same values as `values`.
- **uniques**: ndarray, Index, or Categorical
  - The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

### Note

Even if there’s a missing value in `values`, `uniques` will **not** contain an entry for it.

### See also:

- **pandas.cut** Discretize continuous-valued array.
- **pandas.unique** Find the unique value in an array.

### Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```python
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `labels` will be shuffled so that the relationship is maintained.

```python
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```
Missing values are indicated in labels with na_sentinel (-1 by default). Note that missing values are never included in uniques.

```python
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of uniques will differ. For Categoricals, a Categorical is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in uniques.categories, despite not being present in cat.values.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

### 34.6.1.39 pandas.Index.fillna

Index.fillna(value=None, downcast=None)

Fill NA/NaN values with the specified value

- **value** : scalar
  
  Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.

- **downcast** : dict, default is None
  
  a dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

- **Returns**

  - filled [%(klass)s]

### 34.6.1.40 pandas.Index.format

Index.format(name=False, formatter=None, **kwargs)

Render a string representation of the Index
34.6.1.41 pandas.Index.get_duplicates

Index.get_duplicates()
Extract duplicated index elements.

Returns a sorted list of index elements which appear more than once in the index.

Deprecated since version 0.23.0: Use idx[idx.duplicated()].unique() instead

Returns array-like
List of duplicated indexes.

See also:

Index.duplicated Return boolean array denoting duplicates.
Index.drop_duplicates Return Index with duplicates removed.

Examples

Works on different Index of types.

>>> pd.Index([1, 2, 2, 3, 3, 3, 4]).get_duplicates()
[2, 3]
>>> pd.Index([1., 2., 2., 3., 3., 3., 4.]).get_duplicates()
[2.0, 3.0]
>>> pd.Index(['a', 'b', 'b', 'c', 'c', 'd', 'c']).get_duplicates()
['b', 'c']

Note that for a DatetimeIndex, it does not return a list but a new DatetimeIndex:

>>> dates = pd.to_datetime(['2018-01-01', '2018-01-02', '2018-01-03', ...
... '2018-01-03', '2018-01-04', '2018-01-04'],
... format='%Y-%m-%d')
>>> pd.Index(dates).get_duplicates()
DatetimeIndex(['2018-01-03', '2018-01-04'],
    dtype='datetime64[ns]', freq=None)

Sorts duplicated elements even when indexes are unordered.

>>> pd.Index([1, 2, 3, 2, 3, 4, 3]).get_duplicates()
[2, 3]

Return empty array-like structure when all elements are unique.

>>> pd.Index([1, 2, 3, 4]).get_duplicates()
[]
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-02', '2018-01-03'],
... format='%Y-%m-%d')
>>> pd.Index(dates).get_duplicates()
DatetimeIndex([],
    dtype='datetime64[ns]', freq=None)

34.6.1.42 pandas.Index.get_indexer

Index.get_indexer(target, method=None, limit=None, tolerance=None)
Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.
Parameters

- **target** [Index]

- **method** : {None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

- **limit** : int, optional
  - Maximum number of consecutive labels in target to match for inexact matches.

- **tolerance** : optional
  - Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.
  - Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.
  - New in version 0.21.0: (list-like tolerance)

**Returns** **indexer** : ndarray of int

- Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**Examples**

```python
>>> indexer = index.get_indexer(new_index)
>>> new_values = cur_values.take(indexer)
```

### 34.6.1.43 pandas.Index.get_indexer_for

Index.get_indexer_for(target, **kwargs)

- guaranteed return of an indexer even when non-unique
- This dispatches to get_indexer or get_indexer_non_unique as appropriate

### 34.6.1.44 pandas.Index.get_indexer_non_unique

Index.get_indexer_non_unique(target)

- Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

- **target** [Index]
Returns indexer: ndarray of int

Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

missing: ndarray of int

An indexer into the target of the values not found. These correspond to the -1 in the indexer array

34.6.1.45 pandas.Index.get_level_values

Index.get_level_values(level)

Return an Index of values for requested level, equal to the length of the index.

Parameters level: int or str

level is either the integer position of the level in the MultiIndex, or the name of the level.

Returns values: Index

self, as there is only one level in the Index.

See also:

pandas.MultiIndex.get_level_values get values for a level of a MultiIndex

34.6.1.46 pandas.Index.get_loc

Index.get_loc(key, method=None, tolerance=None)

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method: {None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional
  • default: exact matches only.
  • pad / ffill: find the PREVIOUS index value if no exact match.
  • backfill / bfill: use NEXT index value if no exact match
  • nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

tolerance: optional

Maximum distance from index value for inexact matches. The value of the index at the matching location most satisfy the equation abs(index[loc] - key) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtypes must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

Returns
Examples

```python
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1

>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)

>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False,  True, False,  True], dtype=bool)
```

34.6.1.47 pandas.Index.get_slice_bound

*Index.get_slice_bound*(label, side, kind)  
Calculate slice bound that corresponds to given label.  
Returns leftmost (one-past-the-rightmost if side=='right') position of given label.

**Parameters**

- **label** [object]  
- **side** [`{'left', 'right'}`]  
- **kind** [`{'ix', 'loc', 'getitem'}`]

34.6.1.48 pandas.Index.get_value

*Index.get_value*(series, key)  
Fast lookup of value from 1-dimensional ndarray. Only use this if you know what you're doing

34.6.1.49 pandas.Index.get_values

*Index.get_values()*  
Return *Index* data as an *numpy.ndarray*.  

**Returns** *numpy.ndarray*  
A one-dimensional numpy array of the *Index* values.

**See also:**

*Index.values* The attribute that get_values wraps.

**Examples**

Getting the *Index* values of a *DataFrame*:

```python
```
```python
>>> df = pd.DataFrame([[[1, 2, 3], [4, 5, 6], [7, 8, 9]], ...
...     index=['a', 'b', 'c'], columns=['A', 'B', 'C'])
>>> df
                     A    B    C
a  1  2  3
b  4  5  6
c  7  8  9

>>> df.index.get_values()
array(['a', 'b', 'c'], dtype=object)

Standalone Index values:

>>> idx = pd.Index(['1', '2', '3'])
>>> idx.get_values()
array(['1', '2', '3'], dtype=object)

MultiIndex arrays also have only one dimension:

>>> midx = pd.MultiIndex.from_arrays([[1, 2, 3], ['a', 'b', 'c']], ...
...     names=('number', 'letter'))
>>> midx.get_values()
array([(1, 'a'), (2, 'b'), (3, 'c')], dtype=object)
>>> midx.get_values().ndim
1

34.6.1.50 pandas.Index.groupby

Index.groupby(values)

Group the index labels by a given array of values.

Parameters values : array

Values used to determine the groups.

Returns groups : dict

{group name -> group labels}

34.6.1.51 pandas.Index.identical

Index.identical(other)

Similar to equals, but check that other comparable attributes are also equal

34.6.1.52 pandas.Index.insert

Index.insert(loc, item)

Make new Index inserting new item at location. Follows Python list.append semantics for negative values

Parameters

loc [int]

item [object]

Returns

new_index [Index]
34.6.1.53 pandas.Index.intersection

Index.intersection(other)

Form the intersection of two Index objects.

This returns a new Index with elements common to the index and other, preserving the order of the calling index.

Parameters

other [Index or array-like]

Returns

intersection [Index]

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

34.6.1.54 pandas.Index.is_

Index.is_(other)

More flexible, faster check like is but that works through views

Note: this is not the same as Index.identical(), which checks that metadata is also the same.

Parameters other : object

other object to compare against.

Returns

True if both have same underlying data, False otherwise [bool]

34.6.1.55 pandas.Index.is_categorical

Index.is_categorical()

Check if the Index holds categorical data.

Returns boolean

True if the Index is categorical.

See also:

CategoricalIndex Index for categorical data.

Examples
>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ... "Watermelon"]).astype("category")
>>> idx.is_categorical()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False

>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0    Peter
1    Victor
2  Elisabeth
3      Mar
dtype: object
>>> s.index.is_categorical()
False

34.6.1.56 pandas.Index.isin

Index.isin(values, level=None)

Return a boolean array where the index values are in values.

Compute boolean array of whether each index value is found in the passed set of values. The length of
the returned boolean array matches the length of the index.

Parameters values : set or list-like

Sought values.

New in version 0.18.1: Support for values as a set.

level : str or int, optional

Name or position of the index level to use (if the index is a MultiIndex).

Returns is_contained : ndarray

NumPy array of boolean values.

See also:

Series.isin Same for Series.

DataFrame.isin Same method for DataFrames.

Notes

In the case of MultiIndex you must either specify values as a list-like object containing tuples that are the
same length as the number of levels, or specify level. Otherwise it will raise a ValueError.

If level is specified:

• if it is the name of one and only one index level, use that level;
• otherwise it should be a number indicating level position.
Examples

```python
>>> idx = pd.Index([1, 2, 3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
```

Check whether each index value in a list of values.

```python
>>> idx.isin([1, 4])
array([True, False, False])
```

```python
>>> midx = pd.MultiIndex.from_arrays([[1, 2, 3], ['red', 'blue', 'green']], names=('number', 'color'))
>>> midx
MultiIndex(levels=[[1, 2, 3], ['blue', 'green', 'red']],
labels=[[0, 1, 2], [2, 0, 1]],
names=['number', 'color'])
```

Check whether the strings in the ‘color’ level of the MultiIndex are in a list of colors.

```python
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([True, False, False])
```

To check across the levels of a MultiIndex, pass a list of tuples:

```python
>>> midx.isin([(1, 'red'), (3, 'red')])
array([True, False, False])
```

For a DatetimeIndex, string values in `values` are converted to Timestamps.

```python
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
dtype='datetime64[ns]', freq=None)
```

```python
>>> dti.isin(['2000-03-11'])
array([True, False, False])
```

34.6.1.57 pandas.Index.isna

Index.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None, numpy. NaN or pd.NaT, get mapped to True values. Everything else get mapped to False values. Characters such as empty strings ‘’ or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

New in version 0.20.0.

Returns numpy.ndarray

A boolean array of whether my values are NA

See also:

pandas.Index.notna  boolean inverse of isna.
pandas.Index.dropna omit entries with missing values.
pandas.isna top-level isna.
Series.isna detect missing values in Series object.

Examples

Show which entries in a pandas.Index are NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False, True], dtype=bool)
```

Empty strings are not considered NA values. None is considered an NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True], dtype=bool)
```

For datetimes, NaT (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
                           pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
               dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False, True, True, True], dtype=bool)
```

34.6.1.58 pandas.Index.isnull

Index.isnull()  
Detect missing values.  
Return a boolean same-sized object indicating if the values are NA. NA values, such as None, numpy.NaN or pd.NaT, get mapped to True values. Everything else get mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

New in version 0.20.0.

Returns numpy.ndarray

A boolean array of whether my values are NA

See also:

pandas.Index.notna boolean inverse of isna.
pandas.Index.dropna omit entries with missing values.
pandas.isna top-level isna.
Series.isna detect missing values in Series object.
Examples

Show which entries in a pandas.Index are NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.nan])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False, True], dtype=bool)
```

Empty strings are not considered NA values. None is considered an NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True], dtype=bool)
```

For datetimes, NaT (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
... pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
  dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False, True, True, True], dtype=bool)
```

### 34.6.1.59 pandas.Index.item

Index.item()  
return the first element of the underlying data as a python scalar

### 34.6.1.60 pandas.Index.join

Index.join(other, how='left', level=None, return_indexers=False, sort=False)  
this is an internal non-public method

Compute join_index and indexers to conform data structures to the new index.

**Parameters**

- **other** [Index]
- **how** [(‘left’, ‘right’, ‘inner’, ‘outer’)]
- **level** [int or level name, default None]
- **return_indexers** [boolean, default False]
- **sort** : boolean, default False

  Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword)

  New in version 0.20.0.

**Returns**
34.6.1.61 pandas.Index.map

Index.map(mapper, na_action=None)
Map values using input correspondence (a dict, Series, or function).

Parameters
mapper : function, dict, or Series
Mapping correspondence.

na_action : {None, 'ignore'}
If 'ignore', propagate NA values, without passing them to the mapping correspondence.

Returns
applied : Union[Index, MultiIndex], inferred
The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

34.6.1.62 pandas.Index.max

Index.max()
Return the maximum value of the Index.

Returns
scalar
Maximum value.

See also:

Index.min Return the minimum value in an Index.
Series.max Return the maximum value in a Series.
DataFrame.max Return the maximum values in a DataFrame.

Examples

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'

For a MultiIndex, the maximum is determined lexicographically.

>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```
34.6.1.63 pandas.Index.memory_usage

Index.memory_usage(deep=False)
Memory usage of the values

Parameters deep : bool
   Introspect the data deeply, interrogate object dtypes for system-level memory consumption

Returns
   bytes used

See also:
   numpy.ndarray.nbytes

Notes
Memory usage does not include memory consumed by elements that are not components of the array if deep=False or if used on PyPy

34.6.1.64 pandas.Index.min

Index.min()
Return the minimum value of the Index.

Returns scalar
   Minimum value.

See also:
   Index.max  Return the maximum value of the object.
   Series.min  Return the minimum value in a Series.
   DataFrame.min  Return the minimum values in a DataFrame.

Examples

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.min()
('a', 1)
```
34.6.1.65 pandas.Index.notna

`Index.notna()`  
Detect existing (non-missing) values.  

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.

New in version 0.20.0.

**Returns** `numpy.ndarray`  
Boolean array to indicate which entries are not NA.

**See also:**

- `Index.notnull` alias of `notna`
- `Index.isna` inverse of `notna`
- `pandas.notna` top-level `notna`

**Examples**

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

34.6.1.66 pandas.Index.notnull

`Index.notnull()`  
Detect existing (non-missing) values.  

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.

New in version 0.20.0.

**Returns** `numpy.ndarray`  
Boolean array to indicate which entries are not NA.

**See also:**

- `Index.notnull` alias of `notna`
- `Index.isna` inverse of `notna`
- `pandas.notna` top-level `notna`
**Index.notnull** alias of notna

**Index.isna** inverse of notna

**pandas.notna** top-level notna

**Examples**

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([True, True, True, False])
```

**34.6.1.67 pandas.Index.nunique**

**Index.nunique** *(dropna=True)*

Return number of unique elements in the object.

Excludes NA values by default.

- **Parameters** *dropna*: boolean, default True
  - Don’t include NaN in the count.

- **Returns**
  - *nunique* [int]

**34.6.1.68 pandas.Index.putmask**

**Index.putmask** *(mask, value)*

return a new Index of the values set with the mask

See also:

- numpy.ndarray.putmask

**34.6.1.69 pandas.Index.ravel**

**Index.ravel** *(order='C')*

return an ndarray of the flattened values of the underlying data

See also:

- numpy.ndarray.ravel
34.6.1.70 pandas.Index.reindex

Index.reindex (target, method=None, level=None, limit=None, tolerance=None)
Create index with target’s values (move/add/delete values as necessary)

Parameters

target [an iterable]

Returns new_index : pd.Index
Resulting index

indexer : np.ndarray or None
Indices of output values in original index

34.6.1.71 pandas.Index.rename

Index.rename (name, inplace=False)
Set new names on index. Defaults to returning new index.

Parameters name : str or list
name to set

inplace : bool
if True, mutates in place

Returns

new index (of same type and class…etc) [if inplace, returns None]

34.6.1.72 pandas.Index.repeat

Index.repeat (repeats, *args, **kwargs)
Repeat elements of an Index.

Returns a new index where each element of the current index is repeated consecutively a given number of times.

Parameters repeats : int
The number of repetitions for each element.

**kwargs
Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns pandas.Index
Newly created Index with repeated elements.

See also:

Series.repeat Equivalent function for Series
numpy.repeat Underlying implementation
Examples

>>> idx = pd.Index([1, 2, 3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
>>> idx.repeat(2)
Int64Index([1, 1, 2, 2, 3, 3], dtype='int64')
>>> idx.repeat(3)
Int64Index([1, 1, 1, 2, 2, 2, 3, 3, 3], dtype='int64')

34.6.1.73 pandas.Index.searchsorted

Index.searchsorted(value, side='left', sorter=None)
Find indices where elements should be inserted to maintain order.
Find the indices into a sorted IndexOpsMixin self such that, if the corresponding elements in value were
inserted before the indices, the order of self would be preserved.

Parameters value : array_like
  Values to insert into self.
side : {'left', 'right'}, optional
  If 'left', the index of the first suitable location found is given. If 'right', return the
  last such index. If there is no suitable index, return either 0 or N (where N is the
  length of self).
sorter : 1-D array_like, optional
  Optional array of integer indices that sort self into ascending order. They are
typically the result of np.argsort.

Returns indices : array of ints
  Array of insertion points with the same shape as value.

See also:
numpy.searchsorted

Notes

Binary search is used to find the required insertion points.

Examples

>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64

>>> x.searchsorted(4)
array([3])
>>> x.searchsorted([0, 4])
array([0, 3])

>>> x.searchsorted([1, 3], side='left')
array([0, 2])

>>> x.searchsorted([1, 3], side='right')
array([1, 3])

>>> x = pd.Categorical(['apple', 'bread', 'bread',
                     'cheese', 'milk'], ordered=True)
[array(['apple', 'bread', 'bread', 'cheese', 'milk'],
      categories=['apple', 'bread', 'cheese', 'milk'],
      ordered=True, dtype='category')]

>>> x.searchsorted('bread')
array([1])  # Note: an array, not a scalar

>>> x.searchsorted(['bread'], side='right')
array([3])

34.6.1.74 pandas.Index.set_names

Index.set_names(names, level=None, inplace=False)

Set new names on index. Defaults to returning new index.

Parameters

names : str or sequence
  name(s) to set

level : int, level name, or sequence of int/level names (default None)
  If the index is a MultiIndex (hierarchical), level(s) to set (None for all levels).
  Otherwise level must be None

inplace : bool
  if True, mutates in place

Returns

new index (of same type and class...etc) [if inplace, returns None]

Examples

>>> Index([1, 2, 3, 4]).set_names('foo')
Int64Index([1, 2, 3, 4], dtype='int64', name='foo')

>>> Index([1, 2, 3, 4]).set_names(['foo'])
Int64Index([1, 2, 3, 4], dtype='int64', name='foo')

>>> idx = MultiIndex.from_tuples([(1, u'one'), (1, u'two'),
                                (2, u'one'), (2, u'two')],
                               names=['foo', 'bar'])

>>> idx.set_names(['baz', 'quz'])
MultiIndex(levels=[[1, 2], [u'one', u'two']],
           labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
           names=['baz', 'quz'])

(continues on next page)
>>> idx.set_names('baz', level=0)
MultiIndex(levels=[[1, 2], ['one', 'two']],
          labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
          names=['baz', 'bar'])

34.6.1.75 pandas.Index.set_value

Index.set_value(arr, key, value)
Fast lookup of value from 1-dimensional ndarray. Only use this if you know what you’re doing

34.6.1.76 pandas.Index.shift

Index.shift(periods=1, freq=None)
Shift index by desired number of time frequency increments.
This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

Parameters

periods : int, default 1
Number of periods (or increments) to shift by, can be positive or negative.

freq : pandas.DateOffset, pandas.Timedelta or string, optional
Frequency increment to shift by. If None, the index is shifted by its own freq attribute. Offset aliases are valid strings, e.g., ‘D’, ‘W’, ‘M’ etc.

Returns

pandas.Index
shifted index

See also:

Series.shift Shift values of Series.

Notes

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

Examples

Put the first 5 month starts of 2011 into an index.

```python
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01', '2011-04-01',
               '2011-05-01'],
              dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```python
```
The default value of `freq` is the `freq` attribute of the index, which is ‘MS’ (month start) in this example.

```python
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
              '2012-03-01'],
             dtype='datetime64[ns]', freq='MS')
```

### 34.6.1.77 pandas.Index.slice_indexer

Index.[slice_indexer](slice_indexer) *(start=None, end=None, step=None, kind=None)*

For an ordered or unique index, compute the slice indexer for input labels and step.

**Parameters**

- **start**: label, default None
  
  If None, defaults to the beginning

- **end**: label, default None
  
  If None, defaults to the end

- **step**: [int, default None]

- **kind**: [string, default None]

**Returns**

- **indexer**: [slice]

**Raises**

**KeyError**: If key does not exist, or key is not unique and index is not ordered.

**Notes**

This function assumes that the data is sorted, so use at your own peril

**Examples**

This is a method on all index types. For example you can do:

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3)
```

```python
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3)
```
34.6.1.78 pandas.Index.slice_locs

Index.slice_locs(start=None, end=None, step=None, kind=None)

Compute slice locations for input labels.

Parameters

start : label, default None
    If None, defaults to the beginning
end : label, default None
    If None, defaults to the end
step : int, defaults None
    If None, defaults to 1
kind ([‘ix’, ‘loc’, ‘getitem’] or None)

Returns

start, end [int]

See also:

Index.get_loc Get location for a single label

Notes

This method only works if the index is monotonic or unique.

Examples

```python
t>> idx = pd.Index(list('abcd'))
t>> idx.slice_locs(start='b', end='c')
(1, 3)
```

34.6.1.79 pandas.Index.sort_values

Index.sort_values(return_indexer=False, ascending=True)

Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

Parameters

return_indexer : bool, default False
    Should the indices that would sort the index be returned.
ascending : bool, default True
    Should the index values be sorted in an ascending order.

Returns

sorted_index : pandas.Index
    Sorted copy of the index.
indexer : numpy.ndarray, optional
    The indices that the index itself was sorted by.
See also:

*pandas.Series.sort_values* Sort values of a Series.

*pandas.DataFrame.sort_values* Sort values in a DataFrame.

**Examples**

```python
def main():
    idx = pd.Index([10, 100, 1, 1000])
    print(idx)
    print(idx.sort_values())
    print(idx.sort_values(ascending=False, return_indexer=True))

if __name__ == '__main__':
    main()
```

```
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices `idx` was sorted by.

```
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

### 34.6.1.80 pandas.Index.sortlevel

Index.sortlevel(level=None, ascending=True, sort_remaining=None)

For internal compatability with with the Index API

Sort the Index. This is for compat with MultiIndex

**Parameters**

- **ascending** : boolean, default True
  False to sort in descending order

- **level, sort_remaining** are compat parameters

**Returns**

- **sorted_index** [Index]

### 34.6.1.81 pandas.Index.str

Index.str()

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

**Examples**

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```
34.6.1.82 pandas.Index.summary

`Index.summary(name=None)`
Return a summarized representation .. deprecated:: 0.23.0

34.6.1.83 pandas.Index.symmetric_difference

`Index.symmetric_difference(other, result_name=None)`
Compute the symmetric difference of two Index objects. It’s sorted if sorting is possible.

**Parameters**

- `other` [Index or array-like]
- `result_name` [str]

**Returns**

- `symmetric_difference` [Index]

**Notes**

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.

**Examples**

```python
g>>> idx1 = Index([1, 2, 3, 4])
g>>> idx2 = Index([2, 3, 4, 5])
g>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

You can also use the `^` operator:

```python
g>>> idx1 ^ idx2
Int64Index([1, 5], dtype='int64')
```

34.6.1.84 pandas.Index.take

`Index.take(indices, axis=0, allow_fill=True, fill_value=None, **kwargs)`
return a new Index of the values selected by the indices

For internal compatibility with numpy arrays.

**Parameters**

- `indices` : list
- `axis` : int, optional
- `allow_fill` [bool, default True]
fill_value: bool, default None

If allow_fill=True and fill_value is not None, indices specified by -1 is regarded as NA. If Index doesn’t hold NA, raise ValueError

See also:

numpy.ndarray.take

34.6.1.85 pandas.Index.to_frame

Index.to_frame(index=True)
Create a DataFrame with a column containing the Index.

New in version 0.21.0.

Parameters index: boolean, default True

Set the index of the returned DataFrame as the original Index.

Returns DataFrame

DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.
Series.to_frame Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
       Ant
       Bear
       Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
0   Ant
1   Bear
2   Cow
```

34.6.1.86 pandas.Index.to_native_types

Index.to_native_types(slicer=None, **kwargs)
Format specified values of self and return them.

Parameters slicer: int, array-like

An indexer into self that specifies which values are used in the formatting process.

kwargs: dict
Options for specifying how the values should be formatted. These options include the following:

1. **na_rep** [str] The value that serves as a placeholder for NULL values
2. **quoting** [bool or None] Whether or not there are quoted values in *self*
3. **date_format** [str] The format used to represent date-like values

### 34.6.1.87 pandas.Index.to_series

`Index.to_series(index=None, name=None)`

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index

**Parameters**

- **index**: Index, optional
  - index of resulting Series. If None, defaults to original index
- **name**: string, optional
  - name of resulting Series. If None, defaults to name of original index

**Returns**

- Series [dtype will be based on the type of the Index values.]

### 34.6.1.88 pandas.Index.tolist

`Index.tolist()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**See also:**

numpy.ndarray.tolist

### 34.6.1.89 pandas.Index.transpose

`Index.transpose(*args, **kwargs)`

return the transpose, which is by definition self

### 34.6.1.90 pandas.Index.union

`Index.union(other)`

Form the union of two Index objects and sorts if possible.

**Parameters**

- **other**: [Index or array-like]

**Returns**

- union [Index]
Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

34.6.1.91 pandas.Index.unique

`Index.unique(level=None)`

Return unique values in the index. Uniques are returned in order of appearance, this does NOT sort.

**Parameters**
- `level` : int or str, optional, default `None`
  
  Only return values from specified level (for MultiIndex)

**Returns**
- Index without duplicates

See also:
- `unique`, `Series.unique`

34.6.1.92 pandas.Index.value_counts

`Index.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)`

Returns object containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

**Parameters**
- `normalize` : boolean, default `False`
  
  If True then the object returned will contain the relative frequencies of the unique values.

- `sort` : boolean, default `True`
  
  Sort by values

- `ascending` : boolean, default `False`
  
  Sort in ascending order

- `bins` : integer, optional
  
  Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data

- `dropna` : boolean, default `True`
  
  Don’t include counts of NaN.

**Returns**
- `counts` [Series]
34.6.1.93 pandas.Index.where

**Index.where**(cond, other=None)

New in version 0.19.0.

Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other.

**Parameters**

- **cond** [boolean array-like with the same length as self]
- **other** [scalar, or array-like]

34.6.2 Attributes

| **Index.values** | return the underlying data as an ndarray |
| **Index.is_monotonic** | alias for is_monotonic_increasing (deprecated) |
| **Index.is_monotonic_increasing** | return if the index is monotonic increasing (only equal or increasing) values. |
| **Index.is_monotonic_decreasing** | return if the index is monotonic decreasing (only equal or decreasing) values. |
| **Index.is_unique** | return if the index has unique values |
| **Index.has_duplicates** | return if I have any nans; enables various perf speedups |
| **Index.hasnans** | return the dtypes object of the underlying data |
| **Index.dtype** | return the dtypes str of the underlying data |
| **Index.inferred_type** | return a string of the type inferred from the values |
| **Index.is_all_dates** | return a tuple of the shape of the underlying data |
| **Index.name** | return the number of bytes in the underlying data |
| **Index.names** | return the number of dimensions of the underlying data, by definition 1 |
| **Index.nbytes** | return the number of elements in the underlying data |
| **Index.ndim** | return the strides of the underlying data |

### 34.6.2.1 pandas.Index.has_duplicates

Index.

### 34.6.2.2 pandas.Index.is_all_dates

Index.

### 34.6.2.3 pandas.Index.name

Index.

### 34.6.2.4 pandas.Index.names

Index.

### 34.6.2.5 pandas.Index.empty

Index.

### 34.6.3 Modifying and Computations

Index.all(*args, **kwargs) Return whether all elements are True.

Index.any(*args, **kwargs) Return whether any element is True.

Index.argmin([axis]) return a ndarray of the minimum argument indexer

Index.argmax([axis]) return a ndarray of the maximum argument indexer

Index.copy((name, deep, dtype)) Make a copy of this object.

Index.delete(loc) Make new Index with passed location(-s) deleted

Index.drop(labels[, errors]) Make new Index with passed list of labels deleted

Index.drop_duplicates([keep]) Return Index with duplicate values removed.

Index.duplicated([keep]) Indicate duplicate index values.

Index.equals(other) Determines if two Index objects contain the same elements.

Index.factorize([sort, na_sentinel]) Encode the object as an enumerated type or categorical variable.

Index.identical(other) Similar to equals, but check that other comparable attributes are also equal

Index.insert(loc, item) Make new Index inserting new item at location.

Index.is_(other) More flexible, faster check like is but that works through views

### 34.7 Numeric Index
RangeIndex

Mutable Index implementing a monotonic integer range.

Int64Index

Immutable ndarray implementing an ordered, sliceable set.

UInt64Index

Immutable ndarray implementing an ordered, sliceable set.

Float64Index

Immutable ndarray implementing an ordered, sliceable set.

34.7.1 pandas.RangeIndex

class pandas.RangeIndex

Mutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

Parameters:

- **start**: int (default: 0), or other RangeIndex instance.
  
  If int and “stop” is not given, interpreted as “stop” instead.

- **stop**: int (default: 0)

- **step**: int (default: 1)

- **name**: object, optional
  
  Name to be stored in the index

- **copy**: bool, default False
  
  Unused, accepted for homogeneity with other index types.

See also:

- **Index**  The base pandas Index type
- **Int64Index**  Index of int64 data

Attributes

| None |

Methods

- **from_range**(data[, name, dtype])
  
  create RangeIndex from a range (py3), or xrange (py2) object
34.7.1.1 pandas.RangeIndex.from_range

```python
classmethod RangeIndex.from_range(data, name=None, dtype=None, **kwargs)
```
create RangeIndex from a range (py3), or xrange (py2) object

34.7.2 pandas.Int64Index

```python
class pandas.Int64Index
```
Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Int64Index is a special case of `Index` with purely integer labels.

**Parameters**

- `data` [array-like (1-dimensional)]
- `dtype` [NumPy dtype (default: int64)]
- `copy` : bool
  Make a copy of input ndarray
- `name` : object
  Name to be stored in the index

**See also:**

- `Index` The base pandas Index type

**Notes**

An Index instance can **only** contain hashable objects.

**Attributes**

- `None`

**Methods**

- `None`

34.7.3 pandas.UInt64Index

```python
class pandas.UInt64Index
```
Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of `Index` with purely unsigned integer labels.

**Parameters**

- `data` [array-like (1-dimensional)]
- `dtype` [NumPy dtype (default: uint64)]

34.7. Numeric Index
copy : bool
  Make a copy of input ndarray

name : object
  Name to be stored in the index

See also:

Index The base pandas Index type

Notes

An Index instance can only contain hashable objects.

Attributes

Methods

34.7.4 pandas.Float64Index

class pandas.Float64Index
  Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas
objects. Float64Index is a special case of Index with purely float labels.

Parameters

data [array-like (1-dimensional)]
dtype [NumPy dtype (default: float64)]
copy : bool
  Make a copy of input ndarray
name : object
  Name to be stored in the index

See also:

Index The base pandas Index type

Notes

An Index instance can only contain hashable objects.
Attributes

None

Methods

None

`RangeIndex.from_range(data[, name, dtype])` create RangeIndex from a range (py3), or xrange (py2) object

34.8 CategoricalIndex

`CategoricalIndex` Immutable Index implementing an ordered, sliceable set.

34.8.1 pandas.CategoricalIndex

```python
class pandas.CategoricalIndex

Immutable Index implementing an ordered, sliceable set. CategoricalIndex represents a sparsely populated Index with an underlying Categorical.

Parameters

data [array-like or Categorical, (1-dimensional)]
categories : optional, array-like
categories for the CategoricalIndex
ordered : boolean,
designating if the categories are ordered
copy : bool
Make a copy of input ndarray
name : object
Name to be stored in the index

See also:
Categorical, Index
```

Attributes

<table>
<thead>
<tr>
<th>codes</th>
<th>categories</th>
<th>ordered</th>
</tr>
</thead>
</table>

34.8. CategoricalIndex 2149
## Methods

- **rename_categories**(*args, **kwargs)*
  Renames categories.

- **reorder_categories**(*args, **kwargs)*
  Reorders categories as specified in new_categories.

- **add_categories**(*args, **kwargs)*
  Add new categories.

- **remove_categories**(*args, **kwargs)*
  Removes the specified categories.

- **remove_unused_categories**(*args, **kwargs)*
  Removes categories which are not used.

- **set_categories**(*args, **kwargs)*
  Sets the categories to the specified new_categories.

- **as_ordered**(*args, **kwargs)*
  Sets the Categorical to be ordered

- **as_unordered**(*args, **kwargs)*
  Sets the Categorical to be unordered

- **map**(mapper)
  Map values using input correspondence (a dict, Series, or function).

### 34.8.1.1 pandas.CategoricalIndex.rename_categories

CategoricalIndex.rename_categories(*args, **kwargs)*

Renames categories.

**Parameters new_categories** : list-like, dict-like or callable

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.

- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

  New in version 0.21.0.

- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

  New in version 0.23.0.

**Warning**: Currently, Series are considered list like. In a future version of pandas they’ll be considered dict-like.

**inplace** : boolean (default: False)

Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

**Returns cat** : Categorical or None

With inplace=False, the new categorical is returned. With inplace=True, there is no return value.

**Raises ValueError**

If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

**See also:**

rename_categories, add_categories, remove_categories, remove_unused_categories, set_categories
Examples

```python
>>> c = Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

### 34.8.1.2 pandas.CategoricalIndex.reorder_categories

```python
CategoricalIndex.reorder_categories(*args, **kwargs)
```

Reorders categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

**Parameters**

- `new_categories` : Index-like
  - The categories in new order.
  - `ordered` : boolean, optional
    - Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
  - `inplace` : boolean (default: False)
    - Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

- `cat` [Categorical with reordered categories or None if inplace.]

**Raises**

- `ValueError`
  - If the new categories do not contain all old category items or any new ones

**See also:**

- `rename_categories`, `add_categories`, `remove_categories`, `remove_unused_categories`, `set_categories`

### 34.8.1.3 pandas.CategoricalIndex.add_categories

```python
CategoricalIndex.add_categories(*args, **kwargs)
```

Add new categories.
new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- `new_categories`: category or list-like of category
  
The new categories to be included.

- `inplace`: boolean (default: False)
  
  Whether or not to add the categories inplace or return a copy of this categorical with added categories.

**Returns**

- `cat`: [Categorical with new categories added or None if inplace.]

**Raises**

- `ValueError`
  
  If the new categories include old categories or do not validate as categories

**See also:**

- `rename_categories`
- `reorder_categories`
- `remove_categories`
- `remove_unused_categories`
- `set_categories`

### 34.8.1.4 pandas.CategoricalIndex.remove_categories

CategoricalIndex.remove_categories(*args, **kwargs)

Removes the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN.

**Parameters**

- `removals`: category or list of categories
  
The categories which should be removed.

- `inplace`: boolean (default: False)
  
  Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

**Returns**

- `cat`: [Categorical with removed categories or None if inplace.]

**Raises**

- `ValueError`
  
  If the removals are not contained in the categories

**See also:**

- `rename_categories`
- `reorder_categories`
- `add_categories`
- `remove_unused_categories`
- `set_categories`

### 34.8.1.5 pandas.CategoricalIndex.remove_unused_categories

CategoricalIndex.remove_unused_categories(*args, **kwargs)

Removes categories which are not used.

**Parameters**

- `inplace`: boolean (default: False)
  
  Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.
Returns

cat [Categorical with unused categories dropped or None if inplace.]

See also:
rename_categories, reorder_categories, add_categories, remove_categories, set_categories

34.8.1.6 pandas.CategoricalIndex.set_categories

CategoricalIndex.set_categories(*args, **kwargs)
Sets the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If rename==True, the categories will simple be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes on python3, which does not considers a S1 string equal to a single char python string.

Parameters new_categories : Index-like
The categories in new order.

ordered : boolean, (default: False)
Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

rename : boolean (default: False)
Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.

inplace : boolean (default: False)
Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

cat [Categorical with reordered categories or None if inplace.]

Raises ValueError
If new_categories does not validate as categories

See also:
rename_categories, reorder_categories, add_categories, remove_categories, remove_unused_categories

34.8.1.7 pandas.CategoricalIndex.as_ordered

CategoricalIndex.as_ordered(*args, **kwargs)
Sets the Categorical to be ordered

Parameters inplace : boolean (default: False)
Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to True

34.8.1.8 pandas.CategoricalIndex.as_unordered

CategoricalIndex.as_unordered(*args, **kwargs)

Sets the Categorical to be unordered

Parameters inplace : boolean (default: False)

Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to False

34.8.1.9 pandas.CategoricalIndex.map

CategoricalIndex.map(mapper)

Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a CategoricalIndex which has the same order property as the original, otherwise an Index is returned.

If a dict or Series is used any unmapped category is mapped to NaN. Note that if this happens an Index will be returned.

Parameters mapper : function, dict, or Series

Mapping correspondence.

Returns pandas.CategoricalIndex or pandas.Index

Mapped index.

See also:

Index.map Apply a mapping correspondence on an Index.
Series.map Apply a mapping correspondence on a Series.
Series.apply Apply more complex functions on a Series.

Examples

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                   ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                  ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                                                         'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:
If the mapping is not one-to-one an `Index` is returned:

```python
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a `dict` is used, all unmapped categories are mapped to `NaN` and the result is an `Index`:

```python
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

### 34.8.2 Categorical Components

<table>
<thead>

</tbody>
</table>

#### 34.8.2.1 pandas.CategoricalIndex.codes

Returns the codes of the categories.

#### 34.8.2.2 pandas.CategoricalIndex.categories

Returns the categories of the CategoricalIndex.
34.9 IntervalIndex

**IntervalIndex**

Immutable Index implementing an ordered, sliceable set.

34.9.1 pandas.IntervalIndex

```python
class pandas.IntervalIndex
```

Immutable Index implementing an ordered, sliceable set. IntervalIndex represents an Index of Interval objects that are all closed on the same side.

New in version 0.20.0.

**Warning:** The indexing behaviors are provisional and may change in a future version of pandas.

**Parameters**

- **data**: array-like (1-dimensional)
  
  Array-like containing Interval objects from which to build the IntervalIndex

- **closed**: {'left', 'right', 'both', 'neither'}, default 'right'
  
  Whether the intervals are closed on the left-side, right-side, both or neither.

- **name**: object, optional
  
  Name to be stored in the index.

- **copy**: boolean, default False
  
  Copy the meta-data

- **dtype**: dtype or None, default None
  
  If None, dtype will be inferred

New in version 0.23.0.

**See also:**

- **Index**: The base pandas Index type
- **Interval**: A bounded slice-like interval; the elements of an IntervalIndex
- **interval_range**: Function to create a fixed frequency IntervalIndex
- **cut, qcut**

**Notes**

See the user guide for more.
Examples

A new `IntervalIndex` is typically constructed using `interval_range()`:

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]
closed='right', dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

Attributes

<table>
<thead>

<td>Return the right endpoints of each Interval in the <code>IntervalIndex</code> as an Index</td>
</tr>
<tr>
<td><code>values</code></td>
<td>Return the <code>IntervalIndex</code>’s data as a numpy array of Interval objects (with dtype='object')</td>
</tr>
</tbody>
</table>

34.9.1.1 pandas.IntervalIndex.closed

`IntervalIndex.closed`  
Whether the intervals are closed on the left-side, right-side, both or neither

34.9.1.2 pandas.IntervalIndex.is_non_overlapping_monotonic

`IntervalIndex.is_non_overlapping_monotonic`  
Return True if the `IntervalIndex` is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False

34.9.1.3 pandas.IntervalIndex.left

`IntervalIndex.left`  
Return the left endpoints of each Interval in the `IntervalIndex` as an Index
34.9.1.4 pandas.IntervalIndex.length

IntervalIndex.length
Return an Index with entries denoting the length of each Interval in the IntervalIndex

34.9.1.5 pandas.IntervalIndex.mid

IntervalIndex.mid
Return the midpoint of each Interval in the IntervalIndex as an Index

34.9.1.6 pandas.IntervalIndex.right

IntervalIndex.right
Return the right endpoints of each Interval in the IntervalIndex as an Index

34.9.1.7 pandas.IntervalIndex.values

IntervalIndex.values
Return the IntervalIndex’s data as a numpy array of Interval objects (with dtype='object')

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contains(key)</td>
<td>Return a boolean indicating if the key is IN the index</td>
</tr>
<tr>
<td>from_arrays(left, right[, closed, name, ...])</td>
<td>Construct from two arrays defining the left and right bounds.</td>
</tr>
<tr>
<td>from_breaks(breaks[, closed, name, copy, dtype])</td>
<td>Construct an IntervalIndex from an array of splits</td>
</tr>
<tr>
<td>from_tuples(data[, closed, name, copy, dtype])</td>
<td>Construct an IntervalIndex from a list/array of tuples</td>
</tr>
<tr>
<td>get_indexer(target[, method, limit, tolerance])</td>
<td>Compute indexer and mask for new index given the current index.</td>
</tr>
<tr>
<td>get_loc(key[, method])</td>
<td>Get integer location, slice or boolean mask for requested label.</td>
</tr>
</tbody>
</table>

34.9.1.8 pandas.IntervalIndex.contains

IntervalIndex.contains(key)
Return a boolean indicating if the key is IN the index

We accept / allow keys to be not just actual objects.

Parameters

key  [int, float, Interval]

Returns

boolean
34.9.1.9 pandas.IntervalIndex.from_arrays

**classmethod** IntervalIndex.from_arrays(left, right, closed='right', name=None, copy=False, dtype=None)

Construct from two arrays defining the left and right bounds.

**Parameters**
- **left**: array-like (1-dimensional)
  Left bounds for each interval.
- **right**: array-like (1-dimensional)
  Right bounds for each interval.
- **closed**: {'left', 'right', 'both', 'neither'}, default 'right'
  Whether the intervals are closed on the left-side, right-side, both or neither.
- **name**: object, optional
  Name to be stored in the index.
- **copy**: boolean, default False
  Copy the data.
- **dtype**: dtype, optional
  If None, dtype will be inferred. New in version 0.23.0.

**Returns**
- **index**: [IntervalIndex]

**Raises** ValueError

When a value is missing in only one of left or right. When a value in left is greater than the corresponding value in right.

**See also:**
- **interval_range** Function to create a fixed frequency IntervalIndex.
- **IntervalIndex.from_breaks** Construct an IntervalIndex from an array of splits.
- **IntervalIndex.from_tuples** Construct an IntervalIndex from a list/array of tuples.

**Notes**

Each element of left must be less than or equal to the right element at the same position. If an element is missing, it must be missing in both left and right. A TypeError is raised when using an unsupported type for left or right. At the moment, 'category', 'object', and 'string' subtypes are not supported.

**Examples**

```python
>>> pd.IntervalIndex.from_arrays([[0, 1, 2], [1, 2, 3]])
IntervalIndex([(0, 1], (1, 2], (2, 3]),
closed='right',
dtype='interval[int64]')
```
If you want to segment different groups of people based on ages, you can apply the method as follows:

```python
>>> ages = pd.IntervalIndex.from_arrays([0, 2, 13], [2, 13, 19], closed='left')
>>> ages
IntervalIndex([0, 2), (2, 13), (13, 19)], closed='left', dtype='interval[int64]')
```

```python
>>> s = pd.Series(['baby', 'kid', 'teen'], ages)
>>> s
[0, 2) baby
[2, 13) kid
[13, 19) teen
dtype: object
```

Values may be missing, but they must be missing in both arrays.

```python
>>> pd.IntervalIndex.from_arrays([0, np.nan, 13], [2, np.nan, 19])
IntervalIndex(([0.0, 2.0], nan, (13.0, 19.0]], closed='right', dtype='interval[float64]')
```

### 34.9.1.10 pandas.IntervalIndex.from_breaks

**classmethod** `IntervalIndex.from_breaks`(breaks, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array of splits

**Parameters**
breaks : array-like (1-dimensional)
    Left and right bounds for each interval.

closed : {'left', 'right', 'both', 'neither'}, default 'right'
    Whether the intervals are closed on the left-side, right-side, both or neither.

name : object, optional
    Name to be stored in the index.

copy : boolean, default False
    copy the data

dtype : dtype or None, default None
    If None, dtype will be inferred

New in version 0.23.0.

**See also:**

* `interval_range` Function to create a fixed frequency IntervalIndex

* `IntervalIndex.from_arrays` Construct an IntervalIndex from a left and right array

* `IntervalIndex.from_tuples` Construct an IntervalIndex from a list/array of tuples
Examples

```python
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]
    closed='right',
    dtype='interval[int64]')
```

### 34.9.1.11 pandas.IntervalIndex.from_tuples

**classmethod** `IntervalIndex.from_tuples` (data, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from a list/array of tuples

**Parameters**

- **data**: array-like (1-dimensional)
  - Array of tuples
- **closed**: {'left', 'right', 'both', 'neither'}, default 'right'
  - Whether the intervals are closed on the left-side, right-side, both or neither.
- **name**: object, optional
  - Name to be stored in the index.
- **copy**: boolean, default False
  - by-default copy the data, this is compat only and ignored
- **dtype**: dtype or None, default None
  - If None, dtype will be inferred

**See also:**

- `interval_range` Function to create a fixed frequency IntervalIndex
- `IntervalIndex.from_arrays` Construct an IntervalIndex from a left and right array
- `IntervalIndex.from_breaks` Construct an IntervalIndex from an array of splits

**Examples**

```python
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]
    closed='right', dtype='interval[int64]')
```

### 34.9.1.12 pandas.IntervalIndex.get_indexer

**IntervalIndex.get_indexer** (target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

- **target**: [IntervalIndex or list of Intervals]
**method** : {None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** : int, optional

Maximum number of consecutive labels in target to match for inexact matches.

**tolerance** : optional

Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

**Returns indexer** : ndarray of int

Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**Examples**

```python
>>> indexer = index.get_indexer(new_index)
>>> new_values = cur_values.take(indexer)
```

### 34.9.1.13 pandas.IntervalIndex.get_loc

**IntervalIndex.get_loc(key, method=None)**

Get integer location, slice or boolean mask for requested label.

**Parameters**

- key [label]
- method : {None}, optional
  - default: matches where the label is within an interval only.

**Returns**

- loc [int if unique index, slice if monotonic index, else mask]
Examples

```python
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply an interval or an location for a point inside an interval.

```python
>>> index.get_loc(pd.Interval(0, 2))
da[[0, 1], dtype=int64]
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```python
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i2, i3])
>>> overlapping_index.get_loc(1.5)
da[[0, 1], dtype=int64]
```

### 34.9.2 IntervalIndex Components

- `IntervalIndex.from_arrays(left, right[, ...])`: Construct from two arrays defining the left and right bounds.
- `IntervalIndex.from_tuples(data[, closed, ...])`: Construct an `IntervalIndex` from a list/array of tuples.
- `IntervalIndex.from_breaks(breaks[, closed, ...])`: Construct an `IntervalIndex` from an array of splits.
- `IntervalIndex.contains(key)`: Return a boolean indicating if the key is IN the index.
- `IntervalIndex.left`: Return the left endpoints of each Interval in the `IntervalIndex` as an Index.
- `IntervalIndex.right`: Return the right endpoints of each Interval in the `IntervalIndex` as an Index.
- `IntervalIndex.mid`: Return the midpoint of each Interval in the `IntervalIndex` as an Index.
- `IntervalIndex.closed`: Whether the intervals are closed on the left-side, right-side, both or neither.
- `IntervalIndex.length`: Return an Index with entries denoting the length of each Interval in the `IntervalIndex`.
- `IntervalIndex.values`: Return the `IntervalIndex`’s data as a numpy array of Interval objects (with dtype='object').
- `IntervalIndex.is_non_overlapping_monotonic`: Return True if the `IntervalIndex` is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
- `IntervalIndex.get_loc(key[, method])`: Get integer location, slice or boolean mask for requested label.
- `IntervalIndex.get_indexer(target[, method, ...])`: Compute indexer and mask for new index given the current index.
34.10 MultiIndex

**class pandas.MultiIndex**

A multi-level, or hierarchical, index object for pandas objects

**Parameters**

- **levels**: sequence of arrays
  - The unique labels for each level
- **labels**: sequence of arrays
  - Integers for each level designating which label at each location
- **sortorder**: optional int
  - Level of sortedness (must be lexicographically sorted by that level)
- **names**: optional sequence of objects
  - Names for each of the index levels. (name is accepted for compat)
- **copy**: boolean, default False
  - Copy the meta-data
- **verify_integrity**: boolean, default True
  - Check that the levels/labels are consistent and valid

**See also:**

- `MultiIndex.from_arrays` Convert list of arrays to MultiIndex
- `MultiIndex.from_product` Create a MultiIndex from the cartesian product of iterables
- `MultiIndex.from_tuples` Convert list of tuples to a MultiIndex
- `Index` The base pandas Index type

**Notes**

See the user guide for more.

**Examples**

A new MultiIndex is typically constructed using one of the helper methods `MultiIndex.from_arrays()`, `MultiIndex.from_product()` and `MultiIndex.from_tuples()`. For example (using `from_arrays`):

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex(levels=[[1, 2], ['blue', 'red']],
            codes=[[0, 0, 1, 1], [1, 0, 0, 1]], names=('number', 'color'))
```

(continues on next page)
labels=[[0, 0, 1, 1], [1, 0, 1, 0]],
names=['number', 'color'])

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.

| remove_unused_levels() | create a new MultiIndex from the current that removing unused levels, meaning that they are not expressed in the labels |

34.10.1.4 pandas.MultiIndex.from_arrays

classmethod MultiIndex.from_arrays(arrays, sortorder=None, names=None)

Convert arrays to MultiIndex

Parameters:
- arrays: list / sequence of array-likes
  - Each array-like gives one level’s value for each data point. len(arrays) is the number of levels.
- sortorder: int or None
  - Level of sortedness (must be lexicographically sorted by that level)

Returns:
- index [MultiIndex]

See also:
- MultiIndex.from_tuples Convert list of tuples to MultiIndex
- MultiIndex.from_product Make a MultiIndex from cartesian product of iterables

Examples

```python
>>> arrays = [[[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> MultiIndex.from_arrays(arrays, names=('number', 'color'))
```

34.10.1.5 pandas.MultiIndex.from_tuples

classmethod MultiIndex.from_tuples(tuples, sortorder=None, names=None)

Convert list of tuples to MultiIndex

Parameters:
- tuples: list / sequence of tuple-likes
  - Each tuple is the index of one row/column.
- sortorder: int or None
  - Level of sortedness (must be lexicographically sorted by that level)

Returns:
- index [MultiIndex]

See also:
- MultiIndex.from_arrays Convert list of arrays to MultiIndex
- MultiIndex.from_product Make a MultiIndex from cartesian product of iterables
Examples

```python
>>> tuples = [(1, u'red'), (1, u'blue'),
            (2, u'red'), (2, u'blue')]
>>> MultiIndex.from_tuples(tuples, names=('number', 'color'))
```

### 34.10.1.6 pandas.MultiIndex.from_product

**classmethod MultiIndex.from_product**(iterables, sortorder=None, names=None)

Make a MultiIndex from the cartesian product of multiple iterables

**Parameters**
- iterables : list / sequence of iterables
  
  Each iterable has unique labels for each level of the index.
- sortorder : int or None
  
  Level of sortedness (must be lexicographically sorted by that level).
- names : list / sequence of strings or None
  
  Names for the levels in the index.

**Returns**
- index [MultiIndex]

**See also:**

- `MultiIndex.from_arrays` Convert list of arrays to MultiIndex
- `MultiIndex.from_tuples` Convert list of tuples to MultiIndex

### Examples

```python
>>> numbers = [0, 1, 2]
>>> colors = [u'green', u'purple']
>>> MultiIndex.from_product([numbers, colors],
                           names=['number', 'color'])
MultiIndex(levels=[[0, 1, 2], [u'green', u'purple']],
           labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
           names=['number', 'color'])
```

### 34.10.1.7 pandas.MultiIndex.set_levels

**MultiIndex.set_levels**(levels, level=None, inplace=False, verify_integrity=True)

Set new levels on MultiIndex. Defaults to returning new index.

**Parameters**
- levels : sequence or list of sequence
  
  new level(s) to apply
- level : int, level name, or sequence of int/level names (default None)
  
  level(s) to set (None for all levels)
- inplace : bool
if True, mutates in place

**verify_integrity** : bool (default True)

if True, checks that levels and labels are compatible

**Returns**

new index (of same type and class... etc)

**Examples**

```python
>>> idx = MultiIndex.from_tuples([(1, u'one'), (1, u'two'),
                                    (2, u'one'), (2, u'two')],
                                   names=['foo', 'bar'])

>>> idx.set_levels([['a','b'], [1,2]],
                  inplace=False, verify_integrity=True)
MultiIndex(levels=[[u'a', u'b'], [1, 2]],
          labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
          names=[u'foo', u'bar'])

>>> idx.set_labels(['a','b'], level='bar')
MultiIndex(levels=[[1, 2], [u'a', u'b']],
          labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
          names=[u'foo', u'bar'])

34.10.1.8 pandas.MultiIndex.set_labels

MultiIndex.set_labels(labels, level=None, inplace=False, verify_integrity=True)

Set new labels on MultiIndex. Defaults to returning new index.

**Parameters**

- **labels** : sequence or list of sequence
  new labels to apply

- **level** : int, level name, or sequence of int/level names (default None)
  level(s) to set (None for all levels)

- **inplace** : bool
  if True, mutates in place

- **verify_integrity** : bool (default True)
  if True, checks that levels and labels are compatible

**Returns**

new index (of same type and class... etc)
Examples

```python
>>> idx = MultiIndex.from_tuples([(1, u'one'), (1, u'two'),
                               (2, u'one'), (2, u'two')],
                               names=['foo', 'bar'])
>>> idx.set_labels(((1,0,1,0), [0,0,1,1]))
MultiIndex(levels=[[1, 2], [u'one', u'two']],
           labels=[[1, 0, 1, 0], [0, 0, 1, 1]],
           names=['foo', 'bar'])
>>> idx.set_labels([[1,0,1,0], [0,0,1,1]], level=0)
MultiIndex(levels=[[1, 2], [u'one', u'two']],
           labels=[[1, 0, 1, 0], [0, 0, 1, 1]],
           names=['foo', 'bar'])
>>> idx.set_labels([[0,0,1,1], [0,0,1,1]], level='bar')
MultiIndex(levels=[[1, 2], [u'one', u'two']],
           labels=[[0, 0, 1, 1], [0, 0, 1, 1]],
           names=['foo', 'bar'])
>>> idx.set_labels(((1,0,1,0), [0,0,1,1]), level=[0,1])
MultiIndex(levels=[[1, 2], [u'one', u'two']],
           labels=[[1, 0, 1, 0], [0, 0, 1, 1]],
           names=['foo', 'bar'])
```

34.10.1.9 **pandas.MultiIndex.to_hierarchical**

`MultiIndex.to_hierarchical(n_repeat, n_shuffle=1)`

Return a MultiIndex reshaped to conform to the shapes given by `n_repeat` and `n_shuffle`. Useful to replicate and rearrange a MultiIndex for combination with another Index with `n_repeat` items.

**Parameters**

- `n_repeat` : int
  Number of times to repeat the labels on self

- `n_shuffle` : int
  Controls the reordering of the labels. If the result is going to be an inner level in a MultiIndex, `n_shuffle` will need to be greater than one. The size of each label must divisible by `n_shuffle`.

**Returns**

- MultiIndex

Examples

```python
>>> idx = MultiIndex.from_tuples([(1, u'one'), (1, u'two'), (2, u'one'), (2, u'two')],
                                names=['foo', 'bar'])
>>> idx.to_hierarchical(3)
MultiIndex(levels=[[1, 2], [u'one', u'two']],
           labels=[[0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1, 1],
                   [0, 0, 0, 1, 1, 1, 0, 0, 0, 1, 1, 1]])
```
34.10.1.10 pandas.MultiIndex.to_frame

MultiIndex.to_frame(index=True)
Create a DataFrame with the levels of the MultiIndex as columns.
New in version 0.20.0.

Parameters

- **index**: boolean, default True
  Set the index of the returned DataFrame as the original MultiIndex.

Returns

- **DataFrame**: a DataFrame containing the original MultiIndex data.

34.10.1.11 pandas.MultiIndex.is_lexsorted

MultiIndex.is_lexsorted()
Return True if the labels are lexicographically sorted

34.10.1.12 pandas.MultiIndex.sortlevel

MultiIndex.sortlevel(level=0, ascending=True, sort_remaining=True)
Sort MultiIndex at the requested level. The result will respect the original ordering of the associated factor at that level.

Parameters

- **level**: list-like, int or str, default 0
  If a string is given, must be a name of the level. If list-like must be names or ints of levels.

- **ascending**: boolean, default True
  False to sort in descending order. Can also be a list to specify a directed ordering.

- **sort_remaining**: [sort by the remaining levels after level.]

Returns

- **sorted_index**: pd.MultiIndex
  Resulting index

- **indexer**: np.ndarray
  Indices of output values in original index

34.10.1.13 pandas.MultiIndex.droplevel

MultiIndex.droplevel(level=0)
Return Index with requested level removed. If MultiIndex has only 2 levels, the result will be of Index type not MultiIndex.

Parameters

- **level**: [int/level name or list thereof]

Returns

- **index**: [Index or MultiIndex]
Notes

Does not check if result index is unique or not

34.10.1.14 pandas.MultiIndex.swaplevel

MultiIndex.swaplevel \(i=-2, j=-1\)

Swap level \(i\) with level \(j\).

Calling this method does not change the ordering of the values.

**Parameters**

- **i**: int, str, default -2
  - First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.
- **j**: int, str, default -1
  - Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

**Returns**

MultiIndex

A new MultiIndex

.. versionchanged:: 0.18.1

The indexes \(i\) and \(j\) are now optional, and default to the two innermost levels of the index.

See also:

Series.swaplevel Swap levels \(i\) and \(j\) in a MultiIndex

Dataframe.swaplevel Swap levels \(i\) and \(j\) in a MultiIndex on a particular axis

Examples

```python
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
                     labels=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
labels=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi.swaplevel(0, 1)
MultiIndex(levels=[['bb', 'aa'], ['a', 'b']],
labels=[[0, 1, 0, 1], [0, 0, 1, 1]])
```

34.10.1.15 pandas.MultiIndex.reorder_levels

MultiIndex.reorder_levels \((order)\)

Rearrange levels using input order. May not drop or duplicate levels
34.10.1.16 pandas.MultiIndex.remove_unused_levels

`MultiIndex.remove_unused_levels()`
create a new MultiIndex from the current that removing unused levels, meaning that they are not expressed in the labels.

The resulting MultiIndex will have the same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

New in version 0.20.0.

**Returns**

`MultiIndex`

**Examples**

```python
code
>>> i = pd.MultiIndex.from_product([range(2), list('ab')])
MultiIndex(levels=[[0, 1], ['a', 'b']],
           labels=[[0, 0, 1, 1], [0, 1, 0, 1]])

>>> i[2:]
MultiIndex(levels=[[0, 1], ['a', 'b']],
           labels=[[1, 1], [0, 1]])

The 0 from the first level is not represented and can be removed

>>> i[2:].remove_unused_levels()
MultiIndex(levels=[[1], ['a', 'b']],
           labels=[[0, 0], [0, 1]])
```

34.10.2 pandas.IndexSlice

**pandas.IndexSlice** = `<pandas.core.indexing._IndexSlice object>`
Create an object to more easily perform multi-index slicing

**Examples**

```python
code
>>> midx = pd.MultiIndex.from_product([['A0', 'A1'], ['B0', 'B1', 'B2', 'B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
                          index=midx, columns=columns)

Using the default slice command:

```python
code
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
    foo  bar
A0  B0  0  1
    B1  2  3
```
Using the IndexSlice class for a more intuitive command:

```python
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
  foo  bar
A0  B0  0  1
   B1  2  3
A1  B0  8  9
   B1 10 11
```

### 34.10.3 MultiIndex Constructors

- `MultiIndex.from_arrays(arrays[, sortorder, ...])`: Convert arrays to MultiIndex
- `MultiIndex.from_tuples(tuples[, sortorder, ...])`: Convert list of tuples to MultiIndex
- `MultiIndex.from_product(iterables[, ...])`: Make a MultiIndex from the cartesian product of multiple iterables

### 34.10.4 MultiIndex Attributes

- `MultiIndex.names`: Names of levels in MultiIndex
- `MultiIndex.levels`: MultiIndex labels
- `MultiIndex.nlevels`: Integer number of levels in this MultiIndex.
- `MultiIndex.levshape`: A tuple with the length of each level.

#### 34.10.4.1 pandas.MultiIndex.levels

- `MultiIndex.levels`

#### 34.10.4.2 pandas.MultiIndex.labels

- `MultiIndex.labels`

### 34.10.5 MultiIndex Components

- `MultiIndex.set_levels(levels[, level, ...])`: Set new levels on MultiIndex.
- `MultiIndex.set_labels(labels[, level, ...])`: Set new labels on MultiIndex.
- `MultiIndex.to_hierarchical(n_repeat[, n_shuffle])`: Return a MultiIndex reshaped to conform to the shapes given by n_repeat and n_shuffle.
- `MultiIndex.to_frame([index])`: Create a DataFrame with the levels of the MultiIndex as columns.

</tr>
</tbody>
</table>

34.10.5.1 pandas.MultiIndex.unique

MultiIndex.unique (level=None)
Return unique values in the index. Uniques are returned in order of appearance, this does NOT sort.

**Parameters**

- **level**: int or str, optional, default None
  - Only return values from specified level (for MultiIndex)
  - New in version 0.23.0.

**Returns**

- Index without duplicates

**See also:**

- `unique`, `Series.unique`

34.10.6 MultiIndex Selecting

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MultiIndex.get_loc()</code></td>
<td>Get location for a label or a tuple of labels as an integer, slice or boolean mask.</td>
</tr>
<tr>
<td><code>MultiIndex.get_indexer()</code></td>
<td>Compute indexer and mask for new index given the current index.</td>
</tr>
<tr>
<td><code>MultiIndex.get_level_values()</code></td>
<td>Return vector of label values for requested level, equal to the length of the index.</td>
</tr>
</tbody>
</table>

34.10.6.1 pandas.MultiIndex.get_loc

MultiIndex.get_loc (key, method=None)
Get location for a label or a tuple of labels as an integer, slice or boolean mask.

**Parameters**

- **key**: [label or tuple of labels (one for each level)]
- **method**: [None]

**Returns**

- **loc**: int, slice object or boolean mask
  - If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

**See also:**

- `Index.get_loc` get_loc method for (single-level) index.

**MultiIndex.slice_locs** Get slice location given start label(s) and end label(s).

**MultiIndex.get_locs** Get location for a label/slice/list/mask or a sequence of such.

### Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use `MultiIndex.get_locs()` instead.

### Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_loc('b')
slice(1, 3, None)

>>> mi.get_loc(('b', 'e'))
1
```

#### 34.10.6.2 pandas.MultiIndex.get_indexer

**MultiIndex.get_indexer** *(target, method=None, limit=None, tolerance=None)*

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

**Parameters**

- **target** [MultiIndex or list of tuples]
- **method** : {None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** : int, optional
  - Maximum number of consecutive labels in `target` to match for inexact matches.
- **tolerance** : optional
  - Maximum distance between original and new labels for inexact matches.
  - The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.
  - Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

- **indexer** : ndarray of int

---

### 34.10. MultiIndex

---

2175
Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```python
>>> indexer = index.get_indexer(new_index)
>>> new_values = cur_values.take(indexer)
```

### 34.10.6.3 pandas.MultiIndex.get_level_values

#### MultiIndex.get_level_values(level)

Return vector of label values for requested level, equal to the length of the index.

- **Parameters**
  - `level`: int or str
    - level is either the integer position of the level in the MultiIndex, or the name of the level.

- **Returns**
  - `values`: Index
    - values is a level of this MultiIndex converted to a single `Index` (or subclass thereof).

**Examples**

Create a MultiIndex:

```python
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))  
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```python
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

### 34.11 DatetimeIndex

**DatetimeIndex**

Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata such as frequency information.

**34.11.1 pandas.DatetimeIndex**

- **class** pandas.DatetimeIndex
  
  Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata such as frequency information.

  - **Parameters**
    - `data`: array-like (1-dimensional), optional
Optional datetime-like data to construct index with

**copy** : bool

Make a copy of input ndarray

**freq** : string or pandas offset object, optional

One of pandas date offset strings or corresponding objects

**start** : starting value, datetime-like, optional

If data is None, start is used as the start point in generating regular timestamp data.

**periods** : int, optional, > 0

Number of periods to generate, if generating index. Takes precedence over end argument

**end** : end time, datetime-like, optional

If periods is None, generated index will extend to first conforming time on or just past end argument

**closed** : string or None, default None

Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None)

**tz** [pytz.timezone or dateutil.tz.tzfile]

**ambiguous** : ‘infer’, bool-ndarray, ‘NaT’, default ‘raise’

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

**name** : object

Name to be stored in the index

**dayfirst** : bool, default False

If True, parse dates in data with the day first order

**yearfirst** : bool, default False

If True parse dates in data with the year first order

See also:

**Index**  The base pandas Index type

**TimedeltaIndex**  Index of timedelta64 data

**PeriodIndex**  Index of Period data

**pandas.to_datetime**  Convert argument to datetime
Notes

To learn more about the frequency strings, please see this link.

</table>

34.11.1.1 pandas.DatetimeIndex.year

DatetimeIndex.**year**

The year of the datetime
34.11.2 pandas.DatetimeIndex.month

DatetimeIndex.month

   The month as January=1, December=12

34.11.3 pandas.DatetimeIndex.day

DatetimeIndex.day

   The days of the datetime

34.11.4 pandas.DatetimeIndex.hour

DatetimeIndex.hour

   The hours of the datetime

34.11.5 pandas.DatetimeIndex.minute

DatetimeIndex.minute

   The minutes of the datetime

34.11.6 pandas.DatetimeIndex.second

DatetimeIndex.second

   The seconds of the datetime

34.11.7 pandas.DatetimeIndex.microsecond

DatetimeIndex.microsecond

   The microseconds of the datetime

34.11.8 pandas.DatetimeIndex.nanosecond

DatetimeIndex.nanosecond

   The nanoseconds of the datetime

34.11.9 pandas.DatetimeIndex.date

DatetimeIndex.date

   Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without time-zone information).

34.11.10 pandas.DatetimeIndex.time

DatetimeIndex.time

   Returns numpy array of datetime.time. The time part of the Timestamps.
34.11.1.11 pandas.DatetimeIndex.dayofyear

DatetimeIndex.dayofyear
The ordinal day of the year

34.11.1.12 pandas.DatetimeIndex.weekofyear

DatetimeIndex.weekofyear
The week ordinal of the year

34.11.1.13 pandas.DatetimeIndex.week

DatetimeIndex.week
The week ordinal of the year

34.11.1.14 pandas.DatetimeIndex.dayofweek

DatetimeIndex.dayofweek
The day of the week with Monday=0, Sunday=6

34.11.1.15 pandas.DatetimeIndex.weekday

DatetimeIndex.weekday
The day of the week with Monday=0, Sunday=6

34.11.1.16 pandas.DatetimeIndex.quarter

DatetimeIndex.quarter
The quarter of the date

34.11.1.17 pandas.DatetimeIndex.freq

DatetimeIndex.freq
Return the frequency object if it is set, otherwise None

34.11.1.18 pandas.DatetimeIndex.freqstr

DatetimeIndex.freqstr
Return the frequency object as a string if it is set, otherwise None

34.11.1.19 pandas.DatetimeIndex.is_month_start

DatetimeIndex.is_month_start
Logical indicating if first day of month (defined by frequency)
34.11.1.20 pandas.DatetimeIndex.is_month_end

**DatetimeIndex.is_month_end**

Indicator for whether the date is the last day of the month.

**Returns** Series or array

For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

*is_month_start* Indicator for whether the date is the first day of the month.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> dates
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> dates.dt.is_month_end
0   False
1    True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_end
array([False,  True, False], dtype=bool)
```

34.11.1.21 pandas.DatetimeIndex.is_quarter_start

**DatetimeIndex.is_quarter_start**

Indicator for whether the date is the first day of a quarter.

**Returns** is_quarter_start : Series or DatetimeIndex

The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

*quarter* Return the quarter of the date.

*is_quarter_end* Similar property for indicating the quarter start.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", 
... periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter, 
... is_quarter_start=df.dates.dt.is_quarter_start)

<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_start</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>

>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'], 
... dtype='datetime64[ns]', freq='D')

>>> idx.is_quarter_start
array([False, False, True, False])

34.11.1.22 pandas.DatetimeIndex.is_quarter_end

DatetimeIndex.is_quarter_end
Indicator for whether the date is the last day of a quarter.

Returns is_quarter_end : Series or DatetimeIndex
The same type as the original data with boolean values. Series will have the same
name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on Date
timeIndex.

>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", 
... periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter, 
... is_quarter_end=df.dates.dt.is_quarter_end)

<table>

<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>

>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'], 
... dtype='datetime64[ns]', freq='D')
>>> idx.is_quarter_end
array([False,  True, False, False])

34.11.1.23 pandas.DatetimeIndex.is_year_start

```
DatetimeIndex.is_year_start
```
Indicate whether the date is the first day of a year.

**Returns** Series or DatetimeIndex

The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

*is_year_end* Similar property indicating the last day of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0  2017-12-30
1  2017-12-31
2  2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_start
0  False
1  False
2   True
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_year_start
array([False, False,  True])
```

34.11.1.24 pandas.DatetimeIndex.is_year_end

```
DatetimeIndex.is_year_end
```
Indicate whether the date is the last day of the year.

**Returns** Series or DatetimeIndex

The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**
**is_year_start**  Similar property indicating the start of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0  2017-12-30
1  2017-12-31
2  2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_end
0   False
1    True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
               dtype='datetime64[ns]', freq='D')

>>> idx.is_year_end
array([False,  True, False])
```

### 34.11.1.25 pandas.DatetimeIndex.is_leap_year

**DatetimeIndex.is_leap_year**

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

**Returns**  Series or ndarray

Booleans indicating if dates belong to a leap year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```python
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
               dtype='datetime64[ns]', freq='A-DEC')

>>> idx.is_leap_year
array([ True, False, False], dtype=bool)
```
>>> dates = pd.Series(idx)
>>> dates_series
0 2012-12-31
1 2013-12-31
2 2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0   True
1  False
2  False
dtype: bool

34.11.1.26 pandas.DatetimeIndex.inferred_freq

`DatetimeIndex.inferred_freq`

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>normalize()</td>

</tr>
<tr>
<td>to_frame([index])</td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td>month_name([locale])</td>
<td>Return the month names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td>day_name([locale])</td>
<td>Return the day names of the DateTimeIndex with specified locale.</td>
</tr>
</tbody>
</table>
### 34.11.1.27 pandas.DatetimeIndex.normalize

**Datet imeIndex.normalize()**

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

**Returns** DatetimeIndex or Series

The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- `floor` Floor the datetimes to the specified freq.
- `ceil` Ceil the datetimes to the specified freq.
- `round` Round the datetimes to the specified freq.

**Examples**

```python
>>> idx = pd.DatetimeIndex(start='2014-08-01 10:00', freq='H',
                        ...                  periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

### 34.11.1.28 pandas.DatetimeIndex.strftime

**Datet imeIndex.strftime(date_format)**

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc

**Parameters**

- `date_format` : str
  
  Date format string (e.g. “%Y-%m-%d”).

**Returns**

Index

Index of formatted strings

**See also:**

- `pandas.to_datetime` Convert the given argument to datetime
**DatetimeIndex.normalize** Return DatetimeIndex with times to midnight.

**DatetimeIndex.round** Round the DatetimeIndex to the specified freq.

**DatetimeIndex.floor** Floor the DatetimeIndex to the specified freq.

**Examples**

```python
g = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                  periods=3, freq='s')
g.strftime('%B %d, %Y, %r')
```

Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
dtype='object')

---

34.11.1.29 pandas.DatetimeIndex.snap

DatetimeIndex.snap(freq='S')
Snap time stamps to nearest occurring frequency

34.11.1.30 pandas.DatetimeIndex.tz_convert

DatetimeIndex.tz_convert(tz)
Convert tz-aware DatetimeIndex from one time zone to another.

**Parameters**

tz : string, pytz.timezone, dateutil.tz.tzfile or None

Time zone for time. Corresponding timestamps would be converted to this time
zone of the DatetimeIndex. A tz of None will convert to UTC and remove the
timezone information.

**Returns**

normalized [DatetimeIndex]

**Raises**

TypeError

If DatetimeIndex is tz-naive.

**See also:**

**DatetimeIndex.tz** A timezone that has a variable offset from UTC

**DatetineIndex.tz_localize** Localize tz-naive DatetimeIndex to a given time zone, or remove
timezone from a tz-aware DatetimeIndex.

**Examples**

With the tz parameter, we can change the DatetimeIndex to other time zones:

```python
dti = pd.DatetimeIndex(start='2014-08-01 09:00',
                      freq='H', periods=3, tz='Europe/Berlin')
```
```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
               dtype='datetime64[ns,Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
               dtype='datetime64[ns,US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.DatetimeIndex(start='2014-08-01 09:00', freq='H',
                         ...     periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
               dtype='datetime64[ns,Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
               dtype='datetime64[ns]', freq='H')
```

### 34.11.1.31 pandas.DatetimeIndex.tz_localize

`DatetimeIndex.tz_localize(tz, ambiguous='raise', errors='raise')`

Localize tz-naive DatetimeIndex to tz-aware DatetimeIndex.

This method takes a time zone (tz) naive DatetimeIndex object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

**Parameters**

- `tz`: string, pytz.timezone, dateutil.tz.tzfile or None
  
  Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

- `ambiguous`: str {'infer', 'NaT', 'raise'} or bool array, default 'raise'
  
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  
  - bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)

- `errors`: {'raise', 'coerce'}, default 'raise'
  
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times
  
  - ‘raise’ will raise a NonExistentTimeError if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time)
• ‘coerce’ will return NaT if the timestamp cannot be converted to the specified time zone

New in version 0.19.0.

Returns DatetimeIndex

Index converted to the specified time zone.

Raises TypeError

If the DatetimeIndex is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
```
```
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00', '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
```
```
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00', '2018-03-02 09:00:00-05:00', '2018-03-03 09:00:00-05:00'], dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
```
```
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00', '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq='D')
```

34.11.1.32 pandas.DatetimeIndex.round

DatetimeIndex.round(freq, *args, **kwargs)

round the data to the specified freq.

Parameters freq : str or Offset

The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

Returns DatetimeIndex, TimedeltaIndex, or Series

Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises
ValueError if the ‘freq’ cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

34.11.1.33 pandas.DatetimeIndex.floor

DatetimeIndex.floor(freq)

floor the data to the specified freq.

Parameters

freq : str or Offset

The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

Returns

DatetimeIndex, TimedeltaIndex, or Series

Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the ‘freq’ cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq='H')
```

(continues on next page)
Series

```python
>>> pd.Series(rng).dt.floor("H")
0  2018-01-01 11:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]
```

34.11.1.34 pandas.DatetimeIndex.ceil

DatetimeIndex.ceil(freq)

ceil the data to the specified freq.

Parameters

- `freq`: str or Offset

  The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

Returns

- DatetimeIndex, TimedeltaIndex, or Series

  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

- ValueError if the ‘freq’ cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```
34.11.1.35 pandas.DatetimeIndex.to_period

`DatetimeIndex.to_period(freq=None)`

Cast to PeriodIndex at a particular frequency.

Converts DatetimeIndex to PeriodIndex.

Parameters `freq` : string or Offset, optional

One of pandas’ offset strings or an Offset object. Will be inferred by default.

Returns

PeriodIndex

Raises ValueError

When converting a DatetimeIndex with non-regular values, so that a frequency cannot be inferred.

See also:

`pandas.PeriodIndex` Immutable ndarray holding ordinal values

`pandas.DatetimeIndex.to_pydatetime` Return DatetimeIndex as object

Examples

```python
>>> df = pd.DataFrame({"y": [1,2,3]},
...   index=pd.to_datetime(["2000-03-31 00:00:00",
...   "2000-05-31 00:00:00",
...   "2000-08-31 00:00:00"])
... df.index.to_period("M")
PeriodIndex(["2000-03", "2000-05", "2000-08"],
          dtype='period[M]', freq='M')
```

Infer the daily frequency

```python
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(["2017-01-01", "2017-01-02"],
            dtype='period[D]', freq='D')
```

34.11.1.36 pandas.DatetimeIndex.to_perioddelta

`DatetimeIndex.to_perioddelta(freq)`

Calculate TimedeltaIndex of difference between index values and index converted to periodIndex at specified freq. Used for vectorized offsets

Parameters

`freq` : Period frequency

Returns

`y` : TimedeltaIndex
34.11.1.37 pandas.DatetimeIndex.to_pydatetime

DatetimeIndex.to_pydatetime()
Return DatetimeIndex as object ndarray of datetime.datetime objects

Returns

datetimes [ndarray]

34.11.1.38 pandas.DatetimeIndex.to_series

DatetimeIndex.to_series(keep_tz=False, index=None, name=None)
Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index

Parameters keep_tz : optional, defaults False.
return the data keeping the timezone.
If keep_tz is True:
If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.
Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.
If keep_tz is False:
Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

index : Index, optional
index of resulting Series. If None, defaults to original index

name : string, optional
name of resulting Series. If None, defaults to name of original index

Returns

Series

34.11.1.39 pandas.DatetimeIndex.to_frame

DatetimeIndex.to_frame(index=True)
Create a DataFrame with a column containing the Index.
New in version 0.21.0.

Parameters index : boolean, default True
Set the index of the returned DataFrame as the original Index.

Returns DataFrame
DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.
Series.to_frame Convert Series to DataFrame.
34.11.1.40 pandas.DatetimeIndex.month_name

```
DatetimeIndex.month_name(locale=None)
```

Return the month names of the DateTimeIndex with specified locale.

**Parameters**

- **locale**: string, default None (English locale)
  
  locale determining the language in which to return the month name

**Returns**

- **month_names**: Index
  
  Index of month names

.. versionadded:: 0.23.0

34.11.1.41 pandas.DatetimeIndex.day_name

```
DatetimeIndex.day_name(locale=None)
```

Return the day names of the DateTimeIndex with specified locale.

**Parameters**

- **locale**: string, default None (English locale)
  
  locale determining the language in which to return the day name

**Returns**

- **month_names**: Index
  
  Index of day names

.. versionadded:: 0.23.0

</tbody>
</table>

### 34.11.2.1 pandas.DatetimeIndex.tz

**DatetimeIndex.tz**

### 34.11.3 Selecting

**DatetimeIndex.indexer_at_time(time[, asof])**

Returns index locations of index values at particular time of day (e.g., 9:30AM).

**DatetimeIndex.indexer_between_time(...[, ...])**

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

### 34.11.3.1 pandas.DatetimeIndex.indexer_at_time

**DatetimeIndex.indexer_at_time(time, asof=False)**

Returns index locations of index values at particular time of day (e.g. 9:30AM).

**Parameters**

- **time**: datetime.time or string
  
  datetime.time or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

**Returns**
values_at_time  [array of integers]

See also:

indexer_between_time, DataFrame.at_time

34.11.3.2 pandas.DatetimeIndex.indexer_between_time

DatetimeIndex.indexer_between_time(start_time, end_time, include_start=True, include_end=True)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

Parameters start_time, end_time : datetime.time, str

datetime.time or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

include_start  [boolean, default True]

include_end  [boolean, default True]

Returns

values_between_time  [array of integers]

See also:

indexer_at_time, DataFrame.between_time

### 34.12 TimedeltaIndex

#### class pandas.TimedeltaIndex

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects

**Parameters**

- **data**: array-like (1-dimensional), optional
  - Optional timedelta-like data to construct index with

- **unit**: unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional
  - which is an integer/float number

- **freq**: a frequency for the index, optional

- **copy**: bool
  - Make a copy of input ndarray

- **start**: starting value, timedelta-like, optional
  - If data is None, start is used as the start point in generating regular timedelta data.

- **periods**: int, optional, > 0
  - Number of periods to generate, if generating index. Takes precedence over end argument

- **end**: end time, timedelta-like, optional
  - If periods is none, generated index will extend to first conforming time on or just past end argument

- **closed**: string or None, default None
  - Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None)

- **name**: object
  - Name to be stored in the index

**See also:**
**Index**  The base pandas Index type

**Timedelta**  Represents a duration between two dates or times.

**DatetimeIndex**  Index of datetime64 data

**PeriodIndex**  Index of Period data

**Notes**

To learn more about the frequency strings, please see this link.

**Attributes**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>days</code></td>
<td>Number of days for each element.</td>
</tr>
<tr>
<td><code>seconds</code></td>
<td>Number of seconds (&gt;= 0 and less than 1 day) for each element.</td>
</tr>
<tr>
<td><code>microseconds</code></td>
<td>Number of microseconds (&gt;= 0 and less than 1 second) for each element.</td>
</tr>
<tr>
<td><code>nanoseconds</code></td>
<td>Number of nanoseconds (&gt;= 0 and less than 1 microsecond) for each element.</td>
</tr>
<tr>
<td><code>components</code></td>
<td>Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.</td>
</tr>
<tr>
<td><code>inferred_freq</code></td>
<td>Tries to return a string representing a frequency guess, generated by infer_freq.</td>
</tr>
</tbody>
</table>

**34.12.1.1 pandas.TimedeltaIndex.days**

`TimedeltaIndex.days`  
Number of days for each element.

**34.12.1.2 pandas.TimedeltaIndex.seconds**

`TimedeltaIndex.seconds`  
Number of seconds (>= 0 and less than 1 day) for each element.

**34.12.1.3 pandas.TimedeltaIndex.microseconds**

`TimedeltaIndex.microseconds`  
Number of microseconds (>= 0 and less than 1 second) for each element.

**34.12.1.4 pandas.TimedeltaIndex.nanoseconds**

`TimedeltaIndex.nanoseconds`  
Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
34.12.1.5 pandas.TimedeltaIndex.components

TimedeltaIndex.components

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

Returns

a DataFrame

34.12.1.6 pandas.TimedeltaIndex.inferred_freq

TimedeltaIndex.inferred_freq

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_pytimedelta()</td>
<td>Return TimedeltaIndex as object ndarray of datetime.timedelta objects</td>
</tr>
<tr>
<td>to_series(index, name)</td>
<td>Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index</td>
</tr>
<tr>

<td>ceil the data to the specified freq.</td>
</tr>
<tr>
<td>to_frame(index)</td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
</tbody>
</table>

34.12.1.7 pandas.TimedeltaIndex.to_pytimedelta

TimedeltaIndex.to_pytimedelta()

Return TimedeltaIndex as object ndarray of datetime.timedelta objects

Returns

datetimes [ndarray]

34.12.1.8 pandas.TimedeltaIndex.to_series

TimedeltaIndex.to_series(index=None, name=None)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index

Parameters

index : Index, optional

index of resulting Series. If None, defaults to original index

name : string, optional

name of resulting Series. If None, defaults to name of original index

Returns

Series [dtype will be based on the type of the Index values.]
### 34.12.1.9 pandas.TimedeltaIndex.round

`TimedeltaIndex.round(freq, *args, **kwargs)`

round the data to the specified `freq`.

**Parameters**  
`freq` : str or Offset  
The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.

**Returns**  
`DatetimeIndex, TimedeltaIndex, or Series`  
Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**  
`ValueError` if the ‘freq’ cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.round("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]
```

### 34.12.1.10 pandas.TimedeltaIndex.floor

`TimedeltaIndex.floor(freq)`

floor the data to the specified `freq`.

**Parameters**  
`freq` : str or Offset  
The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.

**Returns**  
`DatetimeIndex, TimedeltaIndex, or Series`  
Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**  
None
ValueError if the ‘freq’ cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
               dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0   2018-01-01 11:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

34.12.1.11 pandas.TimedeltaIndex.ceil

TimedeltaIndex.ceil(freq)

Ceil the data to the specified `freq`.

Parameters

- `freq` : str or Offset

  The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See `frequency aliases` for a list of possible `freq` values.

Returns

- DatetimeIndex, TimedeltaIndex, or Series

  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

- ValueError if the ‘freq’ cannot be converted.

Examples

```
```
Series

```python
>>> pd.Series(rng).dt.ceil("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 13:00:00
dtype: datetime64[ns]
```

34.12.1.12 `pandas.TimedeltaIndex.to_frame`

TimedeltaIndex.{to_frame}(index=True)
Create a DataFrame with a column containing the Index.

New in version 0.21.0.

**Parameters**
- **index**: boolean, default True
  
  Set the index of the returned DataFrame as the original Index.

**Returns**
Dataframe

DataFrame containing the original Index data.

**See also:**

- `Index.to_series` Convert an Index to a Series.
- `Series.to_frame` Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
0   Ant
1   Bear
2   Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
   0   Ant
   1   Bear
   2   Cow
```

### 34.13 PeriodIndex

**PeriodIndex**

Immutable ndarray holding ordinal values indicating regular periods in time such as particular years, quarters, months, etc.

#### 34.13.1 pandas.PeriodIndex

**class pandas.PeriodIndex**

Immutable ndarray holding ordinal values indicating regular periods in time such as particular years, quarters, months, etc.

Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

**Parameters**

- `data`: array-like (1-dimensional), optional
  - Optional period-like data to construct index with
    - `copy`: bool
      - Make a copy of input ndarray
    - `freq`: string or period object, optional
      - One of pandas period strings or corresponding objects
    - `start`: starting value, period-like, optional
      - If data is None, used as the start point in generating regular period data.
**periods** : int, optional, > 0
   Number of periods to generate, if generating index. Takes precedence over end argument

**end** : end value, period-like, optional
   If periods is none, generated index will extend to first conforming period on or just past end argument

**year** [int, array, or Series, default None]
**month** [int, array, or Series, default None]
**quarter** [int, array, or Series, default None]
**day** [int, array, or Series, default None]
**hour** [int, array, or Series, default None]
**minute** [int, array, or Series, default None]
**second** [int, array, or Series, default None]
**tz** : object, default None
   Timezone for converting datetime64 data to Periods

**dtype** [str or PeriodDtype, default None]

**See also:**

- **Index** The base pandas Index type
- **Period** Represents a period of time
- **DatetimeIndex** Index with datetime64 data
- **TimedeltaIndex** Index of timedelta64 data

**Examples**

```python
>>> idx = PeriodIndex(year=year_arr, quarter=q_arr)

>>> idx2 = PeriodIndex(start='2000', end='2010', freq='A')
```

**Attributes**

| **day** | The days of the period |
| **dayofweek** | The day of the week with Monday=0, Sunday=6 |
| **dayofyear** | The ordinal day of the year |
| **days_in_month** | The number of days in the month |
| **daysinmonth** | The number of days in the month |
| **freq** | Return the frequency object if it is set, otherwise None |

34.13.1.1 pandas.PeriodIndex.day

PeriodIndex.day
    The days of the period

34.13.1.2 pandas.PeriodIndex.dayofweek

PeriodIndex.dayofweek
    The day of the week with Monday=0, Sunday=6

34.13.1.3 pandas.PeriodIndex.dayofyear

PeriodIndex.dayofyear
    The ordinal day of the year

34.13.1.4 pandas.PeriodIndex.days_in_month

PeriodIndex.days_in_month
    The number of days in the month

34.13.1.5 pandas.PeriodIndex.daysinmonth

PeriodIndex.daysinmonth
    The number of days in the month

34.13.1.6 pandas.PeriodIndex.freq

PeriodIndex.freq
    Return the frequency object if it is set, otherwise None

34.13.1.7 pandas.PeriodIndex.freqstr

PeriodIndex.freqstr
    Return the frequency object as a string if it is set, otherwise None
34.13.1.8 pandas.PeriodIndex.hour

PeriodIndex.hour
The hour of the period

34.13.1.9 pandas.PeriodIndex.is_leap_year

PeriodIndex.is_leap_year
Logical indicating if the date belongs to a leap year

34.13.1.10 pandas.PeriodIndex.minute

PeriodIndex.minute
The minute of the period

34.13.1.11 pandas.PeriodIndex.month

PeriodIndex.month
The month as January=1, December=12

34.13.1.12 pandas.PeriodIndex.quarter

PeriodIndex.quarter
The quarter of the date

34.13.1.13 pandas.PeriodIndex.second

PeriodIndex.second
The second of the period

34.13.1.14 pandas.PeriodIndex.week

PeriodIndex.week
The week ordinal of the year

34.13.1.15 pandas.PeriodIndex.weekday

PeriodIndex.weekday
The day of the week with Monday=0, Sunday=6

34.13.1.16 pandas.PeriodIndex.weekofyear

PeriodIndex.weekofyear
The week ordinal of the year
34.13.1.17 pandas.PeriodIndex.year

PeriodIndex.year
The year of the period

<table>
<thead>
<tr>
<th>end_time</th>
<th>qyear</th>
<th>start_time</th>
</tr>
</thead>
</table>

Methods

*asfreq([freq, how])* Convert the PeriodIndex to the specified frequency `freq`.

*strftime(date_format)* Convert to Index using specified date_format.

*to_timestamp([freq, how])* Cast to DatetimeIndex

*tz_convert(tz)* Convert tz-aware DatetimeIndex from one time zone to another (using pytz/dateutil)

*tz_localize(tz[, ambiguous])* Localize tz-naive DatetimeIndex to given time zone (using pytz/dateutil), or remove timezone from tz-aware DatetimeIndex

34.13.1.18 pandas.PeriodIndex.asfreq

PeriodIndex.asfreq(freq=None, how='E')
Convert the PeriodIndex to the specified frequency `freq`.

**Parameters**

freq : str
    a frequency

how : str {'E', 'S'}
    ‘E’, ‘END’, or ‘FINISH’ for end, ‘S’, ‘START’, or ‘BEGIN’ for start. Whether the elements should be aligned to the end or start within pa period. January 31st (‘END’) vs. January 1st (‘START’) for example.

**Returns**

new [PeriodIndex with the new frequency]

**Examples**

```python
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx
<class 'pandas.core.indexes.period.PeriodIndex'>
[2010, ..., 2015]
Length: 6, Freq: A-DEC

>>> pidx.asfreq('M')
<class 'pandas.core.indexes.period.PeriodIndex'>
[2010-12, ..., 2015-12]
Length: 6, Freq: M
```
>>> pidx.asfreq('M', how='S')
<class 'pandas.core.indexes.period.PeriodIndex'>
[2010-01, ..., 2015-01]
Length: 6, Freq: M

34.13.19 pandas.PeriodIndex.strftime

PeriodIndex.<strong>strftime</strong>(<em>date_format</em>)
Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in <a>python string format doc</a>

**Parameters**

<code>date_format</code> : str
Date format string (e.g. "%Y-%m-%d").

**Returns**

Index
Index of formatted strings

**See also:**

- <a>pandas.to_datetime</a> Convert the given argument to datetime
- <a>DatetimeIndex.normalize</a> Return DatetimeIndex with times to midnight.
- <a>DatetimeIndex.round</a> Round the DatetimeIndex to the specified freq.
- <a>DatetimeIndex.floor</a> Floor the DatetimeIndex to the specified freq.

**Examples**

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
dtype='object')
```

34.13.1.20 pandas.PeriodIndex.to_timestamp

PeriodIndex.<strong>to_timestamp</strong>(<em>freq=None, how='start'</em>)
Cast to DatetimeIndex

**Parameters**

<code>freq</code> : string or DateOffset, optional
Target frequency. The default is ‘D’ for week or longer, ‘S’ otherwise

<code>how</code> : ['s', 'e', 'start', 'end']

**Returns**

DatetimeIndex
34.13.1.21 pandas.PeriodIndex.tz_convert

PeriodIndex.tz_convert(tz)
Convert tz-aware DatetimeIndex from one time zone to another (using pytz/dateutil)

Parameters tz : string, pytz.timezone, dateutil.tz.tzfile or None
Time zone for time. Corresponding timestamps would be converted to time zone
of the TimeSeries. None will remove timezone holding UTC time.

Returns
normalized [DatetimeIndex]

Notes
Not currently implemented for PeriodIndex

34.13.1.22 pandas.PeriodIndex.tz_localize

PeriodIndex.tz_localize(tz, ambiguous='raise')
Localize tz-naive DatetimeIndex to given time zone (using pytz/dateutil), or remove timezone from tz-
aware DatetimeIndex

Parameters tz : string, pytz.timezone, dateutil.tz.tzfile or None
Time zone for time. Corresponding timestamps would be converted to time zone
of the TimeSeries. None will remove timezone holding local time.

Returns
localized [DatetimeIndex]

Notes
Not currently implemented for PeriodIndex

34.14 Scalars

34.14.1 Period

Period Represents a period of time

34.14.1.1 pandas.Period

class pandas.Period

Represents a period of time

Parameters

value : Period or compat.string_types, default None

The time period represented (e.g., ‘4Q2005’)

freq : str, default None
One of pandas period strings or corresponding objects

- **year** [int, default None]
- **month** [int, default 1]
- **quarter** [int, default None]
- **day** [int, default 1]
- **hour** [int, default 0]
- **minute** [int, default 0]
- **second** [int, default 0]

## Attributes

<td>Get the second component of the Period.</td>
</tr>
<tr>
<td><code>start_time</code></td>
<td>Get the Timestamp for the start of the period.</td>
</tr>
<tr>
<td><code>week</code></td>
<td>Get the week of the year on the given Period.</td>
</tr>
</tbody>
</table>

### pandas.Period.day

- **`Period.day`**
  - Get day of the month that a Period falls on.
  - **Returns**
    - int
  - **See also:**
    - `Period.dayofweek` Get the day of the week
    - `Period.dayofyear` Get the day of the year

### Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

pandas.Period.dayofweek

Period.dayofweek
Return the day of the week.

This attribute returns the day of the week on which the particular date for the given period occurs depending on the frequency with Monday=0, Sunday=6.

Returns Int

Range from 0 to 6 (included).

See also:

Period.dayofyear Return the day of the year.
Period.daysinmonth Return the number of days in that month.

Examples

```python
>>> period1 = pd.Period('2012-1-1 19:00', freq='H')
>>> period1
Period('2012-01-01 19:00', 'H')
>>> period1.dayofweek
6
```

```python
>>> period2 = pd.Period('2013-1-9 11:00', freq='H')
>>> period2
Period('2013-01-09 11:00', 'H')
>>> period2.dayofweek
2
```

pandas.Period.dayofyear

Period.dayofyear
Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns int

The day of year.

See also:

Period.day Return the day of the month.
Period.dayofweek Return the day of week.
PeriodIndex.dayofyear Return the day of year of all indexes.

Examples
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.dayofyear
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.dayofyear
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.dayofyear
1

pandas.Period.days_in_month

Period.days_in_month
Get the total number of days in the month that this period falls on.

Returns
int

See also:

Period.daysinmonth Gets the number of days in the month.
DatetimeIndex.daysinmonth Gets the number of days in the month.
calendar.monthrange Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

Examples

```python
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28

>>> pd.Period('2018-03-01').days_in_month
31
```

Handles the leap year case as well:

```python
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

pandas.Period.daysinmonth

Period.daysinmonth
Get the total number of days of the month that the Period falls in.

Returns
int

See also:
**Period.days_in_month**  Return the days of the month

**Period.dayofyear**  Return the day of the year

### Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

**pandas.Period.hour**

*Period.hour*  Get the hour of the day component of the Period.

**Returns**  int

The hour as an integer, between 0 and 23.

**See also:**

- **Period.second**  Get the second component of the Period.
- **Period.minute**  Get the minute component of the Period.

### Examples

```python
>>> p.hour
13
```

Period longer than a day

```python
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

**pandas.Period.minute**

*Period.minute*  Get minute of the hour component of the Period.

**Returns**  int

The minute as an integer, between 0 and 59.

**See also:**

- **Period.hour**  Get the hour component of the Period.
- **Period.second**  Get the second component of the Period.
Examples

```python
>>> p.minute
3
```

pandas.Period.second

Period.second
Get the second component of the Period.

Returns int
The second of the Period (ranges from 0 to 59).

See also:

Period.hour Get the hour component of the Period.
Period.minute Get the minute component of the Period.

Examples

```python
>>> p.second
12
```

pandas.Period.start_time

Period.start_time
Get the Timestamp for the start of the period.

Returns
Timestamp

See also:

Period.end_time Return the end Timestamp.
Period.dayofyear Return the day of year.
Period.daysinmonth Return the days in that month.
Period.dayofweek Return the day of the week.

Examples

```python
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> period.start_time
Timestamp('2012-01-01 00:00:00')
```

```python
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

**pandas.Period.week**

*Period.week*  
Get the week of the year on the given Period.

**Returns**

*int*

**See also:**

*Period.dayofweek* Get the day component of the Period.  
*Periodweekday* Get the day component of the Period.

**Examples**

```python
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10
```

```python
>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5
```

```python
>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

<table>
<thead>
<tr>
<th>end_time</th>

<th>freqstr</th>
<th>is_leap_year</th>
<th>month</th>
<th>ordinal</th>
<th>quarter</th>
<th>qyear</th>
<th>weekday</th>
<th>weekofyear</th>
<th>year</th>
</tr>
</thead>
</table>

**Methods**
<table>
<thead>
<tr>
<th>pandas Period.asfreq</th>
<th>Convert Period to desired frequency, either at the start or end of the interval</th>
</tr>
</thead>
<tbody>
<tr>
<td>freq [string]</td>
<td>how : {'E', 'S', 'end', 'start'}, default 'end'</td>
</tr>
<tr>
<td>Returns</td>
<td>resampled [Period]</td>
</tr>
</tbody>
</table>

**pandas Period.strftime**

Period.strftime()  Returns the string representation of the Period, depending on the selected fmt. fmt must be a string containing one or several directives. The method recognizes the same directives as the time.strftime() function of the standard Python distribution, as well as the specific additional directives %f, %F, %q. (formatting & docs originally from scikits.timeries)
<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Locale’s abbreviated weekday name.</td>
<td></td>
</tr>
<tr>
<td>%A</td>
<td>Locale’s full weekday name.</td>
<td></td>
</tr>
<tr>
<td>%b</td>
<td>Locale’s abbreviated month name.</td>
<td></td>
</tr>
<tr>
<td>%B</td>
<td>Locale’s full month name.</td>
<td></td>
</tr>
<tr>
<td>%c</td>
<td>Locale’s appropriate date and time representation.</td>
<td></td>
</tr>
<tr>
<td>%d</td>
<td>Day of the month as a decimal number [01,31].</td>
<td></td>
</tr>
<tr>
<td>%f</td>
<td>‘Fiscal’ year without a century as a decimal number [00,99]</td>
<td>(1)</td>
</tr>
<tr>
<td>%F</td>
<td>‘Fiscal’ year with a century as a decimal number</td>
<td>(2)</td>
</tr>
<tr>
<td>%H</td>
<td>Hour (24-hour clock) as a decimal number [00,23].</td>
<td></td>
</tr>
<tr>
<td>%I</td>
<td>Hour (12-hour clock) as a decimal number [01,12].</td>
<td></td>
</tr>
<tr>
<td>%j</td>
<td>Day of the year as a decimal number [001,366].</td>
<td></td>
</tr>
<tr>
<td>%m</td>
<td>Month as a decimal number [01,12].</td>
<td></td>
</tr>
<tr>
<td>%M</td>
<td>Minute as a decimal number [00,59].</td>
<td></td>
</tr>
<tr>
<td>%p</td>
<td>Locale’s equivalent of either AM or PM.</td>
<td>(3)</td>
</tr>
<tr>
<td>%q</td>
<td>Quarter as a decimal number [01,04]</td>
<td></td>
</tr>
<tr>
<td>%S</td>
<td>Second as a decimal number [00,61].</td>
<td>(4)</td>
</tr>
<tr>
<td>%U</td>
<td>Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%w</td>
<td>Weekday as a decimal number [0(Sunday),6].</td>
<td></td>
</tr>
<tr>
<td>%W</td>
<td>Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%x</td>
<td>Locale's appropriate date representation.</td>
<td></td>
</tr>
<tr>
<td>%X</td>
<td>Locale's appropriate time representation.</td>
<td></td>
</tr>
<tr>
<td>%y</td>
<td>Year without century as a decimal number [00,99].</td>
<td></td>
</tr>
<tr>
<td>%Y</td>
<td>Year with century as a decimal number.</td>
<td></td>
</tr>
<tr>
<td>%Z</td>
<td>Time zone name (no characters if no time zone exists).</td>
<td></td>
</tr>
<tr>
<td>%%</td>
<td>A literal ‘%’ character.</td>
<td></td>
</tr>
</tbody>
</table>

**Notes**

1. The %f directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the qyear attribute.

2. The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the qyear attribute.

3. The %p directive only affects the output hour field if the %I directive is used to parse the hour.

4. The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.

5. The %U and %W directives are only used in calculations when the day of the week and the year are specified.

**Examples**
```python
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b.%d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

### pandas.Period.to_timestamp

Period.to_timestamp()  
Return the Timestamp representation of the Period at the target frequency at the specified end (how) of the Period  

**Parameters**  
freq: string or DateOffset  
Target frequency. Default is ‘D’ if self.freq is week or longer and ‘S’ otherwise  

how: str, default ‘S’ (start)  

**Returns**  
Timestamp

---

34.14.3.1 pandas.Period.now

Period.now()

34.14.4 Timestamp

Timestamp

34.14.4.1 pandas.Timestamp

class pandas.Timestamp

Pandas replacement for datetime.datetime

Timestamp is the pandas equivalent of python’s Datetime and is interchangeable with it in most cases. It’s the type used for the entries that make up a DatetimeIndex, and other timeseries oriented data structures in pandas.

Parameters:

- ts_input : datetime-like, str, int, float
  Value to be converted to Timestamp
- freq : str, DateOffset
  Offset which Timestamp will have
- tz : str, pytz.timezone, dateutil.tz.tzfile or None
  Time zone for time which Timestamp will have.
- unit : str
  Unit used for conversion if ts_input is of type int or float. The valid values are ‘D’, ‘h’, ‘m’, ‘s’, ‘ms’, ‘us’, and ‘ns’. For example, ‘s’ means seconds and ‘ms’ means milliseconds.
- year, month, day : int
  New in version 0.19.0.
- hour, minute, second, microsecond : int, optional, default 0
  New in version 0.19.0.
- nanosecond : int, optional, default 0
New in version 0.23.0.

**tzinfo** : datetime.tzinfo, optional, default None

New in version 0.19.0.

## Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

## Examples

Using the primary calling convention:

This converts a datetime-like string >>> pd.Timestamp('2017-01-01T12') Timestamp('2017-01-01 12:00:00')

This converts a float representing a Unix epoch in units of seconds >>> pd.Timestamp(1513393355.5, unit='s') Timestamp('2017-12-16 03:02:35.500000')

This converts an int representing a Unix-epoch in units of seconds and for a particular time-zone >>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific') Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')

Using the other two forms that mimic the API for `datetime.datetime`:

```python
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')

>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

## Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tz</code></td>
<td>Alias for <code>tzinfo</code></td>
</tr>
<tr>
<td><code>weekday_name</code></td>
<td>(DEPRECATED)</td>
</tr>
</tbody>
</table>

### pandas.Timestamp.tz

```
Timestamp.tz
```

Alias for `tzinfo`

### pandas.Timestamp.weekday_name

```
Timestamp.weekday_name
```

Deprecated since version 0.23.0: Use `Timestamp.day_name()` instead
<table>
<thead>
<tr>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>astimezone</td>
</tr>
<tr>
<td>cell</td>
</tr>
<tr>
<td>combine(date, time)</td>
</tr>
<tr>
<td>ctime</td>

</tr>
</tbody>
</table>

- **astimezone**: Convert tz-aware Timestamp to another time zone.
- **cell**: Return a new Timestamp ceiled to this resolution.
- **combine(date, time)**: date, time -> datetime with same date and time fields.
- **ctime**: Return ctime() style string.
- **date**: Return date object with same year, month and day.
- **day_name**: Return the day name of the Timestamp with specified locale.
- **dst**: Return self.tzinfo.dst(self).
- **floor**: return a new Timestamp floored to this resolution.
- **fromordinal(ordinal[, freq, tz])**: passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself.
- **fromtimestamp(timestamp[, tz])**: timestamp[, tz] -> tz’s local time from POSIX timestamp.
- **isocalendar**: Return a 3-tuple containing ISO year, week number, and weekday.
- **isoweekday**: Return the day of the week represented by the date.

</tbody>
</table>

**pandas.Timestamp.astimezone**

Timestamp.astimezone

Convert tz-aware Timestamp to another time zone.

**Parameters**

- **tz** : str, pytz.timezone, dateutil.tz.tzfile or None
  
  Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

**Returns**

- **converted** [Timestamp]

**Raises**

- **TypeError**
  
  If Timestamp is tz-naive.
pandas.Timestamp.ceil

`Timestamp.ceil`
return a new `Timestamp` ceiled to this resolution

Parameters

- `freq` [a freq string indicating the ceiling resolution]

pandas.Timestamp.combine

classmethod `Timestamp.combine`(`date`, `time`)
date, time -> datetime with same date and time fields

pandas.Timestamp.ctime

`Timestamp.ctime()`
Return ctime() style string.

pandas.Timestamp.date

`Timestamp.date()`
Return date object with same year, month and day.

pandas.Timestamp.day_name

`Timestamp.day_name`
Return the day name of the `Timestamp` with specified locale.

Parameters

- `locale` : string, default None (English locale)
locale determining the language in which to return the day name

Returns

- `day_name` [string]

.. versionadded:: 0.23.0

pandas.Timestamp.dst

`Timestamp.dst()`
Return self.tzinfo.dst(self).

pandas.Timestamp.floor

`Timestamp.floor`
return a new `Timestamp` floored to this resolution

Parameters

- `freq` [a freq string indicating the flooring resolution]
pandas.Timestamp.fromordinal

**classmethod** Timestamp.**fromordinal** *(ordinal, freq=None, tz=None)*

Passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself.

**Parameters**

- **ordinal**: int
date corresponding to a proleptic Gregorian ordinal
- **freq**: str, DateOffset
  Offset which Timestamp will have
- **tz**: str, pytz.timezone, dateutil.tz.tzfile or None
  Time zone for time which Timestamp will have.

pandas.Timestamp.fromtimestamp

**classmethod** Timestamp.**fromtimestamp** *(ts)*
timestamp[, tz] -> tz’s local time from POSIX timestamp.

pandas.Timestamp.isocalendar

Timestamp.**isocalendar**()
Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoweekday

Timestamp.**isoweekday**()
Return the day of the week represented by the date. Monday == 1 … Sunday == 7

pandas.Timestamp.month_name

Timestamp.**month_name**
Return the month name of the Timestamp with specified locale.

**Parameters**

- **locale**: string, default None (English locale)
  locale determining the language in which to return the month name

**Returns**

- **month_name** [string]
  .. versionadded:: 0.23.0

pandas.Timestamp.normalize

Timestamp.**normalize**
Normalize Timestamp to midnight, preserving tz information.
pandas.Timestamp.now

```python
classmethod Timestamp.now(tz=None)

Returns new Timestamp object representing current time local to tz.

Parameters
    tz : str or timezone object, default None
        Timezone to localize to
```

pandas.Timestamp.replace

```python
Timestamp.replace

implements datetime.replace, handles nanoseconds

Parameters
    year [int, optional]
    month [int, optional]
    day [int, optional]
    hour [int, optional]
    minute [int, optional]
    second [int, optional]
    microsecond [int, optional]
    nanosecond: int, optional
    tzinfo [tz-convertible, optional]
    fold : int, optional, default is 0
        added in 3.6, NotImplemented

Returns
    Timestamp with fields replaced
```

pandas.Timestamp.round

```python
Timestamp.round

Round the Timestamp to the specified resolution

Parameters
    freq [a freq string indicating the rounding resolution]

Returns
    a new Timestamp rounded to the given resolution of 'freq'

Raises
    ValueError if the freq cannot be converted
pandas.Timestamp.strftime

Timestamp.strftime()
  format -> strftime() style string.

pandas.Timestamp.strptime

Timestamp.strptime()
  string, format -> new datetime parsed from a string (like time.strptime()).

pandas.Timestamp.time

Timestamp.time()
  Return time object with same time but with tzinfo=None.

pandas.Timestamp.timestamp

Timestamp.timestamp()
  Return POSIX timestamp as float.

pandas.Timestamp.timetuple

Timestamp.timetuple()
  Return time tuple, compatible with time.localtime().

pandas.Timestamp.timetz

Timestamp.timetz()
  Return time object with same time and tzinfo.

pandas.Timestamp.to_datetime64

Timestamp.to_datetime64()
  Returns a numpy.datetime64 object with ‘ns’ precision

pandas.Timestamp.to_julian_date

Timestamp.to_julian_date
  Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

pandas.Timestamp.to_period

Timestamp.to_period
  Return an period of which this timestamp is an observation.
pandas.Timestamp.to_pydatetime

Timestamp.to_pydatetime()
Convert a Timestamp object to a native Python datetime object.
If warn=True, issue a warning if nanoseconds is nonzero.

pandas.Timestamp.today

classmethod Timestamp.today(cls, tz=None)
Return the current time in the local timezone. This differs from datetime.today() in that it can be localized
to a passed timezone.

Parameters tz : str or timezone object, default None
    Timezone to localize to

pandas.Timestamp.toordinal

Timestamp.toordinal()
Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

pandas.Timestamp.tz_convert

Timestamp.tz_convert
Convert tz-aware Timestamp to another time zone.

Parameters tz : str, pytz.timezone, dateutil.tz.tzfile or None
    Time zone for time which Timestamp will be converted to. None will remove
timezone holding UTC time.

Returns
    converted [Timestamp]

 Raises TypeError
    If Timestamp is tz-naive.

pandas.Timestamp.tz_localize

Timestamp.tz_localize
Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

Parameters tz : str, pytz.timezone, dateutil.tz.tzfile or None
    Time zone for time which Timestamp will be converted to. None will remove
timezone holding local time.

ambiguous : bool, ‘NaT’, default ‘raise’
    • bool contains flags to determine if time is dst or not (note that this flag is only appli-
cable for ambiguous fall dst dates)
    • ‘NaT’ will return NaT for an ambiguous time
• ‘raise’ will raise an AmbiguousTimeError for an ambiguous time

errors: ‘raise’, ‘coerce’, default ‘raise’

• ‘raise’ will raise a NonExistentTimeError if a timestamp is not valid in the specified timezone (e.g. due to a transition from or to DST time)

• ‘coerce’ will return NaT if the timestamp can not be converted into the specified timezone

New in version 0.19.0.

Returns

localized [Timestamp]

Raises TypeError

If the Timestamp is tz-aware and tz is not None.

pandas.Timestamp.tzname

Timestamp.tzname()
Return self.tzinfo.tzname(self).

pandas.Timestamp.utcfromtimestamp

classmethod Timestamp.utcfromtimestamp(ts)
Construct a naive UTC datetime from a POSIX timestamp.

pandas.Timestamp.utcnow

classmethod Timestamp.utcnow()
Return a new Timestamp representing UTC day and time.

pandas.Timestamp.utcoffset

Timestamp.utcoffset()
Return self.tzinfo.utcoffset(self).

pandas.Timestamp.utctimetuple

Timestamp.utctimetuple()
Return UTC time tuple, compatible with time.localtime().

pandas.Timestamp.weekday

Timestamp.weekday()
Return the day of the week represented by the date. Monday == 0 . . . Sunday == 6

### 34.14.7 Interval

#### 34.14.7.1 pandas.Interval

```
class pandas.Interval
```

Immutable object implementing an Interval, a bounded slice-like interval.

New in version 0.20.0.

- **Parameters**
  - `left`: orderable scalar
    - Left bound for the interval.
  - `right`: orderable scalar

#### 34.14. Scalars

2235
Right bound for the interval.

closed : {'left', 'right', 'both', 'neither'}, default 'right'

Whether the interval is closed on the left-side, right-side, both or neither.

closed : {'right', 'left', 'both', 'neither'}, default 'right'

Whether the interval is closed on the left-side, right-side, both or neither. See the
Notes for more detailed explanation.

See also:

IntervalIndex  An Index of Interval objects that are all closed on the same side.
cut  Convert continuous data into discrete bins (Categorical of Interval objects).
qcut  Convert continuous data into bins (Categorical of Interval objects) based on quantiles.
Period  Represents a period of time.

Notes

The parameters left and right must be from the same type, you must be able to compare them and they must
satisfy left <= right.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval
[0, 5] is characterized by the conditions 0 <= x <= 5. This is what closed='both' stands for. An
open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval (0,
5) is characterized by the conditions 0 < x < 5. This is what closed='neither' stands for. Intervals
can also be half-open or half-closed, i.e. [0, 5) is described by 0 <= x < 5 (closed='left') and (0,
5] is described by 0 < x <= 5 (closed='right').

Examples

It is possible to build Intervals of different types, like numeric ones:

```python
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```python
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so 0 < x <= 5):

```python
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length
You can operate with + and * over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```python
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```python
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
... pd.Timestamp('2018-01-01 00:00:00'),
... closed='left')
>>> pd.Timestamp('2017-01-01 00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

And also you can create string intervals

```python
>>> volume_1 = pd.Interval('Ant', 'Dog', closed='both')
>>> 'Bee' in volume_1
True
```

**pandas.Interval.closed**

`Interval.closed`

Whether the interval is closed on the left-side, right-side, both or neither

**pandas.Interval.closed_left**

`Interval.closed_left`

Check if the interval is closed on the left side.
For the meaning of `closed` and `open` see `Interval`.

**Returns** bool

True if the Interval is closed on the left-side, else False.

**pandas.Interval.closed_right**

`Interval.closed_right`

Check if the interval is closed on the right side.

For the meaning of `closed` and `open` see `Interval`.

**Returns** bool

True if the Interval is closed on the left-side, else False.

**pandas.Interval.left**

`Interval.left`

Left bound for the interval

**pandas.Interval.length**

`Interval.length`

Return the length of the Interval

**pandas.Interval.mid**

`Interval.mid`

Return the midpoint of the Interval

**pandas.Interval.open_left**

`Interval.open_left`

Check if the interval is open on the left side.

For the meaning of `closed` and `open` see `Interval`.

**Returns** bool

True if the Interval is closed on the left-side, else False.

**pandas.Interval.open_right**

`Interval.open_right`

Check if the interval is open on the right side.

For the meaning of `closed` and `open` see `Interval`.

**Returns** bool

True if the Interval is closed on the left-side, else False.
pandas.Interval.right

```
Interval.right
Right bound for the interval
```

### 34.14.9 Timedelta

<table>
<thead>
<tr>
<th>Timedelta</th>
<th>Represents a duration, the difference between two dates or times.</th>
</tr>
</thead>
</table>

#### 34.14.9.1 pandas.Timedelta

**class** `pandas.Timedelta`

Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.

**Parameters**

- `value` [Timedelta, timedelta, np.timedelta64, string, or integer]
- `unit` : string, {'ns', 'us', 'ms', 's', 'm', 'h', 'D'}, optional
  - Denote the unit of the input, if input is an integer. Default ‘ns’.
- `days`, `seconds`, `milliseconds`,
- `milliseconds`, `minutes`, `hours`, `weeks` : numeric, optional
  - Values for construction in compat with datetime.timedelta. np ints and floats will be coerced to python ints and floats.

**Notes**

The `.value` attribute is always in ns.
Attributes

<table>

</tr>
<tr>
<td><code>delta</code></td>
<td>Return the timedelta in nanoseconds (ns), for internal compatibility.</td>
</tr>
<tr>
<td><code>microseconds</code></td>
<td>Number of microseconds (&gt;= 0 and less than 1 second).</td>
</tr>
<tr>
<td><code>nanoseconds</code></td>
<td>Return the number of nanoseconds (n), where 0 &lt;= n &lt; 1 microsecond.</td>
</tr>
<tr>
<td><code>resolution</code></td>
<td>return a string representing the lowest resolution that we have</td>
</tr>
<tr>
<td><code>seconds</code></td>
<td>Number of seconds (&gt;= 0 and less than 1 day).</td>
</tr>
</tbody>
</table>

**pandas.Timedelta.asm8**

Timedelta.asm8

return a numpy timedelta64 array view of myself

**pandas.Timedelta.components**

Timedelta.components

Return a Components NamedTuple-like

**pandas.Timedelta.days**

Timedelta.days

Number of days.

**pandas.Timedelta.delta**

Timedelta.delta

Return the timedelta in nanoseconds (ns), for internal compatibility.

**Returns int**

Timedelta in nanoseconds.

**Examples**

```python
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
86400000000042

>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000000
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000

>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

**pandas.Timedelta.microseconds**

Timedelta.microseconds

Number of microseconds (>= 0 and less than 1 second).

**pandas.Timedelta.nanoseconds**

Timedelta.nanoseconds

Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.

Returns int

Number of nanoseconds.

See also:

**Timedelta.components** Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

**Examples**

**Using string input**

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.nanoseconds
42
```

**Using integer input**

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

**pandas.Timedelta.resolution**

Timedelta.resolution

return a string representing the lowest resolution that we have

**pandas.Timedelta.seconds**

Timedelta.seconds

Number of seconds (>= 0 and less than 1 day).

### pandas.Timedelta.ceil

Timedelta.<u>ceil</u>
return a new Timedelta ceiled to this resolution

**Parameters**

- `freq` [a freq string indicating the ceiling resolution]

### pandas.Timedelta.floor

Timedelta.<u>floor</u>
return a new Timedelta floored to this resolution

**Parameters**

- `freq` [a freq string indicating the flooring resolution]

### pandas.Timedelta.isoformat

Timedelta.<u>isoformat</u>()

New in version 0.20.0.

**Returns**

- `formatted` [str]

**See also:**

- `Timestamp.isoformat`
Notes

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0’s are removed from the seconds component after the decimal. We do not pad components, so it’s ...TSH..., not ...T05H...

Examples

```python
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
                   milliseconds=10, microseconds=10, nanoseconds=12)
>>> td.isoformat()
'P6DT0H50M3.010010012S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0MS'
```

pandas.Timedelta.round

Timedelta.round

Round the Timedelta to the specified resolution

Parameters

- freq  [a freq string indicating the rounding resolution]

Returns

- a new Timedelta rounded to the given resolution of ‘freq’

Raises

- ValueError if the freq cannot be converted

pandas.Timedelta.to_pytimedelta

Timedelta.to_pytimedelta()

return an actual datetime.timedelta object note: we lose nanosecond resolution if any

pandas.Timedelta.to_timedelta64

Timedelta.to_timedelta64()

Returns a numpy.timedelta64 object with ‘ns’ precision

pandas.Timedelta.total_seconds

Timedelta.total_seconds()

Total duration of timedelta in seconds (to ns precision)
pandas: powerful Python data analysis toolkit, Release 0.23.3

pandas.Timedelta.view

Timedelta.view()
array view compat

34.14.11 Methods
### Timedelta Methods

- **Timedelta.ceil**
  - return a new Timedelta ceiled to this resolution

- **Timedelta.floor**
  - return a new Timedelta floored to this resolution

- **Timedelta.isoformat**

- **Timedelta.round**
  - Round the Timedelta to the specified resolution

- **Timedelta.to_pytimedelta**
  - return an actual datetime.timedelta object note: we lose nanosecond resolution if any

- **Timedelta.to_timedelta64**
  - Returns a numpy.timedelta64 object with 'ns' precision

- **Timedelta.total_seconds**
  - Total duration of timedelta in seconds (to ns precision)

### 34.15 Frequencies

- **to_offset(freq)**
  - Return DateOffset object from string or tuple representation or datetime.timedelta object

#### 34.15.1 pandas.tseries.frequencies.to_offset

**pandas.tseries.frequencies.to_offset(freq)**
- Return DateOffset object from string or tuple representation or datetime.timedelta object

**Parameters**

- **freq** [str, tuple, datetime.timedelta, DateOffset or None]

**Returns**

- **delta** : DateOffset
  - None if freq is None

**Raises**

- **ValueError**
  - If freq is an invalid frequency

**See also:**

- pandas.DateOffset

**Examples**

```python
>>> to_offset('5min')
<5 * Minutes>

>>> to_offset('1D1H')
<25 * Hours>

>>> to_offset(('W', 2))
<2 * Weeks: weekday=6>

>>> to_offset((2, 'B'))
<2 * BusinessDays>

>>> to_offset(datetime.timedelta(days=1))
<Day>
```

**34.15. Frequencies** 2245
Rolling objects are returned by `.rolling` calls: `pandas.DataFrame.rolling()`, `pandas.Series.rolling()`, etc. Expanding objects are returned by `.expanding` calls: `pandas.DataFrame.expanding()`, `pandas.Series.expanding()`, etc. EWM objects are returned by `.ewm` calls: `pandas.DataFrame.ewm()`, `pandas.Series.ewm()`, etc.

#### 34.16.1.1 pandas.core.window.Rolling.count

`Rolling.count()`

The rolling count of any non-NaN observations inside the window.

**Returns:** Series or DataFrame

Returned object type is determined by the caller of the rolling calculation.

**See also:**

- `pandas.Series.rolling` Calling object with Series data
- `pandas.DataFrame.rolling` Calling object with DataFrames
- `pandas.DataFrame.count` Count of the full DataFrame
Examples

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
                      0 1.0
                     1 2.0
                     2 1.0
                     3 1.0
        dtype: float64
>>> s.rolling(3).count()
                      0 1.0
                     1 2.0
                     2 2.0
                     3 2.0
        dtype: float64
>>> s.rolling(4).count()
                      0 1.0
                     1 2.0
                     2 2.0
                     3 3.0
        dtype: float64
```

34.16.1.2 pandas.core.window.Rolling.sum

Rolling.sum(*args, **kwargs)
Calculate rolling sum of given DataFrame or Series.

Parameters *args, **kwargs
For compatibility with other rolling methods. Has no effect on the computed value.

Returns Series or DataFrame
Same type as the input, with the same index, containing the rolling sum.

See also:
Series.sum Reducing sum for Series.
DataFrame.sum Reducing sum for DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
    0  1
    1  2
    2  3
    3  4
    4  5
dtype: int64

>>> s.rolling(3).sum()
                      0  NaN
                     1  NaN
                     2  NaN
                     3  NaN
```
2 6.0
3 9.0
4 12.0
dtype: float64

>>> s.expanding(3).sum()
0 NaN
1 NaN
2 6.0
3 10.0
4 15.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0 NaN
1 6.0
2 9.0
3 12.0
4 NaN
dtype: float64

For DataFrame, each rolling sum is computed column-wise.

>>> df = pd.DataFrame({'A': s, 'B': s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25

>>> df.rolling(3).sum()
   A  B
0  NaN NaN
1  NaN NaN
2  6.0 14.0
3  9.0 29.0
4  12.0 50.0

34.16.1.3 pandas.core.window.Rolling.mean

Rolling.mean(*args, **kwargs)
Calculate the rolling mean of the values.

Parameters

*args
Under Review.

**kwargs
Under Review.

Returns

Series or DataFrame
Returned object type is determined by the caller of the rolling calculation.
See also:

**Series.rolling** Calling object with Series data

**DataFrame.rolling** Calling object with DataFrames

**Series.mean** Equivalent method for Series

**DataFrame.mean** Equivalent method for DataFrame

### Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```python
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

### 34.16.1.4 pandas.core.window.Rolling.median

Rolling.**median**(**kwargs)

Calculate the rolling median.

**Parameters** **kwargs

For compatibility with other rolling methods. Has no effect on the computed median.

**Returns** Series or DataFrame

Returned type is the same as the original object.

See also:

**Series.rolling** Calling object with Series data

**DataFrame.rolling** Calling object with DataFrames

**Series.median** Equivalent method for Series

**DataFrame.median** Equivalent method for DataFrame

### Examples

Compute the rolling median of a series with a window size of 3.
```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

34.16.1.5 pandas.core.window.Rolling.var

Rolling.var(ddof=1, *args, **kwargs)

Calculate unbiased rolling variance.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters:
- **ddof**: int, default 1
  Delta Degrees of Freedom. The divisor used in calculations is \(N - ddof\), where \(N\) represents the number of elements.

- *args, **kwargs
  For NumPy compatibility. No additional arguments are used.

Returns:
- **Series or DataFrame**
  Returns the same object type as the caller of the rolling calculation.

See also:
- Series.rolling Calling object with Series data
- DataFrame.rolling Calling object with DataFrames
- Series.var Equivalent method for Series
- DataFrame.var Equivalent method for DataFrame
- numpy.var Equivalent method for Numpy array

Notes

The default \(ddof\) of 1 used in Series.var() is different than the default \(ddof\) of 0 in numpy.var().

A minimum of 1 period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0    NaN
1    NaN
2  0.333333
3  1.000000
4  1.000000
5  1.333333
```
34.16.1.6 pandas.core.window.Rolling.std

Rolling.std(ddof=1, *args, **kwargs)
Calculate rolling standard deviation.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters ddof : int, default 1
Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

*args, **kwargs
For NumPy compatibility. No additional arguments are used.

Returns Series or DataFrame
Returns the same object type as the caller of the rolling calculation.

See also:
Series.rolling Calling object with Series data
DataFrame.rolling Calling object with DataFrames
Series.std Equivalent method for Series
DataFrame.std Equivalent method for DataFrame
numpy.std Equivalent method for Numpy array

Notes
The default ddof of 1 used in Series.std is different than the default ddof of 0 in numpy.std.
A minimum of one period is required for the rolling calculation.

Examples
```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0    NaN
1    NaN
2   0.577350
3   1.000000
4   1.000000
5   1.154701
6    0.000000
dtype: float64
>>> s.expanding(3).std()
0    NaN
1    NaN
2   0.577350
3   0.957427
4   0.894427
5   0.836660
6   0.786796
dtype: float64
```

### 34.16.1.7 pandas.core.window.Rolling.min

Rolling.min(*args, **kwargs)

Calculate the rolling minimum.

**Parameters**

**kwargs

- Under Review.

**Returns**

Series or DataFrame

- Returned object type is determined by the caller of the rolling calculation.

**See also:**

- Series.rolling Calling object with a Series
- DataFrame.rolling Calling object with a DataFrame
- Series.min Similar method for Series
- DataFrame.min Similar method for DataFrame

**Examples**

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0   NaN
1   NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```
34.16.1.8 pandas.core.window.Rolling.max

Rolling.max(*args, **kwargs)

rolling maximum

Returns

same type as input

See also:

pandas.Series.rolling, pandas.DataFrame.rolling

34.16.1.9 pandas.core.window.Rolling.corr

Rolling.corr(other=None, pairwise=None, **kwargs)

rolling sample correlation

Parameters other : Series, DataFrame, or ndarray, optional

if not supplied then will default to self and produce pairwise output

pairwise : bool, default None

If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

Returns

same type as input

See also:

pandas.Series.rolling, pandas.DataFrame.rolling

34.16.1.10 pandas.core.window.Rolling.cov

Rolling.cov(other=None, pairwise=None, ddof=1, **kwargs)

rolling sample covariance

Parameters other : Series, DataFrame, or ndarray, optional

if not supplied then will default to self and produce pairwise output

pairwise : bool, default None

If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof : int, default 1

Delta Degrees of Freedom. The divisor used in calculations is N − ddof, where N represents the number of elements.

Returns

same type as input
34.16.1.11 pandas.core.window.Rolling.skew

Rolling.skew(**kwargs)
Unbiased rolling skewness

Returns
same type as input

See also:
pandas.Series.rolling, pandas.DataFrame.rolling

34.16.1.12 pandas.core.window.Rolling.kurt

Rolling.kurt(**kwargs)
Calculate unbiased rolling kurtosis.
This function uses Fisher’s definition of kurtosis without bias.

Parameters **kwargs
Under Review.

Returns Series or DataFrame
Returned object type is determined by the caller of the rolling calculation

See also:
Series.rolling Calling object with Series data
DataFrame.rolling Calling object with DataFrames
Series.kurt Equivalent method for Series
DataFrame.kurt Equivalent method for DataFrame
scipy.stats.skew Third moment of a probability density
scipy.stats.kurtosis Reference SciPy method

Notes
A minimum of 4 periods is required for the rolling calculation.

Examples
The example below will show a rolling calculation with a window size of four matching the equivalent function
call using scipy.stats.
```python
>>> arr = [1, 2, 3, 4, 999]
>>> fmt = "/{0:.6f}"  # limit the printed precision to 6 digits
>>> import scipy.stats
>>> print(fmt.format(scipy.stats.kurtosis(arr[:-1], bias=False)))
-1.200000
>>> print(fmt.format(scipy.stats.kurtosis(arr[1:], bias=False)))
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0 NaN
1 NaN
2 NaN
3 -1.200000
4  3.999946
dtype: float64
```

34.16.1.13 pandas.core.window.Rolling.apply

Rolling.apply(func, raw=None, args=(), kwags={})

Rolling function apply

Parameters

- **func**: function
  
  Must produce a single value from an ndarray input if raw=True or a Series if raw=False

- **raw**: bool, default None
  
  - False: passes each row or column as a Series to the function.
  
  - True or None: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

  The raw parameter is required and will show a FutureWarning if not passed. In the future raw will default to False.

  New in version 0.23.0.

*args and **kwargs are passed to the function

Returns

same type as input

See also:

pandas.Series.rolling, pandas.DataFrame.rolling

34.16.1.14 pandas.core.window.Rolling.aggregate

Rolling.aggregate(arg, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

Parameters

- **func**: function, string, dictionary, or list of string/functions

  Function to use for aggregating the data. If a function, must either work when passed a Series/DataFrame or when passed to Series/DataFrame.apply. For a DataFrame, can pass a dict, if the keys are DataFrame column names.
Accepted combinations are:

- string function name.
- function.
- list of functions.
- dict of column names -> functions (or list of functions).

*args

Positional arguments to pass to func.

**kwargs

Keyword arguments to pass to func.

Returns

aggregated [Series/DataFrame]

See also:

pandas.Series.rolling, pandas.DataFrame.rolling

Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'])
>>> df
    A       B       C
0 -2.385977 -0.102758  0.438822
1 -1.004295  0.905829 -0.954544
2  0.735167 -0.165272 -1.619346
3 -0.702657 -1.340923 -0.706334
4 -0.246845  0.211596 -0.901819
5  2.463718  3.157577 -1.380906
6 -1.142255  2.340594 -0.039875
7  1.396598 -1.647453  1.677227
8 -0.543425  1.761277 -0.220481
9 -0.640505  0.289374 -1.550670

>>> df.rolling(3).sum()
    A       B       C
0   NaN     NaN     NaN
1   NaN     NaN     NaN
2 -2.655105  0.637799 -2.135068
3 -0.971785 -0.600366 -3.280224
4 -0.214334 -1.294599 -3.227500
5  1.514216  2.028250 -2.989060
6  1.074618  5.709767 -2.322600
7  2.718061  3.850718  0.256446
8 -0.289082  2.454418  1.416871
9  0.212668  0.403198 -0.093924
```
>>> df.rolling(3).agg({'A':'sum', 'B':'min'})
   A   B
0  NaN NaN
1  NaN NaN
2 -2.655105 -0.165272
3 -0.971785 -1.340923
4 -0.214334 -1.340923
5  1.514216 -1.340923
6  1.074618  0.211596
7  2.718061 -1.647453
8 -0.289082 -1.647453
9  0.212668 -1.647453

34.16.15 pandas.core.window.Rolling.quantile

Rolling.quantile(quantile, interpolation='linear', **kwargs)

rolling quantile.

Parameters quantile : float

Quantile to compute. 0 <= quantile <= 1.

interpolation : {'linear', 'lower', 'higher', 'midpoint', 'nearest'}

New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired
quantile lies between two data points i and j:

• linear: i + (j - i) * fraction, where fraction is the fractional part of the index
  surrounded by i and j.
• lower: i.
• higher: j.
• nearest: i or j whichever is nearest.
• midpoint: (i + j) / 2.

**kwargs:

For compatibility with other rolling methods. Has no effect on the result.

Returns Series or DataFrame

Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.quantile Computes value at the given quantile over all data in Series.

pandas.DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0   NaN
```

(continues on next page)
1 1.0
2 2.0
3 3.0
dtype: float64

```python
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0  NaN
1  1.5
2  2.5
3  3.5
dtype: float64
```

### 34.16.16 pandas.core.window.Window.mean

`Window.mean(*args, **kwargs)`

Calculate the window mean of the values.

**Parameters**

*args

Under Review.

**kwargs

Under Review.

**Returns**

Series or DataFrame

Returned object type is determined by the caller of the window calculation.

**See also:**

Series.window Calling object with Series data

DataFrame.window Calling object with DataFrames

Series.mean Equivalent method for Series

DataFrame.mean Equivalent method for DataFrame

#### Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0  NaN
1  1.5
2  2.5
3  3.5
dtype: float64
```

```python
>>> s.rolling(3).mean()
0  NaN
1  NaN
2  2.0
3  3.0
dtype: float64
```
### pandas.core.window.Window.sum

**Window.sum(*args, **kwargs)**

Calculate window sum of given DataFrame or Series.

**Parameters**

*args, **kwargs

For compatibility with other window methods. Has no effect on the computed value.

**Returns**

Series or DataFrame

Same type as the input, with the same index, containing the window sum.

**See also:**

- Series.sum Reducing sum for Series.
- DataFrame.sum Reducing sum for DataFrame.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4, 5])

>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64

>>> s.rolling(3).sum()
0   NaN
1   NaN
2    6.0
3    9.0
4   12.0
dtype: float64

>>> s.expanding(3).sum()
0   NaN
1   NaN
2    6.0
3    9.0
4   15.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0   NaN
1    6.0
2    9.0
3   12.0
4   NaN
dtype: float64
```

For DataFrame, each window sum is computed column-wise.
```python
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25

>>> df.rolling(3).sum()
   A   B
0  NaN NaN
1  NaN NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0
```

</table>

#### 34.16.2.1 pandas.core.window.Expanding.count

**Expanding.count(**kwars)**

The expanding count of any non-NaN observations inside the window.

**Returns** Series or DataFrame

Returned object type is determined by the caller of the expanding calculation.

**See also:**

- `pandas.Series.expanding` Calling object with Series data
- `pandas.DataFrame.expanding` Calling object with DataFrames
- `pandas.DataFrame.count` Count of the full DataFrame
Examples

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0 1.0
1 2.0
2 1.0
3 1.0
dtype: float64
>>> s.rolling(3).count()
0 1.0
1 2.0
2 2.0
3 2.0
dtype: float64
>>> s.rolling(4).count()
0 1.0
1 2.0
2 2.0
3 3.0
dtype: float64
```

34.16.2.2 pandas.core.window.Expanding.sum

Expanding.sum(*args, **kwargs)
Calculate expanding sum of given DataFrame or Series.

**Parameters**
*args, **kwargs
For compatibility with other expanding methods. Has no effect on the computed value.

**Returns**
Series or DataFrame
Same type as the input, with the same index, containing the expanding sum.

**See also:**

Series.sum Reducing sum for Series.
DataFrame.sum Reducing sum for DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0 1
1 2
2 3
3 4
4 5
dtype: int64
>>> s.rolling(3).sum()
0 NaN
```

(continues on next page)
1 NaN
2 6.0
3 9.0
4 12.0
dtype: float64

```python
>>> s.expanding(3).sum()
0  NaN
1  NaN
2  6.0
3  10.0
4  15.0
dtype: float64
```

```python
>>> s.rolling(3, center=True).sum()
0  NaN
1  6.0
2  9.0
3  12.0
4  NaN
dtype: float64
```

For DataFrame, each expanding sum is computed column-wise.

```python
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A   B
0  1   1
1  2   4
2  3   9
3  4  16
4  5  25

>>> df.rolling(3).sum()
   A   B
0  NaN NaN
1  NaN NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0
```

34.16.2.3  pandas.core.window.Expanding.mean

`Expanding.mean(*args, **kwargs)`

Calculate the expanding mean of the values.

**Parameters**

- **args**
  - Under Review.
- **kwargs**
  - Under Review.

**Returns**

- Series or DataFrame
  - Returned object type is determined by the caller of the expanding calculation.
See also:

**Series.expanding** Calling object with Series data

**DataFrame.expanding** Calling object with DataFrames

**Series.mean** Equivalent method for Series

**DataFrame.mean** Equivalent method for DataFrame

**Examples**

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64

>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

### 34.16.2.4 pandas.core.window.Expanding.median

**Expanding.median(**kwargs**)

Calculate the expanding median.

**Parameters** **kwargs

For compatibility with other expanding methods. Has no effect on the computed median.

**Returns** Series or DataFrame

Returned type is the same as the original object.

See also:

**Series.expanding** Calling object with Series data

**DataFrame.expanding** Calling object with DataFrames

**Series.median** Equivalent method for Series

**DataFrame.median** Equivalent method for DataFrame

**Examples**

Compute the rolling median of a series with a window size of 3.
pandas: powerful Python data analysis toolkit, Release 0.23.3

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0   NaN
1   NaN
2   1.0
3   2.0
4   3.0
dtype: float64
```

### 34.16.2.5 pandas.core.window.Expanding.var

Expanding.var(ddof=1, *args, **kwargs)

Calculate unbiased expanding variance.

Normalized by N-1 by default. This can be changed using the `ddof` argument.

**Parameters**

- `ddof` : int, default 1
  
  Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

- `*args, **kwargs`
  
  For NumPy compatibility. No additional arguments are used.

**Returns**

Series or DataFrame

Returns the same object type as the caller of the expanding calculation.

See also:

- `Series.expanding` Calling object with Series data
- `DataFrame.expanding` Calling object with DataFrames
- `Series.var` Equivalent method for Series
- `DataFrame.var` Equivalent method for DataFrame
- `numpy.var` Equivalent method for Numpy array

**Notes**

The default `ddof` of 1 used in `Series.var()` is different than the default `ddof` of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

**Examples**

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0   NaN
1   NaN
2  0.333333
3  1.000000
4  1.000000
5  1.333333
```
34.16.2.6 pandas.core.window.Expanding.std

Expanding.std(ddof=1, *args, **kwargs)

Calculate expanding standard deviation.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

ddof : int, default 1
   Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N
   represents the number of elements.

*args, **kwargs
   For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame
   Returns the same object type as the caller of the expanding calculation.

See also:

Series.expanding Calling object with Series data
DataFrame.expanding Calling object with DataFrames
Series.std Equivalent method for Series
DataFrame.std Equivalent method for DataFrame
numpy.std Equivalent method for Numpy array

Notes

The default ddof of 1 used in Series.std is different than the default ddof of 0 in numpy.std.
A minimum of one period is required for the rolling calculation.

Examples
```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0      NaN
1      NaN
2  0.577350
3  1.000000
4  1.000000
5  1.154701
6      NaN
dtype: float64

>>> s.expanding(3).std()
0      NaN
1      NaN
2  0.577350
3  0.957427
4  0.894427
5  0.836660
6  0.786796
dtype: float64
```

34.16.2.7 pandas.core.window.Expanding.min

Expanding.min(*args, **kwargs)

Calculate the expanding minimum.

Parameters  **kwargs

Under Review.

Returns  Series or DataFrame

Returned object type is determined by the caller of the expanding calculation.

See also:

- Series.expanding Calling object with a Series
- DataFrame.expanding Calling object with a DataFrame
- Series.min Similar method for Series
- DataFrame.min Similar method for DataFrame

Examples

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0      NaN
1      NaN
2   3.000000
3   2.000000
4   2.000000
dtype: float64
```
34.16.2.8 pandas.core.window.Expanding.max

Expanding.max(*args, **kwargs)

expanding maximum

Returns

same type as input

See also:

pandas.Series.expanding, pandas.DataFrame.expanding

34.16.2.9 pandas.core.window.Expanding.corr

Expanding.corr(other=None, pairwise=None, **kwargs)

expanding sample correlation

Parameters

other : Series, DataFrame, or ndarray, optional

if not supplied then will default to self and produce pairwise output

pairwise : bool, default None

If False then only matching columns between self and other will be used and the
output will be a DataFrame. If True then all pairwise combinations will be calculated
and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In
the case of missing elements, only complete pairwise observations will be used.

Returns

same type as input

See also:

pandas.Series.expanding, pandas.DataFrame.expanding

34.16.2.10 pandas.core.window.Expanding.cov

Expanding.cov(other=None, pairwise=None, ddof=1, **kwargs)

expanding sample covariance

Parameters

other : Series, DataFrame, or ndarray, optional

if not supplied then will default to self and produce pairwise output

pairwise : bool, default None

If False then only matching columns between self and other will be used and the
output will be a DataFrame. If True then all pairwise combinations will be calculated
and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs.
In the case of missing elements, only complete pairwise observations will be used.

ddof : int, default 1

Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N
represents the number of elements.

Returns

same type as input
See also:

```
pandas.Series.expanding, pandas.DataFrame.expanding
```

### 34.16.2.11 pandas.core.window.Expanding.skew

`Expanding.skew(**kwargs)`  
Unbiased expanding skewness  

**Returns**  

same type as input  

See also:

```
pandas.Series.expanding, pandas.DataFrame.expanding
```

### 34.16.2.12 pandas.core.window.Expanding.kurt

`Expanding.kurt(**kwargs)`  
Calculate unbiased expanding kurtosis.  

This function uses Fisher’s definition of kurtosis without bias.  

**Parameters**  
**kwargs  

Under Review.  

**Returns**  
Series or DataFrame  

Returned object type is determined by the caller of the expanding calculation  

See also:

```
Series.expanding Calling object with Series data  
DataFrame.expanding Calling object with DataFrames  
Series.kurt Equivalent method for Series  
DataFrame.kurt Equivalent method for DataFrame  
scipy.stats.skew Third moment of a probability density  
scipy.stats.kurtosis Reference SciPy method
```

**Notes**

A minimum of 4 periods is required for the expanding calculation.  

**Examples**

The example below will show an expanding calculation with a window size of four matching the equivalent function call using `scipy.stats`.  

---

*pandas: powerful Python data analysis toolkit, Release 0.23.3*
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> fmt = "{0:.6f}" # limit the printed precision to 6 digits
>>> print(fmt.format(scipy.stats.kurtosis(arr[:-1], bias=False)))
-1.200000
>>> print(fmt.format(scipy.stats.kurtosis(arr, bias=False)))
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0    NaN
1    NaN
2    NaN
3 -1.200000
4  4.999874
dtype: float64

34.16.2.13 pandas.core.window.Expanding.apply

Expanding. **apply** *(func, raw=None, args=(), kwargs=())*

expanding function apply

**Parameters**  

*func* : function

Must produce a single value from an ndarray input if raw=True or a Series if raw=False

*raw* : bool, default None

- **False** : passes each row or column as a Series to the function.
- **True or None** : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

The raw parameter is required and will show a FutureWarning if not passed. In the future raw will default to False.

New in version 0.23.0.

*args and **kwargs are passed to the function

**Returns**

same type as input

See also:

pandas.Series.expanding, pandas.DataFrame.expanding

34.16.2.14 pandas.core.window.Expanding.aggregate

Expanding. **aggregate** *(arg, *args, **kwargs)*

Aggregate using one or more operations over the specified axis.

**Parameters**  

*func* : function, string, dictionary, or list of string/functions

Function to use for aggregating the data. If a function, must either work when passed a Series/DataFrame or when passed to Series/DataFrame.apply. For a DataFrame, can pass a dict, if the keys are DataFrame column names.
Accepted combinations are:

- string function name.
- function.
- list of functions.
- dict of column names -> functions (or list of functions).

*args

Positional arguments to pass to func.

**kwargs

Keyword arguments to pass to func.

Returns

aggregated [Series/DataFrame]

See also:

Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'])
```

```
A    B    C
0 -2.385977 -0.102758 0.438822
1 -1.004295 0.905829 -0.954544
2 0.735167 -0.165272 -1.619346
3 -0.702657 -1.340923 -0.706334
4 -0.246845 0.211596 -0.901819
5 2.463718 3.157577 -1.380906
6 -1.142255 2.340594 -0.039875
7 1.396598 -1.647453 1.677227
8 -0.543425 1.761277 -0.220481
9 -0.640505 0.289374 -1.550670
```

```python
>>> df.ewm(alpha=0.5).mean()
```

```
A    B    C
0 -2.385977 -0.102758 0.438822
1 -1.464856 0.569633 -0.901819
2 -0.207700 0.149687 -1.135379
3 -0.471677 -0.645305 -0.906555
4 -0.355635 -0.203033 -0.904111
5 1.076417 1.503943 -1.146293
6 -0.041654 1.925562 -0.588728
7 0.680292 0.132049 0.548693
```

(continues on next page)
34.16.2.15 pandas.core.window.Expanding.quantile

Expanding. quantile (quantile, interpolation='linear', **kwargs)

expanding quantile.

Parameters quantile : float

Quantile to compute. 0 <= quantile <= 1.

interpolation : ['linear', 'lower', 'higher', 'midpoint', 'nearest']

New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:

• linear: \( i + (j - i) * \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).

• lower: \( i \).

• higher: \( j \).

• nearest: \( i \) or \( j \) whichever is nearest.

• midpoint: \( (i + j) / 2 \).

**kwargs:

For compatibility with other expanding methods. Has no effect on the result.

Returns Series or DataFrame

Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.quantile Computes value at the given quantile over all data in Series.

pandas.DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0     NaN
1     1.0
2     2.0
3     3.0
dtype: float64
```

```python
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0     NaN
1     1.5
2     2.5
```
34.16.3 Exponentially-weighted moving window functions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>EWM.mean(*args, **kwargs)</code></td>
<td>exponential weighted moving average</td>
</tr>
<tr>
<td><code>EWM.std(*args, **kwargs)</code></td>
<td>exponential weighted moving stddev</td>
</tr>
<tr>
<td><code>EWM.var(*args, **kwargs)</code></td>
<td>exponential weighted moving variance</td>
</tr>
<tr>
<td><code>EWM.corr(*other, pairwise)</code></td>
<td>exponential weighted sample correlation</td>
</tr>
<tr>
<td><code>EWM.cov(*other, pairwise)</code></td>
<td>exponential weighted sample covariance</td>
</tr>
</tbody>
</table>

34.16.3.1 pandas.core.window.EWM.mean

```python
EWM.mean(*args, **kwargs)
```

**Exponential weighted moving average**

Returns

same type as input

See also:

`pandas.Series.ewm, pandas.DataFrame.ewm`

34.16.3.2 pandas.core.window.EWM.std

```python
EWM.std(*args, **kwargs)
```

**Exponential weighted moving stddev**

Parameters

- `bias` : boolean, default False
  
  Use a standard estimation bias correction

Returns

same type as input

See also:

`pandas.Series.ewm, pandas.DataFrame.ewm`

34.16.3.3 pandas.core.window.EWM.var

```python
EWM.var(*args, **kwargs)
```

**Exponential weighted moving variance**

Parameters

- `bias` : boolean, default False
  
  Use a standard estimation bias correction

Returns

same type as input

See also:

`pandas.Series.ewm, pandas.DataFrame.ewm`
34.16.3.4 pandas.core.window.EWM.corr

`EWM.corr(other=None, pairwise=None, **kwargs)`

exponential weighted sample correlation

**Parameters**

- `other` : Series, DataFrame, or ndarray, optional
  - if not supplied then will default to self and produce pairwise output

- `pairwise` : bool, default None
  - If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

- `bias` : boolean, default False
  - Use a standard estimation bias correction

**Returns**

- same type as input

**See also:**

`pandas.Series.ewm, pandas.DataFrame.ewm`

34.16.3.5 pandas.core.window.EWM.cov

`EWM.cov(other=None, pairwise=None, bias=False, **kwargs)`

exponential weighted sample covariance

**Parameters**

- `other` : Series, DataFrame, or ndarray, optional
  - if not supplied then will default to self and produce pairwise output

- `pairwise` : bool, default None
  - If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

- `bias` : boolean, default False
  - Use a standard estimation bias correction

**Returns**

- same type as input

**See also:**

`pandas.Series.ewm, pandas.DataFrame.ewm`

34.17 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.
34.17.1 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>GroupBy.__iter__()</code></td>
<td>Groupby iterator</td>
</tr>
<tr>
<td><code>GroupBy.groups</code></td>
<td>dict {group name -&gt; group labels}</td>
</tr>
<tr>
<td><code>GroupBy.indices</code></td>
<td>dict {group name -&gt; group indices}</td>
</tr>
<tr>
<td><code>GroupBy.get_group</code></td>
<td>Constructs NDFrame from group with provided name</td>
</tr>
</tbody>
</table>

34.17.1.1 pandas.core.groupby.GroupBy.__iter__

`GroupBy.__iter__()`  
Groupby iterator  

Returns  

Generator yielding sequence of (name, subsetted object)  
for each group

34.17.1.2 pandas.core.groupby.GroupBy.groups

`GroupBy.groups`  
dict {group name -> group labels}

34.17.1.3 pandas.core.groupby.GroupBy.indices

`GroupBy.indices`  
dict {group name -> group indices}

34.17.1.4 pandas.core.groupby.GroupBy.get_group

`GroupBy.get_group(name, obj=None)`  
Constructs NDFrame from group with provided name  

Parameters

- `name`: object  
  the name of the group to get as a DataFrame  
- `obj`: NDFrame, default None  
  the NDFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used  

Returns

- `group` [type of obj]

34.17.1.5 pandas.Grouper

`class pandas.Grouper(key=None, level=None, freq=None, axis=0, sort=False)`  
A Grouper allows the user to specify a groupby instruction for a target object
This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

These are local specifications and will override ‘global’ settings, that is the parameters axis and level which are passed to the groupby itself.

**Parameters**

- **key** : string, defaults to None
  - groupby key, which selects the grouping column of the target

- **level** : name/number, defaults to None
  - the level for the target index

- **freq** : string / frequency object, defaults to None
  - This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of available frequencies, please see here.

- **axis** : [number/name of the axis, defaults to 0]

- **sort** : boolean, default to False
  - whether to sort the resulting labels

**additional kwargs to control time-like groupers (when ‘freq’ is passed)**

- **closed** : [closed end of interval; ‘left’ or ‘right’]

- **label** : [interval boundary to use for labeling; ‘left’ or ‘right’]

- **convention** : {'start', 'end', 'e', 's'}
  - If grouper is PeriodIndex

**base, loffset**

**Returns**

A specification for a groupby instruction

**Examples**

Syntactic sugar for `df.groupby('A')`

```python
>>> df.groupby(Grouper(key='A'))
```

Specify a resample operation on the column ‘date’

```python
>>> df.groupby(Grouper(key='date', freq='60s'))
```

Specify a resample operation on the level ‘date’ on the columns axis with a frequency of 60s

```python
>>> df.groupby(Grouper(level='date', freq='60s', axis=1))
```

34.17.2 Function application

<table>
<thead>
<tr>
<th>GroupBy.apply(func, *args, **kwargs)</th>
<th>Apply function func group-wise and combine the results together.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GroupBy.aggregate(func, *args, **kwargs)</td>
<td>GroupBy.transform(func, *args, **kwargs)</td>
</tr>
<tr>
<td>GroupBy.pipe(func, *args, **kwargs)</td>
<td>Apply a function func with arguments to this GroupBy object and return the function’s result.</td>
</tr>
</tbody>
</table>

34.17.2.1 pandas.core.groupby.GroupBy.apply

GroupBy.**apply**(func, *args, **kwargs)

Apply function func group-wise and combine the results together.

The function passed to apply must take a dataframe as its first argument and return a dataframe, a series or a scalar. apply will then take care of combining the results back together into a single dataframe or series. apply is therefore a highly flexible grouping method.

While apply is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods. Pandas offers a wide range of method that will be much faster than using apply for their specific purposes, so try to use them before reaching for apply.

**Parameters**

- **func**: function
  - A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments
  - **args, kwargs**: tuple and dict
    - Optional positional and keyword arguments to pass to func

**Returns**

- **applied**: [Series or DataFrame]

**See also**

- **pipe**: Apply function to the full GroupBy object instead of to each group.
  - aggregate, transform

**Notes**

In the current implementation apply calls func twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if func has side-effects, as they will take effect twice for the first group.
**Examples**

```python
>>> df = pd.DataFrame({'A': 'a a b'.split(), 'B': [1,2,3], 'C': [4,6, 5]})
>>> g = df.groupby('A')
```

From `df` above we can see that `g` has two groups, `a`, `b`. Calling `apply` in various ways, we can get different grouping results:

Example 1: below the function passed to `apply` takes a dataframe as its argument and returns a dataframe. `apply` combines the result for each group together into a new dataframe:

```python
>>> g.apply(lambda x: x / x.sum())
   B   C
0  0.333333  0.4
1  0.666667  0.6
2  1.000000  1.0
```

Example 2: The function passed to `apply` takes a dataframe as its argument and returns a series. `apply` combines the result for each group together into a new dataframe:

```python
>>> g.apply(lambda x: x.max() - x.min())
   B   C
A
a 1 2
b 0 0
```

Example 3: The function passed to `apply` takes a dataframe as its argument and returns a scalar. `apply` combines the result for each group together into a series, including setting the index as appropriate:

```python
>>> g.apply(lambda x: x.C.max() - x.B.min())
A
a 5
b 2
dtype: int64
```

34.17.2.2 pandas.core.groupby.GroupBy.aggregate

`GroupBy.aggregate(func, *args, **kwargs)`

34.17.2.3 pandas.core.groupby.GroupBy.transform

`GroupBy.transform(func, *args, **kwargs)`

34.17.2.4 pandas.core.groupby.GroupBy.pipe

`GroupBy.pipe(func, *args, **kwargs)`

Apply a function `func` with arguments to this `GroupBy` object and return the function’s result.

New in version 0.21.0.

Use `.pipe` when you want to improve readability by chaining together functions that expect Series, DataFrame, GroupBy or Resampler objects. Instead of writing...
You can write

```python
(df.groupby('group')
  .pipe(f)
  .pipe(g, arg1=a)
  .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- **func**: callable or tuple of (callable, string)
  
  Function to apply to this GroupBy object or, alternatively, a (callable, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the GroupBy object.

- **args**: iterable, optional
  
  positional arguments passed into `func`.

- **kwargs**: dict, optional
  
  a dictionary of keyword arguments passed into `func`.

**Returns**

- **object** [the return type of `func`]

**See also:**

- `pandas.Series.pipe` Apply a function with arguments to a series
- `pandas.DataFrame.pipe` Apply a function with arguments to a dataframe
- `apply` Apply function to each group instead of to the full GroupBy object.

**Notes**

See more [here](#)

**Examples**

```python
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4
```

To get the difference between each groups maximum and minimum value in one pass, you can do

```python
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
```

A
a 2
b 2
### 34.17.3 Computations / Descriptive Stats

</table>

#### 34.17.3.1 pandas.core.groupby.GroupBy.all

GroupBy.all (skipna=True)

Returns True if all values in the group are truthful, else False

**Parameters** skipna: bool, default True

Flag to ignore nan values during truth testing

**See also:**

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

#### 34.17.3.2 pandas.core.groupby.GroupBy.any

GroupBy.any (skipna=True)

Returns True if any value in the group is truthful, else False
Parameters `skipna` : bool, default True
Flag to ignore nan values during truth testing

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.3 pandas.core.groupby.GroupBy.bfill

`GroupBy.bfill(limit=None)`
Backward fill the values

Parameters `limit` : integer, optional
  limit of how many values to fill

See also:
Series.backfill, DataFrame.backfill, Series.fillna, DataFrame.fillna

34.17.3.4 pandas.core.groupby.GroupBy.count

`GroupBy.count()`
Compute count of group, excluding missing values

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.5 pandas.core.groupby.GroupBy.cumcount

`GroupBy.cumcount(ascending=True)`
Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```python
>>> self.apply(lambda x: Series(np.arange(len(x)), x.index))
```

Parameters `ascending` : bool, default True
  If False, number in reverse, from length of group - 1 to 0.

See also:

`ngroup` Number the groups themselves.

Examples

```python
>>> df = pd.DataFrame([['a'], ['a'], ['a'], ['b'], ['b'], ['a']],
                    columns=['A'])
>>> df
  A
0 a
1 a
2 a
```
3  b
4  b
5  a

```python
>>> df.groupby('A').cumcount()
0  0
1  1
2  2
3  0
4  1
5  3
dtype: int64

>>> df.groupby('A').cumcount(ascending=False)
0  3
1  2
2  1
3  1
4  0
5  0
dtype: int64
```

34.17.3.6 pandas.core.groupby.GroupBy.ffill

GroupBy.ffill(limit=None)
Forward fill the values

Parameters

limit : integer, optional
limit of how many values to fill

See also:

Series.pad, DataFrame.pad, Series.fillna, DataFrame.fillna

34.17.3.7 pandas.core.groupby.GroupBy.first

GroupBy.first(**kwargs)
Compute first of group values

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.8 pandas.core.groupby.GroupBy.head

GroupBy.head(n=5)
Returns first n rows of each group.

Essentially equivalent to .apply(lambda x: x.head(n)), except ignores as_index flag.

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
Examples

```python
>>> df = DataFrame([[1, 2], [1, 4], [5, 6]],
                 columns=['A', 'B'])
>>> df.groupby('A', as_index=False).head(1)
     A   B
0  1   2
2  5   6
>>> df.groupby('A').head(1)
     A   B
0  1   2
2  5   6
```

34.17.3.9 pandas.core.groupby.GroupBy.last

GroupBy.last(**kwargs)
Compute last of group values

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.10 pandas.core.groupby.GroupBy.max

GroupBy.max(**kwargs)
Compute max of group values

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.11 pandas.core.groupby.GroupBy.mean

GroupBy.mean(*args, **kwargs)
Compute mean of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.12 pandas.core.groupby.GroupBy.median

GroupBy.median(**kwargs)
Compute median of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
34.17.3.13 pandas.core.groupby.GroupBy.min

`GroupBy.min(**kwargs)`

Compute min of group values

See also:

`pandas.Series.groupby`, `pandas.DataFrame.groupby`, `pandas.Panel.groupby`

34.17.3.14 pandas.core.groupby.GroupBy.ngroup

`GroupBy.ngroup(ascending=True)`

Number each group from 0 to the number of groups - 1.

This is the enumerative complement of cumcount. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

New in version 0.20.2.

Parameters ascending : bool, default True

If False, number in reverse, from number of group - 1 to 0.

See also:

`cumcount` Number the rows in each group.

Examples

```python
>>> df = pd.DataFrame({'A': list('aabba')})
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
0  0
1  0
2  0
3  1
4  1
5  0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0  1
1  1
2  1
3  0
4  0
5  1
dtype: int64
>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
0  0
1  0
(continues on next page)```
34.17.3.15 pandas.core.groupby.GroupBy.nth

**GroupBy.nth**(n, dropna=None)

Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.

If dropna, will take the nth non-null row, dropna is either Truthy (if a Series) or ‘all’, ‘any’ (if a DataFrame); this is equivalent to calling dropna(how=dropna) before the groupby.

**Parameters**

- **n**: int or list of ints
  - a single nth value for the row or a list of nth values
- **dropna**: None or str, optional
  - apply the specified dropna operation before counting which row is the nth row. Needs to be None, ‘any’ or ‘all’

**See also:**

- `pandas.Series.groupby`
- `pandas.DataFrame.groupby`
- `pandas.Panel.groupby`

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
                    'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A  
1 NaN
2  3.0
>>> g.nth(1)
   B
A  
1  2.0
2  5.0
>>> g.nth(-1)
   B
A  
1  4.0
2  5.0
>>> g.nth([0, 1])
   B
A  
1 NaN
1  2.0
2  3.0
2  5.0
```

Specifying dropna allows count ignoring NaN
>>> g.nth(0, dropna='any')
   B
   A
   1 2.0
   2 3.0

NaNs denote group exhausted when using dropna

>>> g.nth(3, dropna='any')
   B
   A
   1 NaN
   2 NaN

Specifying as_index=False in groupby keeps the original index.

>>> df.groupby('A', as_index=False).nth(1)
   A  B
   1 1 2.0
   4 2 5.0

34.17.3.16 pandas.core.groupby.GroupBy.ohlc

GroupBy.ohlc()  
Compute sum of values, excluding missing values For multiple groupings, the result index will be a MultiIndex  
See also:  
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.17 pandas.core.groupby.GroupBy.prod

GroupBy.prod(**kwags)
Compute prod of group values  
See also:  
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.18 pandas.core.groupby.GroupBy.rank

GroupBy.rank(method='average', ascending=True, na_option='keep', pct=False, axis=0)
Provides the rank of values within each group.  
Parameters method : {'average', 'min', 'max', 'first', 'dense'}, default 'average'  
  • average: average rank of group  
  • min: lowest rank in group  
  • max: highest rank in group  
  • first: ranks assigned in order they appear in the array  
  • dense: like 'min', but rank always increases by 1 between groups  
  ascending : boolean, default True
False for ranks by high (1) to low (N)

**na_option**: {'keep', 'top', 'bottom'}, default 'keep'
- keep: leave NA values where they are
- top: smallest rank if ascending
- bottom: smallest rank if descending

**pct**: boolean, default False
Compute percentage rank of data within each group

**axis**: int, default 0
The axis of the object over which to compute the rank.

**Returns**

DataFrame with ranking of values within each group

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

---

### 34.17.3.19 pandas.core.groupby.GroupBy.pct_change

**GroupBy.pct_change**(periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calcuate pct_change of each value to previous entry in group

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

---

### 34.17.3.20 pandas.core.groupby.GroupBy.size

**GroupBy.size()**
Compute group sizes

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

---

### 34.17.3.21 pandas.core.groupby.GroupBy.sem

**GroupBy.sem**(ddof=1)
Compute standard error of the mean of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

**Parameters**

- **ddof**: integer, default 1
degrees of freedom

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
34.17.3.22 pandas.core.groupby.GroupBy.std

GroupBy.std(ddof=1, *args, **kwargs)
Compute standard deviation of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

Parameters ddof : integer, default 1
degrees of freedom

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.23 pandas.core.groupby.GroupBy.sum

GroupBy.sum(**kwargs)
Compute sum of group values

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.24 pandas.core.groupby.GroupBy.var

GroupBy.var(ddof=1, *args, **kwargs)
Compute variance of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

Parameters ddof : integer, default 1
degrees of freedom

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.25 pandas.core.groupby.GroupBy.tail

GroupBy.tail(n=5)
Returns last n rows of each group
Essentially equivalent to .apply(lambda x: x.tail(n)), except ignores as_index flag.

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

Examples

```python
>>> df = DataFrame([[['a', 1], ['a', 2], ['b', 1], ['b', 2]],
                      columns=['A', 'B'])
>>> df.groupby('A').tail(1)
     A  B
  1  a  2
  3  b  2
```
The following methods are available in both SeriesGroupBy and DataFrameGroupBy objects, but may differ slightly, usually in that the DataFrameGroupBy version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

34.17.3.26 pandas.core.groupby.DataFrameGroupBy.agg

DataFrameGroupBy.agg(arg, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**  
func : function, string, dictionary, or list of string/functions  
Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply. For a DataFrame, can pass a dict, if the keys are DataFrame column names.

Accepted combinations are:
  • string function name.
  • function.
  • list of functions.
  • dict of column names -> functions (or list of functions).

*args  
Positional arguments to pass to func.

**kwargs  
Keyword arguments to pass to func.

**Returns**  
aggregated [DataFrame]

See also:  
pandas.DataFrame.groupby.apply, pandas.DataFrame.groupby.transform, pandas.DataFrame.aggregate

**Notes**  
agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**
>>> df = pd.DataFrame({'A': [1, 1, 2, 2],
...              'B': [1, 2, 3, 4],
...              'C': np.random.randn(4)})

>>> df
    A  B     C
0  1  1  0.362838
1  1  2  0.227877
2  2  3  1.267767
3  2  4 -0.562860

The aggregation is for each column.

>>> df.groupby('A').agg('min')

   B   C
A
  1  1  0.227877
  2  3 -0.562860

Multiple aggregations

>>> df.groupby('A').agg(['min', 'max'])

   B     C
   min   max
A
  1  1   2   0.227877  0.362838
  2  3  4 -0.562860  1.267767

Select a column for aggregation

>>> df.groupby('A').B.agg(['min', 'max'])

   min max
A
  1   1   2
  2   3  4

Different aggregations per column

>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})

   B   C
   min   max   sum
A
  1   1   2  0.590716
  2   3   4  0.704907

34.17.3.27 pandas.core.groupby.DataFrameGroupBy.all

DataFrameGroupBy.all((skipna=True))

Returns True if all values in the group are truthful, else False

Parameters skipna : bool, default True

Flag to ignore nan values during truth testing

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
34.17.3.28 pandas.core.groupby.DataFrameGroupBy.any

DataFrameGroupBy.any(skipna=True)
Returns True if any value in the group is truthful, else False

Parameters skipna: bool, default True
Flag to ignore nan values during truth testing

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.29 pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.bfill(limit=None)
Backward fill the values

Parameters limit: integer, optional
limit of how many values to fill

See also:
Series.backfill, DataFrame.backfill, Series.fillna, DataFrame.fillna

34.17.3.30 pandas.core.groupby.DataFrameGroupBy.corr

DataFrameGroupBy.corr
Compute pairwise correlation of columns, excluding NA/null values

Parameters method: {'pearson', 'kendall', 'spearman'}
• pearson: standard correlation coefficient
• kendall: Kendall Tau correlation coefficient
• spearman: Spearman rank correlation

min_periods: int, optional
Minimum number of observations required per pair of columns to have a valid result.
Currently only available for pearson and spearman correlation

Returns
y [DataFrame]

34.17.3.31 pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.count()
Compute count of group, excluding missing values

34.17.3.32 pandas.core.groupby.DataFrameGroupBy.cov

DataFrameGroupBy.cov
Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.
Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters **min_periods** : int, optional

Minimum number of observations required per pair of columns to have a valid result.

Returns **DataFrame**

The covariance matrix of the series of the DataFrame.

See also:

- **pandas.Series.cov** compute covariance with another Series
- **pandas.core.window.EWM.cov** exponential weighted sample covariance
- **pandas.core.window.Expanding.cov** expanding sample covariance
- **pandas.core.window.Rolling.cov** rolling sample covariance

Notes

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-1.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

Examples

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
                     columns=['dogs', 'cats'])
>>> df.cov()
   dogs  cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667

>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
                     columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
       a          b         c          d          e
   a  0.998438 -0.020161  0.059277 -0.008943  0.014144
   b -0.020161  1.059352 -0.008543 -0.024738  0.009826
   c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
   d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
   e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```
Minimum number of periods

This method also supports an optional min_periods keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
   a         b         c
a  0.316741  NaN -0.150812
b  NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

34.17.3.33 pandas.core.groupby.DataFrameGroupBy.cummax

DataFrameGroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group

See also:
```
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
```

34.17.3.34 pandas.core.groupby.DataFrameGroupBy.cummin

DataFrameGroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group

See also:
```
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
```

34.17.3.35 pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group

See also:
```
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
```

34.17.3.36 pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group

See also:
```
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
```
DataFrameGroupBy.describe(**kwargs)

Generates descriptive statistics that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

**percentiles** : list-like of numbers, optional

The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

**include** : ‘all’, list-like of dtypes or None (default), optional

A white list of data types to include in the result. Ignored for Series. Here are the options:

- ‘all’ : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

**exclude** : list-like of dtypes or None (default), optional,

A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.

**Returns**

**summary** : Series/DataFrame of summary statistics

**See also**:

DataFrame.count, DataFrame.max, DataFrame.min, DataFrame.mean, DataFrame.std, DataFrame.select_dtypes

**Notes**

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Timestamps also include the first and last items.
If multiple object values have the highest count, then the **count** and **top** results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a **DataFrame**, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The **include** and **exclude** parameters can be used to limit which columns in a **DataFrame** are analyzed for the output. The parameters are ignored when analyzing a **Series**.

### Examples

**Describing a numeric Series.**

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
            count   mean    std     min   25%   50%   75%    max
0         3.0     2.0     1.0     1.0   1.5   2.0   2.5     3.0
```

**Describing a categorical Series.**

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
            count  unique    top    freq
dtype: object
```

**Describing a timestamp Series.**

```python
>>> s = pd.Series([np.datetime64("2000-01-01"),
...                 np.datetime64("2010-01-01"),
...                 np.datetime64("2010-01-01")])
>>> s.describe()
            count  unique  top                         first  last
dtype: object
```

**Describing a DataFrame.** By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'object': ['a', 'b', 'c'],
...                      'numeric': [1, 2, 3],
...                      'categorical': pd.Categorical(['d','e','f'])})
```

(continues on next page)
... })
>>> df.describe()
   numeric
      count  3.0
      mean  2.0
      std  1.0
      min  1.0
     25%  1.5
     50%  2.0
     75%  2.5
        max 3.0

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
   categorical   numeric   object
      count   3.0      3.0      3.0
     unique   3.0      NaN      3.0
      top      f       NaN       c
      freq     1.0      NaN      1.0
      mean     NaN      2.0      NaN
      std      NaN      1.0      NaN
      min      NaN      1.0      NaN
     25%      NaN      1.5      NaN
     50%      NaN      2.0      NaN
     75%      NaN      2.5      NaN
        max     NaN      3.0      NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
   count  3.0
      mean  2.0
      std  1.0
      min  1.0
     25%  1.5
     50%  2.0
     75%  2.5
        max 3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
   numeric
      count  3.0
      mean  2.0
      std  1.0
      min  1.0
     25%  1.5
     50%  2.0
     75%  2.5
        max 3.0
```

Including only string columns in a DataFrame description.
Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
```

```plaintext
categorical
count 3
unique 3
top f
freq 1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
```

```plaintext
categorical object
count 3 3
unique 3 3
top f c
freq 1 1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.object])
```

```plaintext
categorical numeric
count 3 3.0
unique 3 NaN
top f NaN
freq 1 NaN
mean NaN 2.0
std NaN 1.0
min NaN 1.0
25% NaN 1.5
50% NaN 2.0
75% NaN 2.5
max NaN 3.0
```

### 34.17.3.38 pandas.core.groupby.DataFrameGroupBy.diff

**DataFrameGroupBy.diff**

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is the element in the same column of the previous row).

**Parameters**

- **periods**: int, default 1
  
  Periods to shift for calculating difference, accepts negative values.

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  
  Take difference over rows (0) or columns (1).

  New in version 0.16.1..
Returns

diffed [DataFrame]

See also:

Series.diff First discrete difference for a Series.
DataFrame.pct_change Percent change over given number of periods.
DataFrame.shift Shift index by desired number of periods with an optional time freq.

Examples

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
```

```python
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```python
>>> df.diff()
    a   b   c
0 NaN NaN NaN
1  1.0 NaN NaN
2  1.0  1.0  3.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

Difference with previous column

```python
>>> df.diff(axis=1)
    a   b   c
0  NaN  0.0  0.0
1  NaN -1.0  3.0
2  NaN -1.0  7.0
3  NaN -1.0 13.0
4  NaN  0.0 20.0
5  NaN  2.0 28.0
```

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
    a   b   c
0  NaN NaN NaN
1  NaN NaN NaN
2  NaN NaN NaN
3  3.0  2.0 15.0
4  3.0  4.0 21.0
5  3.0  6.0 27.0
```
Difference with following row

```python
>>> df.diff(periods=-1)
   a   b   c
0 -1.0 0.0 3.0
1 -1.0 1.0 5.0
2 -1.0 1.0 7.0
3 -1.0 2.0 9.0
4 -1.0 3.0 11.0
5  NaN NaN NaN
```

### 34.17.3.39 pandas.core.groupby.DataFrameGroupBy.ffill

DataFrameGroupBy.**ffill** *(limit=None)*

Forward fill the values

**Parameters**

- **limit**: integer, optional
  - limit of how many values to fill

**See also:**
- Series.pad, DataFrame.pad, Series.fillna, DataFrame.fillna

### 34.17.3.40 pandas.core.groupby.DataFrameGroupBy.fillna

DataFrameGroupBy.**fillna**

Fill NA/NaN values using the specified method

**Parameters**

- **value**: scalar, dict, Series, or DataFrame
  - Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **method**: {'backfill', 'bfill', 'pad', 'ffill', None}, default None
  - Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

- **axis**: [0 or 'index', 1 or 'columns']

- **inplace**: boolean, default False
  - If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

- **limit**: int, default None
  - If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast**: dict, default is None
a dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

Returns

filled [DataFrame]

See also:

interpolate Fill NaN values using interpolation.

reindex, asfreq

Examples

```python
def = pd.DataFrame([[np.nan, 2, np.nan, 0],
                   [3, 4, np.nan, 1],
                   [np.nan, np.nan, np.nan, 5],
                   [np.nan, 3, np.nan, 4]],
                   columns=list('ABCD'))
def
A     B     C     D
0     NaN   2.0   NaN   0
1     3.0   4.0   NaN   1
2     NaN   NaN   NaN   5
3     NaN   3.0   NaN   4
```
Replace all NaN elements with 0s.

```python
def.fillna(0)
A     B     C     D
0     0.0   2.0   0.0   0
1     3.0   4.0   0.0   1
2     0.0   0.0   0.0   5
3     0.0   3.0   0.0   4
```
We can also propagate non-null values forward or backward.

```python
def.fillna(method='ffill')
A     B     C     D
0     NaN   2.0   NaN   0
1     3.0   4.0   NaN   1
2     3.0   4.0   NaN   5
3     3.0   3.0   NaN   4
```
Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
def.fillna(value=values)
A     B     C     D
0     0.0   2.0   2.0   0
1     3.0   4.0   2.0   1
2     0.0   1.0   2.0   5
3     0.0   3.0   2.0   4
```
Only replace the first NaN element.
>>> df.fillna(value=values, limit=1)
A  B  C  D
0  0.0 2.0 2.0  0
1  3.0 4.0  NaN  1
2  NaN 1.0  NaN  5
3  NaN 3.0  NaN  4

34.17.3.41 pandas.core.groupby.DataFrameGroupBy.filter

DataFrameGroupBy.filter (func, dropna=True, *args, **kwargs)

Return a copy of a DataFrame excluding elements from groups that do not satisfy the boolean criterion specified by func.

Parameters f: function

Function to apply to each subframe. Should return True or False.

dropna : Drop groups that do not pass the filter. True by default;
if False, groups that evaluate False are filled with NaNs.

Returns

filtered [DataFrame]

Notes

Each subframe is endowed the attribute ‘name’ in case you need to know which group you are working on.

Examples

>>> import pandas as pd
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
... 'foo', 'bar'],
... 'B' : [1, 2, 3, 4, 5, 6],
... 'C' : [2.0, 5.0, 8.0, 1.0, 2.0, 9.0]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambdax: x['B'].mean() > 3.)
   A  B  C
1  bar 2  5.0
3  bar 4  1.0
5  bar 6  9.0

34.17.3.42 pandas.core.groupby.DataFrameGroupBy.hist

DataFrameGroupBy.hist

Make a histogram of the DataFrame’s.

A histogram is a representation of the distribution of data. This function calls matplotlib.pyplot.hist(), on each series in the DataFrame, resulting in one histogram per column.

Parameters data: DataFrame

The pandas object holding the data.
column : string or sequence
    If passed, will be used to limit data to a subset of columns.

by : object, optional
    If passed, then used to form histograms for separate groups.

grid : boolean, default True
    Whether to show axis grid lines.

xlabelsizesize : int, default None
    If specified changes the x-axis label size.
xrots : float, default None
    Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90
degrees clockwise.

ylabelsizesize : int, default None
    If specified changes the y-axis label size.
yrots : float, default None
    Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90
degrees clockwise.

ax : Matplotlib axes object, default None
    The axes to plot the histogram on.

sharex : boolean, default True if ax is None else False
    In case subplots=True, share x axis and set some x axis labels to invisible; defaults
to True if ax is None otherwise False if an ax is passed in. Note that passing in both
an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey : boolean, default False
    In case subplots=True, share y axis and set some y axis labels to invisible.

figsizesize : tuple
    The size in inches of the figure to create. Uses the value in matplotlib.rcParams by
default.

layout : tuple, optional
    Tuple of (rows, columns) for the layout of the histograms.

bins : integer or sequence, default 10
    Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are
calculated and returned. If bins is a sequence, gives bin edges, including left edge of
first bin and right edge of last bin. In this case, bins is returned unmodified.

**kwds
    All other plotting keyword arguments to be passed to matplotlib.pyplot.
    hist().

Returns
    axes [matplotlib.AxesSubplot or numpy.ndarray of them]

See also:
**Examples**

This example draws a histogram based on the length and width of some animals, displayed in three bins.

```python
>>> df = pd.DataFrame(
...     {'length': [1.5, 0.5, 1.2, 0.9, 3],
...      'width': [0.7, 0.2, 0.15, 0.2, 1.1]},
...     index= ['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

### 34.17.3.43 pandas.core.groupby.DataFrameGroupBy.idxmax

DataFrameGroupBy. **idxmax**

Return index of first occurrence of maximum over requested axis. NA/null values are excluded.

**Parameters**

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise
- **skipna**: boolean, default True
  - Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- **idxmax**: [Series]

**Raises**

- ValueError
  - If the row/column is empty

**See also**

- Series.idxmax

**Notes**

This method is the DataFrame version of numpy.argmax.

### 34.17.3.44 pandas.core.groupby.DataFrameGroupBy.idxmin

DataFrameGroupBy. **idxmin**

Return index of first occurrence of minimum over requested axis. NA/null values are excluded.

**Parameters**

- **axis**: {0 or ‘index’, 1 or ‘columns’}, default 0
  - 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise
- **skipna**: boolean, default True
  - Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- **idxmin**: [Series]

**Raises**

- ValueError
  - If the row/column is empty
• If the row/column is empty

See also:
Series.idxmin

Notes
This method is the DataFrame version of ndarray.argmin.

34.17.3.45 pandas.core.groupby.DataFrameGroupBy.mad

DataFrameGroupBy.mad
Return the mean absolute deviation of the values for the requested axis

Parameters
axis [(index (0), columns (1))]
skipna : boolean, default True
Excluding NA/null values when computing the result.
level : int or level name, default None
If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
numeric_only : boolean, default None
Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
mad [Series or DataFrame (if level specified)]

34.17.3.46 pandas.core.groupby.DataFrameGroupBy.pct_change

DataFrameGroupBy.pct_change(periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calculating pct_change of each value to previous entry in group

See also:
pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.17.3.47 pandas.core.groupby.DataFrameGroupBy.plot

DataFrameGroupBy.plot
Class implementing the .plot attribute for groupby objects

34.17.3.48 pandas.core.groupby.DataFrameGroupBy.quantile

DataFrameGroupBy.quantile
Return values at the given quantile over requested axis, a la numpy.percentile.

Parameters q : float or array-like, default 0.5 (50% quantile)
0 <= q <= 1, the quantile(s) to compute

**axis** : {0, 1, ‘index’, ‘columns’} (default 0)

0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise

**numeric_only** : boolean, default True

If False, the quantile of datetime and timedelta data will be computed as well

**interpolation** : {'linear', 'lower', 'higher', 'midpoint', 'nearest'}

New in version 0.18.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points \(i\) and \(j\):

- **linear**: \(i + (j - i) * \text{fraction}\), where \(\text{fraction}\) is the fractional part of the index surrounded by \(i\) and \(j\).
- **lower**: \(i\).
- **higher**: \(j\).
- **nearest**: \(i\) or \(j\) whichever is nearest.
- **midpoint**: \((i + j) / 2\).

**Returns** quantiles : Series or DataFrame

- If \(q\) is an array, a DataFrame will be returned where the index is \(q\), the columns are the columns of self, and the values are the quantiles.
- If \(q\) is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.

See also:

*pandas.core.window.Rolling.quantile*

**Examples**

```python
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
                    columns=['a', 'b'])
>>> df.quantile(.1)
a 1.3
b 3.7
dtype: float64
>>> df.quantile([.1, .5])
   a  b
0.1 1.3 3.7
0.5 2.5 55.0
```

Specifying **numeric_only=False** will also compute the quantile of datetime and timedelta data.

```python
>>> df = pd.DataFrame({'A': [1, 2],
                     'B': [pd.Timestamp('2010'),
                          pd.Timestamp('2011')],
                     'C': [pd.Timedelta('1 days'),
                          pd.Timedelta('2 days')]})
>>> df.quantile(0.5, numeric_only=False)
  A
0.5 1.5
(continues on next page)```
34.17.3.49 pandas.core.groupby.DataFrameGroupBy.rank

DataFrameGroupBy.rank (method='average', ascending=True, na_option='keep', pct=False, axis=0)

Provides the rank of values within each group.

Parameters

- **method** : {'average', 'min', 'max', 'first', 'dense'}, default 'average'
  - average: average rank of group
  - min: lowest rank in group
  - max: highest rank in group
  - first: ranks assigned in order they appear in the array
  - dense: like 'min', but rank always increases by 1 between groups

- **ascending** : boolean, default True
  - False for ranks by high (1) to low (N)

- **na_option** : {'keep', 'top', 'bottom'}, default 'keep'
  - keep: leave NA values where they are
  - top: smallest rank if ascending
  - bottom: smallest rank if descending

- **pct** : boolean, default False
  - Compute percentage rank of data within each group

- **axis** : int, default 0
  - The axis of the object over which to compute the rank.

Returns

- DataFrame with ranking of values within each group

See also:

34.17.3.50 pandas.core.groupby.DataFrameGroupBy.resample

DataFrameGroupBy.resample (rule, *args, **kwargs)

Provide resampling when using a TimeGrouper Return a new grouper with our resampler appended

See also:

34.17.3.51 pandas.core.groupby.DataFrameGroupBy.shift

DataFrameGroupBy.shift(periods=1, freq=None, axis=0)
Shift each group by periods observations

Parameters:
- **periods**: integer, default 1
  - number of periods to shift
- **freq**: [frequency string]
- **axis**: [axis to shift, default 0]

See also:

34.17.3.52 pandas.core.groupby.DataFrameGroupBy.size

DataFrameGroupBy.size()
Compute group sizes

See also:

34.17.3.53 pandas.core.groupby.DataFrameGroupBy.skew

DataFrameGroupBy.skew
Return unbiased skew over requested axis Normalized by N-1

Parameters:
- **axis**: [index (0), columns (1)]
- **skipna**: boolean, default True
  - Exclude NA/null values when computing the result.
- **level**: int or level name, default None
  - If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
- **numeric_only**: boolean, default None
  - Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns:
- **skew**: [Series or DataFrame (if level specified)]

34.17.3.54 pandas.core.groupby.DataFrameGroupBy.take

DataFrameGroupBy.take
Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.
Parameters

indices : array-like

An array of ints indicating which positions to take.

axis : {0 or ‘index’, 1 or ‘columns’, None}, default 0

The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

convert : bool, default True

Whether to convert negative indices into positive ones. For example, -1 would map to the len(axis) - 1. The conversions are similar to the behavior of indexing a regular Python list.

Deprecated since version 0.21.0: In the future, negative indices will always be converted.

is_copy : bool, default True

Whether to return a copy of the original object or not.

**kwargs

For compatibility with numpy.take(). Has no effect on the output.

Returns

taken : type of caller

An array-like containing the elements taken from the object.

See also:

DataFrame.loc  Select a subset of a DataFrame by labels.

DataFrame.iloc  Select a subset of a DataFrame by positions.

numpy.take  Take elements from an array along an axis.

Examples

```python
def = pd.DataFrame([('falcon', 'bird', 389.0),
                     ('parrot', 'bird', 24.0),
                     ('lion', 'mammal', 80.5),
                     ('monkey', 'mammal', np.nan)],
                     columns=['name', 'class', 'max_speed'],
                     index=[0, 2, 3, 1])
def
   name  class     max_speed
0  falcon  bird       389.0
2  parrot  bird        24.0
3   lion  mammal       80.5
1  monkey  mammal        NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That’s because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
def.take([0, 3])
   name  class     max_speed
0  falcon  bird       389.0
1  monkey  mammal        NaN
```
Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
>>> df.take([1, 2], axis=1)
class max_speed
0   bird   389.0
2   bird    24.0
3 mammal   80.5
1 mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
name   class max_speed
1 monkey  mammal     NaN
3     lion  mammal    80.5
```

### 34.17.3.55 pandas.core.groupby.DataFrameGroupBy.tshift

**DataFrameGroupBy.tshift**

Shift the time index, using the index’s frequency if available.

**Parameters**
- **periods**: int
  Number of periods to move, can be positive or negative
- **freq**: DateOffset, timedelta, or time rule string, default None
  Increment to use from the tseries module or time rule (e.g. ‘EOM’)
- **axis**: int or basestring
  Corresponds to the axis that contains the Index

**Returns**
- **shifted**: [NDFrame]

**Notes**

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

The following methods are available only for SeriesGroupBy objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SeriesGroupBy.nlargest</code></td>
<td>Return the largest $n$ elements.</td>
</tr>
<tr>
<td><code>SeriesGroupBy.nsmallest</code></td>
<td>Return the smallest $n$ elements.</td>
</tr>
<tr>

<tr>
<td><code>SeriesGroupBy.is_monotonic_decreasing</code></td>
<td>Return boolean if values in the object are mono-</td>
</tr>
<tr>
<td></td>
<td>tonic_decreasing</td>
</tr>
</tbody>
</table>
The `nlargest` method returns the largest elements in a Series, sorted in descending order. It takes two parameters:

- `n`: an integer indicating the number of largest elements to return.
- `keep`: a string indicating how to handle duplicate values. It can be set to `'first'` or `'last'`, with the default being `'first'`.

The `nlargest` method returns a Series containing the `n` largest values, sorted in descending order. It is noted to be faster than `sort_values(ascending=False).head(n)` for small `n` relative to the size of the Series object.

The `nsmallest` method returns the smallest elements in a Series, sorted in ascending order. It has similar parameters:

- `n`: an integer indicating the number of smallest elements to return.
- `keep`: a string indicating how to handle duplicate values. It can be set to `'first'` or `'last'`, with the default being `'first'`.

The `nsmallest` method returns a Series containing the `n` smallest values, sorted in ascending order. It is noted to be faster than `.sort_values(ascending=True).head(n)` for small `n` relative to the size of the Series object.

**Examples**

```python
def generate_series():
    s = pd.Series(np.random.randn(10**6))
    return s

generate_series().nlargest(10)
```

```python
def generate_series():
    s = pd.Series(np.random.randn(10**6))
    return s

generate_series().nsmallest(10)
```
Returns `bottom_n`: Series

The n smallest values in the Series, in sorted order

See also:

Series.nlargest

Notes

Faster than `.sort_values().head(n)` for small n relative to the size of the Series object.

Examples

```python
>>> import pandas as pd
>>> import numpy as np

>>> s = pd.Series(np.random.randn(10**6))
>>> s.nsmallest(10)  # only sorts up to the N requested
  288532   -4.954580
    732345   -4.835960
      64803   -4.812550
       446457   -4.609998
        501225   -4.483945
       669476   -4.472935
       973615   -4.401699
      621279   -4.355126
      773916   -4.347355
        359919   -4.331927
 dtype: float64
```

34.17.3.58 pandas.core.groupby.SeriesGroupBy.nunique

`SeriesGroupBy.nunique(dropna=True)`

Returns number of unique elements in the group

34.17.3.59 pandas.core.groupby.SeriesGroupBy.unique

`SeriesGroupBy.unique`

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns `ndarray` or `Categorical`

The unique values returned as a NumPy array. In case of categorical data type, returned as a Categorical.

See also:

`pandas.unique` top-level unique method for any 1-d array-like object.

`Index.unique` return Index with unique values from an Index object.
Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])

>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern') ... for _ in range(3)]).unique()
array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'), ... ordered=True)).unique()
[b, a, c]
Categories (3, object): [a < b < c]
```

34.17.3.60 pandas.core.groupby.SeriesGroupBy.value_counts

```python
SeriesGroupBy.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)
```

34.17.3.61 pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing

```python
SeriesGroupBy.is_monotonic_increasing
Return boolean if values in the object are monotonic_increasing
New in version 0.19.0.
Returns
is_monotonic [boolean]
```

34.17.3.62 pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing

```python
SeriesGroupBy.is_monotonic_decreasing
Return boolean if values in the object are monotonic_decreasing
New in version 0.19.0.
Returns
is_monotonic_decreasing [boolean]
```

The following methods are available only for DataFrameGroupBy objects.
DataFrameGroupBy.corrwith

Compute pairwise correlation between rows or columns of two DataFrame objects.

Parameters

other [DataFrame, Series]
axis : {0 or ‘index’, 1 or ‘columns’}, default 0
  0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise
drop : boolean, default False
  Drop missing indices from result, default returns union of all

Returns
correls [Series]

DataFrameGroupBy.boxplot

Make box plots from DataFrameGroupBy data.

Parameters

grouped [Grouped DataFrame]
subplots :
  • False - no subplots will be used
  • True - create a subplot for each group
column : column name or list of names, or vector
  Can be any valid input to groupby

fontsize [int or string]
rot [label rotation angle]
grid [Setting this to True will show the grid]
ax [Matplotlib axis object, default None]
figsize [A tuple (width, height) in inches]
layout : tuple (optional)
  (rows, columns) for the layout of the plot

**kwds : Keyword Arguments
All other plotting keyword arguments to be passed to matplotlib’s boxplot function

Returns

dict of key/value = group key/DataFrame.boxplot return value
or DataFrame.boxplot return value in case subplots=figures=False

Examples

```python
>>> import pandas
>>> import numpy as np
>>> import itertools

>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pandas.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])
>>> data = np.random.randn(len(index), 4)
>>> df = pandas.DataFrame(data, columns=list('ABCD'), index=index)

>>> grouped = df.groupby(level='lvl1')
>>> boxplot_frame_groupby(grouped)

>>> grouped = df.unstack(level='lvl1').groupby(level=0, axis=1)
>>> boxplot_frame_groupby(grouped, subplots=False)
```

34.18 Resampling

Resampler objects are returned by resample calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

34.18.1 Indexing, iteration

```
Resampler.__iter__(): Groupby iterator
Resampler.groups
        dict {group name -> group labels}
Resampler.indices
        dict {group name -> group indices}
Resampler.get_group(name[, obj])
        Constructs NDFrame from group with provided name
```

34.18.1.1 pandas.core.resample.Resampler.__iter__

Resampler.__iter__():
    Groupby iterator

    Returns
    Generator yielding sequence of (name, subsetted object)
    for each group

34.18.1.2 pandas.core.resample.Resampler.groups

Resampler.groups:
    dict {group name -> group labels}
34.18.1.3 pandas.core.resample.Resampler.indices

Resampler.indices
   dict {group name -> group indices}

34.18.1.4 pandas.core.resample.Resampler.get_group

Resampler.get_group(name, obj=None)
   Constructs NDFrame from group with provided name
   Parameters name : object
      the name of the group to get as a DataFrame
   obj : NDFrame, default None
      the NDFrame to take the DataFrame out of. If it is None, the object groupby was
called on will be used
   Returns
      group [type of obj]

34.18.2 Function application

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resampler.apply(arg, *args, **kwargs)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>Resampler.aggregate(arg, *args, **kwargs)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>Resampler.transform(arg, *args, **kwargs)</td>
<td>Call function producing a like-indexed Series on each group and return a Series with the transformed values</td>
</tr>
<tr>
<td>Resampler.pipe(func, *args, **kwargs)</td>
<td>Apply a function func with arguments to this Resampler object and return the function’s result.</td>
</tr>
</tbody>
</table>

34.18.2.1 pandas.core.resample.Resampler.apply

Resampler.apply(arg, *args, **kwargs)
   Aggregate using one or more operations over the specified axis.
   Parameters func : function, string, dictionary, or list of string/functions
      Function to use for aggregating the data. If a function, must either work when passed
      a DataFrame or when passed to DataFrame.apply. For a DataFrame, can pass a dict,
      if the keys are DataFrame column names.
      Accepted combinations are:
      • string function name.
      • function.
      • list of functions.
      • dict of column names -> functions (or list of functions).
      *args
         Positional arguments to pass to func.
**kwargs

Keyword arguments to pass to `func`.

Returns

`aggregated [DataFrame]`

See also:

- pandas.DataFrame.groupby.aggregate
- pandas.DataFrame.resample.transform
- pandas.DataFrame.aggregate

Notes

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = Series([1,2,3,4,5],
              index=pd.date_range('20130101',
                                  periods=5,freq='s'))
2013-01-01 00:00:00  1
2013-01-01 00:00:01  2
2013-01-01 00:00:02  3
2013-01-01 00:00:03  4
2013-01-01 00:00:04  5
Freq: S, dtype: int64
```

```python
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start, base=0]
```

```python
>>> r.agg(np.sum)
2013-01-01 00:00:00   3
2013-01-01 00:00:02   7
2013-01-01 00:00:04   5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum','mean','max'])
                      sum  mean  max
2013-01-01 00:00:00   3  1.5   2
2013-01-01 00:00:02   7  3.5   4
2013-01-01 00:00:04   5  5.0   5
```

```python
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
         'total' : np.sum})
         total  result
2013-01-01 00:00:00   3  2.121320
2013-01-01 00:00:04   5  NaN
```
34.18.2.2 pandas.core.resample.Resampler.aggregate

Resampler.aggregate(arg, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters
func : function, string, dictionary, or list of string/functions
Function to use for aggregating the data. If a function, must either work when passed
a DataFrame or when passed to DataFrame.apply. For a DataFrame, can pass a dict,
if the keys are DataFrame column names.
Accepted combinations are:
• string function name.
• function.
• list of functions.
• dict of column names -> functions (or list of functions).

*args
Positional arguments to pass to func.

**kwargs
Keyword arguments to pass to func.

Returns
aggregated [DataFrame]

See also:
pandas.DataFrame.groupby.aggregate, pandas.DataFrame.resample.transform,
pandas.DataFrame.aggregate

Notes
agg is an alias for aggregate. Use the alias.
A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = Series([1,2,3,4,5],
               index=pd.date_range('20130101',
                                   periods=5, freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```python
>>> r = s.resample('2s')
```

```python
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start, base=0]
```
34.18.2.3 pandas.core.resample.Resampler.transform

Resampler.transform(arg, *args, **kwargs)

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

Parameters

func : function

To apply to each group. Should return a Series with the same index.

Returns

transformed [Series]

Examples

>>> resampled.transform(lambda x: (x - x.mean()) / x.std())

34.18.2.4 pandas.core.resample.Resampler.pipe

Resampler.pipe(func, *args, **kwargs)

Apply a function func with arguments to this Resampler object and return the function’s result.

New in version 0.23.0.

Use .pipe when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group'))), arg1=a, arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
...   .pipe(f)
...   .pipe(g, arg1=a)
...   .pipe(h, arg2=b, arg3=c))
```
which is much more readable.

**Parameters**

**func**: callable or tuple of (callable, string)

Function to apply to this Resampler object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Resampler object.

**args**: iterable, optional

Positional arguments passed into func.

**kwparams**: dict, optional

A dictionary of keyword arguments passed into func.

**Returns**

**object**: [the return type of func.]

See also:

- `pandas.Series.pipe` Apply a function with arguments to a series
- `pandas.DataFrame.pipe` Apply a function with arguments to a dataframe
- `apply` Apply function to each group instead of to the full Resampler object.

**Notes**

See more [here](#)

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
                   index=pd.date_range('2012-08-02', periods=4))
```

```text
>>> df
   A
2012-08-02  1
2012-08-03  2
2012-08-04  3
2012-08-05  4
```

To get the difference between each 2-day period’s maximum and minimum value in one pass, you can do

```python
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
   A
2012-08-02  1
2012-08-04  1
```

34.18.3.1 pandas.core.resample.Resampler.ffill

Resampler.ffill (limit=None)
Forward fill the values

Parameters

- **limit**: integer, optional
  - limit of how many values to fill

Returns

- an upsampled Series

See also:

- Series.fillna, DataFrame.fillna

34.18.3.2 pandas.core.resample.Resampler.backfill

Resampler.backfill (limit=None)
Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [R30]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

- **limit**: integer, optional
  - Limit of how many values to fill.

Returns

- Series, DataFrame
  - An upsampled Series or DataFrame with backward filled NaN values.

See also:

- bfill  Alias of backfill.
- fillna  Fill NaN values using the specified method, which can be ‘backfill’.
- nearest  Fill NaN values with nearest neighbor starting from center.
- pad  Forward fill NaN values.
- pandas.Series.fillna  Fill NaN values in the Series using the specified method, which can be ‘backfill’.
- pandas.DataFrame.fillna  Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.
References

[R30]

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
...                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```python
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                    index=pd.date_range('20180101', periods=3,
...                                          freq='h'))
>>> df
   a    b
2018-01-01 2.0  1
2018-01-01 NaN  3
2018-01-01 6.0  5
```

```python
>>> df.resample('30min').backfill()
   a    b
2018-01-01 2.0  1
2018-01-01 NaN  3
2018-01-01 NaN  3
2018-01-01 6.0  5
2018-01-01 6.0  5
```
34.18.3.3 pandas.core.resample.Resampler.bfill

Resampler.bfill(limit=None)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [R31]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

limit: integer, optional

Limit of how many values to fill.

Returns

Series, DataFrame

An upsampled Series or DataFrame with backward filled NaN values.

See also:

bfill Alias of backfill.

fillna Fill NaN values using the specified method, which can be 'backfill'.

nearest Fill NaN values with nearest neighbor starting from center.

pad Forward fill NaN values.

dataforces.Series.fillna Fill NaN values in the Series using the specified method, which can be 'backfill'.

dataforces.DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be 'backfill'.

2018-01-01 01:45:00 6.0 5.0
2018-01-01 02:00:00 6.0 5.0
```
34.18.3.4 pandas.core.resample.Resampler.pad

Resampler.pad(limit=None)

Forward fill the values

**Parameters**

- limit : integer, optional
  
  limit of how many values to fill

**Returns**

- an upsampled Series

**See also:**

Series.fillna, DataFrame.fillna

34.18.3.5 pandas.core.resample.Resampler.nearest

Resampler.nearest(limit=None)

Fill values with nearest neighbor starting from center

**Parameters**

- limit : integer, optional
  
  limit of how many values to fill

New in version 0.21.0.

**Returns**

- an upsampled Series

**See also:**

Series.fillna, DataFrame.fillna

34.18.3.6 pandas.core.resample.Resampler.fillna

Resampler.fillna(method, limit=None)

Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values \([R32]\). When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

**Parameters**

- method : {'pad', 'backfill', 'ffill', 'bfill', 'nearest'}
  
  Method to use for filling holes in resampled data
  
  - ‘pad’ or ‘ffill’: use previous valid observation to fill gap (forward fill).
  
  - ‘backfill’ or ‘bfill’: use next valid observation to fill gap.
  
  - ‘nearest’: use nearest valid observation to fill gap.

- limit : integer, optional
  
  Limit of how many consecutive missing values to fill.

**Returns**

Series or DataFrame

An upsampled Series or DataFrame with missing values filled.

**See also:**
backfill  Backward fill NaN values in the resampled data.

pad  Forward fill NaN values in the resampled data.

nearest  Fill NaN values in the resampled data with nearest neighbor starting from center.

interpolate  Fill NaN values using interpolation.

pandas.Series.fillna  Fill NaN values in the Series using the specified method, which can be ‘bfill’ and ‘ffill’.

pandas.DataFrame.fillna  Fill NaN values in the DataFrame using the specified method, which can be ‘bfill’ and ‘ffill’.

References

[R32]

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00 1
2018-01-01 01:00:00 2
2018-01-01 02:00:00 3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```python
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 2.0
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 2.0
2018-01-01 01:00:00 2.0
2018-01-01 01:30:00 3.0
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 NaN
2018-01-01 00:30:00 2.0
2018-01-01 00:45:00 2.0
2018-01-01 01:00:00 2.0
2018-01-01 01:15:00 NaN
2018-01-01 01:30:00 3.0
Freq: 15T, dtype: int64
```

(continues on next page)
2018-01-01 01:45:00 3.0
2018-01-01 02:00:00 3.0
Freq: 15T, dtype: float64

```python
>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 1
2018-01-01 01:00:00 2
2018-01-01 01:30:00 2
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

Missing values present before the upsampling are not affected.

```python
>>> sm = pd.Series([1, None, 3],
                  index=pd.date_range('20180101', periods=3, freq='h'))
```

```python
>>> sm
2018-01-01 00:00:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 02:00:00 3.0
Freq: H, dtype: float64
```

```python
>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

DataFrame resampling is done column-wise. All the same options are available.
```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                   index=pd.date_range('20180101', periods=3,
                   freq='h'))

>>> df
    a   b
2018-01-01 00:00:00 2.0 1
2018-01-01 01:00:00 NaN 3
2018-01-01 02:00:00 6.0 5

>>> df.resample('30min').fillna("bfill")
    a   b
2018-01-01 00:00:00 2.0 1
2018-01-01 00:30:00 NaN 3
2018-01-01 01:00:00 NaN 3
2018-01-01 01:30:00 6.0 5
2018-01-01 02:00:00 6.0 5
```

### 34.18.3.7 pandas.core.resample.Resampler.asfreq

Resampler.asfreq(fill_value=None)

return the values at the new freq, essentially a reindex

**Parameters** fill_value: scalar, optional

Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

**See also:**

Series.asfreq, DataFrame.asfreq

### 34.18.3.8 pandas.core.resample.Resampler.interpolate

Resampler.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)

Interpolate values according to different methods.

New in version 0.18.1.

Please note that only method='linear' is supported for DataFrames/Series with a MultiIndex.

**Parameters** method : {'linear', 'time', 'index', 'values', 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'barycentric', 'krogh', 'polynomial', 'spline', 'piecewise_polynomial', 'from_derivatives', 'pchip', 'akima'}

- ‘linear’: ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes. default
- ‘time’: interpolation works on daily and higher resolution data to interpolate given length of interval
- ‘index’, ‘values’: use the actual numerical values of the index
- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘barycentric’, ‘polynomial’ is passed to scipy.interpolate.interp1d. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g.

34.18. Resampling  2327
df.interpolate(method='polynomial', order=4). These use the actual numerical values of the index.

- ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ are all wrappers around the scipy interpolation methods of similar names. These use the actual numerical values of the index. For more information on their behavior, see the scipy documentation and tutorial documentation

- ‘from_derivatives’ refers to BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18

New in version 0.18.1: Added support for the ‘akima’ method. Added interpolate method ‘from_derivatives’ which replaces ‘piecewise_polynomial’ in scipy 0.18; backwards-compatible with scipy < 0.18

axis : {0, 1}, default 0

- 0: fill column-by-column
- 1: fill row-by-row

limit : int, default None.

- Maximum number of consecutive NaNs to fill. Must be greater than 0.

limit_direction : [{'forward', 'backward', 'both'}, default ‘forward’]

limit_area : {'inside', 'outside'}, default None

- None: (default) no fill restriction
- ‘inside’ Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’ Only fill NaNs outside valid values (extrapolate).

If limit is specified, consecutive NaNs will be filled in this direction.

New in version 0.21.0.

inplace : bool, default False

- Update the NDFrame in place if possible.

downcast : optional, ‘infer’ or None, defaults to None

- Downcast dtypes if possible.

kwargs : [keyword arguments to pass on to the interpolating function.]

Returns

Series or DataFrame of same shape interpolated at the NaNs

See also:

reindex, replace, fillna

Examples

Filling in NaNs
```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s.interpolate()
0 0
1 1
2 2
3 3
dtype: float64
```

#### 34.18.4.1 pandas.core.resample.Resampler.count

Resampler.count(_method='count')

Compute count of group, excluding missing values

**See also:**

`pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby`

#### 34.18.4.2 pandas.core.resample.Resampler.nunique

Resampler.nunique(_method='nunique')

Returns number of unique elements in the group

#### 34.18.4.3 pandas.core.resample.Resampler.first

Resampler.first(_method='first', *args, **kwargs)

Compute first of group values

**See also:**

`pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby`

34.18. Resampling 2329
34.18.4.4 pandas.core.resample.Resampler.last

Resampler.last(_method='last', *args, **kwargs)
Compute last of group values

See also:
      pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.5 pandas.core.resample.Resampler.max

Resampler.max(_method='max', *args, **kwargs)
Compute max of group values

See also:
      pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.6 pandas.core.resample.Resampler.mean

Resampler.mean(_method='mean', *args, **kwargs)
Compute mean of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

See also:
      pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.7 pandas.core.resample.Resampler.median

Resampler.median(_method='median', *args, **kwargs)
Compute median of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

See also:
      pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.8 pandas.core.resample.Resampler.min

Resampler.min(_method='min', *args, **kwargs)
Compute min of group values

See also:
      pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.9 pandas.core.resample.Resampler.ohlc

Resampler.ohlc(_method='ohlc', *args, **kwargs)
Compute sum of values, excluding missing values For multiple groupings, the result index will be a MultiIndex

See also:
      pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
34.18.4.10 pandas.core.resample.Resampler.prod

Resampler.prod(_method='prod', min_count=0, *args, **kwargs)
Compute prod of group values

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.11 pandas.core.resample.Resampler.size

Resampler.size()
Compute group sizes

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.12 pandas.core.resample.Resampler.sem

Resampler.sem(_method='sem', *args, **kwargs)
Compute standard error of the mean of groups, excluding missing values
For multiple groupings, the result index will be a MultiIndex

Parameters
d dof : integer, default 1
   degrees of freedom

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby

34.18.4.13 pandas.core.resample.Resampler.std

Resampler.std(ddof=1, *args, **kwargs)
Compute standard deviation of groups, excluding missing values

Parameters
d dof : [integer, default 1]
degrees of freedom

34.18.4.14 pandas.core.resample.Resampler.sum

Resampler.sum(_method='sum', min_count=0, *args, **kwargs)
Compute sum of group values

See also:

pandas.Series.groupby, pandas.DataFrame.groupby, pandas.Panel.groupby
34.18.4.15 pandas.core.resample.Resampler.var

Resampler.var(ddof=1, *args, **kwargs)
Compute variance of groups, excluding missing values

Parameters

ddf [integer, default 1]
degrees of freedom

34.19 Style

Styler objects are returned by pandas.DataFrame.style.

34.19.1 Styler Constructor

Styler(data[, precision, table_styles, ...])
Helps style a DataFrame or Series according to the data with HTML and CSS.

Styler.from_custom_template(searchpath, name)
Factory function for creating a subclass of Styler with a custom template and Jinja environment.

34.19.1.1 pandas.io.formats.style.Styler

class pandas.io.formats.style.Styler(data, precision=None, table_styles=None, uuid=None, caption=None, table_attributes=None)
Helps style a DataFrame or Series according to the data with HTML and CSS.

Parameters

data: Series or DataFrame
precision: int
    precision to round floats to, defaults to pd.options.display.precision
table_styles: list-like, default None
    list of {selector: (attr, value)} dicts; see Notes
uuid: str, default None
    a unique identifier to avoid CSS collisions; generated automatically
caption: str, default None
    caption to attach to the table

See also:
pandas.DataFrame.style

Notes

Most styling will be done by passing style functions into Styler.apply or Styler.applymap. Style functions should return values with strings containing CSS 'attr: value' that will be applied to the indicated cells.
If using in the Jupyter notebook, Styler has defined a \_repr_html\_ to automatically render itself. Otherwise call Styler.render to get the generated HTML.

CSS classes are attached to the generated HTML:

- Index and Column names include index\_name and level\_k where k is its level in a MultiIndex
- Index label cells include
  - row\_heading
  - row\_n where n is the numeric position of the row
  - level\_k where k is the level in a MultiIndex
- Column label cells include *col\_heading* *col\_n where n is the numeric position of the column
  *level\_k* where k is the level in a MultiIndex
- Blank cells include blank
- Data cells include data

**Attributes**

<table>
<thead>
<tr>
<th>env</th>
<th>(Jinja2 Environment)</th>
</tr>
</thead>
<tbody>
<tr>
<td>template</td>
<td>(Jinja2 Template)</td>
</tr>
<tr>
<td>loader</td>
<td>(Jinja2 Loader)</td>
</tr>
</tbody>
</table>

**Methods**

- **apply(func[, axis, subset])** Apply a function column-wise, row-wise, or table-wise, updating the HTML representation with the result.
- **applymap(func[, subset])** Apply a function elementwise, updating the HTML representation with the result.
- **background\_gradient([cmap, low, high, axis, ...])** Color the background in a gradient according to the data in each column (optionally row).
- **bar([subset, axis, color, width, align])** Color the background color proportional to the values in each column.
- **clear()** “Reset” the styler, removing any previously applied styles.
- **export()** Export the styles to applied to the current Styler.
- **format(formatter[, subset])** Format the text display value of cells.
- **from\_custom\_template(searchpath, name)** Factory function for creating a subclass of Styler with a custom template and Jinja environment.
- **hide\_columns(subset)** Hide columns from rendering.
- **hide\_index()** Hide any indices from rendering.
- **highlight\_max([subset, color, axis])** Highlight the maximum by shading the background
- **highlight\_min([subset, color, axis])** Highlight the minimum by shading the background
- **highlight\_null([null\_color])** Shade the background null\_color for missing values.
- **render(****kwargs)** Render the built up styles to HTML
- **set\_caption(caption)** Set the caption on a Styler

</tbody>
</table>

**pandas.io.formats.style.Styler.apply**

Styler.apply (func, axis=0, subset=None, **kwargs)

Apply a function column-wise, row-wise, or table-wise, updating the HTML representation with the result.

**Parameters**

- **func**: function
  
  `func` should take a Series or DataFrame (depending on `axis`), and return an object with the same shape. Must return a DataFrame with identical index and column labels when `axis=None`.

  - **axis**: int, str or None
    
    apply to each column (`axis=0` or `'index'`) or to each row (`axis=1` or `'columns'`) or to the entire DataFrame at once with `axis=None`.

  - **subset**: IndexSlice
    
    a valid indexer to limit data to before applying the function. Consider using a pandas.IndexSlice.

  - **kwargs**: dict
    
    pass along to `func`

**Returns**

- `self` [Styler]

**Notes**

The output shape of `func` should match the input, i.e. if `x` is the input row, column, or table (depending on `axis`), then `func(x.shape) == x.shape` should be true.

This is similar to DataFrame.apply, except that `axis=None` applies the function to the entire DataFrame at once, rather than column-wise or row-wise.
Examples

```python
>>> def highlight_max(x):
...     return [f'background-color: yellow' if v == x.max() else ''
...     for v in x]
...
>>> df = pd.DataFrame(np.random.randn(5, 2))
>>> df.style.apply(highlight_max)
```

**pandas.io.formats.style.Styler.applymap**

Styler.applymap (func, subset=None, **kwargs)

Apply a function elementwise, updating the HTML representation with the result.

- **Parameters**
  - `func`: function
    - `func` should take a scalar and return a scalar
  - `subset`: IndexSlice
    - a valid indexer to limit data to before applying the function. Consider using a pandas.IndexSlice
  - `kwargs`: dict
    - pass along to `func`

- **Returns**
  - `self` [Styler]

See also:

Styler.where

**pandas.io.formats.style.Styler.background_gradient**

Styler.background_gradient (cmap='PuBu', low=0, high=0, axis=0, subset=None)

Color the background in a gradient according to the data in each column (optionally row). Requires matplotlib.

- **Parameters**
  - `cmap`: str or colormap
    - matplotlib colormap
  - `low`, `high`: float
    - compress the range by these values.
  - `axis`: int or str
    - 1 or ‘columns’ for columnwise, 0 or ‘index’ for rowwise
  - `subset`: IndexSlice
    - a valid slice for data to limit the style application to

- **Returns**
  - `self` [Styler]
Notes

Tune low and high to keep the text legible by not using the entire range of the color map. These extend
the range of the data by low * (x.max() - x.min()) and high * (x.max() - x.min())
before normalizing.

**pandas.io.formats.style.Styler.bar**

Styler.bar(subset=None, axis=0, color='#d65f5f', width=100, align='left')

Color the background color proportional to the values in each column. Excludes non-numeric data by
default.

**Parameters**

- **subset**: IndexSlice, default None
  - A valid slice for data to limit the style application to
- **axis**: int
- **color**: str or 2-tuple/list
  - If a str is passed, the color is the same for both negative and positive numbers. If
    2-tuple/list is used, the first element is the color_negative and the second is the
    color_positive (eg: ['#d65f5f', '#5fba7d'])
- **width**: float
  - A number between 0 or 100. The largest value will cover width percent of the
    cell’s width
- **align**: {'left', 'zero', 'mid'}, default ‘left’
  - 'left': the min value starts at the left of the cell
  - 'zero': a value of zero is located at the center of the cell
  - 'mid': the center of the cell is at (max-min)/2, or if values are all negative (positive)
    the zero is aligned at the right (left) of the cell

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.clear**

Styler.clear()

“Reset” the styler, removing any previously applied styles. Returns None.

**pandas.io.formats.style.Styler.export**

Styler.export()

Export the styles to applied to the current Styler. Can be applied to a second style with Styler.use.

**Returns**

styles: list
See also:

Styler.use

pandas.io.formats.style.Styler.format

Styler.format (formatter, subset=None)

Format the text display value of cells.

New in version 0.18.0.

Parameters

- **formatter**: str, callable, or dict
- **subset**: IndexSlice

  An argument to DataFrame.loc that restricts which elements formatter is applied to.

Returns

self [Styler]

Notes

formatter is either an a or a dict {column name: a} where a is one of

- str: this will be wrapped in: a.format(x)
- callable: called with the value of an individual cell

The default display value for numeric values is the “general” (g) format with pd.options.display.precision.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(4, 2), columns=['a', 'b'])
>>> df.style.format("{:.2%}")
>>> df['c'] = ['a', 'b', 'c', 'd']
>>> df.style.format({'c': str.upper})
```

pandas.io.formats.style.Styler.from_custom_template

classmethod Styler.from_custom_template (searchpath, name)

Factory function for creating a subclass of Styler with a custom template and Jinja environment.

Parameters

- **searchpath**: str or list
  
  Path or paths of directories containing the templates

- **name**: str
  
  Name of your custom template to use for rendering

Returns

MyStyler : subclass of Styler

has the correct env and template class attributes set.
**pandas.io.formats.style.Styler.hide_columns**

Styler.hide_columns(subset)
Hide columns from rendering.
New in version 0.23.0.

**Parameters**

- **subset**: IndexSlice
  An argument to DataFrame.loc that identifies which columns are hidden.

**Returns**

- self [Styler]

**pandas.io.formats.style.Styler.hide_index**

Styler.hide_index()
Hide any indices from rendering.
New in version 0.23.0.

**Returns**

- self [Styler]

**pandas.io.formats.style.Styler.highlight_max**

Styler.highlight_max(subset=None, color='yellow', axis=0)
Highlight the maximum by shading the background

**Parameters**

- **subset**: IndexSlice, default None
  a valid slice for data to limit the style application to

- **color**: str, default ‘yellow’

- **axis**: int, str, or None; default 0
  0 or ‘index’ for columnwise (default), 1 or ‘columns’ for rowwise, or None for tablewise

**Returns**

- self [Styler]

**pandas.io.formats.style.Styler.highlight_min**

Styler.highlight_min(subset=None, color='yellow', axis=0)
Highlight the minimum by shading the background

**Parameters**

- **subset**: IndexSlice, default None
  a valid slice for data to limit the style application to

- **color**: str, default ‘yellow’

- **axis**: int, str, or None; default 0
0 or ‘index’ for columnwise (default), 1 or ‘columns’ for rowwise, or None for tablewise

Returns

self [Styler]

pandas.io.formats.style.Styler.highlight_null

Styler.highlight_null(null_color='red')
Shade the background null_color for missing values.

Parameters

null_color: str

Returns

self [Styler]

pandas.io.formats.style.Styler.render

Styler.render(**kwargs)
Render the built up styles to HTML

Parameters **kwargs:

Any additional keyword arguments are passed through to self.template.
render. This is useful when you need to provide additional variables for a
custom template.

New in version 0.20.

Returns rendered: str

the rendered HTML

Notes

Styler objects have defined the _repr_html_ method which automatically calls self.render() when it’s the last item in a Notebook cell. When calling Styler.render() directly, wrap the result in IPython.display.HTML to view the rendered HTML in the notebook.

Pandas uses the following keys in render. Arguments passed in **kwargs take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- precision
- table_styles
- caption
- table_attributes
**pandas.io.formats.style.Styler.set_caption**

Styler.set_caption(caption)

Set the caption on a Styler

**Parameters**

- caption: str

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.set_precision**

Styler.set_precision(precision)

Set the precision used to render.

**Parameters**

- precision: int

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.set_properties**

Styler.set_properties(subset=None, **kwargs)

Convenience method for setting one or more non-data dependent properties or each cell.

**Parameters**

- subset: IndexSlice

- **kwargs**: property: value pairs to be set for each cell

**Returns**

self [Styler]

**Examples**

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{"background-color": "yellow"})
```

**pandas.io.formats.style.Styler.set_table_attributes**

Styler.set_table_attributes(attributes)

Set the table attributes. These are the items that show up in the opening <table> tag in addition to automatic (by default) id.

**Parameters**

- attributes:
attributes [string]

Returns

self [Styler]

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

**pandas.io.formats.style.Styler.set_table_styles**

Styler.set_table_styles(table_styles)

Set the table styles on a Styler. These are placed in a <style> tag before the generated HTML table.

Parameters table_styles: list

Each individual table_style should be a dictionary with selector and props keys. selector should be a CSS selector that the style will be applied to (automatically prefixed by the table’s UUID) and props should be a list of tuples with (attribute, value).

Returns

self [Styler]

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_styles(
... [{'selector': 'tr:hover',
... 'props': [('background-color', 'yellow')]}]
... )
```

**pandas.io.formats.style.Styler.set_uuid**

Styler.set_uuid(uuid)

Set the uuid for a Styler.

Parameters

uuid: str

Returns

self [Styler]
**pandas.io.formats.style.Styler.to_excel**

**Styler.to_excel** *(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)*

Write Styler to an excel sheet

New in version 0.20.

**Parameters**

- **excel_writer**: string or ExcelWriter object
  - File path or existing ExcelWriter
- **sheet_name**: string, default ‘Sheet1’
  - Name of sheet which will contain DataFrame
- **na_rep**: string, default ‘’
  - Missing data representation
- **float_format**: string, default None
  - Format string for floating point numbers
- **columns**: sequence, optional
  - Columns to write
- **header**: boolean or list of string, default True
  - Write out the column names. If a list of strings is given it is assumed to be aliases for the column names
- **index**: boolean, default True
  - Write row names (index)
- **index_label**: string or sequence, default None
  - Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow**: 
  - upper left cell row to dump data frame
- **startcol**: 
  - upper left cell column to dump data frame
- **engine**: string, default None
  - write engine to use - you can also set this via the options io.excel.xlsx.writer, io.excel.xls.writer, and io.excel.xlsm.writer.
- **merge_cells**: boolean, default True
  - Write MultiIndex and Hierarchical Rows as merged cells.
- **encoding**: string, default None
  - encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- **inf_rep**: string, default ‘inf’
Representation for infinity (there is no native representation for infinity in Excel)

**freeze_panes**: tuple of integer (length 2), default None

Specifies the one-based bottommost row and rightmost column that is to be frozen

New in version 0.20.0.

**Notes**

If passing an existing ExcelWriter object, then the sheet will be added to the existing workbook. This can be used to save different DataFrames to one workbook:

```python
>>> writer = pd.ExcelWriter('output.xlsx')
>>> df1.to_excel(writer, 'Sheet1')
>>> df2.to_excel(writer, 'Sheet2')
>>> writer.save()
```

For compatibility with to_csv, to_excel serializes lists and dicts to strings before writing.

**pandas.io.formats.style.Styler.use**

Styler.use(styless)

Set the styles on the current Styler, possibly using styles from Styler.export.

**Parameters**

- **styles**: list

  list of style functions

**Returns**

- **self** [Styler]

**See also:**

Styler.export

**pandas.io.formats.style.Styler.where**

Styler.where(cond, value=None, other=None, subset=None, **kwargs)

Apply a function elementwise, updating the HTML representation with a style which is selected in accordance with the return value of a function.

New in version 0.21.0.

**Parameters**

- **cond**: callable

  cond should take a scalar and return a boolean

- **value**: str

  applied when cond returns true

- **other**: str

  applied when cond returns false

- **subset**: IndexSlice

  a valid indexer to limit data to before applying the function. Consider using a pandas.IndexSlice
kwarg : dict

   pass along to cond

Returns

self [Styler]

See also:

Styler.applymap

34.19.2 Styler Attributes

Styler.env
Styler.template
Styler.loader

34.19.2.1 pandas.io.formats.style.Styler.env

Styler.env = <jinja2.environment.Environment object>

34.19.2.2 pandas.io.formats.style.Styler.template

Styler.template = <Template 'html.tpl'>

34.19.2.3 pandas.io.formats.style.Styler.loader

Styler.loader = <jinja2.loaders.PackageLoader object>

34.19.3 Style Application

Styler.apply(func[, axis, subset]) Apply a function column-wise, row-wise, or table-wise, updating the HTML representation with the result.

Styler.applymap(func[, subset]) Apply a function elementwise, updating the HTML representation with the result.

Styler.where(cond, value[, other, subset]) Apply a function elementwise, updating the HTML representation with a style which is selected in accordance with the return value of a function.

Styler.format(formatter[, subset]) Format the text display value of cells.

Styler.set_precision(precision) Set the precision used to render.

Styler.set_table_styles(table_styles) Set the table styles on a Styler.

Styler.set_table_attributes(attributes) Set the table attributes.

Styler.set_caption(caption) Set the caption on a Styler.

Styler.set_properties([subset]) Convenience method for setting one or more non-data dependent properties or each cell.

Styler.set_uuid(uuid) Set the uuid for a Styler.

Styler.clear() “Reset” the styler, removing any previously applied styles.
34.19.4 Built-in Styles

<table>

<td>Register Pandas Formatters and Converters with matplotlib</td>
</tr>
<tr>
<td><code>scatter_matrix(frame[, alpha, figsize, ax, ...])</code></td>
<td>Draw a matrix of scatter plots.</td>
</tr>
</tbody>
</table>

34.20.1 `pandas.plotting.andrews_curves`

`pandas.plotting.andrews_curves(frame, class_column, ax=None, samples=200, color=None, colormap=None, **kwds)`

Generates a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

\[ f(t) = x_1/\sqrt{2} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \ldots \]

Where \( x \) coefficients correspond to the values of each dimension and \( t \) is linearly spaced between -\( \pi \) and +\( \pi \). Each row of frame then corresponds to a single curve.

**Parameters**

- `frame`: DataFrame
Data to be plotted, preferably normalized to (0.0, 1.0)

class_column [Name of the column containing class names]
ax [matplotlib axes object, default None]
samples [Number of points to plot in each curve]

color: list or tuple, optional
Colors to use for the different classes

colormap : str or matplotlib colormap object, default None
Colormap to select colors from. If string, load colormap with that name from matplotlib.

kwds: keywords
Options to pass to matplotlib plotting method

Returns
ax: Matplotlib axis object

34.20.2 pandas.plotting.bootstrap_plot

pandas.plotting.bootstrap_plot (series, fig=None, size=50, samples=500, **kwds)
Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relaying on random sampling with replacement [R33]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

Parameters series : pandas.Series
Pandas Series from where to get the samplings for the bootstrapping.

fig : matplotlib.figure.Figure, default None
If given, it will use the fig reference for plotting instead of creating a new one with default parameters.

size : int, default 50
Number of data points to consider during each sampling. It must be greater or equal than the length of the series.

samples : int, default 500
Number of times the bootstrap procedure is performed.

**kwds :
Options to pass to matplotlib plotting method.

Returns fig : matplotlib.figure.Figure
Matplotlib figure

See also:
pandas.DataFrame.plot Basic plotting for DataFrame objects.
pandas.Series.plot Basic plotting for Series objects.
Examples

```python
>>> import numpy as np
>>> s = pd.Series(np.random.uniform(size=100))
>>> fig = pd.plotting.bootstrap_plot(s)
```

34.20.3 pandas.plotting.deregister_matplotlib_converters

```python
pandas.plotting.deregister_matplotlib_converters()
```

Remove pandas' formatters and converters

Removes the custom converters added by register(). This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas' own types like Timestamp and Period are removed completely. Converters for types pandas overwrites, like datetime.datetime, are restored to their original value.

See also:

deregister_matplotlib_converters

34.20.4 pandas.plotting.lag_plot

```python
pandas.plotting.lag_plot(series, lag=1, ax=None, **kwds)
```

Lag plot for time series.

Parameters

- `series`: Time series
- `lag`: lag of the scatter plot, default 1
- `ax`: Matplotlib axis object, optional
- `kwds`: Matplotlib scatter method keyword arguments, optional

Returns

- `ax`: Matplotlib axis object

34.20.5 pandas.plotting.parallel_coordinates

```python
pandas.plotting.parallel_coordinates(frame, class_column, cols=None, ax=None, color=None, use_columns=False, xticks=None, colormap=None, axvlines=True, axvlines_kwds=None, sort_labels=False, **kwds)
```

Parallel coordinates plotting.

Parameters

- `frame`: DataFrame
- `class_column`: str
  Column name containing class names
- `cols`: list, optional
  A list of column names to use
pandas: powerful Python data analysis toolkit, Release 0.23.3

ax: matplotlib.axis, optional
    matplotlib axis object

color: list or tuple, optional
    Colors to use for the different classes

use_columns: bool, optional
    If true, columns will be used as xticks

xticks: list or tuple, optional
    A list of values to use for xticks

colormap: str or matplotlib colormap, default None
    Colormap to use for line colors.

axvlines: bool, optional
    If true, vertical lines will be added at each xtick

axvlines_kwds: keywords, optional
    Options to be passed to axvline method for vertical lines

sort_labels: bool, False
    Sort class_column labels, useful when assigning colors
    New in version 0.20.0.

kwds: keywords
    Options to pass to matplotlib plotting method

Returns

ax: matplotlib axis object

Examples

```python
>>> from pandas import read_csv
>>> from pandas.tools.plotting import parallel_coordinates
>>> from matplotlib import pyplot as plt
>>> df = read_csv('https://raw.github.com/pandas-dev/pandas/master/pandas/tests/data/iris.csv')
>>> parallel_coordinates(df, 'Name', color=('#556270', '#4ECDC4', '#C7F464'))
>>> plt.show()
```

34.20.6 pandas.plotting.radviz

pandas.plotting.radviz(frame, class_column, ax=None, color=None, colormap=None, **kwds)
    Plot a multidimensional dataset in 2D.

    Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated Series in the DataFrame are placed closer on the unit circle.
RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the original article describing RadViz.

**Parameters**

- **frame**: `DataFrame`
  - Pandas object holding the data.
- **class_column**: `str`
  - Column name containing the name of the data point category.
- **ax**: `matplotlib.axes.Axes`, optional
  - A plot instance to which to add the information.
- **color**: list[str] or tuple[str], optional
  - Assign a color to each category. Example: ['blue', 'green'].
- **colormap**: str or `matplotlib.colors.Colormap`, default None
  - Colormap to select colors from. If string, load colormap with that name from matplotlib.
- **kwds**: optional
  - Options to pass to matplotlib scatter plotting method.

**Returns**

- **axes**: [matplotlib.axes.Axes]

**See also:**

- `pandas.plotting.andrews_curves` Plot clustering visualization

**Examples**

```python
>>> df = pd.DataFrame({
...   'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
...   'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
...   'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
...   'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
...   'Category': ['virginica', 'virginica', 'setosa', 'virginica', 'virginica', 'versicolor', 'versicolor', 'setosa', 'virginica', 'setosa']
... })
>>> rad_viz = pd.plotting.radviz(df, 'Category')
```
This function modifies the global `matplotlib.units.registry` dictionary. Pandas adds custom converters for

- `pd.Timestamp`
- `pd.Period`
- `np.datetime64`
- `datetime.datetime`
- `datetime.date`
- `datetime.time`

**See also:**

deregister_matplotlib_converter

### 34.20.8 pandas.plotting.scatter_matrix

#### pandas.plotting.scatter_matrix(frame, alpha=0.5, figsize=None, ax=None, grid=False, diagonal='hist', marker='.', density_kwds=None, hist_kwds=None, range_padding=0.05, **kwds)

Draw a matrix of scatter plots.

**Parameters**

- **frame** [DataFrame]
- **alpha** : float, optional
  amount of transparency applied
- **figsize** : (float, float), optional
  a tuple (width, height) in inches
- **ax** [Matplotlib axis object, optional]
- **grid** : bool, optional
  setting this to True will show the grid
- **diagonal** : {'hist', 'kde'}
  pick between 'kde' and 'hist' for either Kernel Density Estimation or Histogram plot in the diagonal
- **marker** : str, optional
  Matplotlib marker type, default ‘.’
- **hist_kwds** : other plotting keyword arguments
  To be passed to hist function
- **density_kwds** : other plotting keyword arguments
  To be passed to kernel density estimate plot
- **range_padding** : float, optional
  relative extension of axis range in x and y with respect to \((x_{\text{max}} - x_{\text{min}})\) or \((y_{\text{max}} - y_{\text{min}})\), default 0.05
kwds : other plotting keyword arguments

To be passed to scatter function

Examples

```python
>>> df = DataFrame(np.random.randn(1000, 4), columns=['A','B','C','D'])
>>> scatter_matrix(df, alpha=0.2)
```

34.21 General utility functions

34.21.1 Working with options

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>describe_option</code></td>
<td>Prints the description for one or more registered options.</td>
</tr>
<tr>
<td><code>reset_option</code></td>
<td>Reset one or more options to their default value.</td>
</tr>
<tr>
<td><code>get_option</code></td>
<td>Retrieves the value of the specified option.</td>
</tr>
<tr>
<td><code>set_option</code></td>
<td>Sets the value of the specified option.</td>
</tr>
<tr>
<td><code>option_context</code></td>
<td>Context manager to temporarily set options in the with statement context.</td>
</tr>
</tbody>
</table>

34.21.1.1 pandas.describe_option

```python
pandas.describe_option(pat[, _print_desc]) = <pandas.core.config.CallableDynamicDoc object>
```

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:

- `compute.[use_bottleneck, use_numexpr]`
- `display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html.[border, table_schema, use_mathjax]`
- `display.[large_repr]`
- `display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode.[ambiguous_as_wide, east_asian_width]`
- `display.[width]`
- `html.[border]`
- `io.excel.xls.[writer]`
- `io.excel.xlsm.[writer]`
- `io.excel.xlsx.[writer]`
• io.hdf.[default_format, dropna_table]
• io.parquet.[engine]
• mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
• plotting.matplotlib.[register_converters]

Parameters

pat : str
    Regexp pattern. All matching keys will have their description displayed.

_print_desc : bool, default True
    If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

Returns

None by default, the description(s) as a unicode string if _print_desc is False

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True
    Valid values: False,True [default: True] [currently: True]

compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
    Valid values: False,True [default: True] [currently: True]

display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

display.colheader_justify ['left' / 'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

display.column_space No description available. [default: 12] [currently: 12]

display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]

display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

2352 Chapter 34. API Reference
display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

display.large_repr [‘truncate’/’info’] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]

display.latex.longtable: bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False, True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

display.max_seq_items [int or None] when pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string. If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]
display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’) Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1] (Deprecated, use display.html.border instead.)

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
mode.use_inf_as_null  [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.matplotlib.register_converters  [bool] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]

34.21.1.2 pandas.reset_option

pandas.reset_option (pat) = <pandas.core.config.CallableDynamicDoc object>
Reset one or more options to their default value.

Pass “all” as argument to reset all options.

Available options:
- compute.[use_bottleneck, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- html.[border]
- io.excel.xls.[writer]
- io.excel.xlsm.[writer]
- io.excel.xlsx.[writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.matplotlib.[register_converters]

Parameters pat : str/regex
If specified only options matching prefix* will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns
None
Notes

The available options with their descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]

- **display.chop_threshold** [float or None] If set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

- **display.column_space** No description available. [default: 12] [currently: 12]

- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]

- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. [default: False] [default: False] [currently: False]

- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. [default: True] [default: True] [currently: True]

- **display.large_repr** ['truncate’/’info’] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

- **display.large_repr** ['truncate’/’info’] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]

- **display.latex.longtable**:bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: False] [currently: False]

- **display.latex.multicolumn**:bool This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]

- **display.latex.multicolumn_format**:bool This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: 1] [currently: 1]
display.latex.multirow  [bool] This specifies if the to_latex method of a DataFrame uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr  [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories  [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

display.max_columns  [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth  [int] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. [default: 50] [currently: 50]

display.max_info_columns  [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows  [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows  [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

display.max_seq_items  [int or None] when pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage  [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

display.multi_sparse  [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html  [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth  [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision  [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

display.show_dimensions  [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide  [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
pandas: powerful Python data analysis toolkit, Release 0.23.3

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1] (Deprecated, use display.html.border instead.)
io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)
plotting.matplotlib.register_converters [bool] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]

34.21.1.3 pandas.get_option

pandas.get_option(pat) = <pandas.core.config.CallableDynamicDoc object>
Retrieves the value of the specified option.

Available options:
• compute.[use_bottleneck, use_numexpr]
• display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
• display.html.[border, table_schema, use_mathjax]
• display.[large_repr]
Parameters `pat` : str

Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

`result` [the value of the option]

Raises

`OptionError` [if no such option exists]

Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **display.chop_threshold** [float or None] If set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- **display.colheader_justify** ["left"/'right"] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- **display.column_space** No description available. [default: 12] [currently: 12]
- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

34.21. General utility functions
display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]

display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

display.large_repr ['truncate’/’info’) For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: False] [currently: True]

display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
**display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

**display.max_rows** [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

**display.max_seq_items** [int or None] when pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

**display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True, False, ‘deep’ [default: True] [currently: True]

**display.multi_sparse** [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

**display.notebook_repr_html** [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

**display.pprint_nest_depth** [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

**display.precision** [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

**display.show_dimensions** [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

**display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

**html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1] (Deprecated, use display.html.border instead.)

**io.hdf.default_format** [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)
plotting.matplotlib.register_converters [bool] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]

34.21.1.4 pandas.set_option

pandas.set_option (pat, value) = <pandas.core.config.CallableDynamicDoc object>
Sets the value of the specified option.
Available options:
• compute.[use_bottleneck, use_numexpr]
• display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
• display.html.[border, table_schema, use_mathjax]
• display.[large_repr]
• display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
• display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
• display.unicode.[ambiguous_as_wide, east_asian_width]
• display.[width]
• html.[border]
• io.excel.xls.[writer]
• io.excel.xlsm.[writer]
• io.excel.xlsx.[writer]
• io.hdf.[default_format, dropna_table]
• io.parquet.[engine]
• mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
• plotting.matplotlib.[register_converters]
Parameters pat : str

Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

value :

new value of option.

Returns

None

Raises

OptionError if no such option exists

Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
  Valid values: False,True [default: True] [currently: True]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
  Valid values: False,True [default: True] [currently: True]

- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFor-
  matter. [default: right] [currently: right]

- **display.column_space** No description available. [default: 12] [currently: 12]

- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default:
  False] [currently: False]

- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default:
  False] [currently: False]

- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be
  used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]

- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames
  across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame
  HTML repr. [default: 1] [currently: 1]

- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using Math-
  Jax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
pandas: powerful Python data analysis toolkit, Release 0.23.3

**display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

**display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]

**display.latex.longtable** :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

**display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

**display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

**display.latex.multirow** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

**display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

**display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

**display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

**display.max_colwidth** [int] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. [default: 50] [currently: 50]

**display.max_info_columns** [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

**display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

**display.max_rows** [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

**display.max_seq_items** [int or None] when pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

**display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

**display.multi_sparse** [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html  [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth  [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
display.precision  [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]
display.show_dimensions  [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide  [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.unicode.east_asian_width  [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.width  [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

html.border  [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1] (Deprecated, use display.html.border instead.)
io.hdf.default_format  [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table  [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment  [string] Raise an exception, warn, or no action if trying to use chained assignment. The default is warn [default: warn] [currently: warn]

mode.sim_interactive  [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na  [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null  [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.matplotlib.register_converters  [bool] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]
34.21.1.5 pandas.option_context

**class pandas.option_context(**args)**

Context manager to temporarily set options in the with statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...])`.

**Examples**

```python
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...    ...
```

34.21.2 Testing functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>testing.assert_frame_equal(left, right[, ...])</code></td>
<td>Check that left and right DataFrame are equal.</td>
</tr>
<tr>
<td><code>testing.assert_series_equal(left, right[, ...])</code></td>
<td>Check that left and right Series are equal.</td>
</tr>
<tr>
<td><code>testing.assert_index_equal(left, right[, ...])</code></td>
<td>Check that left and right Index are equal.</td>
</tr>
</tbody>
</table>

34.21.2.1 pandas.testing.assert_frame_equal

```python
pandas.testing.assert_frame_equal(left, right, check_dtype=True, check_index_type='equiv', check_column_type='equiv', check_frame_type=True, check_less_precise=False, by_blocks=False, check_datetimelike_compat=False, check_categorical=True, check_like=False, obj='DataFrame')
```

Check that left and right DataFrame are equal.

**Parameters**

- `left` [DataFrame]
- `right` [DataFrame]
- `check_dtype` : bool, default True
  
  Whether to check the DataFrame dtype is identical.
- `check_index_type` : bool / string `{equiv}`, default False
  
  Whether to check the Index class, dtype and inferred_type are identical.
- `check_column_type` : bool / string `{equiv}`, default False
  
  Whether to check the columns class, dtype and inferred_type are identical.
- `check_frame_type` : bool, default False
  
  Whether to check the DataFrame class is identical.
- `check_less_precise` : bool or int, default False
  
  Whether to check the DataFrame are less precise.
Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare

**check_names** : bool, default True
Whether to check the Index names attribute.

**by_blocks** : bool, default False
Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

**check_exact** : bool, default False
Whether to compare number exactly.

**check_datetime_like_compat** : bool, default False
Compare datetime-like which is comparable ignoring dtype.

**check_categorical** : bool, default True
Whether to compare internal Categorical exactly.

**check_like** : bool, default False
If true, ignore the order of rows & columns

**obj** : str, default ‘DataFrame’
Specify object name being compared, internally used to show appropriate assertion message

### 34.21.2.2 pandas.testing.assert_series_equal

`pandas.testing.assert_series_equal(left, right, check_dtype=True, check_index_type='equiv', check_series_type=True, check_less_precise=False, check_names=True, check_exact=True, check_datetime_like_compat=False, check_categorical=True, obj='Series')`

Check that left and right Series are equal.

**Parameters**

- **left** [Series]
- **right** [Series]

**check_dtype** : bool, default True
Whether to check the Series dtype is identical.

**check_index_type** : bool / string (`'equiv'`), default `equiv`
Whether to check the Index class, dtype and inferred_type are identical.

**check_series_type** : bool, default True
Whether to check the Series class is identical.

**check_less_precise** : bool or int, default False
Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare

---

**34.21. General utility functions**

2367
check_exact : bool, default False
    Whether to compare number exactly.
check_names : bool, default True
    Whether to check the Series and Index names attribute.
check_datetimelike_compat : bool, default False
    Compare datetime-like which is comparable ignoring dtype.
check_categorical : bool, default True
    Whether to compare internal Categorical exactly.
obj : str, default ‘Series’
    Specify object name being compared, internally used to show appropriate assertion message

34.21.2.3 pandas.testing.assert_index_equal

pandas.testing.assert_index_equal(left, right, exact='equiv', check_names=True, check_less_precise=False, check_exact=True, check_categorical=True, obj='Index')

Check that left and right Index are equal.

Parameters

left [Index]
right [Index]
exact : bool / string {‘equiv’}, default False
    Whether to check the Index class, dtype and inferred_type are identical. If ‘equiv’, then RangeIndex can be substituted for Int64Index as well.
check_names : bool, default True
    Whether to check the names attribute.
check_less_precise : bool or int, default False
    Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare
check_exact : bool, default True
    Whether to compare number exactly.
check_categorical : bool, default True
    Whether to compare internal Categorical exactly.
obj : str, default ‘Index’
    Specify object name being compared, internally used to show appropriate assertion message

34.21.3 Exceptions and warnings
### pandas.errors.DtypeWarning

**Warning raised when reading different dtypes in a column from a file.**

**Raised for a dtype incompatibility.** This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

**See also:**

- `pandas.read_csv` Read CSV (comma-separated) file into a DataFrame.
- `pandas.read_table` Read general delimited file into a DataFrame.

**Notes**

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

**Examples**

This example creates and reads a large CSV file with a column that contains `int` and `str`.

```python
>>> df = pd.DataFrame({'a': ([1] * 100000 + ['X'] * 100000 +
... ['1'] * 100000),
... 'b': ['b'] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types
```

Important to notice that `df2` will contain both `str` and `int` for the same input, ‘1’.

---

**34.21.3.1 pandas.errors.DtypeWarning**

- **exception** `pandas.errors.DtypeWarning`
  - Warning raised when reading different dtypes in a column from a file.
  - Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.
  - **See also:**
    - `pandas.read_csv` Read CSV (comma-separated) file into a DataFrame.
    - `pandas.read_table` Read general delimited file into a DataFrame.

- **Notes**
  - This warning is issued when dealing with larger files because the dtype checking happens per chunk read.
  - Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

- **Examples**
  - This example creates and reads a large CSV file with a column that contains `int` and `str`.
    ```python
    >>> df = pd.DataFrame({'a': ([1] * 100000 + ['X'] * 100000 +
    ... ['1'] * 100000),
    ... 'b': ['b'] * 300000})
    >>> df.to_csv('test.csv', index=False)
    >>> df2 = pd.read_csv('test.csv')
    ... # DtypeWarning: Columns (0) have mixed types
    ```
  - Important to notice that `df2` will contain both `str` and `int` for the same input, ‘1’.
One way to solve this issue is using the `dtype` parameter in the `read_csv` and `read_table` functions to explicit the conversion:

```python
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})
No warning was issued.
```

### 34.21.3.2 pandas.errors.EmptyDataError

**exception pandas.errors.EmptyDataError**

Exception that is thrown in `pd.read_csv` (by both the C and Python engines) when empty data or header is encountered.

### 34.21.3.3 pandas.errors.OutOfBoundsDatetime

**exception pandas.errors.OutOfBoundsDatetime**

### 34.21.3.4 pandas.errors.ParserError

**exception pandas.errors.ParserError**

Exception that is raised by an error encountered in `pd.read_csv`.

### 34.21.3.5 pandas.errors.ParserWarning

**exception pandas.errors.ParserWarning**

Warning raised when reading a file that doesn’t use the default ‘c’ parser.

Raised by `pd.read_csv` and `pd.read_table` when it is necessary to change parsers, generally from the default ‘c’ parser to ‘python’.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, ‘c’ unsupported options include the following parameters:

1. `sep` other than a single character (e.g. regex separators)
2. `skipfooter` higher than 0
3. `sep=None` with `rim_whitespace=False`
The warning can be avoided by adding `engine='python'` as a parameter in `pd.read_csv` and `pd.read_table` methods.

See also:

- **pd.read_csv** Read CSV (comma-separated) file into DataFrame.
- **pd.read_table** Read general delimited file into DataFrame.

### Examples

Using a `sep` in `pd.read_csv` other than a single character:

```python
>>> import io
>>> csv = u'''a;b;c
... 1;1,8
... 1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]')
... # ParserWarning: Falling back to the 'python' engine...
```

Adding `engine='python'` to `pd.read_csv` removes the Warning:

```python
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]', engine='python')
```

## pandas.errors.PerformanceWarning

**exception pandas.errors.PerformanceWarning**

Warning raised when there is a possible performance impact.

## pandas.errors.UnsortedIndexError

**exception pandas.errors.UnsortedIndexError**

Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of `KeyError`.

New in version 0.20.0.

## pandas.errors.UnsupportedFunctionCall

**exception pandas.errors.UnsupportedFunctionCall**

Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

### Data types related functionality

| api.types.union_categoricals(to_union[, ...,]) | Combine list-like of Categorical-like, unioning categories. |
| api.types.infer_dtype | Efficiently infer the type of a passed val, or list-like array of values. |

Continued on next page
Table 184 – continued from previous page

| api.types.pandas_dtype (dtype) | Converts input into a pandas only dtype object or a numpy dtype object. |

34.21.4.1 pandas.api.types.union_categoricals

**pandas.api.types.union_categoricals**

Parameters `to_union` : list-like of Categorical, CategoricalIndex, or Series with dtype='category'

`sort_categories` : boolean, default False

If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.

`ignore_order` : boolean, default False

If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

New in version 0.20.0.

Returns

`result` [Categorical]

Raises **TypeError**

• all inputs do not have the same dtype
• all inputs do not have the same ordered property
• all inputs are ordered and their categories are not identical
• sort_categories=True and Categoricals are ordered

**ValueError**

Empty list of categoricals passed

Notes

To learn more about categories, see link

Examples

```python
>>> from pandas.api.types import union_categoricals

If you want to combine categoricals that do not necessarily have the same categories, union_categoricals will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

>>> a = pd.Categorical(["b", "c"])
>>> b = pd.Categorical(["a", "b"])
>>> union_categoricals([a, b])
```
By default, the resulting categories will be ordered as they appear in the categories of the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python
>>> union_categoricals([a, b], sort_categories=True)
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also `append` for).

```python
>>> a = pd.Categorical(['a', 'b'], ordered=True)
>>> b = pd.Categorical(['a', 'b', 'a'], ordered=True)
>>> union_categoricals([a, b])
[a, b, a, b, a]
Categories (2, object): [a < b]
```

Raises `TypeError` because the categories are ordered and not identical.

```python
>>> a = pd.Categorical(['a', 'b'], ordered=True)
>>> b = pd.Categorical(['a', 'b', 'c'], ordered=True)
>>> union_categoricals([a, b])
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
>>> a = pd.Categorical(['a', 'b', 'c'], ordered=True)
>>> b = pd.Categorical(['c', 'b', 'a'], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`.

```python
>>> a = pd.Series(['b', 'c'], dtype='category')
>>> b = pd.Series(['a', 'b'], dtype='category')
>>> union_categoricals([a, b])
```

### 34.21.4.2 pandas.api.types.infer_dtype

`pandas.api.types.infer_dtype()`

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

**Parameters**

- `value` [scalar, list, ndarray, or pandas type]
- `skipna` : bool, default False
Ignore NaN values when inferring the type. The default of \texttt{False} will be deprecated in a later version of pandas.

New in version 0.21.0.

**Returns**

string describing the common type of the input data.

Results can include:

- string
- unicode
- bytes
- floating
- integer
- mixed-integer
- mixed-integer-float
- decimal
- complex
- categorical
- boolean
- datetime64
- datetime
- date
- timedelta64
- timedelta
- time
- period
- mixed

**Raises**

\texttt{TypeError} if ndarray-like but cannot infer the dtype

**Notes**

- ‘mixed’ is the catchall for anything that is not otherwise specialized
- ‘mixed-integer-float’ are floats and integers
- ‘mixed-integer’ are integers mixed with non-integers
### Examples

```python
>>> infer_dtypes(['foo', 'bar'])
'string'

>>> infer_dtypes(['a', np.nan, 'b'], skipna=True)
'string'

>>> infer_dtypes(['a', np.nan, 'b'], skipna=False)
'mixed'

>>> infer_dtypes([b'foo', b'bar'])
'bytes'

>>> infer_dtypes([1, 2, 3])
'integer'

>>> infer_dtypes([1, 2, 3.5])
'mixed-integer-float'

>>> infer_dtypes([1.0, 2.0, 3.5])
'floating'

>>> infer_dtypes(['a', 1])
'mixed-integer'

>>> infer_dtypes([Decimal(1), Decimal(2.0)])
'decimal'

>>> infer_dtypes([True, False])
'boolean'

>>> infer_dtypes([True, False, np.nan])
'mixed'

>>> infer_dtypes([pd.Timestamp('20130101')])
'datetime'

>>> infer_dtypes([datetime.date(2013, 1, 1)])
'date'

>>> infer_dtypes([np.datetime64('2013-01-01')])
'datetime64'

>>> infer_dtypes([datetime.timedelta(0, 1, 1)])
'timedelta'

>>> infer_dtypes(pd.Series(list('aabc')).astype('category'))
'categorical'
```
pandas: powerful Python data analysis toolkit, Release 0.23.3

34.21.4.3 pandas.api.types.pandas_dtype

```python
pandas.api.types.pandas_dtype(dtype)
```

Converts input into a pandas only dtype object or a numpy dtype object.

**Parameters**

dtype [object to be converted]

**Returns**

np.dtype or a pandas dtype

Dtype introspection

### 34.21.4.4 pandas.api.types.is_bool_dtype

**pandas.api.types.is_bool_dtype(arr_or_dtype)**

Check whether the provided array or dtype is of a boolean dtype.

**Parameters**
- **arr_or_dtype**: array-like

**The array or dtype to check.**

**Returns**
- **boolean**: [Whether or not the array or dtype is of a boolean dtype.]

**Examples**

```python
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
```

### 34.21.4.5 pandas.api.types.is_categorical_dtype

**pandas.api.types.is_categorical_dtype(arr_or_dtype)**

Check whether an array-like or dtype is of the Categorical dtype.

**Parameters**
- **arr_or_dtype**: array-like

**The array-like or dtype to check.**

**Returns**
- **boolean**: Whether or not the array-like or dtype is of the Categorical dtype.

**Examples**

```python
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
```

(continues on next page)
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True

34.21.4.6 pandas.api.types.is_complex_dtype

pandas.api.types.is_complex_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a complex dtype.

Parameters
arr_or_dtype: array-like
The array or dtype to check.

Returns

boolean [Whether or not the array or dtype is of a complex dtype.]

Examples

>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True

34.21.4.7 pandas.api.types.is_datetime64_any_dtype

pandas.api.types.is_datetime64_any_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64 dtype.

Parameters
arr_or_dtype: array-like
The array or dtype to check.

Returns

boolean [Whether or not the array or dtype is of the datetime64 dtype.]

Examples
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64)  # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3],
            dtype=np.datetime64))
True

34.21.4.8 pandas.api.types.is_datetime64_dtype

pandas.api.types.is_datetime64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype : array-like
The array-like or dtype to check.

Returns

boolean : Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False

34.21.4.9 pandas.api.types.is_datetime64_ns_dtype

pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype : array-like
The array or dtype to check.

Returns

boolean [Whether or not the array or dtype is of the datetime64[ns] dtype.]
### Examples

```python
>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64)  # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype=np.datetime64))  # no unit
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64[ps]"))  # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))  # has 'ns' unit
True
```

### 34.21.4.10 pandas.api.types.is_datetime64tz_dtype

**pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)**

Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

**Parameters**

- **arr_or_dtype**: array-like
  
The array-like or dtype to check.

**Returns**

- **boolean**: Whether or not the array-like or dtype is of a DatetimeTZDType dtype.

### Examples

```python
>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3]))  # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
```

```python
dtype = DatetimeTZDtype("ns", tz="US/Eastern")
s = pd.Series([], dtype=dtype)
is_datetime64tz_dtype(dtype)
True
is_datetime64tz_dtype(s)
True
```
34.21.4.11 pandas.api.types.is_extension_type

pandas.api.types.is_extension_type(arr)

Check whether an array-like is of a pandas extension class instance.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters arr : array-like

The array-like to check.

Returns boolean : Whether or not the array-like is of a pandas extension class instance.

Examples

```python
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>> cat = pd.Categorical([1, 2, 3])
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.SparseArray([1, 2, 3]))
True
>>> is_extension_type(pd.SparseSeries([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True
```

34.21.4.12 pandas.api.types.is_float_dtype

pandas.api.types.is_float_dtype(arr_or_dtype)

Check whether the provided array or dtype is of a float dtype.

Parameters arr_or_dtype : array-like

The array or dtype to check.

Returns
**boolean** [Whether or not the array or dtype is of a float dtype.]

### Examples

```python
>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True
```

#### 34.21.4.13 pandas.api.types.is_int64_dtype

**pandas.api.types.is_int64_dtype**

The array or dtype to check.

**Parameters**

- **arr_or_dtype**: array-like

**Returns**

- **boolean** [Whether or not the array or dtype is of the int64 dtype.]

### Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

### Examples

```python
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64)  # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.]))  # float
False
```
34.21.4.14 pandas.api.types.is_integer_dtype

pandas.api.types.is_integer_dtype(arr_or_dtype)
Check whether the provided array or dtypes is of an integer dtype.
Unlike in in_any_int_dtype, timedelta64 instances will return False.

Parameters

arr_or_dtype : array-like
The array or dtype to check.

Returns

boolean : Whether or not the array or dtype is of an integer dtype
and not an instance of timedelta64.

Examples

>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.])) # float
False

34.21.4.15 pandas.api.types.is_interval_dtype

pandas.api.types.is_interval_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Interval dtype.

Parameters

arr_or_dtype : array-like
The array-like or dtype to check.

Returns

boolean : Whether or not the array-like or dtype is of the Interval dtype.
Examples

```python
>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
```

### 34.21.4.16 pandas.api.types.is_numeric_dtype

**pandas.api.types.is_numeric_dtype(arr_or_dtype)**

Check whether the provided array or dtype is of a numeric dtype.

**Parameters**

- **arr_or_dtype**: array-like
  
The array or dtype to check.

**Returns**

- **boolean**: [Whether or not the array or dtype is of a numeric dtype.]

#### Examples

```python
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

### 34.21.4.17 pandas.api.types.is_object_dtype

**pandas.api.types.is_object_dtype(arr_or_dtype)**

Check whether an array-like or dtype is of the object dtype.
Parameters `arr_or_dtype` : array-like

The array-like or dtype to check.

Returns

`boolean` [Whether or not the array-like or dtype is of the object dtype.]

Examples

```python
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

### 34.21.4.18 pandas.api.types.is_period_dtype

`pandas.api.types.is_period_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Period dtype.

Parameters `arr_or_dtype` : array-like

The array-like or dtype to check.

Returns

`boolean` [Whether or not the array-like or dtype is of the Period dtype.]

Examples

```python
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

### 34.21.4.19 pandas.api.types.is_signed_integer_dtype

`pandas.api.types.is_signed_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in `in_any_int_dtype`, timedelta64 instances will return False.

Parameters `arr_or_dtype` : array-like
The array or dtype to check.

**Returns** boolean : Whether or not the array or dtype is of a signed integer dtype and not an instance of timedelta64.

**Examples**

```python
>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64)  # unsigned
False
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

34.21.4.20 `pandas.api.types.is_string_dtype`

`pandas.api.types.is_string_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the string dtype.

**Parameters** arr_or_dtype : array-like

The array or dtype to check.

**Returns**

boolean [Whether or not the array or dtype is of the string dtype.]

**Examples**

```python
>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>> is_string_dtype('a', 'b'))
True
```
34.21.4.21 pandas.api.types.is_timedelta64_dtype

pandas.api.types.is_timedelta64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters
arr_or_dtype : array-like
   The array-like or dtype to check.

Returns
boolean : Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False

34.21.4.22 pandas.api.types.is_timedelta64_ns_dtype

pandas.api.types.is_timedelta64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the timedelta64[ns] dtype.
This is a very specific dtype, so generic ones like np.timedelta64 will return False if passed into this function.

Parameters
arr_or_dtype : array-like
   The array or dtype to check.

Returns
boolean : Whether or not the array or dtype is of the timedelta64[ns] dtype.

Examples

>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]'))  # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False
34.21.4.23 pandas.api.types.is_unsigned_integer_dtype

pandas.api.types.is_unsigned_integer_dtype(arr_or_dtype)
Check whether the provided array or dtype is of an unsigned integer dtype.

Parameters arr_or_dtype : array-like
The array or dtype to check.

Returns boolean : Whether or not the array or dtype is of an unsigned integer dtype.

Examples

```python
>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int)  # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2]))  # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True
```

34.21.4.24 pandas.api.types.is_sparse

pandas.api.types.is_sparse(arr)
Check whether an array-like is a pandas sparse array.

Parameters arr : array-like
The array-like to check.

Returns
boolean [Whether or not the array-like is a pandas sparse array.]

Examples

```python
>>> is_sparse(np.array([1, 2, 3]))
False
>>> is_sparse(pd.SparseArray([1, 2, 3]))
True
>>> is_sparse(pd.SparseSeries([1, 2, 3]))
True
```

This function checks only for pandas sparse array instances, so sparse arrays from other libraries will return False.
```python
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([1, 2, 3]))
False
```

Iterable introspection

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api.types.is_dict_like(obj)</td>
<td>Check if the object is dict-like.</td>
</tr>
<tr>

<td>Check if the object is an iterator.</td>
</tr>
</tbody>
</table>

### 34.21.4.25 pandas.api.types.is_dict_like

`pandas.api.types.is_dict_like(obj)`
Check if the object is dict-like.

**Parameters**
- `obj` [The object to check.]

**Returns**
- `is_dict_like` : bool
  Whether `obj` has dict-like properties.

### 34.21.4.26 pandas.api.types.is_file_like

`pandas.api.types.is_file_like(obj)`
Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a `read` and/or `write` method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

New in version 0.20.0.

**Parameters**
- `obj` [The object to check.]

**Returns**
- `is_file_like` : bool
  Whether `obj` has file-like properties.
Examples

```python
>>> buffer(StringIO("data"))
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```

34.21.4.27 pandas.api.types.is_list_like

```python
def is_list_like(obj):
    """Check if the object is list-like.
    """
    # Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.
    # Strings and datetime objects, however, are not considered list-like.

    Parameters
    ----------
    obj : The object to check.

    Returns
    -------
    is_list_like : bool
        Whether `obj` has list-like properties.
```

Examples

```python
>>> is_list_like([1, 2, 3])
True
>>> is_list_like({1, 2, 3})
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
```

34.21.4.28 pandas.api.types.is_named_tuple

```python
def is_named_tuple(obj):
    """Check if the object is a named tuple.
    """
    # Parameters
    # obj : The object to check.

    Returns
    -------
    is_named_tuple : bool
        Whether `obj` is a named tuple.
```

Examples
34.21.4.29 pandas.api.types.is_iterator

pandas.api.types.is_iterator(obj)
Check if the object is an iterator.
For example, lists are considered iterators but not strings or datetime objects.

Parameters

obj [The object to check.]

Returns is_iter : bool
Whether obj is an iterator.

Examples

>>> is_iterator([1, 2, 3])
True
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False

Scalar introspection

<td>Return True if given value is scalar.</td>
</tr>
</tbody>
</table>
34.21.4.30 pandas.api.types.is_bool

pandas.api.types.is_bool()

34.21.4.31 pandas.api.types.is_categorical

pandas.api.types.is_categorical(arr)
Check whether an array-like is a Categorical instance.

Parameters
arr : array-like
The array-like to check.

Returns
boolean [Whether or not the array-like is of a Categorical instance.]

Examples

```python
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```python
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

34.21.4.32 pandas.api.types.is_complex

pandas.api.types.is_complex()

34.21.4.33 pandas.api.types.is_datetimetz

pandas.api.types.is_datetimetz(arr)
Check whether an array-like is a datetime array-like with a timezone component in its dtype.

Parameters
arr : array-like
The array-like to check.

Returns
boolean : Whether or not the array-like is a datetime array-like with a timezone component in its dtype.

Examples

```python
>>> is_datetimetz([1, 2, 3])
False
```
Although the following examples are both DatetimeIndex objects, the first one returns False because it has no timezone component unlike the second one, which returns True.

>>> is_datetimetz(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_datetimetz(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True

The object need not be a DatetimeIndex object. It just needs to have a dtype which has a timezone component.

>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetimetz(s)
True

34.21.4.34 pandas.api.types.is_float

pandas.api.types.is_float()

34.21.4.35 pandas.api.types.is_hashable

pandas.api.types.is_hashable(obj)

Return True if hash(obj) will succeed, False otherwise.

Some types will pass a test against collections.Hashable but fail when they are actually hashed with hash().

Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.

Examples

>>> a = ([],)
>>> isinstance(a, collections.Hashable)
True
>>> is_hashable(a)
False

34.21.4.36 pandas.api.types.is_integer

pandas.api.types.is_integer()

34.21.4.37 pandas.api.types.is_interval

pandas.api.types.is_interval()

34.21.4.38 pandas.api.types.is_number

pandas.api.types.is_number(obj)

Check if the object is a number.

Returns True when the object is a number, and False if is not.

Parameters

obj : any type
The object to check if is a number.

**Returns** `is_number` : bool

Whether `obj` is a number or not.

**See also:**

`pandas.api.types.is_integer` checks a subgroup of numbers

**Examples**

```python
>>> pd.api.types.is_number(1)
True
>>> pd.api.types.is_number(7.15)
True
Booleans are valid because they are int subclass.

>>> pd.api.types.is_number(False)
True

>>> pd.api.types.is_number("foo")
False
>>> pd.api.types.is_number("5")
False
```

### 34.21.4.39 pandas.api.types.is_period

`pandas.api.types.is_period(arr)`

Check whether an array-like is a periodical index.

**Parameters** `arr` : array-like

The array-like to check.

**Returns**

`boolean` [Whether or not the array-like is a periodical index.]

**Examples**

```python
>>> is_period([1, 2, 3])
False
>>> is_period(pd.Index([1, 2, 3]))
False
>>> is_period(pd.PeriodIndex(["2017-01-01"], freq="D"))
True
```

### 34.21.4.40 pandas.api.types.is_re

`pandas.api.types.is_re(obj)`

Check if the object is a regex pattern instance.
Parameters

  obj [The object to check.]

Returns is_regex : bool

  Whether obj is a regex pattern.

Examples

```python
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

34.21.4.41 pandas.api.types.is_re_compilable

pandas.api.types.is_re_compilable(obj)

Check if the object can be compiled into a regex pattern instance.

Parameters

  obj [The object to check.]

Returns is_regex_compilable : bool

  Whether obj can be compiled as a regex pattern.

Examples

```python
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

34.21.4.42 pandas.api.types.is_scalar

pandas.api.types.is_scalar()

Return True if given value is scalar.

This includes: - numpy array scalar (e.g. np.int64) - Python builtin numerics - Python builtin byte arrays and strings - None - instances of datetime.datetime - instances of datetime.timedelta - Period - instances of decimal.Decimal - Interval - DateOffset

34.22 Extensions

These are primarily intended for library authors looking to extend pandas objects.

- `api.extensions.register_dataframe_accessor(name)` Register a custom accessor on DataFrame objects.
- `api.extensions.register_series_accessor(name)` Register a custom accessor on Series objects.
- `api.extensions.register_index_accessor(name)` Register a custom accessor on Index objects.
34.22.1 pandas.api.extensions.register_dataframe_accessor

pandas.api.extensions.register_dataframe_accessor(name)
Register a custom accessor on DataFrame objects.

Parameters name : str
Name under which the accessor should be registered. A warning is issued if this
name conflicts with a preexisting attribute.

See also:
register_series_accessor, register_index_accessor

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the
signature must be

```python
def __init__(self, pandas_object):
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your ac-
cessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor(object):
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
```

(continues on next page)
Back in an interactive IPython session:

```python
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10), 'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

### 34.22.2 pandas.api.extensions.register_series_accessor

The function `pandas.api.extensions.register_series_accessor(name)` is used to register a custom accessor on Series objects.

**Parameters**

- **name**: str
  - Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

**See also**

- `register_dataframe_accessor`, `register_index_accessor`

**Notes**

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
  ... AttributeError: Can only use .dt accessor with datetimelike values
```

**Examples**

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor(object):
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

@property
```
```python
def center(self):
    # return the geographic center point of this DataFrame
    lat = self._obj.latitude
    lon = self._obj.longitude
    return (float(lon.mean()), float(lat.mean()))

def plot(self):
    # plot this array's data on a map, e.g., using Cartopy
    pass
```

Back in an interactive IPython session:

```python
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                     'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

### 34.22.3 pandas.api.extensions.register_index_accessor

pandas.api.extensions.register_index_accessor(name)

Register a custom accessor on Index objects.

**Parameters** name : str

Name under which the accessor should be registered. A warning is issued if this
name conflicts with a preexisting attribute.

**See also:**

register_dataframe_accessor, register_series_accessor

**Notes**

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your ac-
cesso r has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
... AttributeError: Can only use .dt accessor with datetimelike values
```

**Examples**

In your library code:
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor(object):
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

def plot(self):
    # plot this array's data on a map, e.g., using Cartopy
    pass

Back in an interactive IPython session:

```python
>>> ds = pd.DataFrame({
    'longitude': np.linspace(0, 10),
    'latitude': np.linspace(0, 20)
})

>>> ds.geo.center
(5.0, 10.0)

>>> ds.geo.plot()
# plots data on a map
```

34.22.4 pandas.api.extensions.ExtensionDtype

class pandas.api.extensions.ExtensionDtype
A custom data type, to be paired with an ExtensionArray.
New in version 0.23.0.

Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `type`
- `name`
- `construct_from_string`

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError) and no register method is provided for registering virtual subclasses.

Attributes
kind
A character code (one of `biufcmMOSUV`), default `O`

name
A string identifying the data type.
	names
Ordered list of field names, or None if there are no fields.

type
The scalar type for the array, e.g.

34.22.4.1 pandas.api.extensions.ExtensionDtype.kind

ExtensionDtype.kind
A character code (one of `biufcmMOSUV`), default `O`

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably `O` for object if the extension type cannot be represented as a built-in NumPy type.

See also:

numpy.dtype.kind

34.22.4.2 pandas.api.extensions.ExtensionDtype.name

ExtensionDtype.name
A string identifying the data type.

Will be used for display in, e.g. Series.dtype

34.22.4.3 pandas.api.extensions.ExtensionDtype.names

ExtensionDtype.names
Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

34.22.4.4 pandas.api.extensions.ExtensionDtype.type

ExtensionDtype.type
The scalar type for the array, e.g. int

It's expected ExtensionArray[item] returns an instance of ExtensionDtype.type for scalar item.

Methods

construct_from_string(string) Attempt to construct this type from a string.

is_dtype(dtype) Check if we match `dtype`.

34.22.4.5 pandas.api.extensions.ExtensionDtype.construct_from_string

classmethod ExtensionDtype.construct_from_string(string) Attempt to construct this type from a string.

Parameters
string [str]

Returns

self [instance of ‘cls’]

Raises TypeError

If a class cannot be constructed from this ‘string’.

Examples

If the extension dtype can be constructed without any arguments, the following may be an adequate implementation.

```python
>>> @classmethod
... def construct_from_string(cls, string)
... if string == cls.name:
...     return cls()
... else:
...     raise TypeError("Cannot construct a '{}/' from "
...                 "'{}/'".format(cls, string))
```

34.22.4.6 pandas.api.extensions.ExtensionDtype.is_dtype

classmethod ExtensionDtype.is_dtype(dtype)

Check if we match ‘dtype’.

Parameters dtype : object

The object to check.

Returns

is_dtype [bool]

Notes

The default implementation is True if

1. cls.construct_from_string(dtype) is an instance of cls.
2. dtype is an object and is an instance of cls
3. dtype has a dtype attribute, and any of the above conditions is true for dtype.dtype.

34.22.5 pandas.api.extensions.ExtensionArray

class pandas.api.extensions.ExtensionArray

Abstract base class for custom 1-D array types.

pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a DataFrame or Series.

New in version 0.23.0.
Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- _from_sequence
- _from_factorized
- __getitem__
- __len__
- dtype
- nbytes
- isna
- take
- copy
- _concat_same_type

An additional method is available to satisfy pandas’ internal, private block API.

- _formatting_values

Some methods require casting the ExtensionArray to an ndarray of Python objects with self.astype(object), which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- fillna
- unique
- factorize / _values_for_factorize
- argsort / _values_for_argsort

This class does not inherit from ‘abc.ABCMeta’ for performance reasons. Methods and properties required by the interface raise pandas.errors.AbstractMethodError and no register method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, pandas.Categorical is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called .values or ._values to ensure full compatibility with pandas internals. But other names as .data, ._data, ._items,... can be freely used.

Attributes

<table>
<thead>
<tr>
<th>dtype</th>
<th>An instance of ‘ExtensionDtype’.</th>
</tr>
</thead>
<tbody>
<tr>
<td>nbytes</td>
<td>The number of bytes needed to store this object in memory.</td>
</tr>
</tbody>
</table>
Table 191 – continued from previous page

<table>
<thead>
<tr>
<th>ndim</th>
<th>Extension Arrays are only allowed to be 1-dimensional.</th>
</tr>
</thead>
<tbody>
<tr>
<td>shape</td>
<td>Return a tuple of the array dimensions.</td>
</tr>
</tbody>
</table>

34.22.5.1 pandas.api.extensions.ExtensionArray.dtype

ExtensionArray.**dtype**

An instance of ‘ExtensionDtype’.

34.22.5.2 pandas.api.extensions.ExtensionArray.nbytes

ExtensionArray.**nbytes**

The number of bytes needed to store this object in memory.

34.22.5.3 pandas.api.extensions.ExtensionArray.ndim

ExtensionArray.**ndim**

Extension Arrays are only allowed to be 1-dimensional.

34.22.5.4 pandas.api.extensions.ExtensionArray.shape

ExtensionArray.**shape**

Return a tuple of the array dimensions.

Methods

- **argsort**(ascending, kind)
  Return the indices that would sort this array.
- **astype**(dtype, copy)
  Cast to a NumPy array with ‘dtype’.
- **copy**(deep)
  Return a copy of the array.
- **factorize**(na_sentinel)
  Encode the extension array as an enumerated type.
- **fillna**(value, method, limit)
  Fill NA/NaN values using the specified method.
- **isna**
  Boolean NumPy array indicating if each value is missing.
- **take**(indices[, allow_fill, fill_value])
  Take elements from an array.
- **unique**
  Compute the ExtensionArray of unique values.

34.22.5.5 pandas.api.extensions.ExtensionArray.argsort

ExtensionArray.**argsort**(ascending=True, kind='quicksort', *args, **kwargs)

Return the indices that would sort this array.

**Parameters**

- **ascending**: bool, default True
  Whether the indices should result in an ascending or descending sort.
- **kind**: ‘quicksort’, ‘mergesort’, ‘heapsort’, optional
  Sorting algorithm.
- **args**, **kwargs**:
passed through to `numpy.argsort()`.

**Returns**  
`index_array : ndarray`  
Array of indices that sort `self`.

**See also:**

`numpy.argsort`  
Sorting implementation used internally.

### 34.22.5.6 pandas.api.extensions.ExtensionArray.astype

ExtensionArray` .astype(dtype, copy=True)`  
Cast to a NumPy array with ‘dtype’.

**Parameters**  
`dtype : str or dtype`  
Typecode or data-type to which the array is cast.

`copy : bool, default True`  
Whether to copy the data, even if not necessary. If False, a copy is made only if the old `dtype` does not match the new `dtype`.

**Returns**  
`array : ndarray`  
NumPy ndarray with ‘dtype’ for its `dtype`.

### 34.22.5.7 pandas.api.extensions.ExtensionArray.copy

ExtensionArray` .copy(deep=False)`  
Return a copy of the array.

**Parameters**  
`deep : bool, default False`  
Also copy the underlying data backing this array.

**Returns**  
ExtensionArray

### 34.22.5.8 pandas.api.extensions.ExtensionArray.factorize

ExtensionArray` .factorize(na_sentinel=-1)`  
Encode the extension array as an enumerated type.

**Parameters**  
`na_sentinel : int, default -1`  
Value to use in the `labels` array to indicate missing values.

**Returns**  
`labels : ndarray`  
An integer NumPy array that’s an indexer into the original ExtensionArray.

`uniques : ExtensionArray`  
An ExtensionArray containing the unique values of `self`.

**Note:** `uniques` will *not* contain an entry for the NA value of the ExtensionArray if there are any missing values present in `self`.
See also:

`pandas.factorize` Top-level factorize method that dispatches here.

Notes

`pandas.factorize()` offers a sort keyword as well.

34.22.5.9 pandas.api.extensions.ExtensionArray.fillna

ExtensionArray.fillna(value=None, method=None, limit=None)
Fill NA/NaN values using the specified method.

Parameters

value : scalar, array-like
    If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like ‘value’ can be given. It’s expected that the array-like have the same length as ‘self’.

method : {'backfill', 'bfill', 'pad', 'ffill', None}, default None
    Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

limit : int, default None
    If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

filled [ExtensionArray with NA/NaN filled]

34.22.5.10 pandas.api.extensions.ExtensionArray.isna

ExtensionArray.isna()
Boolean NumPy array indicating if each value is missing.
This should return a 1-D array the same length as ‘self’.

34.22.5.11 pandas.api.extensions.ExtensionArray.take

ExtensionArray.take(indices, allow_fill=False, fill_value=None)
Take elements from an array.

Parameters

indices : sequence of integers
    Indices to be taken.

allow_fill : bool, default False
    How to handle negative values in indices.
pandas: powerful Python data analysis toolkit, Release 0.23.3

- False: negative values in indices indicate positional indices from the right (the default). This is similar to numpy.take().

- True: negative values in indices indicate missing values. These values are set to fill_value. Any other other negative values raise a ValueError.

**fill_value**: any, optional

Fill value to use for NA-indices when allow_fill is True. This may be None, in which case the default NA value for the type, self.dtype.na_value, is used.

For many ExtensionArrays, there will be two representations of fill_value: a user-facing “boxed” scalar, and a low-level physical NA value. fill_value should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

**Returns**

- ExtensionArray

**Raises**

- IndexError

When the indices are out of bounds for the array.

- ValueError

When indices contains negative values other than -1 and allow_fill is True.

**See also:**

numpy.take, pandas.api.extensions.take

**Notes**

ExtensionArray.take is called by Series.__getitem__, .loc, .iloc, when indices is a sequence of values. Additionally, it’s called by Series.reindex(), or any other method that causes realignment, with a fill_value.

**Examples**

Here’s an example implementation, which relies on casting the extension array to object dtype. This uses the helper method pandas.api.extensions.take().

```python
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.
    result = take(data, indices, fill_value=fill_value,
```

(continues on next page)
34.22.5.12 pandas.api.extensions.ExtensionArray.unique

ExtensionArray.unique()
Compute the ExtensionArray of unique values.

Returns
uniques [ExtensionArray]

34.22.6 pandas.Index.asi8

Index.asi8 = None

34.22.7 pandas.Index.holds_integer

Index.holds_integer()

34.22.8 pandas.Index.is_type_compatible

Index.is_type_compatible(kind)

34.22.9 pandas.Index.nlevels

Index.nlevels

34.22.10 pandas.Index.sort

Index.sort(*args, **kwargs)

34.22.11 pandas.Panel.agg

Panel.agg(func, *args, **kwargs)

34.22.12 pandas.Panel.aggregate

Panel.aggregate(func, *args, **kwargs)

34.22.13 pandas.Panel.is_copy

Panel.is_copy
34.22.14 pandas.Series.imag

Series.imag

34.22.15 pandas.Series.real

Series.real
This section will focus on downstream applications of pandas.

35.1 Storing pandas DataFrame objects in Apache Parquet format

The Apache Parquet format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```plaintext
5: optional list<KeyValue> key_value_metadata
```

where `KeyValue` is

```plaintext
struct KeyValue {
    1: required string key
    2: optional string value
}
```

So that a pandas.DataFrame can be faithfully reconstructed, we store a pandas metadata key in the FileMetaData with the value stored as:

```plaintext
{"index_columns": ['__index_level_0__', '__index_level_1__', ...],
'column_indexes': [<ci0>, <ci1>, ..., <ciN>],
'columns': [<c0>, <c1>, ...],
'pandas_version': $VERSION}
```

Here, <c0>/<ci0> and so forth are dictionaries containing the metadata for each column. This has JSON form:

```plaintext
{"name": column_name,
'pandas_type': pandas_type,
'numpy_type': numpy_type,
'metadata': metadata}
```

`pandas_type` is the logical type of the column, and is one of:

- **Boolean**: 'bool'
- **Integers**: 'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'
- **Floats**: 'float16', 'float32', 'float64'
- **Date and Time Types**: 'datetime', 'datetimetz', 'timedelta'
- **String**: 'unicode', 'bytes'
- Categorical: 'categorical'
- Other Python objects: 'object'

The `numpy_type` is the physical storage type of the column, which is the result of `str(dtype)` for the underlying NumPy array that holds the data. So for `datetimetz` this is `datetime64[ns]` and for categorical, it may be any of the supported integer categorical types.

The `metadata` field is `None` except for:

- `datetimetz`: {'timezone': zone, 'unit': 'ns'}, e.g. {'timezone': 'America/New_York', 'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
- `categorical`: {'num_categories': K, 'ordered': is_ordered, 'type': $TYPE}
  - Here 'type' is optional, and can be a nested pandas type specification here (but not categorical)
- `unicode`: {'encoding': encoding}
  - The encoding is optional, and if not present is UTF-8
- `object`: {'encoding': encoding}. Objects can be serialized and stored in `BYTE_ARRAY` Parquet columns. The encoding can be one of:
  - 'pickle'
  - 'msgpack'
  - 'bson'
  - 'json'
- `timedelta`: {'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds. This metadata is optional altogether

For types other than these, the 'metadata' key can be omitted. Implementations can assume `None` if the key is not present.

As an example of fully-formed metadata:

```
{"index_columns": ["__index_level_0__"],
'column_indexes': [
  {
    'name': None,
    'pandas_type': 'string',
    'numpy_type': 'object',
    'metadata': None
  }
],
'columns': [
  {
    'name': 'c0',
    'pandas_type': 'int8',
    'numpy_type': 'int8',
    'metadata': None,
  },
  {
    'name': 'c1',
    'pandas_type': 'bytes',
    'numpy_type': 'object',
    'metadata': None,
  },
  {
    'name': 'c2',
    'pandas_type': 'categorical',
    'numpy_type': 'int16',
    'metadata': {'num_categories': 1000, 'ordered': False},
  },
  {
    'name': 'c3',
    'pandas_type': 'datetimetz',
    'numpy_type': 'datetime64[ns]',
  }
}
```
35.1. Storing pandas DataFrame objects in Apache Parquet format

```json
'metadata': {'timezone': 'America/Los_Angeles'},
{'name': 'c4',
 'pandas_type': 'object',
 'numpy_type': 'object',
 'metadata': {'encoding': 'pickle'}},
{'name': '__index_level_0__',
 'pandas_type': 'int64',
 'numpy_type': 'int64',
 'metadata': None}
],
'pandas_version': '0.20.0')
```
This section will provide a look into some of pandas internals. It’s primarily intended for developers of pandas itself.

### 36.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- **Index**: the generic “ordered set” object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do $O(1)$ lookups.
- **Int64Index**: a version of Index highly optimized for 64-bit integer data, such as time stamps
- **Float64Index**: a version of Index highly optimized for 64-bit float data
- **MultiIndex**: the standard hierarchical index object
- **DatetimeIndex**: An Index object with Timestamp boxed elements (impl are the int64 values)
- **TimedeltaIndex**: An Index object with Timedelta boxed elements (impl are the int64 values)
- **PeriodIndex**: An Index object with Period elements

There are functions that make the creation of a regular index easy:

- **date_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Python datetime objects
- **period_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Period objects, representing Timespans

The motivation for having an Index class in the first place was to enable different implementations of indexing. This means that it’s possible for you, the user, to implement a custom Index subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an Index must define are one or more of the following (depending on how incompatible the new object internals are with the Index functions):

- **get_loc**: returns an “indexer” (an integer, or in some cases a slice object) for a label
- **slice_locs**: returns the “range” to slice between two labels
- **get_indexer**: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
- **get_indexer_non_unique**: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
- **reindex**: Does any pre-conversion of the input index then calls get_indexer
• union, intersection: computes the union or intersection of two Index objects
• insert: Inserts a new label into an Index, yielding a new object
• delete: Delete a label, yielding a new object
• drop: Deletes a set of labels
• take: Analogous to ndarray.take

36.1.1 MultiIndex

Internally, the MultiIndex consists of a few things: the levels, the integer labels, and the level names:

```
In [1]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first', 'second'])

In [2]: index
Out[2]:
MultiIndex(levels=[[0, 1, 2], ['one', 'two']],
          labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
          names=['first', 'second'])

In [3]: index.levels
Out[3]:
FrozenList([[0, 1, 2], ['one', 'two']])

In [4]: index.labels
Out[4]:
FrozenList([[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]])

In [5]: index.names
Out[5]:
FrozenList(['first', 'second'])
```

You can probably guess that the labels determine which unique element is identified with that location at each layer of the index. It’s important to note that sortedness is determined solely from the integer labels and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors from_tuples and from_arrays ensure that this is true, but if you compute the levels and labels yourself, please be careful.

36.1.2 Values

Pandas extends NumPy’s type system with custom types, like Categorical or datetimes with a timezone, so we have multiple notions of “values”. For 1-D containers (Index classes and Series) we have the following convention:

• cls._ndarray_values is always a NumPy ndarray. Ideally, _ndarray_values is cheap to compute. For example, for a Categorical, this returns the codes, not the array of objects.

• cls._values refers is the “best possible” array. This could be an ndarray, ExtensionArray, or in Index subclass (note: we’re in the process of removing the index subclasses here so that it’s always an ndarray or ExtensionArray).

So, for example, Series[category]._values is a Categorical, while Series[category]._ndarray_values is the underlying codes.
36.2 Subclassing pandas Data Structures

This section has been moved to Subclassing pandas Data Structures.
While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. Pandas offers a few options for extending pandas.

### 37.1 Registering Custom Accessors

Libraries can use the decorators `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s `__init__` method gets the object being decorated. For example:

```python
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor(object):
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the `geo` namespace:

```bash
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                     'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our pandas Ecosystem page.
37.2 Extension Types

New in version 0.23.0.

**Warning:** The pandas.api.extension.ExtensionDtype and pandas.api.extension.ExtensionArray APIs are new and experimental. They may change between versions without warning.

Pandas defines an interface for implementing data types and arrays that extend NumPy’s type system. Pandas itself uses the extension system for some types that aren’t built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like pandas.isna() will dispatch to the extension type’s implementation.

If you’re building a library that implements the interface, please publicize it on Extension Data Types.

The interface consists of two classes.

### 37.2.1 ExtensionDtype

A pandas.api.extension.ExtensionDtype is similar to a numpy.dtype object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the type property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be ipaddress.IPv4Address.

See the extension dtype source for interface definition.

### 37.2.2 ExtensionArray

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the dtype attribute.

Pandas makes no restrictions on how an extension array is created via its __new__ or __init__, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for Categorical).

They may be backed by none, one, or many NumPy arrays. For example, pandas.Categorical is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the extension array source for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py.

To use a test, subclass it:

```python
from pandas.tests.extension import base
```

(continues on next page)
class TestConstructors(base.BaseConstructorsTests):
    pass

See https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py for a list of all the tests available.

37.3 Subclassing pandas Data Structures

Warning: There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with pipe
2. Use composition. See here.
3. Extending by registering an accessor
4. Extending by extension type

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

Note: You can find a nice example in geopandas project.

37.3.1 Override Constructor Properties

Each data structure has several constructor properties for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 constructor properties to be defined:

• _constructor: Used when a manipulation result has the same dimensions as the original.
• _constructor_sliced: Used when a manipulation result has one lower dimension(s) as the original, such as DataFrame single columns slicing.
• _constructor_expanddim: Used when a manipulation result has one higher dimension as the original, such as Series.to_frame() and DataFrame.to_panel().

Following table shows how pandas data structures define constructor properties by default.

<table>
<thead>
<tr>
<th>Property Attributes</th>
<th>Series</th>
<th>DataFrame</th>
</tr>
</thead>
<tbody>
<tr>
<td>_constructor</td>
<td>Series</td>
<td>DataFrame</td>
</tr>
<tr>
<td>_constructor_sliced</td>
<td>NotImplementedError</td>
<td>Series</td>
</tr>
<tr>
<td>_constructor_expanddim</td>
<td>DataFrame</td>
<td>Panel</td>
</tr>
</tbody>
</table>

Below example shows how to define SubclassedSeries and SubclassedDataFrame overriding constructor properties.
class SubclassedSeries(Series):
    @property
def _constructor(self):
        return SubclassedSeries

    @property
def _constructor_expanddim(self):
        return SubclassedDataFrame

class SubclassedDataFrame(DataFrame):
    @property
def _constructor(self):
        return SubclassedDataFrame

    @property
def _constructor_sliced(self):
        return SubclassedSeries

>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df[['A', 'B']]  
>>> sliced1
   A  B
0  1  4
1  2  5
2  3  6

>>> type(sliced1)
<class '__main__.SubclassedDataFrame'>

>>> sliced2 = df['A']
>>> sliced2
0  1
1  2
2  3
Name: A, dtype: int64

>>> type(sliced2)
<class '__main__.SubclassedSeries'>
37.3.2 Define Original Properties

To let original data structures have additional properties, you should let pandas know what properties are added. pandas maps unknown properties to data names overriding __getattribute__. Defining original properties can be done in one of 2 ways:

1. Define _internal_names and _internal_names_set for temporary properties which WILL NOT be passed to manipulation results.

2. Define _metadata for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “internal_cache” as a temporary property and “added_property” as a normal property

```python
class SubclassedDataFrame2(DataFrame):
    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ['internal_cache']
    _internal_names_set = set(_internal_names)
    # normal properties
    _metadata = ['added_property']

    @property
def _constructor(self):
        return SubclassedDataFrame2

>>> df = SubclassedDataFrame2({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
    A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
>>> df.internal_cache = 'cached'
>>> df.added_property = 'property'
    A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
>>> df.internal_cache
    cached
>>> df.added_property
    property

# properties defined in _internal_names is reset after manipulation
>>> df[['A', 'B']].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df[['A', 'B']].added_property
    property
```
This is the list of changes to pandas between each release. For full details, see the commit logs at http://github.com/pandas-dev/pandas

What is it

pandas is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, real world data analysis in Python. Additionally, it has the broader goal of becoming the most powerful and flexible open source data analysis / manipulation tool available in any language.

Where to get it

- Source code: http://github.com/pandas-dev/pandas
- Binary installers on PyPI: https://pypi.org/project/pandas
- Documentation: http://pandas.pydata.org

38.1 pandas 0.23.2

Release date: July 5, 2018

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes.

See the full whatsnew for a list of all the changes.

38.1.1 Thanks

A total of 17 people contributed to this release. People with a “+” by their names contributed a patch for the first time.

- David Krych
- Jacopo Rota +
- Jeff Reback
- Jeremy Schendel
- Joris Van den Bossche
- Kalyan Gokhale
- Matthew Roeschke
- Michael Odintsoy +
- Ming Li
38.2 pandas 0.23.1

Release date: June 12, 2018

This is a minor release from 0.23.0 and includes a number of bug fixes and performance improvements. See the full whatsnew for a list of all the changes.

38.2.1 Thanks

A total of 30 people contributed to this release. People with a “+” by their names contributed a patch for the first time.

- Adam J. Stewart
- Adam Kim +
- Aly Sivji
- Chalmer Lowe +
- Damini Satya +

- Pyry Kovanen +
- Stefano Cianciulli
- Tom Augspurger
38.3 pandas 0.23.0

Release date: May 15, 2018

This is a major release from 0.22.0 and includes a number of API changes, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- **Round-trippable JSON format with ‘table’ orient.**
- **Instantiation from dicts respects order for Python 3.6+**.
- **Dependent column arguments for assign.**
- **Merging / sorting on a combination of columns and index levels.**
- **Extending Pandas with custom types.**
- **Excluding unobserved categories from groupby.**
- **Changes to make output shape of DataFrame.apply consistent.**

See the full whatsnew for a list of all the changes.

38.3.1 Thanks

A total of 328 people contributed to this release. People with a “+” by their names contributed a patch for the first time.

38.4 pandas 0.22.0

Release date: December 29, 2017

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note.

The only changes are:

- The sum of an empty or all-NA Series is now 0
- The product of an empty or all-NA Series is now 1
- We’ve added a min_count parameter to .sum() and .prod() controlling the minimum number of valid values for the result to be valid. If fewer than min_count non-NA values are present, the result is NA. The default is 0. To return NaN, the 0.21 behavior, use min_count=1.

See the v0.22.0 Whatsnew overview for further explanation of all the places in the library this affects.

38.5 pandas 0.21.1

Release date: December 12, 2017

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore matplotlib datetime plotting functionality. This should resolve issues for users who relied implicitly on pandas to plot datetimes with matplotlib. See here.
- Improvements to the Parquet IO functions introduced in 0.21.0. See here.

See the v0.21.1 Whatsnew overview for an extensive list of all the changes for 0.21.1.

38.5.1 Thanks

38.6 pandas 0.21.0

Release date: October 27, 2017

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Integration with Apache Parquet, including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see here.
- New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see here.
- The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether bottleneck is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see here.
- Compatibility fixes for pypy, see here.
- Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see here.
- Addition of the new methods `DataFrame.infer_objects` (see here) and `GroupBy.pipe` (see here).
- Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a KeyError in a future version, see here.

See the v0.21.0 Whatsnew overview for an extensive list of all enhancements and bugs that have been fixed in 0.21.0

38.7 pandas 0.20.0 / 0.20.1

Release date: May 5, 2017

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• New `.agg()` API for Series/DataFrame similar to the groupby-rolling-resample API’s, see here
• Integration with the feather-format, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see here.
• The `.ix` indexer has been deprecated, see here
• Panel has been deprecated, see here
• Addition of an IntervalIndex and Interval scalar type, see here
• Improved user API when grouping by index levels in `.groupby()`, see here
• Improved support for UInt64 dtypes, see here
• A new orient for JSON serialization, orient='table', that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see here
• Experimental support for exporting styled DataFrames (DataFrame.style) to Excel, see here
• Window binary corr/cov operations now return a MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see here
• Support for S3 handling now uses s3fs, see here
• Google BigQuery support now uses the pandas-gbq library, see here
See the v0.20.1 Whatsnew overview for an extensive list of all enhancements and bugs that have been fixed in 0.20.1.

Note: This is a combined release for 0.20.0 and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas’ utils routines. (GH16250)

38.8 pandas 0.19.2

**Release date:** December 24, 2016

This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements.

Highlights include:
• Compatibility with Python 3.6
• Added a Pandas Cheat Sheet. (GH13202).

See the v0.19.2 Whatssnew page for an overview of all bugs that have been fixed in 0.19.2.

38.10 pandas 0.19.0

Release date: October 2, 2016

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• `merge_asof()` for asof-style time-series joining, see here
• `.rolling()` is now time-series aware, see here
• `read_csv()` now supports parsing Categorical data, see here
• A function `union_categorical()` has been added for combining categoricals, see here
• `PeriodIndex` now has its own period dtype, and changed to be more consistent with other Index classes. See here
• Sparse data structures gained enhanced support of int and bool dtypes, see here
• Comparison operations with `Series` no longer ignores the index, see here for an overview of the API changes.
• Introduction of a pandas development API for utility functions, see here.
• Deprecation of Panel4D and PanelND. We recommend to represent these types of n-dimensional data with the xarray package.
• Removal of the previously deprecated modules pandas.io.data, pandas.io.wb, pandas.tools.rplot.

See the v0.19.0 Whatsnew overview for an extensive list of all enhancements and bugs that have been fixed in 0.19.0.

38.11 pandas 0.18.1

Release date: (May 3, 2016)

This is a minor release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements.

Highlights include:

- `.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(...)`, `.expanding(...)` and `.resample(...)` per group, see [here](#).
- `pd.to_datetime()` has gained the ability to assemble dates from a DataFrame, see [here](#).
- Method chaining improvements, see [here](#).
- Custom business hour offset, see [here](#).
- Many bug fixes in the handling of sparse, see [here](#).
- Expanded the Tutorials section with a feature on modern pandas, courtesy of [@TomAugxburger](#) (GH13045).

See the [v0.18.1 Whatsnew](#) overview for an extensive list of all enhancements and bugs that have been fixed in 0.18.1.

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Moving and expanding window functions are now methods on Series and DataFrame, similar to `.groupby`, see here.
- Adding support for a `RangeIndex` as a specialized form of the `Int64Index` for memory savings, see here.
- API breaking change to the `resample` method to make it more `.groupby` like, see here.
- Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a `TypeError`, see here.
- The `.to_xarray()` function has been added for compatibility with the `xarray` package, see here.
- The `read_sas` function has been enhanced to read `sas7bdat` files, see here.
- Addition of the `.str.extractall()` method, and API changes to the `.str.extract()` method and `.str.cat()` method.
- `pd.test()` top-level nose test runner is available (GH4327).

See the v0.18.0 Whatsnew overview for an extensive list of all enhancements and bugs that have been fixed in 0.18.0.

This is a minor release from 0.17.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements.

Highlights include:

- Support for Conditional HTML Formatting, see [here](#)
- Releasing the GIL on the csv reader & other ops, see [here](#)
- Regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)

See the [v0.17.1 Whatsnew overview](#) for an extensive list of all enhancements and bugs that have been fixed in 0.17.1.

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see here
- Plotting methods are now available as attributes of the .plot accessor, see here
- The sorting API has been revamped to remove some long-time inconsistencies, see here
- Support for a datetime64[ns] with timezones as a first-class dtype, see here
- The default for to_datetime will now be to raise when presented with unparsable formats, previously this would return the original input. Also, date parse functions now return consistent results. See here
- The default for dropna in HDFStore has changed to False, to store by default all rows even if they are all NaN, see here
- Datetime accessor (dt) now supports Series.dt.strftime to generate formatted strings for datetimelikes, and Series.dt.total_seconds to generate each duration of the timedelta in seconds. See here
- Period and PeriodIndex can handle multiplied freq like 3D, which corresponding to 3 days span. See here
- Development installed versions of pandas will now have PEP440 compliant version strings (GH9518)
- Development support for benchmarking with the Air Speed Velocity library (GH8316)
• Support for reading SAS xport files, see here
• Documentation comparing SAS to pandas, see here
• Removal of the automatic TimeSeries broadcasting, deprecated since 0.8.0, see here
• Display format with plain text can optionally align with Unicode East Asian Width, see here
• Compatibility with Python 3.5 (GH11097)
• Compatibility with matplotlib 1.5.0 (GH11111)

See the v0.17.0 Whatsnew overview for an extensive list of all enhancements and bugs that have been fixed in 0.17.0.

38.15 pandas 0.16.2

**Release date:** (June 12, 2015)

This is a minor release from 0.16.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements.

Highlights include:

- A new pipe method, see [here](#)
- Documentation on how to use numba with pandas, see [here](#)

See the v0.16.2 Whatsnew overview for an extensive list of all enhancements and bugs that have been fixed in 0.16.2.

38.17 pandas 0.16.0

Release date: (March 22, 2015)

This is a major release from 0.15.2 and includes a number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

- DataFrame.assign method, see here
- Series.to_coo/from_coo methods to interact with scipy.sparse, see here
- Backwards incompatible change to Timedelta to conform the .seconds attribute with datetime.timedelta, see here
- Changes to the .loc slicing API to conform with the behavior of .ix see here
- Changes to the default for ordering in the Categorical constructor, see here
- The pandas.tools.rplot, pandas.sandbox.qtpandas and pandas.rpy modules are deprecated. We refer users to external packages like seaborn, pandas-qt and rpy2 for similar or equivalent functionality, see here

See the v0.16.0 Whatsnew overview or the issue tracker on GitHub for an extensive list of all API changes, enhancements and bugs that have been fixed in 0.16.0.

38.20  pandas 0.15.0

Release date:  (October 18, 2014)

This is a major release from 0.14.1 and includes a number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

- Drop support for NumPy < 1.7.0 (GH7711)
- The Categorical type was integrated as a first-class pandas type, see here
- New scalar type Timedelta, and a new index type TimedeltaIndex, see here
- New DataFrame default display for df.info() to include memory usage, see Memory Usage
- New datetimelike properties accessor .dt for Series, see Datetimelike Properties
- Split indexing documentation into Indexing and Selecting Data and MultiIndex / Advanced Indexing
- Split out string methods documentation into Working with Text Data
- read_csv will now by default ignore blank lines when parsing, see here
- API change in using Indexes in set operations, see here
- Internal refactoring of the Index class to no longer sub-class ndarray, see Internal Refactoring
- dropping support for PyTables less than version 3.0.0, and numexpr less than version 2.1 (GH7990)

See the v0.15.0 Whatsnew overview or the issue tracker on GitHub for an extensive list of all API changes, enhancements and bugs that have been fixed in 0.15.0.

38.21 pandas 0.14.1

Release date: (July 11, 2014)

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

• New methods select_dtypes() to select columns based on the dtype and sem() to calculate the standard error of the mean.
• Support for dateutil timezones (see docs).
• Support for ignoring full line comments in the `read_csv()` text parser.
• New documentation section on `Options and Settings`.
• Lots of bug fixes.

See the `v0.14.1 Whatsnew` overview or the issue tracker on GitHub for an extensive list of all API changes, enhancements and bugs that have been fixed in 0.14.1.

38.22 pandas 0.14.0

Release date: (May 31, 2014)

This is a major release from 0.13.1 and includes a number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

- Officially support Python 3.4
- SQL interfaces updated to use sqlalchemy, see here.
- Display interface changes, see here
- MultiIndexing using Slicers, see here.
- Ability to join a singly-indexed DataFrame with a multi-indexed DataFrame, see here
- More consistency in groupby results and more flexible groupby specifications, see here
- Holiday calendars are now supported in CustomBusinessDay, see here
- Several improvements in plotting functions, including: hexbin, area and pie plots, see here.
- Performance doc section on I/O operations, see here

See the v0.14.0 Whatsnew overview or the issue tracker on GitHub for an extensive list of all API changes, enhancements and bugs that have been fixed in 0.14.0.

38.23 pandas 0.13.1

**Release date:** (February 3, 2014)

### 38.23.1 New Features

- Added `date_format` and `datetime_format` attribute to `ExcelWriter` (GH4133)

### 38.23.2 API Changes

- `Series.sort` will raise a `ValueError` (rather than a `TypeError`) on sorting an object that is a view of another (GH5856, GH5853)
- `Raise/Warn SettingWithCopyError` (according to the option `chained_assignment` in more cases, when detecting chained assignment, related (GH5938, GH6025)
• DataFrame.head(0) returns self instead of empty frame (GH5846)
• autocorrelation_plot now accepts **kwargs. (GH5623)
• convert_objects now accepts a convert_timedeltas='coerce' argument to allow forced dtype conversion of timedeltas (GH5458, issue: 5689)
• Add NaN and nan to the default set of NA values (GH5952). See NA Values.
• NDFrame now has an equals method. (GH5283)
• DataFrame.apply will use the reduce argument to determine whether a Series or a DataFrame should be returned when the DataFrame is empty (GH6007).

38.23.3 Experimental Features

38.23.4 Improvements to existing features

• perf improvements in Series datetime/timedelta binary operations (GH5801)
• option_context context manager now available as top-level API (GH5752)
• df.info() view now display dtype info per column (GH5682)
• df.info() now honors option max_info_rows, disable null counts for large frames (GH5974)
• perf improvements in DataFrame count/dropna for axis=1
• Series.str.contains now has a regex=False keyword which can be faster for plain (non-regex) string patterns. (GH5879)
• support dtypes property on Series/Panel/Panel4D
• extend Panel.apply to allow arbitrary functions (rather than only ufuncs) (GH1148) allow multiple axes to be used to operate on slabs of a Panel
• The ArrayFormatter for datetime and timedelta64 now intelligently limit precision based on the values in the array (GH3401)
• pd.show_versions() is now available for convenience when reporting issues.
• perf improvements to Series.str.extract (GH5944)
• perf improvements in dtypes/ftypes methods (GH5968)
• perf improvements in indexing with object dtypes (GH5968)
• improved dtype inference for timedelta like passed to constructors (GH5458, GH5689)
• escape special characters when writing to latex (issue: 5374)
• perf improvements in DataFrame.apply (GH6013)
• pd.read_csv and pd.to_datetime learned a new infer_datetime_format keyword which greatly improves parsing perf in many cases. Thanks to @lexical for suggesting and @danbirkken for rapidly implementing. (GH5490, issue: 6021)
• add ability to recognize ‘%p’ format code (am/pm) to date parsers when the specific format is supplied (GH5361)
• Fix performance regression in JSON IO (GH5765)
• performance regression in Index construction from Series (GH6150)
38.23.5 Bug Fixes

- Bug in `io.wb.get_countries` not including all countries (GH6008)
- Bug in Series replace with timestamp dict (GH5797)
  - `read_csv/read_table` now respects the `prefix` kwarg (GH5732).
- Bug in selection with missing values via `.ix` from a duplicate indexed DataFrame failing (GH5835)
- Fix issue of boolean comparison on empty DataFrames (GH5808)
- Bug in isnull handling NaT in an object array (GH5443)
- Bug in `to_datetime` when passed a np.nan or integer datelike and a format string (GH5863)
- Bug in groupby dtype conversion with datetimelike (GH5869)
- Regression in handling of empty Series as indexers to Series (GH5877)
- Bug in internal caching, related to (GH5727)
- Testing bug in reading JSON/msgpack from a non-filepath on windows under py3 (GH5874)
- Bug when assigning to .ix[tuple(...)] (GH5896)
- Bug in fully reindexing a Panel (GH5905)
- Bug in idxmin/max with object dtypes (GH5914)
- Bug in `BusinessDay` when adding n days to a date not on offset when n>5 and n%5==0 (GH5890)
- Bug in assigning to chained series with a series via ix (GH5928)
- Bug in creating an empty DataFrame, copying, then assigning (GH5932)
- Bug in DataFrame.tail with empty frame (GH5846)
- Bug in propagating metadata on `resample` (GH5862)
- Fixed string-representation of NaT to be “NaT” (GH5708)
- Fixed string-representation for Timestamp to show nanoseconds if present (GH5912)
- `pd.match` not returning passed sentinel
- `Panel.to_frame()` no longer fails when `major_axis` is a MultiIndex (GH5402).
- Bug in `pd.read_msgpack` with inferring a DateTimeIndex frequency incorrectly (GH5947)
- Fixed `to_datetime` for array with both Tz-aware datetimes and NaT’s (GH5961)
- Bug in rolling skew/kurtosis when passed a Series with bad data (GH5749)
- Bug in scipy `interpolate` methods with a datetime index (GH5975)
- Bug in NaT comparison if a mixed datetime/np.datetime64 with NaT were passed (GH5968)
- Fixed bug with `pd.concat` losing dtype information if all inputs are empty (GH5742)
- Recent changes in IPython cause warnings to be emitted when using previous versions of pandas in QTConsole, now fixed. If you’re using an older version and need to suppress the warnings, see (GH5922).
- Bug in merging `timedelta` dtypes (GH5695)
- Bug in plotting `scatter_matrix` function. Wrong alignment among diagonal and off-diagonal plots, see (GH5497).
- Regression in Series with a multi-index via ix (GH6018)
• Bug in Series.xs with a multi-index (GH6018)
• Bug in Series construction of mixed type with datelike and an integer (which should result in object type and not automatic conversion) (GH6028)
• Possible segfault when chained indexing with an object array under NumPy 1.7.1 (GH6026, GH6056)
• Bug in setting using fancy indexing a single element with a non-scalar (e.g. a list), (GH6043)
• to_sql did not respect if_exists (GH4110 GH4304)
• Regression in .get (None) indexing from 0.12 (GH5652)
• Subtle iloc indexing bug, surfaced in (GH6059)
• Bug with insert of strings into DatetimeIndex (GH5818)
• Fixed unicode bug in to_html/HTML repr (GH6098)
• Fixed missing arg validation in get_options_data (GH6105)
• Bug in assignment with duplicate columns in a frame where the locations are a slice (e.g. next to each other) (GH6120)
• Bug in propagating _ref_locs during construction of a DataFrame with dups index/columns (GH6121)
• Bug in DataFrame.apply when using mixed datelike reductions (GH6125)
• Bug in DataFrame.append when appending a row with different columns (GH6129)
• Bug in DataFrame construction with recarray and non-ns datetime dtype (GH6140)
• Bug in .loc setitem indexing with a datafarm on rhs, multiple item setting, and a datetimelike (GH6152)
• Fixed a bug in query/eval during lexicographic string comparisons (GH6155).
• Fixed a bug in query where the index of a single-element Series was being thrown away (GH6148).
• Bug in HDFStore on appending a dataframe with multi-indexed columns to an existing table (GH6167)
• Consistency with dtypes in setting an empty DataFrame (GH6171)
• Bug in selecting on a multi-index HDFStore even in the presence of under specified column spec (GH6169)
• Bug in nanops.var with ddof=1 and 1 elements would sometimes return inf rather than nan on some platforms (GH6136)
• Bug in Series and DataFrame bar plots ignoring the use_index keyword (GH6209)
• Bug in groupby with mixed str/int under python3 fixed; argsort was failing (GH6212)

38.24 pandas 0.13.0

Release date: January 3, 2014

38.24.1 New Features

• plot(kind='kde') now accepts the optional parameters bw_method and ind, passed to scipy.stats.gaussian_kde() (for scipy >= 0.11.0) to set the bandwidth, and to gkde.evaluate() to specify the indices at which it is evaluated, respectively. See scipy docs. (GH4298)
• Added isin method to DataFrame (GH4211)
• `df.to_clipboard()` learned a new `excel` keyword that lets you paste df data directly into excel (enabled by default). (GH5070).

• Clipboard functionality now works with PySide (GH4282)

• New `extract string` method returns regex matches more conveniently (GH4685)

• Auto-detect field widths in `read_fwf` when unspecified (GH4488)

• `to_csv()` now outputs datetime objects according to a specified format string via the `date_format` keyword (GH4313)

• Added `LastWeekOfMonth` `DateOffset` (GH4637)

• Added `cunccount groupby` method (GH4646)

• Added `FY5253`, and `FY5253Quarter` `DateOffsets` (GH4511)

• Added `mode()` method to `Series` and `DataFrame` to get the statistical mode(s) of a column/series. (GH5367)

38.24.2 Experimental Features

• The new `eval()` function implements expression evaluation using `numexpr` behind the scenes. This results in large speedups for complicated expressions involving large DataFrames/Series.

• `DataFrame` has a new `eval()` that evaluates an expression in the context of the `DataFrame`; allows inline expression assignment

• A `query()` method has been added that allows you to select elements of a `DataFrame` using a natural query syntax nearly identical to Python syntax.

• `pd.eval` and friends now evaluate operations involving `datetime64` objects in Python space because `numexpr` cannot handle `NaT` values (GH4897).

• Add msgpack support via `pd.read_msgpack()` and `pd.to_msgpack()` / `df.to_msgpack()` for serialization of arbitrary pandas (and python objects) in a lightweight portable binary format (GH686, GH5506)

• Added PySide support for the `qtpandas DataFrameModel` and `DataFrameWidget`.

• Added `pandas.io.gbq` for reading from (and writing to) Google BigQuery into a DataFrame. (GH4140)

38.24.3 Improvements to existing features

• `read_html` now raises a `URLError` instead of catching and raising a `ValueError` (GH4303, GH4305)

• `read_excel` now supports an integer in its `sheetname` argument giving the index of the sheet to read in (GH4301).

• `get_dummies` works with NaN (GH4446)

• Added a test for `read_clipboard()` and `to_clipboard()` (GH4282)

• Added bins argument to `value_counts` (GH3945), also sort and ascending, now available in `Series` method as well as top-level function.

• Text parser now treats anything that reads like `inf` (“inf”, “Inf”, “-Inf”, “iNf”, etc.) to infinity. (GH4220, GH4219), affecting `read_table`, `read_csv`, etc.

• Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)

• Significant table writing performance improvements in `HDFStore`
- JSON date serialization now performed in low-level C code.
- JSON support for encoding datetime.time
- Expanded JSON docs, more info about orient options and the use of the numpy param when decoding.
- Add drop_level argument to xs (GH4180)
- Can now resample a DataFrame with ohlc (GH2320)
- Index.copy() and MultiIndex.copy() now accept keyword arguments to change attributes (i.e., names, levels, labels) (GH4039)
- Add rename and set_names methods to Index as well as set_names, set_levels, set_labels to MultiIndex. (GH4039) with improved validation for all (GH4039, GH4794)
- A Series of dtype timedelta64[ns] can now be divided/multiplied by an integer series (GH4521)
- A Series of dtype timedelta64[ns] can now be divided by another timedelta64[ns] object to yield a float64 dtyped Series. This is frequency conversion; astyping is also supported.
- Timedelta64 support fillna/ffill/bfill with an integer interpreted as seconds, or a timedelta (GH3371)
- Box numeric ops on timedelta Series (GH4984)
- Datetime64 support fill/bfill
- Performance improvements with __getitem__ on DataFrames with when the key is a column
- Support for using a DatetimeIndex/PeriodsIndex directly in a datelike calculation e.g. s-s.index (GH4629)
- Better/cleaned up exceptions in core/common, io/excel and core/format (GH4721, GH3954), as well as cleaned up test cases in tests/test_frame, tests/test_multilevel (GH4732).
- Performance improvement of timeseries plotting with PeriodIndex and added test to vbench (GH4705 and GH4722)
- Add axis and level keywords to where, so that the other argument can now be an alignable pandas object.
- to_datetime with a format of '%Y%m%d' now parses much faster
- It’s now easier to hook new Excel writers into pandas (just subclass ExcelWriter and register your engine). You can specify an engine in to_excel or in ExcelWriter. You can also specify which writers you want to use by default with config options io.excel.xlsx.writer and io.excel.xls.writer. (GH4745, GH4750)
- Panel.to_excel() now accepts keyword arguments that will be passed to its DataFrame's to_excel() methods. (GH4750)
- Added XlsxWriter as an optional ExcelWriter engine. This is about 5x faster than the default openpyxl xlsx writer and is equivalent in speed to the xlwt xlsx writer module. (GH4542)
- allow DataFrame constructor to accept more list-like objects, e.g. list of collections.Sequence and array.array objects (GH3783, GH4297, GH4851), thanks @lgautier
- DataFrame constructor now accepts a NumPy masked record array (GH3478), thanks @jnothman
- __getitem__ with tuple key (e.g., [:, 2]) on Series without MultiIndex raises ValueError (GH4759, GH4837)
- read_json now raises a (more informative) ValueError when the dict contains a bad key and orient='split' (GH4730, GH4838)
• read_stata now accepts Stata 13 format (GH4291)
• ExcelWriter and ExcelFile can be used as context managers. (GH3441, GH4933)
• pandas is now tested with two different versions of statsmodels (0.4.3 and 0.5.0) (GH4981).
• Better string representations of MultiIndex (including ability to roundtrip via repr). (GH3347, GH4935)
• Both ExcelFile and read_excel to accept an xlrd.Book for the io (formerly path_or_buf) argument; this requires engine to be set. (GH4961).
• concat now gives a more informative error message when passed objects that cannot be concatenated (GH4608).
• Add halflife option to exponentially weighted moving functions (PR GH4998)
• to_dict now takes records as a possible outtype. Returns an array of column-keyed dictionaries. (GH4936)
• tz_localize can infer a fall daylight savings transition based on the structure of unlocalized data (GH4230)
• DatetimeIndex is now in the API documentation
• Improve support for converting R datasets to pandas objects (more informative index for timeseries and numeric, support for factors, dist, and high-dimensional arrays).
• read_html() now supports the parse_dates, tupleize_cols and thousands parameters (GH4770).
• json_normalize() is a new method to allow you to create a flat table from semi-structured JSON data. See the docs (GH1067)
• DataFrame.from_records() will now accept generators (GH4910)
• DataFrame.interpolate() and Series.interpolate() have been expanded to include interpolation methods from scipy. (GH4434, GH1892)
• Series now supports a to_frame method to convert it to a single-column DataFrame (GH5164)
• DatetimeIndex (and date_range) can now be constructed in a left- or right-open fashion using the closed parameter (GH4579)
• Python csv parser now supports usecols (GH4335)
• Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. (GH5271)
• NDFrame.drop() now accepts names as well as integers for the axis argument. (GH5354)
• Added short docstrings to a few methods that were missing them + fixed the docstrings for Panel flex methods. (GH5336)
• NDFrame.drop(), NDFrame.dropna(), and .drop_duplicates() all accept inplace as a keyword argument; however, this only means that the wrapper is updated inplace, a copy is still made internally. (GH1960, GH5247, GH5628, and related GH2325 [still not closed])
• Fixed bug in tools.plotting.andrews_curves so that lines are drawn grouped by color as expected.
• read_excel() now tries to convert integral floats (like 1.0) to int by default. (GH5394)
• Excel writers now have a default option merge_cells into excel() to merge cells in MultiIndex and Hierarchical Rows. Note: using this option it is no longer possible to round trip Excel files with merged MultiIndex and Hierarchical Rows. Set the merge_cells to False to restore the previous behaviour. (GH5254)
• The FRED DataReader now accepts multiple series (issue ‘3413’)
• StataWriter adjusts variable names to Stata’s limitations (GH5709)
38.24.4 API Changes

- **DataFrame.reindex()** and forward/backward filling now raises ValueError if either index is not monotonic (GH4483, GH4484).

- **pandas** now is Python 2/3 compatible without the need for 2to3 thanks to @jtratner. As a result, pandas now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson’s six library into compat. (GH4384, GH4375, GH4372)

- **pandas.util.compat** and **pandas.util.py3compat** have been merged into **pandas.compat**. **pandas.compat** now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of range, filter, map and zip, plus other necessary elements for Python 3 compatibility. `lmap`, `lzip`, `lrange` and `lfilter` all produce lists instead of iterators, for compatibility with `numpy`, `subscripting` and `pandas constructors`. (GH4384, GH4375, GH4372)

- **deprecated iterkv**, which will be removed in a future release (was just an alias of `iteritems` used to get around 2to3’s changes) (GH4384, GH4375, GH4372)

- **Series.get** with negative indexers now returns the same as `[]` (GH4390)

- allow `ix/loc` for Series/DataFrame/Panel to set on any axis even when the single-key is not currently contained in the index for that axis (GH2578, GH5226, GH5632, GH5720, GH5744, GH5756)

- Default export for `to_clipboard` is now csv with a sep of `\t` for compat (GH3368)

- at now will enlarge the object inplace (and return the same) (GH2578)

- **DataFrame.plot** will scatter plot x versus y by passing `kind='scatter'` (GH2215)

- **HDFStore**
  - `append_to_multiple` automatically synchronizes writing rows to multiple tables and adds a `dropna` kwarg (GH4698)
  - handle a passed `Series` in table format (GH4330)
  - added an `is_open` property to indicate if the underlying file handle is_open; a closed store will now report ‘CLOSED’ when viewing the store (rather than raising an error) (GH4409)
  - a close of a **HDFStore** now will close that instance of the **HDFStore** but will only close the actual file if the ref count (by PyTables) w.r.t. all of the open handles are 0. Essentially you have a local instance of HDFStore referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise `ClosedFileError`
  - removed the `_quiet` attribute, replace by a `DuplicateWarning` if retrieving duplicate rows from a table (GH4367)
  - removed the `warn` argument from `open`. Instead a `PossibleDataLossError` exception will be raised if you try to use `mode='w'` with an OPEN file handle (GH4367)
  - allow a passed locations array or mask as a `where` condition (GH4467)
  - add the keyword `dropna=True` to `append` to change whether ALL nan rows are not written to the store (default is True, ALL nan rows are NOT written), also settable via the option `io.hdf.dropna_table` (GH4625)
  - the `format` keyword now replaces the `table` keyword; allowed values are `fixed(f)|table(t)` the Storer format has been renamed to `Fixed`
  - a column multi-index will be recreated properly (GH4710); raise on trying to use a multi-index with data_columns on the same axis
  - `select_as_coordinates` will now return an `Int64Index` of the resultant selection set
- support timedelta64[ns] as a serialization type (GH3577)
- store datetime.date objects as ordinals rather than timetuples to avoid timezone issues (GH2852), thanks @tavismorph and @numpand
- numexpr 2.2.2 fixes incompatibility in PyTables 2.4 (GH4908)
- flush now accepts an fsync parameter, which defaults to False (GH5364)
- unicode indices not supported on table formats (GH5386)
- pass thru store creation arguments; can be used to support in-memory stores
  - JSON
    - added date_unit parameter to specify resolution of timestamps. Options are seconds, milliseconds, microseconds and nanoseconds. (GH4362, GH4498).
    - added default_handler parameter to allow a callable to be passed which will be responsible for handling otherwise unserializable objects. (GH5138)
  - Index and MultiIndex changes (GH4039):
    - Setting levels and labels directly on MultiIndex is now deprecated. Instead, you can use the set_levels() and set_labels() methods.
    - levels, labels and names properties no longer return lists, but instead return containers that do not allow setting of items (‘mostly immutable’)
    - levels, labels and names are validated upon setting and are either copied or shallow-copied.
    - inplace setting of levels or labels now correctly invalidates the cached properties. (GH5238).
    - __deepcopy__ now returns a shallow copy (currently: a view) of the data - allowing metadata changes.
    - MultiIndex.astype() now only allows np.object_-like dtypes and now returns a MultiIndex rather than an Index. (GH4039)
    - Added is_ method to Index that allows fast equality comparison of views (similar to np.
      may_share_memory but no false positives, and changes on levels and labels setting on
      MultiIndex). (GH4859, GH4909)
    - Aliased __iadd__ to __add__. (GH4996)
    - Added is_ method to Index that allows fast equality comparison of views (similar to np.
      may_share_memory but no false positives, and changes on levels and labels setting on
      MultiIndex). (GH4859, GH4909)
  - Infer and downcast dtpe if downcast='infer' is passed to fillna/ffill/bfill (GH4604)
  - __nonzero__ for all NDFrame objects, will now raise a ValueError, this reverts back to (GH1073,
    GH4633) behavior. Add .bool() method to NDFrame objects to facilitate evaluating of single-element
    boolean Series
  - DataFrame.update() no longer raises a DataConflictError, it now will raise a ValueError instead (if necessary) (GH4732)
  - Series.isin() and DataFrame.isin() now raise a TypeError when passed a string (GH4763). Pass
    a list of one element (containing the string) instead.
  - Remove undocumented/unused kind keyword argument from read_excel, and ExcelFile. (GH4713,
    GH4712)
  - The method argument of NDFrame.replace() is valid again, so that a a list can be passed to
    to_replace(GH4743).
• provide automatic dtype conversions on _reduce operations (GH3371)
• exclude non-numerics if mixed types with datelike in _reduce operations (GH3371)
• default for tupleize_cols is now False for both to_csv and read_csv. Fair warning in 0.12 (GH3604)
• moved timedeltas support to pandas.tseries.timedeltas.py; add timedeltas string parsing, add top-level to_timedelta function
• NDFrame now is compatible with Python’s toplevel abs() function (GH4821).
• raise a TypeError on invalid comparison ops on Series/DataFrame (e.g. integer/datetime) (GH4968)
• Added a new index type, Float64Index. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes [],ix,loc for scalar indexing and slicing work exactly the same. Indexing on other index types are preserved (and positional fallback for [],ix), with the exception, that floating point slicing on indexes on non Float64Index will raise a TypeError, e.g. Series(range(5))[3.5:4.5] (GH263, issue:5375)
• Make Categorical repr nicer (GH4368)
• Remove deprecated Factor (GH3650)
• Remove deprecated set_printoptions/reset_printoptions (issue:3046)
• Remove deprecated _verbose_info (GH3215)
• Begin removing methods that don’t make sense on GroupBy objects (GH4887).
• Remove deprecated read_clipboard/to_clipboard/ExcelFile/ExcelWriter from pandas.io.parsers (GH3717)
• All non-Index NDFrames (Series, DataFrame, Panel, Panel4D, SparsePanel, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (add, sub, mul, etc.). SparsePanel does not support pow or mod with non-scalars. (GH3765)
• Arithmetic func factories are now passed real names (suitable for using with super) (GH5240)
• Provide NumPy compatibility with 1.7 for a calling convention like np.prod(pandas_object) as NumPy call with additional keyword args (GH4435)
• Provide __dir__ method (and local context) for tab completion / remove ipython completers code (GH4501)
• Support non-unique axes in a Panel via indexing operations (GH4960)
• .truncate will raise a ValueError if invalid before and afters dates are given (GH5242)
• Timestamp now supports now/today/utcnow class methods (GH5339)
• default for display.max_seq_len is now 100 rather then None. This activates truncated display (“…””) of long sequences in various places. (GH3391)
• All division with NDFrame - likes is now truedivision, regardless of the future import. You can use // and floordiv to do integer division.

```
In [3]: arr = np.array([1, 2, 3, 4])
In [4]: arr2 = np.array([5, 3, 2, 1])
In [5]: arr / arr2
Out[5]: array([0, 0, 1, 4])
In [6]: pd.Series(arr) / pd.Series(arr2)  # no future import required
Out[6]:
```
• raise/warn SettingWithCopyError/Warning exception/warning when setting of a copy thru chained assignment is detected, settable via option mode.chained_assignment

• test the list of NA values in the csv parser. add N/A, #NA as independent default na values (GH5521)

• The refactoring involving ''Series'' deriving from NDFrame breaks rpy2<=2.3.8. an Issue has been opened against rpy2 and a workaround is detailed in GH5698. Thanks @JanSchulz.

• Series.argmin and Series.argmax are now aliased to Series.idxmin and Series.idxmax. These return the index of the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element (GH6214)

38.24.5 Internal Refactoring

In 0.13.0 there is a major refactor primarily to subclass Series from NDFrame, which is the base class currently for DataFrame and Panel, to unify methods and behaviors. Series formerly subclassed directly from ndarray. (GH4080, GH3862, GH816) See Internal Refactoring

• Refactor of series.py/frame.py/panel.py to move common code to generic.py
• added _setup_axes to created generic NDFrame structures
• moved methods
  - from_axes, _wrap_array, axes, ix, loc, iloc, shape, empty, swapaxes, transpose, pop
  - __iter__, keys, __contains__, __len__, __neg__, __invert__
  - convert_objects, as_blocks, as_matrix, values
  - __getstate__, __setstate__ (compat remains in frame/panel)
  - __getattr__, __setattr__
  - _indexed_same, reindex_like, align, where, mask
  - fillna, replace (Series replace is now consistent with DataFrame)
  - filter (also added axis argument to selectively filter on a different axis)
  - reindex, reindex_axis, take
  - truncate (moved to become part of NDFrame)
  - isnull/notnull now available on NDFrame objects
• These are API changes which make Panel more consistent with DataFrame
• swapaxes on a Panel with the same axes specified now return a copy
• support attribute access for setting
• filter supports same API as original DataFrame filter
•fillna refactored to core/generic.py, while > 3ndim is NotImplemented
• Series now inherits from NDFrame rather than directly from ndarray. There are several minor changes that affect the API.
• NumPy functions that do not support the array interface will now return ndarrays rather than series, e.g. np.diff, np.ones_like, np.where
• Series(0.5) would previously return the scalar 0.5, this is no longer supported
• TimeSeries is now an alias for Series. The property is_time_series can be used to distinguish (if desired)
• Refactor of Sparse objects to use BlockManager
• Created a new block type in internals, SparseBlock, which can hold multi- dtypes and is non-consolidatable. SparseSeries and SparseDataFrame now inherit more methods from their hierarchy (Series/DataFrame), and no longer inherit from SparseArray (which instead is the object of the SparseBlock)
• Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
• Operations on sparse structures within DataFrames should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
• enable setitem on SparseSeries for boolean/integer/slices
• SparsePanels implementation is unchanged (e.g. not using BlockManager, needs work)
• added ftypes method to Series/DataFrame, similar to dtypes, but indicates if the underlying is sparse/dense (as well as the dtype)
• All NDFrame objects now have a _prop_attributes, which can be used to indicate various values to propagate to a new object from an existing (e.g. name in Series will follow more automatically now)
• Internal type checking is now done via a suite of generated classes, allowing isinstance(value, klass) without having to directly import the klass, courtesy of @jtratner
• Bug in Series update where the parent frame is not updating its cache based on changes (GH4080, GH5216) or types (GH3217), fillna (GH3386)
• Indexing with dtype conversions fixed (GH4463, GH4204)
• Refactor Series.reindex to core/generic.py (GH4604, GH4618), allow method= in reindexing on a Series to work
• Series.copy no longer accepts the order parameter and is now consistent with NDFrame copy
• Refactor rename methods to core/generic.py; fixes Series.rename for (GH4605), and adds rename with the same signature for Panel
• Series (for index) / Panel (for items) now as attribute access to its elements (GH1903)
• Refactor clip methods to core/generic.py (GH4798)
• Refactor of _get_numeric_data/_get_bool_data to core/generic.py, allowing Series/Panel functionality
• Refactor of Series arithmetic with time-like objects (datetime/timedelta/time etc.) into a separate, cleaned up wrapper class. (GH4613)
• Complex compat for Series with ndarray. (GH4819)
• Removed unnecessary rwproperty from codebase in favor of builtin property. (GH4843)
• Refactor object level numeric methods (mean/sum/min/max...) from object level modules to core/generic.py (GH4435).
• Refactor cum objects to core/generic.py (GH4435), note that these have a more numpy-like function signature.

• `read_html()` now uses `TextParser` to parse HTML data from bs4/lxml (GH4770).

• Removed the `keep_internal` keyword parameter in `pandas/core/groupby.py` because it wasn’t being used (GH5102).

• Base `DateOffsets` are no longer all instantiated on importing pandas, instead they are generated and cached on the fly. The internal representation and handling of `DateOffsets` has also been clarified. (GH5189, related GH5004)

• `MultiIndex` constructor now validates that passed levels and labels are compatible. (GH5213, GH5214)

• Unity `dropna` for Series/DataFrame signature (GH5250), tests from GH5234, courtesy of @rockg

• Rewrite `assert_almost_equal()` in cython for performance (GH4398)

• Added an internal _update_inplace method to facilitate updating `NDFrame` wrappers on inplace ops (only is for convenience of caller, doesn’t actually prevent copies). (GH5247)

38.24.6 Bug Fixes

• `HDFStore`

  – raising an invalid `TypeError` rather than `ValueError` when appending with a different block ordering (GH4096)

  – `read_hdf` was not respecting as passed mode (GH4504)

  – appending a 0-len table will work correctly (GH4273)

  – `to_hdf` was raising when passing both arguments `append` and `table` (GH4584)

  – reading from a store with duplicate columns across dtypes would raise (GH4767)

  – Fixed a bug where `ValueError` wasn’t correctly raised when column names weren’t strings (GH4956)

  – A zero length series written in Fixed format not deserializing properly. (GH4708)

  – Fixed decoding perf issue on pyt3 (GH5441)

  – Validate levels in a multi-index before storing (GH5527)

  – Correctly handle `data_columns` with a Panel (GH5717)

• Fixed bug in `tslib.tz_convert(vals, tz1, tz2)`: it could raise `IndexError` exception while trying to access `trans[pos + 1]` (GH4496)

• The `by` argument now works correctly with the `layout` argument (GH4102, GH4014) in `*.hist` plotting methods

• Fixed bug in `PeriodIndex.map` where using `str` would return the `str` representation of the index (GH4136)

• Fixed test failure `test_time_series_plot_color_with_empty_kwargs` when using custom `matplotlib` default colors (GH4345)

• Fix running of `stata IO tests`. Now uses temporary files to write (GH4353)

• Fixed an issue where `DataFrame.sum` was slower than `DataFrame.mean` for integer valued frames (GH4365)

• `read_html` tests now work with Python 2.6 (GH4351)

• Fixed bug where `network` testing was throwing `NameError` because a local variable was undefined (GH4381)
• In `to_json`, raise if a passed `orient` would cause loss of data because of a duplicate index (GH4359)
• In `to_json`, fix date handling so milliseconds are the default timestamp as the docstring says (GH4362).
• `as_index` is no longer ignored when doing groupby apply (GH4648, GH3417)
• JSON NaT handling fixed, NaTs are now serialized to `null` (GH4498)
• Fixed JSON handling of escapable characters in JSON object keys (GH4593)
• Fixed passing `keep_default_na=False` when `na_values=None` (GH4318)
• Fixed bug with `values` raising an error on a DataFrame with duplicate columns and mixed dtypes, surfaced in (GH4377)
• Fixed bug with duplicate columns and type conversion in `read_json` when `orient='split'` (GH4377)
• Fixed JSON bug where locales with decimal separators other than `.` threw exceptions when encoding / decoding certain values. (GH4918)
• Fix `.iat` indexing with a `PeriodIndex` (GH4390)
• Fixed an issue where `PeriodIndex` joining with self was returning a new instance rather than the same instance (GH4379); also adds a test for this for the other index types
• Fixed a bug with all the dtypes being converted to object when using the CSV cparser with the usecols parameter (GH3192)
• Fix an issue in merging blocks where the resulting DataFrame had partially set _ref_locs (GH4403)
• Fixed an issue where hist subplots were being overwritten when they were called using the top level matplotlib API (GH4408)
• Fixed a bug where calling `Series.astype(str)` would truncate the string (GH4405, GH4437)
• Fixed a py3 compat issue where bytes were being repr'd as tuples (GH4455)
• Fixed Panel attribute naming conflict if item is named ‘a’ (GH3440)
• Fixed an issue where duplicate indexes were raising when plotting (GH4486)
• Fixed an issue where cumsum and cumprod didn’t work with bool dtypes (GH4170, GH4440)
• Fixed Panel slicing issued in `xs` that was returning an incorrect dimmed object (GH4016)
• Fix resampling bug where custom reduce function not used if only one group (GH3849, GH4494)
• Fixed Panel assignment with a transposed frame (GH3830)
• Raise on set indexing with a Panel and a Panel as a value which needs alignment (GH3777)
• frozenset objects now raise in the `Series` constructor (GH4482, GH4480)
• Fixed issue with sorting a duplicate multi-index that has multiple dtypes (GH4516)
• Fixed bug in `DataFrame.set_values` which was causing name attributes to be lost when expanding the index. (GH3742, GH4039)
• Fixed issue where individual names, levels and labels could be set on `MultiIndex` without validation (GH3714, GH4039)
• Fixed (GH3334) in `pivot_table`. Margins did not compute if values is the index.
• Fix bug in having a rhs of `np.timedelta64` or `np.offsets.DateOffset` when operating with date-times (GH4532)
• Fix arithmetic with series/datetimeindex and `np.timedelta64` not working the same (GH4134) and buggy timedelta in NumPy 1.6 (GH4135)
• Fix bug in `pd.read_clipboard` on windows with PY3 (GH4561); not decoding properly
• `tslib.get_period_field()` and `tslib.get_period_field_arr()` now raise if code argument out of range (GH4519, GH4520)
• Fix boolean indexing on an empty series loses index names (GH4235), `infer_dtype` works with empty arrays.
• Fix reindexing with multiple axes; if an axes match was not replacing the current axes, leading to a possible lazy frequency inference issue (GH3317)
• Fixed issue where `DataFrame.apply` was reraising exceptions incorrectly (causing the original stack trace to be truncated).
• Fix selection with `ix/loc` and non_unique selectors (GH4619)
• Fix assignment with `iloc/loc` involving a dtype change in an existing column (GH4312, GH5702) have internal `setitem_with_indexer` in core/indexing to use Block.setitem
• Fixed bug where thousands operator was not handled correctly for floating point numbers in `csv_import` (GH4322)
• Fix an issue with CacheableOffset not properly being used by many DateOffset; this prevented the DateOffset from being cached (GH4609)
• Fix boolean comparison with a DataFrame on the lhs, and a list/tuple on the rhs (GH4576)
• Fix error/dtype conversion with `setitem` of `None` on `Series/DataFrame` (GH4667)
• Fix decoding based on a passed in non-default encoding in `pd.read_stata` (GH4626)
• Fix `DataFrame.from_records` with a plain-vanilla `ndarray`. (GH4727)
• Fix some inconsistencies with `Index.rename` and `MultiIndex.rename`, etc. (GH4718, GH4628)
• Bug in using `iloc/loc` with a cross-sectional and duplicate indices (GH4726)
• Bug with using `QUOTE_NONE` with `to_csv` causing `Exception`. (GH4328)
• Bug with Series indexing not raising an error when the right-hand-side has an incorrect length (GH2702)
• Bug in multi-indexing with a partial string selection as one part of a MultiIndex (GH4758)
• Bug with reindexing on the index with a non-unique index will now raise `ValueError` (GH4746)
• Bug in setting with `loc/ix` a single indexer with a multi-index axis and a NumPy array, related to (GH3777)
• Bug in concatenation with duplicate columns across dtypes not merging with axis=0 (GH4771, GH4975)
• Bug in `iloc` with a slice index failing (GH4771)
• Incorrect error message with no colspecs or width in `read_fwf`. (GH4774)
• Fix bugs in indexing in a Series with a duplicate index (GH4548, GH4550)
• Fixed bug with reading compressed files with `read_fwf` in Python 3. (GH3963)
• Fixed an issue with a duplicate index and assignment with a dtype change (GH4686)
• Fixed an issue related to ticklocs/ticklabels with log scale bar plots across different versions of matplotlib (GH4789)
• Suppressed DeprecationWarning associated with internal calls issued by `repr()` (GH4391)
• Fixed an issue with a duplicate index and duplicate selector with `.loc` (GH4825)
• Fixed an issue with DataFrame.sort_index where, when sorting by a single column and passing a list for ascending, the argument for ascending was being interpreted as True (GH4839, GH4846)

• Fixed Panel.tshift not working. Added freq support to Panel.shift (GH4853)

• Fix an issue in TextFileReader w/ Python engine (i.e. PythonParser) with thousands != “,” (GH4596)

• Bug in getitem with a duplicate index when using where (GH4879)

• Fix Type inference code coerces float column into datetime (GH4601)

• Fixed _ensure_numeric does not check for complex numbers (GH4902)

• Fixed a bug in Series.hist where two figures were being created when the by argument was passed (GH4112, GH4113).

• Fixed a bug in convert_objects for > 2 ndims (GH4937)

• Fixed a bug in DataFrame/Panel cache insertion and subsequent indexing (GH4939, GH5424)

• Fixed string methods for FrozenNDArray and FrozenList (GH4929)

• Fixed a bug with setting invalid or out-of-range values in indexing enlargement scenarios (GH4940)

• Tests for fillna on empty Series (GH4346), thanks @immerrr

• Fixed copy() to shallow copy axes/indices as well and thereby keep separate metadata. (GH4202, GH4830)

• Fixed skiprows option in Python parser for read_csv (GH4382)

• Fixed bug preventing cut from working with np.inf levels without explicitly passing labels (GH3415)

• Fixed wrong check for overlapping in DatetimeIndex.union (GH4564)

• Fixed conflict between thousands separator and date parser in csv_parser (GH4678)

• Fix appending when dtypes are not the same (error showing mixing float/np.datetime64) (GH4993)

• Fix repr for DateOffset. No longer show duplicate entries in kwd. Removed unused offset fields. (GH4638)

• Fixed wrong index name during read_csv if using usecols. Applies to c parser only. (GH4201)

• Timestamp objects can now appear in the left hand side of a comparison operation with a Series or DataFrame object (GH4982).

• Fix a bug when indexing with np.nan via iloc/loc (GH5016)

• Fixed a bug where low memory c parser could create different types in different chunks of the same file. Now coerces to numerical type or raises warning. (GH3866)

• Fix a bug where reshaping a Series to its own shape raised TypeError (GH4554) and other reshaping issues.

• Bug in setting with ix/loc and a mixed int/string index (GH4544)

• Make sure series-series boolean comparisons are label based (GH4947)

• Bug in multi-level indexing with a Timestamp partial indexer (GH4294)

• Tests/fix for multi-index construction of an all-nan frame (GH4078)

• Fixed a bug where read_html() wasn’t correctly inferring values of tables with commas (GH5029)

• Fixed a bug where read_html() wasn’t providing a stable ordering of returned tables (GH4770, GH5029).

• Fixed a bug where read_html() was incorrectly parsing when passed index_col=0 (GH5066).

• Fixed a bug where read_html() was incorrectly inferring the type of headers (GH5048).

• Fixed a bug where DatetimeIndex joins with PeriodIndex caused a stack overflow (GH3899).
• Fixed a bug where groupby objects didn’t allow plots (GH5102).
• Fixed a bug where groupby objects weren’t tab-completing column names (GH5102).
• Fixed a bug where groupby.plot() and friends were duplicating figures multiple times (GH5102).
• Provide automatic conversion of object dtypes on fillna, related (GH5103)
• Fixed a bug where default options were being overwritten in the option parser cleaning (GH5121).
• Treat a list/ndarray identically for iloc indexing with list-like (GH5006)
• Fix MultiIndex.get_level_values() with missing values (GH5074)
• Fix bound checking for Timestamp() with datetime64 input (GH4065)
• Fix a bug where TestReadHtml wasn’t calling the correct read_html() function (GH5150).
• Fix a bug with NDFrame.replace() which made replacement appear as though it was (incorrectly) using regular expressions (GH5143).
• Fix better error message for to_datetime (GH4928)
• Made sure different locales are tested on travis-ci (GH4918). Also adds a couple of utilities for getting locales and setting locales with a context manager.
• Fixed segfault on isnull(MultiIndex) (now raises an error instead) (GH5123, GH5125)
• Allow duplicate indices when performing operations that align (GH5185, GH5639)
• Compound dtypes in a constructor raise NotImplementedError (GH5191)
• Bug in comparing duplicate frames (GH4421) related
• Bug in describe on duplicate frames
• Bug in to_datetime with a format and coerce=True not raising (GH5195)
• Bug in loc setting with multiple indexers and a rhs of a Series that needs broadcasting (GH5206)
• Fixed bug where inplace setting of levels or labels on MultiIndex would not clear cached values property and therefore return wrong values. (GH5215)
• Fixed bug where filtering a grouped DataFrame or Series did not maintain the original ordering (GH4621).
• Fixed Period with a business date freq to always roll-forward if on a non-business date. (GH5203)
• Fixed bug in Excel writers where frames with duplicate column names weren’t written correctly. (GH5235)
• Fixed issue with drop and a non-unique index on Series (GH5248)
• Fixed seg fault in C parser caused by passing more names than columns in the file. (GH5156)
• Fix Series.isin with date/time-like dtypes (GH5021)
• C and Python Parser can now handle the more common multi-index column format which doesn’t have a row for index names (GH4702)
• Bug when trying to use an out-of-bounds date as an object dtype (GH5312)
• Bug when trying to display an embedded PandasObject (GH5324)
• Allows operating of Timestamps to return a datetime if the result is out-of-bounds related (GH5312)
• Fix return value/type signature of initObjToJSON() to be compatible with numpy’s import_array() (GH5334, GH5326)
• Bug when renaming then set_index on a DataFrame (GH5344)
• Test suite no longer leaves around temporary files when testing graphics. (GH5347) (thanks for catching this @yarikoptic!)
• Fixed html tests on win32. (GH4580)
• Make sure that head/tail are iloc based. (GH5370)
• Fixed bug for PeriodIndex string representation if there are 1 or 2 elements. (GH5372)
• The GroupBy methods transform and filter can be used on Series and DataFrames that have repeated (non-unique) indices. (GH4620)
• Fix empty series not printing name in repr (GH4651)
• Make tests create temp files in temp directory by default. (GH5419)
• pd.to_timedelta of a scalar returns a scalar (GH5410)
  • pd.to_timedelta accepts NaN and NaT, returning NaT instead of raising (GH5437)
  • performance improvements in isnull on larger size pandas objects
• Fixed various setitem with 1d ndarray that does not have a matching length to the indexer (GH5508)
• Bug in getitem with a multi-index and iloc (GH5528)
• Bug in delitem on a Series (GH5542)
• Bug fix in apply when using custom function and objects are not mutated (GH5545)
• Bug in selecting from a non-unique index with loc (GH5553)
• Bug in groupby returning non-consistent types when user function returns a None, (GH5592)
• Work around regression in numpy 1.7.0 which erroneously raises IndexError from ndarray.item (GH5666)
• Bug in repeated indexing of object with resultant non-unique index (GH5678)
• Bug in fillna with Series and a passed series/dict (GH5703)
• Bug in groupby transform with a datetime-like grouper (GH5712)
• Bug in multi-index selection in PY3 when using certain keys (GH5725)
• Row-wise concat of differing dtypes failing in certain cases (GH5754)

38.25 pandas 0.12.0

Release date: 2013-07-24

38.25.1 New Features

• pd.read_html() can now parse HTML strings, files or urls and returns a list of DataFrame s courtesy of @cpcloud. (GH3477, GH3605, GH3606)
• Support for reading Amazon S3 files. (GH3504)
• Added module for reading and writing JSON strings/files: pandas.io.json includes to_json DataFrame/Series method, and a read_json top-level reader various issues (GH1226, GH3804, GH3876, GH3867, GH1305)
• Added module for reading and writing Stata files: pandas.io.stata (GH1512) includes to_stata DataFrame method, and a read_stata top-level reader
• Added support for writing in `to_csv` and reading in `read_csv`, multi-index columns. The `header` option in `read_csv` now accepts a list of the rows from which to read the index. Added the option, `tupleize_cols` to provide compatibility for the pre 0.12 behavior of writing and reading multi-index columns via a list of tuples. The default in 0.12 is to write lists of tuples and *not* interpret list of tuples as a multi-index column. Note: The default value will change in 0.12 to make the default *to* write and read multi-index columns in the new format. (GH3571, GH1651, GH3141)

• Add iterator to `Series.str` (GH3638)

• `pd.set_option()` now allows N option, value pairs (GH3667).

• Added keyword parameters for different types of `scatter_matrix` subplots

• A `filter` method on grouped Series or DataFrames returns a subset of the original (GH3680, GH919)

• Access to historical Google Finance data in pandas.io.data (GH3814)

• DataFrame plotting methods can sample column colors from a Matplotlib colormap via the `colormap` keyword. (GH3860)

### 38.25.2 Improvements to existing features

• Fixed various issues with internal pprinting code, the `repr()` for various objects including TimeStamp and Index now produces valid Python code strings and can be used to recreate the object, (GH3038, GH3379, GH3251, GH3460)

• `convert_objects` now accepts a `copy` parameter (defaults to `True`)

• `HDFStore`
  – will retain index attributes (freq,tz,name) on recreation (GH3499, :issue:4098)
  – will warn with a `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
  – support datelike columns with a timezone as `data_columns` (GH2852)
  – table writing performance improvements.
  – support python3 (via `PyTables 3.0.0`) (GH3750)

• Add modulo operator to Series, DataFrame

• `Add date` method to `DatetimeIndex`

• Add `dropna` argument to `pivot_table` (:issue: 3820)

• Simplified the API and added a `describe` method to `Categorical`

• `melt` now accepts the optional parameters `var_name` and `value_name` to specify custom column names of the returned DataFrame (GH3649), thanks @hoechenberger. If `var_name` is not specified and `dataframe.columns.name` is not `None`, then this will be used as the `var_name` (GH4144). Also support for MultiIndex columns.

• clipboard functions use `pyperclip` (no dependencies on Windows, alternative dependencies offered for Linux) (GH3837).

• Plotting functions now raise a `TypeError` before trying to plot anything if the associated objects have a `dtype` of `object` (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric arrays if possible so that you can still plot, for example, an object array with floats. This happens before any drawing takes place which eliminates any spurious plots from showing up.

• Added Faq section on `repr` display options, to help users customize their setup.
- where operations that result in block splitting are much faster (GH3733)
- Series and DataFrame hist methods now take a figsize argument (GH3834)
- DatetimeIndexes no longer try to convert mixed-integer indexes during join operations (GH3877)
- Add unit keyword to Timestamp and to_datetime to enable passing of integers or floats that are in an epoch unit of D, s, ms, us, ns, thanks @mtkini (GH3969) (e.g. unix timestamps or epoch s, with fractional seconds allowed) (GH3540)
- DataFrame corr method (spearman) is now cythonized.
- Improved network test decorator to catch IOError (and therefore URLError as well). Added with_connectivity_check decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new optional_args decorator factory for decorators. (GH3910, GH3914)
- read_csv will now throw a more informative error message when a file contains no columns, e.g., all newline characters
- Added layout keyword to DataFrame.hist() for more customizable layout (GH4050)
- Timestamp.min and Timestamp.max now represent valid Timestamp instances instead of the default date-time.min and datetime.max (respectively), thanks @SleepingPills
- read_html now raises when no tables are found and BeautifulSoup==4.2.0 is detected (GH4214)

38.25.3 API Changes

- HDFStore
  - When removing an object, remove(key) raises KeyError if the key is not a valid store object.
  - raise a TypeError on passing where or columns to select with a Storer; these are invalid parameters at this time (GH4189)
  - can now specify an encoding option to append/put to enable alternate encodings (GH3750)
  - enable support for iterator/chunksize with read_hdf
- The repr() for (Multi)Index now obeys display.max_seq_items rather then NumPy threshold print options. (GH3426, GH3466)
- Added mangle_dupe_cols option to read_table/csv, allowing users to control legacy behaviour re dupe cols (A, A.1, A.2 vs A, A ) (GH3468) Note: The default value will change in 0.12 to the “no mangle” behaviour. If your code relies on this behaviour, explicitly specify mangle_dupe_cols=True in your calls.
- Do not allow astypes on datetime64[ns] except to object, and timedelta64[ns] to object/int (GH3425)
- The behavior of datetime64 dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a TypeError when performed on a Series and return an empty Series when performed on a DataFrame similar to performing these operations on, for example, a DataFrame of slice objects: - sum, prod, mean, std, var, skew, kurt, corr, and cov
- Do not allow datetimelike/timedeltalike creation except with valid types (e.g. cannot pass datetime64[ms]) (GH3423)
- Add squeeze keyword to groupby to allow reduction from DataFrame -> Series if groups are unique. Regression from 0.10.1, partial revert on (GH2893) with (GH3596)
- Raise on iloc when boolean indexing with a label based indexer mask e.g. a boolean Series, even with integer labels, will raise. Since iloc is purely positional based, the labels on the Series are not alignable (GH3631)
• The raise_on_error option to plotting methods is obviated by GH3572, so it is removed. Plots now always raise when data cannot be plotted or the object being plotted has a dtype of object.
• DataFrame.interpolate() is now deprecated. Please use DataFrame.fillna() and DataFrame.replace() instead (GH3582, GH3675, GH3676).
• the method and axis arguments of DataFrame.replace() are deprecated
• DataFrame.replace 's infer_types parameter is removed and now performs conversion by default. (GH3907)
• Deprecated display.height, display.width is now only a formatting option does not control triggering of summary, similar to < 0.11.0.
• Add the keyword allow_duplicates to DataFrame.insert to allow a duplicate column to be inserted if True, default is False (same as prior to 0.12) (GH3679)
• io API changes
  – added pandas.io.api for i/o imports
  – removed Excel support to pandas.io.excel
  – added top-level pd.read_sql and to_sql DataFrame methods
  – removed clipboard support to pandas.io.clipboard
  – replace top-level and instance methods save and load with top-level read_pickle and to_pickle instance method, save and load will give deprecation warning.
• the method and axis arguments of DataFrame.replace() are deprecated
• set FutureWarning to require data_source, and to replace year/month with expiry date in pandas.io options. This is in preparation to add options data from Google (GH3822)
• the method and axis arguments of DataFrame.replace() are deprecated
• Implement __nonzero__ for NDFrame objects (GH3691, GH3696)
• as_matrix with mixed signed and unsigned dtypes will result in 2 x the lcd of the unsigned as an int, maxing with int64, to avoid precision issues (GH3733)
• na_values in a list provided to read_csv/read_excel will match string and numeric versions e.g. na_values=['99'] will match 99 whether the column ends up being int, float, or string (GH3611)
• read_html now defaults to None when reading, and falls back on bs4 + html5lib when lxml fails to parse. a list of parsers to try until success is also valid
• more consistency in the to_datetime return types (give string/array of string inputs) (GH3888)
• The internal pandas class hierarchy has changed (slightly). The previous PandasObject now is called PandasContainer and a new PandasObject has become the baseclass for PandasContainer as well as Index, Categorical, GroupBy, SparseList, and SparseArray (+ their base classes). Currently, PandasObject provides string methods (from StringMixin). (GH4090, GH4092)
• New StringMixin that, given a __unicode__ method, gets Python 2 and Python 3 compatible string methods (_str_, __bytes__, and __repr__). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

38.25.4 Experimental Features

• Added experimental CustomBusinessDay class to support DateOffsets with custom holiday calendars and custom weekmasks. (GH2301)
38.25.5 Bug Fixes

- Fixed an esoteric excel reading bug. xlrd>= 0.9.0 now required for excel support. Should provide python3 support (for reading) which has been lacking. (GH3164)
- Disallow Series constructor called with MultiIndex which caused segfault (GH4187)
- Allow unioning of date ranges sharing a timezone (GH3491)
- Fix to_csv issue when having a large number of rows and NaT in some columns (GH3437)
- .loc was not raising when passed an integer list (GH3449)
- Unordered time series selection was misbehaving when using label slicing (GH3448)
- Fix sorting in a frame with a list of columns which contains datetime64[ns] dtypes (GH3461)
- DataFrames fetched via FRED now handle ‘.’ as a NaN. (GH3469)
- Fix regression in a DataFrame apply with axis=1, objects were not being converted back to base dtypes correctly (GH3480)
- Fix issue when storing uint dtypes in an HDFStore. (GH3493)
- Non-unique index support clarified (GH3468)
  - Addressed handling of dupe columns in df.to_csv new and old (GH3454, GH3457)
  - Fix assigning a new index to a duplicate index in a DataFrame would fail (GH3468)
  - Fix construction of a DataFrame with a duplicate index
  - ref_locs support to allow duplicative indices across dtypes, allows iget support to always find the index (even across dtypes) (GH2194)
  - applymap on a DataFrame with a non-unique index now works (removed warning) (GH2786), and fix (GH3230)
  - Fix to_csv to handle non-unique columns (GH3495)
  - Duplicate indexes with getitem will return items in the correct order (GH3455, GH3457) and handle missing elements like unique indices (GH3561)
  - Duplicate indexes with and empty DataFrame.from_records will return a correct frame (GH3562)
  - Concat to produce a non-unique columns when duplicates are across dtypes is fixed (GH3602)
  - Non-unique indexing with a slice via loc and friends fixed (GH3659)
  - Allow insert/delete to non-unique columns (GH3679)
  - Extend reindex to correctly deal with non-unique indices (GH3679)
  - DataFrame.itertuples() now works with frames with duplicate column names (GH3873)
  - Bug in non-unique indexing via iloc (GH4017); added takeable argument to reindex for location-based taking
    - Allow non-unique indexing in series via .ix/.loc and __getitem__ (GH4246)
    - Fixed non-unique indexing memory allocation issue with .ix/.loc (GH4280)
- Fixed bug in groupby with empty series referencing a variable before assignment. (GH3510)
- Allow index name to be used in groupby for non MultiIndex (GH4014)
- Fixed bug in mixed-frame assignment with aligned series (GH3492)
- Fixed bug in selecting month/quarter/year from a series would not select the time element on the last day (GH3346)
- Fixed a couple of MultiIndex rendering bugs in df.to_html() (GH3547, GH3553)
- Properly convert np.datetime64 objects in a Series (GH3416)
- Raise a TypeError on invalid datetimedelta operations e.g. add datetimes, multiple timedelta x datetime
- Fix .diff on datelike and timedelta operations (GH3100)
- combine_first not returning the same dtype in cases where it can (GH3552)
- Fixed bug with Panel.transpose argument aliases (GH3556)
- Fixed platform bug in PeriodIndex.take (GH3579)
- Fixed bug in incorrect conversion of datetime64[ns] in combine_first (GH3593)
- Fixed bug in reset_index with NaN in a multi-index (GH3586)
-fillna methods now raise a TypeError when the value parameter is a list or tuple.
- Fixed bug where a time-series was being selected in preference to an actual column name in a frame (GH3594)
- Make secondary_y work properly for bar plots (GH3598)
- Fix modulo and integer division on Series,DataFrames to act similarly to float dtypes to return np.nan or np.inf as appropriate (GH3590)
- Fix incorrect dtype on groupby with as_index=False (GH3610)
- Fix read_csv/read_excel to correctly encode identical na_values, e.g. na_values=[-999.0,-999] was failing (GH3611)
- Disable HTML output in qtconsole again. (GH3657)
- Reworked the new repr display logic, which users found confusing. (GH3663)
- Fix indexing issue in ndim >= 3 with iloc (GH3617)
- Correctly parse date columns with embedded (nan/NaT) into datetime64[ns] dtype in read_csv when parse_dates is specified (GH3602)
- Fix not consolidating before to_csv (GH3624)
- Fix alignment issue when setitem in a DataFrame with a piece of a DataFrame (GH3626) or a mixed DataFrame and a Series (GH3668)
- Fix plotting of unordered DatetimeIndex (GH3601)
- sql.write_frame failing when writing a single column to sqlite (GH3628), thanks to @stonebig
- Fix pivoting with nan in the index (GH3558)
- Fix running of bs4 tests when it is not installed (GH3605)
- Fix parsing of html table (GH3606)
- read_html() now only allows a single backend: html5lib (GH3616)
- convert_objects with convert_dates='coerce' was parsing some single-letter strings into today's date
- DataFrame.from_records did not accept empty recarrays (GH3682)
- DataFrame.to_csv will succeed with the deprecated option nanRep. @tdsmith
- DataFrame.to_html and DataFrame.to_latex now accept a path for their first argument (GH3702)
• Fix file tokenization error with r delimiter and quoted fields (GH3453)
• Groupby transform with item-by-item not upcasting correctly (GH3740)
• Incorrectly read a HDFStore multi-index Frame with a column specification (GH3748)
• read_html now correctly skips tests (GH3741)
• PandasObjects raise TypeError when trying to hash (GH3882)
• Fix incorrect arguments passed to concat that are not list-like (e.g. concat(df1,df2)) (GH3481)
• Correctly parse when passed the dtype=str (or other variable-len string dtypes) in read_csv (GH3795)
• Fix index name not propagating when using loc/ix (GH3880)
• Fix groupby when applying a custom function resulting in a returned DataFrame was not converting dtypes (GH3911)
• Fixed a bug where DataFrame.replace with a compiled regular expression in the to_replace argument wasn’t working (GH3907)
• Fixed __truediv__ in Python 2.7 with numexpr installed to actually do true division when dividing two integer arrays with at least 10000 cells total (GH3764)
• Indexing with a string with seconds resolution not selecting from a time index (GH3925)
• csv parsers would loop infinitely if iterator=True but no chunksize was specified (GH3967), Python parser failing with chunksize=1
• Fix index name not propagating when using shift
• Fixed dropna=False being ignored with multi-index stack (GH3997)
• Fixed flattening of columns when renaming MultiIndex columns DataFrame (GH4004)
• Fix Series.clip for datetime series. NA/NaN threshold values will now throw ValueError (GH3996)
• Fixed insertion issue into DataFrame, after rename (GH4032)
• Fixed testing issue where too many sockets where open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
• Fixed failing tests in test_yahoo, test_google where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
• Series.hist will now take the figure from the current environment if one is not passed
• Fixed bug where a 1xN DataFrame would barf on a 1xN mask (GH4071)
• Fixed running of tox under python3 where the pickle import was getting rewritten in an incompatible way (GH4062, GH4063)
• Fixed bug where sharex and sharey were not being passed to grouped_hist (GH4089)
• Fix bug where HDFStore will fail to append because of a different block ordering on-disk (GH4096)
• Better error messages on inserting incompatible columns to a frame (GH4107)
• Fixed bug in DataFrame.replace where a nested dict wasn’t being iterated over when regex=False (GH4115)
• Fixed bug in convert_objects(convert_numeric=True) where a mixed numeric and object Series/Frame was not converting properly (GH4119)
• Fixed bugs in multi-index selection with column multi-index and duplicates (GH4145, GH4146)
• Fixed bug in the parsing of microseconds when using the format argument in to_datetime (GH4152)
• Fixed bug in PandasAutoDateLocator where invert_xaxis triggered incorrectly
MilliSecondLocator (GH3990)
• Fixed bug in Series.where where broadcasting a single element input vector to the length of the series
resulted in multiplying the value inside the input (GH4192)
• Fixed bug in plotting that wasn’t raising on invalid colormap for matplotlib 1.1.1 (GH4215)
• Fixed the legend displaying in DataFrame.plot (kind='kde') (GH4216)
• Fixed bug where Index slices weren’t carrying the name attribute (GH4226)
• Fixed bug in initializing DatetimeIndex with an array of strings in a certain time zone (GH4229)
• Fixed bug where html5lib wasn’t being properly skipped (GH4265)
• Fixed bug where get_data_famafrench wasn’t using the correct file edges (GH4281)

38.26 pandas 0.11.0

Release date: 2013-04-22

38.26.1 New Features

• New documentation section, 10 Minutes to Pandas
• New documentation section, Cookbook
• Allow mixed dtypes (e.g. float32/float64/int32/int16/int8) to coexist in DataFrames and propagate in operations
• Add function to pandas.io.data for retrieving stock index components from Yahoo! finance (GH2795)
• Support slicing with time objects (GH2681)
• Added .iloc attribute, to support strict integer based indexing, analogous to .ix (GH2922)
• Added .loc attribute, to support strict label based indexing, analogous to .ix (GH3053)
• Added .iat attribute, to support fast scalar access via integers (replaces iget_value/iset_value)
• Added .at attribute, to support fast scalar access via labels (replaces get_value/set_value)
• Moved functionality from irow, icoi, iget_value/iset_value to .iloc indexer (via _ixs methods in each object)
• Added support for expression evaluation using the numexpr library
• Added convert=boolean to take routines to translate negative indices to positive, defaults to True
• Added to_series() method to indices, to facilitate the creation of indexers (GH3275)

38.26.2 Improvements to existing features

• Improved performance of df.to_csv() by up to 10x in some cases. (GH3059)
• added blocks attribute to DataFrames, to return a dict of dtypes to homogeneously dtyped DataFrames
• added keyword convert_numeric to convert_objects() to try to convert object dtypes to numeric
types (default is False)
• **convert_dates** in **convert_objects** can now be **coerce** which will return a datetime64[ns] dtype with non-convertibles set as NaT; will preserve an all-nan object (e.g. strings), default is True (to perform soft-conversion)

• Series print output now includes the dtype by default

• Optimize internal reindexing routines (GH2819, GH2867)

• **describe_option()** now reports the default and current value of options.

• Add **format** option to **pandas.to_datetime** with faster conversion of strings that can be parsed with datetime.strptime

• Add **axes** property to **Series** for compatibility

• Add **xs** function to **Series** for compatibility

• Allow **setitem** in a frame where only mixed numerics are present (e.g. int and float), (GH3037)

• **HDFStore**
  – Provide dotted attribute access to **get** from stores (e.g. `store.df == store['df']`)
  – New keywords **iterator=boolean**, and **chunksize=number_in_a_chunk** are provided to support iteration on **select** and **select_as_multiple** (GH3076)
  – support read_hdf/to_hdf API similar to read_csv/to_csv (GH3222)

• Add **squeeze** method to possibly remove length 1 dimensions from an object.

```python
In [1]: p = pd.Panel(np.random.randn(3,4,4),items=['ItemA','ItemB','ItemC'],
               ...: major_axis=pd.date_range('20010102',periods=4),
               ...: minor_axis=['A','B','C','D'])

In [2]: p
Out[2]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2001-01-02 00:00:00 to 2001-01-05 00:00:00
Minor_axis axis: A to D

In [3]: p.reindex(items=['ItemA']).squeeze()

   A   B   C   D
2001-01-02  0.469112 -0.282863 -1.509059 -1.135632
2001-01-03  1.212112 -0.173215  0.119209 -1.044236
2001-01-04 -0.861849 -2.104569 -0.494929  1.071804
2001-01-05  0.721555 -0.706771 -1.039575  0.271860

In [4]: p.reindex(items=['ItemA'],minor=['B']).squeeze()

    2001-01-02 -0.282863
    2001-01-03 -0.173215
    2001-01-04 -2.104569
    2001-01-05 -0.706771
Freq: D, Name: B, dtype: float64
```

• Improvement to Yahoo API access in **pd.io.data.Options** (GH2758)
• added option `display.max_seq_items` to control the number of elements printed per sequence pprinting it. (GH2979)
• added option `display.chop_threshold` to control display of small numerical values. (GH2739)
• added option `display.max_info_rows` to prevent `verbose_info` from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
• `value_counts()` now accepts a “normalize” argument, for normalized histograms. (GH2710).
• `DataFrame.from_records` now accepts not only dicts but any instance of the collections.Mapping ABC.
• Allow selection semantics via a string with a datelike index to work in both Series and DataFrames (GH3070)

```
In [5]: idx = pd.date_range("2001-10-1", periods=5, freq='M')
In [6]: ts = pd.Series(np.random.rand(len(idx)), index=idx)
In [7]: ts['2001']
Out[7]:
2001-10-31  0.838796
2001-11-30  0.897333
2001-12-31  0.732592
Freq: M, dtype: float64
In [8]: df = pd.DataFrame(dict(A = ts))
In [9]: df['2001']
Out[9]:
       A
2001-10-31  0.838796
2001-11-30  0.897333
2001-12-31  0.732592
```

• added option `display.mpl_style` providing a sleeker visual style for plots. Based on https://gist.github.com/huyng/816622 (GH3075).
• Improved performance across several core functions by taking memory ordering of arrays into account. Courtesy of @stephenwlin (GH3130)
• Improved performance of groupby transform method (GH2121)
• Handle “ragged” CSV files missing trailing delimiters in rows with missing fields when also providing explicit list of column names (so the parser knows how many columns to expect in the result) (GH2981)
• On a mixed DataFrame, allow setting with indexers with ndarray/DataFrame on rhs (GH3216)
• Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
• Add `time` method to `DatetimeIndex` (GH3180)
• Return NA when using `Series.str[...]` for values that are not long enough (GH3223)
• Display cursor coordinate information in time-series plots (GH1670)
• `to_html()` now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes &, in addition to < and >. (GH2919)

### 38.26.3 API Changes

• Do not automatically upcast numeric specified dtypes to `int64` or `float64` (GH622 and GH797)
• DataFrame construction of lists and scalars, with no dtype present, will result in casting to int64 or float64, regardless of platform. This is not an apparent change in the API, but noting it.

• Guarantee that convert_objects() for Series/DataFrame always returns a copy

• groupby operations will respect dtypes for numeric float operations (float32/float64); other types will be operated on, and will try to cast back to the input dtype (e.g. if an int is passed, as long as the output doesn’t have nans, then an int will be returned)

• backfill/pad/take/diff/ohlc will now support float32/int16/int8 operations

• Block types will upcast as needed in where/masking operations (GH2793)

• Series now automatically will try to set the correct dtype based on passed datetimelike objects (date-time/Timestamp)
  – timedelta64 are returned in appropriate cases (e.g. Series - Series, when both are datetime64)
  – mixed datetimes and objects (GH2751) in a constructor will be cast correctly
  – astype on datetimes to object are now handled (as well as NaT conversions to np.nan)
  – all timedelta like objects will be correctly assigned to timedelta64 with mixed NaN and/or NaT allowed

• arguments to DataFrame.clip were inconsistent to NumPy and Series clipping (GH2747)

• util.testing.assert_frame_equal now checks the column and index names (GH2964)

• Constructors will now return a more informative ValueError on failures when invalid shapes are passed

• Don’t suppress TypeError in GroupBy.agg (GH3238)

• Methods return None when inplace=True (GH1893)

• HDFStore
  – added the method select_column to select a single column from a table as a Series.
  – deprecated the unique method, can be replicated by select_column(key,column).unique()
  – min_itemsize parameter will now automatically create data_columns for passed keys

• Downcast on pivot if possible (GH3283), adds argument downcast to fillna

• Introduced options display.height/width for explicitly specifying terminal height/width in characters. Deprecated display.line_width, now replaced by display.width. These defaults are in effect for scripts as well, so unless disabled, previously very wide output will now be output as “expand_repr” style wrapped output.

• Various defaults for options (including display.max_rows) have been revised, after a brief survey concluded they were wrong for everyone. Now at w=80,h=60.

• HTML repr output in IPython qtconsole is once again controlled by the option display.notebook_repr_html, and on by default.

### 38.26.4 Bug Fixes

• Fix seg fault on empty data frame when fillna with pad or backfill (GH2778)

• Single element ndarrays of datetimelike objects are handled (e.g. np.array(datetime(2001,1,1,0,0)), w/o dtype being passed

• 0-dim ndarrays with a passed dtype are handled correctly (e.g. np.array(0.,dtype='float32'))

• Fix some boolean indexing inconsistencies in Series.__getitem__/__setitem__ (GH2776)
pandas: powerful Python data analysis toolkit, Release 0.23.3

- Fix issues with DataFrame and Series constructor with integers that overflow int64 and some mixed typed type lists (GH2845)
- HDFStore
  - Fix weird PyTables error when using too many selectors in a where also correctly filter on any number of values in a Term expression (so not using numexpr filtering, but isin filtering)
  - Internally, change all variables to be private-like (now have leading underscore)
  - Fixes for query parsing to correctly interpret boolean and != (GH2849, GH2973)
  - Fixes for pathological case on SparseSeries with 0-len array and compression (GH2931)
  - Fixes bug with writing rows if part of a block was all-nan (GH3012)
  - Exceptions are now ValueError or TypeError as needed
  - A table will now raise if min_itemsize contains fields which are not queryables
- Bug showing up in applymap where some object type columns are converted (GH2909) had an incorrect default in convert_objects
- TimeDeltas
  - Series ops with a Timestamp on the rhs was throwing an exception (GH2898) added tests for Series ops with datetimes,timedeltas,Timestamps, and datelike Series on both lhs and rhs
  - Fixed subtle timedelta64 inference issue on py3 & NumPy 1.7.0 (GH3094)
  - Fixed some formatting issues on timedelta when negative
  - Support null checking on timedelta64, representing (and formatting) with NaT
  - Support setitem with np.nan value, converts to NaT
  - Support min/max ops in a Dataframe (abs not working, nor do we error on non-supported ops)
  - Support idxmin/idxmax/abs/max/min in a Series (GH2989, GH2982)
- Bug on in-place putmasking on an integer series that needs to be converted to float (GH2746)
- Bug in argsort of datetime64[ns] Series with NaT (GH2967)
- Bug in value_counts of datetime64[ns] Series (GH3002)
- Fixed printing of NaT in an index
- Bug in idxmin/idxmax of datetime64[ns] Series with NaT (GH2982)
- Bug in icol, take with negative indicies was producing incorrect return values (see GH2922, GH2892), also check for out-of-bounds indices (GH3029)
- Bug in DataFrame column insertion when the column creation fails, existing frame is left in an irrecoverable state (GH3010)
- Bug in DataFrame update, combine_first where non-specified values could cause dtype changes (GH3016, GH3041)
- Bug in groupby with first/last where dtypes could change (GH3041, GH2763)
- Formatting of an index that has nan was inconsistent or wrong (would fill from other values), (GH2850)
- Unstack of a frame with no nans would always cause dtype upcasting (GH2929)
- Fix scalar datetime.datetime parsing bug in read_csv (GH3071)
- Fixed slow printing of large Dataframes, due to inefficient dtype reporting (GH2807)
• Fixed a segfault when using a function as grouper in groupby (GH3035)
• Fix pretty-printing of infinite data structures (closes GH2978)
• Fixed exception when plotting timeseries bearing a timezone (closes GH2877)
• str.contains ignored na argument (GH2806)
• Substitute warning for segfault when grouping with categorical grouper of mismatched length (GH3011)
• Fix exception in SparseSeries.density (GH2083)
• Fix upsampling bug with closed='left' and daily to daily data (GH3020)
• Fixed missing tick bars on scatter_matrix plot (GH3063)
• Fixed bug in Timestamp(d, tz=foo) when d is date() rather than datet ime() (GH2993)
• series.plot(kind='bar') now respects pylab color schem (GH3115)
• Fixed bug in reshape if not passed correct input, now raises TypeError (GH2719)
• Fixed a bug where Series ctor did not respect ordering if OrderedDict passed in (GH3282)
• Fix NameError issue on RESO_US (GH2787)
• Allow selection in an unordered timeseries to work similarly to an ordered timeseries (GH2437).
• Fix implemented .xs when called with axes=1 and a level parameter (GH2903)
• Timestamp now supports the class method fromordinal similar to datetimes (GH3042)
• Fix issue with indexing a series with a boolean key and specifying a 1-len list on the rhs (GH2745) or a list on the rhs (GH3235)
• Fixed bug in groupby apply when kernel generate list of arrays having unequal len (GH1738)
• fixed handling of rolling_corr with center=True which could produce corr>1 (GH3155)
• Fixed issues where indices can be passed as ‘index/column’ in addition to 0/1 for the axis parameter
• PeriodIndex.tolist now boxes to Period (GH3178)
• PeriodIndex.get_loc KeyError now reports Period instead of ordinal (GH3179)
• df.to_records bug when handling MultiIndex (GH3189)
• Fix Series.__getitem__ segfault when index less than -length (GH3168)
• Fix bug when using Timestamp as a date parser (GH2932)
• Fix bug creating date range from Timestamp with time zone and passing same time zone (GH2926)
• Add comparison operators to Period object (GH2781)
• Fix bug when concatenating two Series into a DataFrame when they have the same name (GH2797)
• Fix automatic color cycling when plotting consecutive timeseries without color arguments (GH2816)
• fixed bug in the pickling of PeriodIndex (GH2891)
• Upcast/split blocks when needed in a mixed DataFrame when setitem with an indexer (GH3216)
• Invoking df.applymap on a dataframe with dupe cols now raises a ValueError (GH2786)
• Apply with invalid returned indices raise correct Exception (GH2808)
• Fixed a bug in plotting log-scale bar plots (GH3247)
• df.plot() grid on/off now obeys the mpl default style, just like series.plot(). (GH3233)
• Fixed a bug in the legend of plotting.andrews_curves() (GH3278)
• Produce a series on apply if we only generate a singular series and have a simple index (GH2893)
• Fix Python ASCII file parsing when integer falls outside of floating point spacing (GH3258)
• fixed pretty printing of sets (GH3294)
• Panel() and Panel.from_dict() now respects ordering when give OrderedDict (GH3303)
• DataFrame where with a datetimelike incorrectly selecting (GH3311)
• Ensure index casts work even in Int64Index
• Fix set_index segfault when passing MultiIndex (GH3308)
• Ensure pickles created in py2 can be read in py3
• Insert ellipsis in MultiIndex summary repr (GH3348)
• Groupby will handle mutation among an input groups columns (and fallback to non-fast apply) (GH3380)
• Eliminated unicode errors on FreeBSD when using MPL GTK backend (GH3360)
• Period.strftime should return unicode strings always (GH3363)
• Respect passed read_* chunksize in get_chunk function (GH3406)

38.27 pandas 0.10.1

Release date: 2013-01-22

38.27.1 New Features

• Add data interface to World Bank WDI pandas.io.wb (GH2592)

38.27.2 API Changes

• Restored inplace=True behavior returning self (same object) with deprecation warning until 0.11 (GH1893)
• HDFStore
  – refactored HDFStore to deal with non-table stores as objects, will allow future enhancements
  – removed keyword compression from put (replaced by keyword complib to be consistent across library)
  – warn PerformanceWarning if you are attempting to store types that will be pickled by PyTables

38.27.3 Improvements to existing features

• HDFStore
  – enables storing of multi-index dataframes (closes GH1277)
  – support data column indexing and selection, via data_columns keyword in append
  – support write chunking to reduce memory footprint, via chunksize keyword to append
  – support automagic indexing via index keyword to append
- support `expectedrows` keyword in append to inform PyTables about the expected table size
- support `start` and `stop` keywords in select to limit the row selection space
- added `get_store` context manager to automatically import with pandas
- added column filtering via `columns` keyword in select
- added methods `append_to_multiple/select_as_multiple/select_as_coordinates` to do multiple-table append/selection
- added support for datetime64 in columns
- added method `unique` to select the unique values in an indexable or data column
- added method `copy` to copy an existing store (and possibly upgrade)
- show the shape of the data on disk for non-table stores when printing the store
- added ability to read PyTables flavor tables (allows compatibility to other HDF5 systems)

- Add `logx` option to DataFrame/Series.plot (GH2327, GH2565)
- Support reading gzipped data from file-like object
- `pivot_table aggfunc` can be anything used in GroupBy.aggregate (GH2643)
- Implement DataFrame merges in case where set cardinalities might overflow 64-bit integer (GH2690)
- Raise exception in C file parser if integer dtype specified and have NA values. (GH2631)
- Attempt to parse ISO8601 format dates when parse_dates=True in read_csv for major performance boost in such cases (GH2698)
- Add methods `neg` and `inv` to Series
- Implement `kind` option in ExcelFile to indicate whether it’s an XLS or XLSX file (GH2613)
- Documented a fast-path in pd.read_csv when parsing iso8601 datetime strings yielding as much as a 20x speedup. (GH5993)

### 38.27.4 Bug Fixes

- Fix read_csv/read_table multithreading issues (GH2608)
- HDFStore
  - correctly handle `nan` elements in string columns; serialize via the `nan_rep` keyword to append
  - raise correctly on non-implemented column types (unicode/date)
  - handle correctly `Term` passed types (e.g. `index<1000, when index is Int64`), (closes GH512)
  - handle Timestamp correctly in data_columns (closes GH2637)
  - contains correctly matches on non-natural names
  - correctly store `float32` dtypes in tables (if not other float types in the same table)
- Fix DataFrame.info bug with UTF8-encoded columns. (GH2576)
- Fix DatetimeIndex handling of FixedOffset tz (GH2604)
- More robust detection of being in IPython session for wide DataFrame console formatting (GH2585)
- Fix platform issues with `file:///` in unit test (GH2564)
- Fix bug and possible segfault when grouping by hierarchical level that contains NA values (GH2616)
• Ensure that MultiIndex tuples can be constructed with NAs (GH2616)
• Fix int64 overflow issue when unstacking MultiIndex with many levels (GH2616)
• Exclude non-numeric data from DataFrame.quantile by default (GH2625)
• Fix a Cython C int64 boxing issue causing read_csv to return incorrect results (GH2599)
• Fix groupby summing performance issue on boolean data (GH2692)
• Don’t bork Series containing datetime64 values with to_datetime (GH2699)
• Fix DataFrame.from_records corner case when passed columns, index column, but empty record list (GH2633)
• Fix C parser-tokenizer bug with trailing fields. (GH2668)
• Don’t exclude non-numeric data from GroupBy.max/min (GH2700)
• Don’t lose time zone when calling DatetimeIndex.drop (GH2621)
• Fix setitem on a Series with a boolean key and a non-scalar as value (GH2686)
• Box datetime64 values in Series.apply/map (GH2627, GH2689)
• Upconvert datetime + datetime64 values when concatenating frames (GH2624)
• Raise a more helpful error message in merge operations when one DataFrame has duplicate columns (GH2649)
• Fix partial date parsing issue occurring only when code is run at EOM (GH2618)
• Prevent MemoryError when using counting sort in sortlevel with high-cardinality MultiIndex objects (GH2684)
• Fix Period resampling bug when all values fall into a single bin (GH2070)
• Fix buggy interaction with usecols argument in read_csv when there is an implicit first index column (GH2654)
• Fix bug in Index.summary() where string format methods were being called incorrectly. (GH3869)

38.28 pandas 0.10.0

Release date: 2012-12-17

38.28.1 New Features

• Brand new high-performance delimited file parsing engine written in C and Cython. 50% or better performance in many standard use cases with a fraction as much memory usage. (GH407, GH821)
• Many new file parser (read_csv, read_table) features:
  – Support for on-the-fly gzip or bz2 decompression (compression option)
  – Ability to get back numpy.recarray instead of DataFrame (as_recarray=True)
  – dtype option: explicit column dtypes
  – usecols option: specify list of columns to be read from a file. Good for reading very wide files with many irrelevant columns (GH1216 GH926, GH2465)
  – Enhanced unicode decoding support via encoding option
  – skipinitialspace dialect option
  – Can specify strings to be recognized as True (true_values) or False (false_values)
– High-performance \textit{delim_whitespace} option for whitespace-delimited files; a preferred alternative to the ‘s+’ regular expression delimiter

– Option to skip “bad” lines (wrong number of fields) that would otherwise have caused an error in the past \textit{(error_bad_lines and warn_bad_lines options)}

– Substantially improved performance in the parsing of integers with thousands markers and lines with comments

– Easy of European (and other) decimal formats \textit{(decimal option)} \textit{(GH584, GH2466)}

– Custom line terminators (e.g. lineterminator='~') \textit{(GH2457)}

– Handling of no trailing commas in CSV files \textit{(GH2333)}

– Ability to handle fractional seconds in date_converters \textit{(GH2209)}

– read_csv allow scalar arg to na_values \textit{(GH1944)}

– Explicit column dtype specification in read_* functions \textit{(GH1858)}

– Easier CSV dialect specification \textit{(GH1743)}

– Improve parser performance when handling special characters \textit{(GH1204)}

• Google Analytics API integration with easy oauth2 workflow \textit{(GH2283)}

• Add error handling to Series.str.encode/decode \textit{(GH2276)}

• Add \textit{where} and \textit{mask} to Series \textit{(GH2337)}

• Grouped histogram via \textit{by} keyword in Series/DataFrame.hist \textit{(GH2186)}

• Support optional \textit{min_periods} keyword in \textit{corr and cov} for both Series and DataFrame \textit{(GH2002)}

• Add \textit{duplicated} and \textit{drop_duplicates} functions to Series \textit{(GH1923)}

• Add docs for \textit{HDFStore table format}

• ‘density’ property in \textit{SparseSeries} \textit{(GH2384)}

• Add \textit{ffill} and \textit{bfill} convenience functions for forward- and backfilling time series data \textit{(GH2284)}

• New option configuration system and functions \textit{set_option, get_option, describe_option, and reset_option. Deprecate set_printoptions and reset_printoptions} \textit{(GH2393)}. You can also access options as attributes via pandas.options.X

• Wide DataFrames can be viewed more easily in the console with new \textit{expand_frame_repr} and \textit{line_width} configuration options. This is on by default now \textit{(GH2436)}

• Scikits.timeseries-like moving window functions via \textit{rolling_window} \textit{(GH1270)}

\subsection*{38.28.2 Experimental Features}

• Add support for Panel4D, a named 4 Dimensional structure

• Add support for ndpanel factory functions, to create custom, domain-specific N-Dimensional containers

\subsection*{38.28.3 API Changes}

• The default binning/labeling behavior for \textit{resample} has been changed to \textit{closed='left', label='left} for daily and lower frequencies. This had been a large source of confusion for users. See “what’s new” page for more on this. \textit{(GH2410)}
• Methods with `inplace` option now return None instead of the calling (modified) object (GH1893)
• The special case DataFrame - TimeSeries doing column-by-column broadcasting has been deprecated. Users should explicitly do e.g. `df.sub(ts, axis=0)` instead. This is a legacy hack and can lead to subtle bugs.
• `inf/-inf` are no longer considered as NA by `isnull/notnull`. To be clear, this is legacy cruft from early pandas. This behavior can be globally re-enabled using the new option `mode.use_inf_as_null` (GH2050, GH1919)
• `pandas.merge` will now default to `sort=False`. For many use cases sorting the join keys is not necessary, and doing it by default is wasteful
• Specify `header=0` explicitly to replace existing column names in file in `read_*` functions.
• Default column names for header-less parsed files (yielded by `read_csv`, etc.) are now the integers 0, 1, .... A new argument `prefix` has been added; to get the v0.9.x behavior specify `prefix='X'` (GH2034). This API change was made to make the default column names more consistent with the DataFrame constructor’s default column names when none are specified.
• DataFrame selection using a boolean frame now preserves input shape
• If function passed to Series.apply yields a Series, result will be a DataFrame (GH2316)
• Values like YES/NO/yes/no will not be considered as boolean by default any longer in the file parsers. This can be customized using the new `true_values` and `false_values` options (GH2360)
• `obj.fillna()` is no longer valid; make `method='pad'` no longer the default option, to be more explicit about what kind of filling to perform. Add `ffill/bfill` convenience functions per above (GH2284)
• `HDFStore.keys()` now returns an absolute path-name for each key
• `to_string()` now always returns a unicode string. (GH2224)
• File parsers will not handle NA sentinel values arising from passed converter functions

38.28.4 Improvements to existing features

• Add `nrows` option to DataFrame.from_records for iterators (GH1794)
• Unstack/reshape algorithm rewrite to avoid high memory use in cases where the number of observed key-tuples is much smaller than the total possible number that could occur (GH2278). Also improves performance in most cases.
• Support duplicate columns in DataFrame.from_records (GH2179)
• Add `normalize` option to Series/DataFrame.asfreq (GH2137)
• SparseSeries and SparseDataFrame construction from empty and scalar values now no longer create dense ndarrays unnecessarily (GH2322)
• HDFStore now supports hierarchical keys (GH2397)
• Support multiple query selection formats for HDFStore tables (GH1996)
• Support del store['df'] syntax to delete HDFStores
• Add multi-dtype support for HDFStore tables
• `min_itemsize` parameter can be specified in HDFStore table creation
• Indexing support in HDFStore tables (GH698)
• Add `line_terminator` option to DataFrame.to_csv (GH2383)
• added implementation of `str(x)/unicode(x)/bytes(x)` to major pandas data structures, which should do the right thing on both py2.x and py3.x. (GH2224)
• Reduce groupby.apply overhead substantially by low-level manipulation of internal NumPy arrays in DataFrames (GH535)
• Implement value_vars in melt and add melt to pandas namespace (GH2412)
• Added boolean comparison operators to Panel
• Enable Series.str.strip/lstrip/rstrip methods to take an argument (GH2411)
• The DataFrame ctor now respects column ordering when given an OrderedDict (GH2455)
• Assigning DatetimeIndex to Series changes the class to TimeSeries (GH2139)
• Improve performance of .value_counts method on non-integer data (GH2480)
• get_level_values method for MultiIndex return Index instead of ndarray (GH2449)
• convert_to_r_dataframe conversion for datetime values (GH2351)
• Allow DataFrame.to_csv to represent inf and nan differently (GH2026)
• Add min_i argument to nancorr to specify minimum required observations (GH2002)
• Add inplace option to sortlevel / sort functions on DataFrame (GH1873)
• Enable DataFrame to accept scalar constructor values like Series (GH1856)
• DataFrame.from_records now takes optional size parameter (GH1794)
• include iris dataset (GH1709)
• No datetime64 DataFrame column conversion of datetime.datetime with tzinfo (GH1581)
• Micro-optimizations in DataFrame for tracking state of internal consolidation (GH217)
• Format parameter in DataFrame.to_csv (GH1525)
• Partial string slicing for DatetimeIndex for daily and higher frequencies (GH2306)
• Implement col_space parameter in to_html and to_string in DataFrame (GH1000)
• Override Series.tolist and box datetime64 types (GH2447)
• Optimize unstack memory usage by compressing indices (GH2278)
• Fix HTML repr in IPython qtconsole if opening window is small (GH2275)
• Escape more special characters in console output (GH2492)
• df.select now invokes bool on the result of crit(x) (GH2487)

38.28.5 Bug Fixes

• Fix major performance regression in DataFrame.iteritems (GH2273)
• Fixes bug when negative period passed to Series/DataFrame.diff (GH2266)
• Escape tabs in console output to avoid alignment issues (GH2038)
• Properly box datetime64 values when retrieving cross-section from mixed-dtype DataFrame (GH2272)
• Fix concatenation bug leading to GH2057, GH2257
• Fix regression in Index console formatting (GH2319)
• Box Period data when assigning PeriodIndex to frame column (GH2243, GH2281)
• Raise exception on calling reset_index on Series with inplace=True (GH2277)
• Enable setting multiple columns in DataFrame with hierarchical columns (GH2295)
• Respect dtype=object in DataFrame constructor (GH2291)
• Fix DatetimeIndex.join bug with tz-aware indexes and how='outer' (GH2317)
• pop(...) and del works with DataFrame with duplicate columns (GH2349)
• Treat empty strings as NA in date parsing (rather than let dateutil do something weird) (GH2263)
• Prevent uint64 -> int64 overflows (GH2355)
• Enable joins between MultiIndex and regular Index (GH2024)
• Fix time zone metadata issue when unioning non-overlapping DatetimeIndex objects (GH2367)
• Raise/handle int64 overflows in parsers (GH2247)
• Deleting of consecutive rows in HDFStore tables is much faster than before
• Appending on a HDFStore would fail if the table was not first created via put
• Use col_space argument as minimum column width in DataFrame.to_html (GH2328)
• Fix tz-aware DatetimeIndex.to_period (GH2232)
• Fix DataFrame row indexing case with MultiIndex (GH2314)
• Fix to_excel exporting issues with Timestamp objects in index (GH2294)
• Fixes assigning scalars and array to hierarchical column chunk (GH1803)
• Fixed a UnicodeDecodeError with series tidy_repr (GH2225)
• Fixed issued with duplicate keys in an index (GH2347, GH2380)
• Fixed issues re: Hash randomization, default on starting w/ py3.3 (GH2331)
• Fixed issue with missing attributes after loading a pickled dataframe (GH2431)
• Fix Timestamp formatting with tzoffset time zone in dateutil 2.1 (GH2443)
• Fix GroupBy.apply issue when using BinGrouper to do ts binning (GH2300)
• Fix issues resulting from datetime.datetime columns being converted to datetime64 when calling DataFrame.apply. (GH2374)
• Raise exception when calling to_panel on non uniquely-indexed frame (GH2441)
• Improved detection of console encoding on IPython zmq frontends (GH2458)
• Preserve time zone when .append-ing two time series (GH2260)
• Box timestamps when calling reset_index on time-zone-aware index rather than creating a tz-less datetime64 column (GH2262)
• Enable searching non-string columns in DataFrame.filter(like=...) (GH2467)
• Fixed issue with losing nanosecond precision upon conversion to DatetimeIndex(GH2252)
• Handle timezones in Datetime.normalize (GH2338)
• Fix test case where dtype specification with endianness causes failures on big endian machines (GH2318)
• Fix plotting bug where upsampling causes data to appear shifted in time (GH2448)
• Fix read_csv failure for UTF-16 with BOM and skiprows(GH2298)
• read_csv with names arg not implicitly setting header=None(GH2459)
• Unrecognized compression mode causes segfault in read_csv(GH2474)
• In read_csv, header=0 and passed names should discard first row (GH2269)
• Correctly route to stdout/stderr in read_table (GH2071)
• Fix exception when Timestamp.to_datetime is called on a Timestamp with tzoffset (GH2471)
• Fixed unintentional conversion of datetime64 to long in groupby.first() (GH2133)
• Union of empty DataFrames now return empty with concatenated index (GH2307)
• DataFrame.sort_index raises more helpful exception if sorting by column with duplicates (GH2488)
• DataFrame.to_string formatters can be list, too (GH2520)
• DataFrame.combine_first will always result in the union of the index and columns, even if one DataFrame is length-zero (GH2525)
• Fix several DataFrame.icol/irow with duplicate indices issues (GH2228, GH2259)
• Use Series names for column names when using concat with axis=1 (GH2489)
• Raise Exception if start, end, periods all passed to date_range (GH2538)
• Fix Panel resampling issue (GH2537)

38.29 pandas 0.9.1

Release date: 2012-11-14

38.29.1 New Features

• Can specify multiple sort orders in DataFrame/Series.sort/sort_index (GH928)
• New top and bottom options for handling NAs in rank (GH1508, GH2159)
• Add where and mask functions to DataFrame (GH2109, GH2151)
• Add at_time and between_time functions to DataFrame (GH2149)
• Add flexible pow and rpow methods to DataFrame (GH2190)

38.29.2 API Changes

• Upsampling period index “spans” intervals. Example: annual periods upsampled to monthly will span all months in each year
• Period.end_time will yield timestamp at last nanosecond in the interval (GH2124, GH2125, GH1764)
• File parsers no longer coerce to float or bool for columns that have custom converters specified (GH2184)

38.29.3 Improvements to existing features

• Time rule inference for week-of-month (e.g. WOM-2FRI) rules (GH2140)
• Improve performance of datetime + business day offset with large number of offset periods
• Improve HTML display of DataFrame objects with hierarchical columns
• Enable referencing of Excel columns by their column names (GH1936)
• DataFrame.dot can accept ndarrays (GH2042)
• Support negative periods in Panel.shift (GH2164)
• Make .drop(...) work with non-unique indexes (GH2101)
• Improve performance of Series/DataFrame.diff (re: GH2087)
• Support unary ~ (__invert__) in DataFrame (GH2110)
• Turn off pandas-style tick locators and formatters (GH2205)
• DataFrame[DataFrame] uses DataFrame.where to compute masked frame (GH2230)

38.29.4 Bug Fixes

• Fix some duplicate-column DataFrame constructor issues (GH2079)
• Fix bar plot color cycle issues (GH2082)
• Fix off-center grid for stacked bar plots (GH2157)
• Fix plotting bug if inferred frequency is offset with N > 1 (GH2126)
• Implement comparisons on date offsets with fixed delta (GH2078)
• Handle inf/-inf correctly in read_* parser functions (GH2041)
• Fix matplotlib unicode interaction bug
• Make WLS r-squared match statsmodels 0.5.0 fixed value
• Fix zero-trimming DataFrame formatting bug
• Correctly compute/box datetime64 min/max values from Series.min/max (GH2083)
• Fix unstacking edge case with unrepresented groups (GH2100)
• Fix Series.str failures when using pipe pattern ‘|’ (GH2119)
• Fix pretty-printing of dict entries in Series, DataFrame (GH2144)
• Cast other datetime64 values to nanoseconds in DataFrame ctor (GH2095)
• Alias Timestamp.astimezone to tz_convert, so will yield Timestamp (GH2060)
• Fix timedelta64 formatting from Series (GH2165, GH2146)
• Handle None values gracefully in dict passed to Panel constructor (GH2075)
• Box datetime64 values as Timestamp objects in Series/DataFrame.iget (GH2148)
• Fix Timestamp indexing bug in DatetimeIndex.insert (GH2155)
• Use index name(s) (if any) in DataFrame.to_records (GH2161)
• Don’t lose index names in Panel.to_frame/DataFrame.to_panel (GH2163)
• Work around length-0 boolean indexing NumPy bug (GH2096)
• Fix partial integer indexing bug in DataFrame.xs (GH2107)
• Fix variety of cut/qcut string-bin formatting bugs (GH1978, GH1979)
• Raise Exception when xs view not possible of MultiIndex’d DataFrame (GH2117)
• Fix groupby(...).first() issue with datetime64 (GH2133)
• Better floating point error robustness in some rolling_* functions (GH2114, GH2527)
• Fix fix NA handling in the middle of Series (GH2128)
• Fix numerical precision issues in diff with integer data (GH2087)
• Fix bug in MultiIndex.__getitem__ with NA values (GH2088)
• Fix DataFrame.from_records dict-arg bug when passing columns (GH2179)
• Fix Series and DataFrame.diff for integer dtypes (GH2087, GH2174)
• Fix bug when taking intersection of DatetimeIndex with empty index (GH2129)
• Pass through timezone information when calling DataFrame.align (GH2127)
• Properly sort when joining on datetime64 values (GH2196)
• Fix indexing bug in which False/True were being coerced to 0/1 (GH2199)
• Many unicode formatting fixes (GH2201)
• Fix improper MultiIndex conversion issue when assigning e.g. DataFrame.index (GH2200)
• Fix conversion of mixed-type DataFrame to ndarray with dup columns (GH2236)
• Fix duplicate columns issue (GH2218, GH2219)
• Fix SparseSeries.__pow__ issue with NA input (GH2220)
• Fix icol with integer sequence failure (GH2228)
• Fixed resampling tz-aware time series issue (GH2245)
• SparseDataFrame.icol was not returning SparseSeries (GH2227, GH2229)
• Enable ExcelWriter to handle PeriodIndex (GH2240)
• Fix issue constructing DataFrame from empty Series with name (GH2234)
• Use console-width detection in interactive sessions only (GH1610)
• Fix parallel_coordinates legend bug with mpl 1.2.0 (GH2237)
• Make tz_localize work in corner case of empty Series (GH2248)

38.30 pandas 0.9.0

Release date: 10/7/2012

38.30.1 New Features

• Add str.encode and str.decode to Series (GH1706)
• Add to_latex method to DataFrame (GH1735)
• Add convenient expanding window equivalents of all rolling_* ops (GH1785)
• Add Options class to pandas.io.data for fetching options data from Yahoo! Finance (GH1748, GH1739)
• Recognize and convert more boolean values in file parsing (Yes, No, TRUE, FALSE, variants thereof) (GH1691, GH1295)
• Add Panel.update method, analogous to DataFrame.update (GH1999, GH1988)
38.30.2 Improvements to existing features

- Proper handling of NA values in merge operations (GH1990)
- Add flags option for re.compile in some Series.str methods (GH1659)
- Parsing of UTC date strings in read_ * functions (GH1693)
- Handle generator input to Series (GH1679)
- Add na_action='ignore' to Series.map to quietly propagate NAs (GH1661)
- Add args/kwds options to Series.apply (GH1829)
- Add inplace option to Series/DataFrame.reset_index (GH1797)
- Add level parameter to Series.reset_index
- Add quoting option for DataFrame.to_csv (GH1902)
- Indicate long column value truncation in DataFrame output with ... (GH1854)
- DataFrame.dot will not do data alignment, and also work with Series (GH1915)
- Add na option for missing data handling in some vectorized string methods (GH1689)
- If index_label=False in DataFrame.to_csv, do not print fields/commas in the text output. Results in easier importing into R (GH1583)
- Can pass tuple/list of axes to DataFrame.dropna to simplify repeated calls (dropping both columns and rows) (GH924)
- Improve DataFrame.to_html output for hierarchically-indexed rows (do not repeat levels) (GH1929)
- TimeSeries.between_time can now select times across midnight (GH1871)
- Enable skip footer parameter in ExcelFile.parse (GH1843)

38.30.3 API Changes

- Change default header names in read_ * functions to more Pythonic X0, X1, etc. instead of X.1, X.2. (GH2000)
- Deprecated day_of_year API removed from PeriodIndex, use dayofyear (GH1723)
- Don’t modify NumPy suppress printoption at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by HDFStore (GH1834, GH1824)
- Legacy cruft removed: pandas.stats.misc.quantileTS
- Use ISO8601 format for Period repr: monthly, daily, and on down (GH1776)
- Empty DataFrame columns are now created as object dtype. This will prevent a class of TypeError that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) (GH1783)
- Setting parts of DataFrame/Panel using ix now aligns input Series/DataFrame (GH1630)
- first and last methods in GroupBy no longer drop non-numeric columns (GH1809)
- Resolved inconsistencies in specifying custom NA values in text parser. na_values of type dict no longer override default NAs unless keep_default_na is set to false explicitly (GH1657)
- Enable skipfooter parameter in text parsers as an alias for skip footer
38.30.4 Bug Fixes

- Perform arithmetic column-by-column in mixed-type DataFrame to avoid type upcasting issues. Caused downstream DataFrame.diff bug (GH1896)
- Fix matplotlib auto-color assignment when no custom spectrum passed. Also respect passed color keyword argument (GH1711)
- Fix resampling logical error with closed='left' (GH1726)
- Fix critical DatetimeIndex.union bugs (GH1730, GH1719, GH1745, GH1702, GH1753)
- Fix critical DatetimeIndex.intersection bug with unanchored offsets (GH1708)
- Fix MM-YYYY time series indexing case (GH1672)
- Fix case where Categorical group key was not being passed into index in GroupBy result (GH1701)
- Handle Ellipsis in Series.__getitem__/__setitem__ (GH1721)
- Fix some bugs with handling datetime64 scalars of other units in NumPy 1.6 and 1.7 (GH1717)
- Fix performance issue in MultiIndex.format (GH1746)
- Fixed GroupBy bugs interacting with DatetimeIndex asof / map methods (GH1677)
- Handle factors with NAs in pandas.rpy (GH1615)
- Fix statsmodels import in pandas.stats.var (GH1734)
- Fix DataFrame repr/info summary with non-unique columns (GH1700)
- Fix Series.iget_value for non-unique indexes (GH1694)
- Don’t lose tzinfo when passing DatetimeIndex as DataFrame column (GH1682)
- Fix tz conversion with time zones that haven’t had any DST transitions since first date in the array (GH1673)
- Fix field access with UTC->local conversion on unsorted arrays (GH1756)
- Fix isnan handling of array-like (list) inputs (GH1755)
- Fix regression in handling of Series in Series constructor (GH1671)
- Fix comparison of Int64Index with DatetimeIndex (GH1681)
- Fix min_periods handling in new rolling_max/min at array start (GH1695)
- Fix errors with how='median' and generic NumPy resampling in some cases caused by SeriesBinGrouper (GH1648, GH1688)
- When grouping by level, exclude unobserved levels (GH1697)
- Don’t lose tzinfo in DatetimeIndex when shifting by different offset (GH1683)
- Hack to support storing data with a zero-length axis in HDFStore (GH1707)
- Fix DatetimeIndex tz-aware range generation issue (GH1674)
- Fix method='time' interpolation with intraday data (GH1698)
- Don’t plot all-NA DataFrame columns as zeros (GH1696)
- Fix bug in scatter_plot with by option (GH1716)
- Fix performance problem in infer_freq with lots of non-unique stamps (GH1686)
- Fix handling of PeriodIndex as argument to create MultiIndex (GH1705)
- Fix re: unicode MultiIndex level names in Series/DataFrame repr (GH1736)
pandas: powerful Python data analysis toolkit, Release 0.23.3

- Handle PeriodIndex in to_datetime instance method (GH1703)
- Support StaticTzInfo in DatetimeIndex infrastructure (GH1692)
- Allow MultiIndex setops with length-0 other type indexes (GH1727)
- Fix handling of DatetimeIndex in DataFrame.to_records (GH1720)
- Fix handling of general objects in isnull on which bool(...) fails (GH1749)
- Fix .ix indexing with MultiIndex ambiguity (GH1678)
- Fix .ix setting logic error with non-unique MultiIndex (GH1750)
- Basic indexing now works on MultiIndex with > 1000000 elements, regression from earlier version of pandas (GH1757)
- Handle non-float64 dtypes in fast DataFrame.corr/cov code paths (GH1761)
- Fix DatetimeIndex.isin to function properly (GH1763)
- Fix conversion of array of tz-aware datetime.datetime to DatetimeIndex with right time zone (GH1777)
- Fix DST issues with generating anchored date ranges (GH1778)
- Fix issue calling sort on result of Series.unique (GH1807)
- Fix numerical issue leading to square root of negative number in rolling_std (GH1840)
- Let Series.str.split accept no arguments (like str.split) (GH1859)
- Allow user to have dateutil 2.1 installed on a Python 2 system (GH1851)
- Catch ImportError less aggressively in pandas/__init__.py (GH1845)
- Fix pip source installation bug when installing from GitHub (GH1805)
- Fix error when window size > array size in rolling_apply (GH1850)
- Fix pip source installation issues via SSH from GitHub
- Fix OLS.summary when column is a tuple (GH1837)
- Fix bug in __doc__ patching when -OO passed to interpreter (GH1792 GH1741 GH1774)
- Fix unicode console encoding issue in IPython notebook (GH1782, GH1768)
- Fix unicode formatting issue with Series.name (GH1782)
- Fix bug in DataFrame.duplicated with datetime64 columns (GH1833)
- Fix bug in Panel internals resulting in error when doing fillna after truncate not changing size of panel (GH1823)
- Prevent segfault due to MultiIndex not being supported in HDFStore table format (GH1848)
- Fix UnboundLocalError in Panel.__setitem__ and add better error (GH1826)
- Fix to_csv issues with list of string entries. Isnull works on list of strings now too (GH1791)
- Fix Timestamp comparisons with datetime values outside the nanosecond range (1677-2262)
- Revert to prior behavior of normalize_date with datetime.date objects (return datetime)
- Fix broken interaction between np.nansum and Series.any/all
- Fix bug with multiple column date parsers (GH1866)
- DatetimeIndex.union(Int64Index) was broken
- Make plot x vs y interface consistent with integer indexing (GH1842)
- set_index inplace modified data even if unique check fails (GH1831)
- Only use Q-OCT/NOV/DEC in quarterly frequency inference (GH1789)
- Upcast to dtype=object when unstacking boolean DataFrame (GH1820)
- Fix float64/float32 merging bug (GH1849)
- Fixes to Period.start_time for non-daily frequencies (GH1857)
- Fix failure when converter used on index_col in read_csv (GH1835)
- Implement PeriodIndex.append so that pandas.concat works correctly (GH1815)
- Avoid Cython out-of-bounds access causing segfault sometimes in pad_2d, backfill_2d
- Fix resampling error with intraday times and anchored target time (like AS-DEC) (GH1772)
- Fix .ix indexing bugs with mixed-integer indexes (GH1799)
- Respect passed color keyword argument in Series.plot (GH1890)
- Fix rolling_min/max when the window is larger than the size of the input array. Check other malformed inputs (GH1899, GH1897)
- Rolling variance / standard deviation with only a single observation in window (GH1884)
- Fix unicode sheet name failure in to_excel (GH1828)
- Override DatetimeIndex.min/max to return Timestamp objects (GH1895)
- Fix column name formatting issue in length-truncated column (GH1906)
- Fix broken handling of copying Index metadata to new instances created by view(...) calls inside the NumPy infrastructure
- Support datetime.date again in DateOffset.rollback/rollforward
- Raise Exception if set passed to Series constructor (GH1913)
- Add TypeError when appending HDFStore table w/ wrong index type (GH1881)
- Don’t raise exception on empty inputs in EW functions (e.g. ewma) (GH1900)
- Make asof work correctly with PeriodIndex (GH1883)
- Fix extlinks in doc build
- Fill boolean DataFrame with NaN when calling shift (GH1814)
- Fix setuptools bug causing pip not to Cythonize .pyx files sometimes
- Fix negative integer indexing regression in .ix from 0.7.x (GH1888)
- Fix error while retrieving timezone and utc offset from subclasses of datetime.tzinfo without .zone and ._utcoffset attributes (GH1922)
- Fix DataFrame formatting of small, non-zero FP numbers (GH1911)
- Various fixes by upcasting of date -> datetime (GH1395)
- Raise better exception when passing multiple functions with the same name, such as lambdas, to GroupBy.aggregate
- Fix DataFrame.apply with axis=1 on a non-unique index (GH1878)
- Proper handling of Index subclasses in pandas.unique (GH1759)
- Set index names in DataFrame.from_records (GH1744)
• Fix time series indexing error with duplicates, under and over hash table size cutoff (GH1821)
• Handle list keys in addition to tuples in DataFrame.xs when partial-indexing a hierarchically-indexed DataFrame (GH1796)
• Support multiple column selection in DataFrame.__getitem__ with duplicate columns (GH1943)
• Fix time zone localization bug causing improper fields (e.g. hours) in time zones that have not had a UTC transition in a long time (GH1946)
• Fix errors when parsing and working with fixed offset timezones (GH1922, GH1928)
• Fix text parser bug when handling UTC datetime objects generated by dateutil (GH1693)
• Fix plotting bug when ‘B’ is the inferred frequency but index actually contains weekends (GH1668, GH1669)
• Fix plot styling bugs (GH1666, GH1665, GH1658)
• Fix plotting bug with index/columns with unicode (GH1685)
• Fix DataFrame constructor bug when passed Series with datetime64 dtype in a dict (GH1680)
• Fixed regression in generating DatetimeIndex using timezone aware datetime.datetime (GH1676)
• Fix DataFrame bug when printing concatenated DataFrames with duplicated columns (GH1675)
• Fixed bug when plotting time series with multiple intraday frequencies (GH1732)
• Fix bug in DataFrame.duplicated to enable iterables other than list-types as input argument (GH1773)
• Fix resample bug when passed list of lambdas as how argument (GH1808)
• Repr fix for MultiIndex level with all NAs (GH1971)
• Fix PeriodIndex slicing bug when slice start/end are out-of-bounds (GH1977)
• Fix read_table bug when parsing unicode (GH1975)
• Fix BlockManager.iget bug when dealing with non-unique MultiIndex as columns (GH1970)
• Fix reset_index bug if both drop and level are specified (GH1957)
• Work around unsafe NumPy object->int casting with Cython function (GH1987)
• Fix datetime64 formatting bug in DataFrame.to_csv (GH1993)
• Default start date in pandas.io.data to 1/1/2000 as the docs say (GH2011)

38.31 pandas 0.8.1

Release date: July 22, 2012

38.31.1 New Features

• Add vectorized, NA-friendly string methods to Series (GH1621, GH620)
• Can pass dict of per-column line styles to DataFrame.plot (GH1559)
• Selective plotting to secondary y-axis on same subplot (GH1640)
• Add new bootstrap_plot plot function
• Add new parallel_coordinates plot function (GH1488)
• Add radviz plot function (GH1566)
• Add `multi_sparse` option to `set_printoptions` to modify display of hierarchical indexes (GH1538)
• Add `dropna` method to Panel (GH171)

38.31.2 Improvements to existing features

• Use moving min/max algorithms from Bottleneck in `rolling_min/rolling_max` for > 100x speedup. (GH1504, GH50)
• Add Cython group median method for >15x speedup (GH1358)
• Drastically improve `to_datetime` performance on ISO8601 datetime strings (with no time zones) (GH1571)
• Improve single-key groupby performance on large data sets, accelerate use of groupby with a Categorical variable
• Add ability to append hierarchical index levels with `set_index` and to drop single levels with `reset_index` (GH1569, GH1577)
• Always apply passed functions in `resample`, even if upsampling (GH1596)
• Avoid unnecessary copies in DataFrame constructor with explicit dtype (GH1572)
• Cleaner DatetimeIndex string representation with 1 or 2 elements (GH1611)
• Improve performance of array-of-Period to PeriodIndex, convert such arrays to PeriodIndex inside Index (GH1215)
• More informative string representation for weekly Period objects (GH1503)
• Accelerate 3-axis multi data selection from homogeneous Panel (GH979)
• Add `adjust` option to `ewma` to disable adjustment factor (GH1584)
• Add new matplotlib converters for high frequency time series plotting (GH1599)
• Handling of tz-aware datetime.datetime objects in `to_datetime`; raise Exception unless utc=True given (GH1581)

38.31.3 Bug Fixes

• Fix NA handling in `DataFrame.to_panel` (GH1582)
• Handle `TypeError` issues inside `PyObject_RichCompareBool` calls in `khash` (GH1318)
• Fix resampling bug to lower case daily frequency (GH1588)
• Fix `kendall/spearman DataFrame.corr` bug with no overlap (GH1595)
• Fix bug in `DataFrame.set_index` (GH1592)
• Don’t ignore axes in `boxplot` if by specified (GH1565)
• Fix `Panel .ix` indexing with integers bug (GH1603)
• Fix Partial indexing bugs (years, months, . . . ) with PeriodIndex (GH1601)
• Fix MultiIndex console formatting issue (GH1606)
• Unordered index with duplicates doesn’t yield scalar location for single entry (GH1586)
• Fix resampling of tz-aware time series with “anchored” freq (GH1591)
• Fix `DataFrame.rank` error on integer data (GH1589)
• Selection of multiple SparseDataFrame columns by list in `__getitem__` (GH1585)
• Override Index.tolist for compatibility with MultiIndex (GH1576)
• Fix hierarchical summing bug with MultiIndex of length 1 (GH1568)
• Work around numpy.concatenate use/bug in Series.set_value (GH1561)
• Ensure Series/DataFrame are sorted before resampling (GH1580)
• Fix unhandled IndexError when indexing very large time series (GH1562)
• Fix DatetimeIndex intersection logic error with irregular indexes (GH1551)
• Fix unit test errors on Python 3 (GH1550)
• Fix .ix indexing bugs in duplicate DataFrame index (GH1201)
• Better handle errors with non-existing objects in HDFStore (GH1254)
• Don’t copy int64 array data in DatetimeIndex when copy=False (GH1624)
• Fix resampling of conforming periods quarterly to annual (GH1622)
• Don’t lose index name on resampling (GH1631)
• Support python-dateutil version 2.1 (GH1637)
• Fix broken scatter_matrix axis labeling, esp. with time series (GH1625)
• Fix cases where extra keywords weren’t being passed on to matplotlib from Series.plot (GH1636)
• Fix BusinessMonthBegin logic for dates before 1st bday of month (GH1645)
• Ensure string alias converted (valid in DatetimeIndex.get_loc) in DataFrame.xs / __getitem__ (GH1644)
• Fix use of string alias timestamps with tz-aware time series (GH1647)
• Fix Series.max/min and Series.describe on len-0 series (GH1650)
• Handle None values in dict passed to concat (GH1649)
• Fix Series.interpolate with method='values' and DatetimeIndex (GH1646)
• Fix IndexError in left merges on a DataFrame with 0-length (GH1628)
• Fix DataFrame column width display with UTF-8 encoded characters (GH1620)
• Handle case in pandas.io.data.get_data_yahoo where Yahoo! returns duplicate dates for most recent business day
• Avoid downsampling when plotting mixed frequencies on the same subplot (GH1619)
• Fix read_csv bug when reading a single line (GH1553)
• Fix bug in C code causing monthly periods prior to December 1969 to be off (GH1570)

38.32 pandas 0.8.0

Release date: 6/29/2012

38.32.1 New Features

• New unified DatetimeIndex class for nanosecond-level timestamp data
• New Timestamp datetime.datetime subclass with easy time zone conversions, and support for nanoseconds
• New PeriodIndex class for timespans, calendar logic, and Period scalar object
• High performance resampling of timestamp and period data. New resample method of all pandas data structures
• New frequency names plus shortcut string aliases like ‘15h’, ‘1h30min’
• Time series string indexing shorthand (GH222)
• Add week, dayofyear array and other timestamp array-valued field accessor functions to DatetimeIndex
• Add GroupBy.prod optimized aggregation function and ‘prod’ fast time series conversion method (GH1018)
• Implement robust frequency inference function and inferred_freq attribute on DatetimeIndex (GH391)
• New tz_convert and tz_localize methods in Series / DataFrame
• Convert DatetimeIndexes to UTC if time zones are different in join/setops (GH864)
• Add limit argument for forward/backward filling to reindex, fillna, etc. (GH825 and others)
• Add support for indexes (dates or otherwise) with duplicates and common sense indexing/selection functionality
• Series/DataFrame.update methods, in-place variant of combine_first (GH961)
• Add match function to API (GH502)
• Add Cython-optimized first, last, min, max, prod functions to GroupBy (GH994, GH1043)
• Dates can be split across multiple columns (GH1227, GH1186)
• Add experimental support for converting pandas DataFrame to R data.frame via rpy2 (GH350, GH1212)
• Can pass list of (name, function) to GroupBy.aggregate to get aggregates in a particular order (GH610)
• Can pass dicts with lists of functions or dicts to GroupBy aggregate to do much more flexible multiple function aggregation (GH642, GH610)
• New ordered_merge functions for merging DataFrames with ordered data. Also supports group-wise merging for panel data (GH813)
• Add keys() method to DataFrame
• Add flexible replace method for replacing potentially values to Series and DataFrame (GH929, GH1241)
• Add ‘kde’ plot kind for Series/DataFrame.plot (GH1059)
• More flexible multiple function aggregation with GroupBy
• Add pct_change function to Series/DataFrame
• Add option to interpolate by Index values in Series.interpolate (GH1206)
• Add max_colwidth option for DataFrame, defaulting to 50
• Conversion of DataFrame through rpy2 to R data.frame (GH1282, )
• Add keys() method on DataFrame (GH1240)
• Add new match function to API (similar to R) (GH502)
• Add dayfirst option to parsers (GH854)
• Add method argument to align method for forward/backward fillin (GH216)
• Add Panel.transpose method for rearranging axes (GH695)
• Add new cut function (patterned after R) for discretizing data into equal range-length bins or arbitrary breaks of your choosing (GH415)
• Add new qcut for cutting with quantiles (GH1378)
• Add `value_counts` top level array method (GH1392)
• Added Andrews curves plot tupe (GH1325)
• Add lag plot (GH1440)
• Add autocorrelation_plot (GH1425)
• Add support for tox and Travis CI (GH1382)
• Add support for Categorical use in GroupBy (GH292)
• Add `any` and `all` methods to DataFrame (GH1416)
• Add `secondary_y` option to Series.plot
• Add experimental `lreshape` function for reshaping wide to long

38.32.2 Improvements to existing features

• Switch to klib/khash-based hash tables in Index classes for better performance in many cases and lower memory footprint
• Shipping some functions from scipy.stats to reduce dependency, e.g. Series.describe and DataFrame.describe (GH1092)
• Can create MultiIndex by passing list of lists or list of arrays to Series, DataFrame constructor, etc. (GH831)
• Can pass arrays in addition to column names to DataFrame.set_index (GH402)
• Improve the speed of “square” reindexing of homogeneous DataFrame objects by significant margin (GH836)
• Handle more dtypes when passed MaskedArrays in DataFrame constructor (GH406)
• Improved performance of join operations on integer keys (GH682)
• Can pass multiple columns to GroupBy object, e.g. grouped[[col1, col2]] to only aggregate a subset of the value columns (GH383)
• Add histogram / kde plot options for scatter_matrix diagonals (GH1237)
• Add inplace option to Series/DataFrame.rename and sort_index, DataFrame.drop_duplicates (GH805, GH207)
• More helpful error message when nothing passed to Series.reindex (GH1267)
• Can mix array and scalars as dict-value inputs to DataFrame ctor (GH1329)
• Use DataFrame columns’ name for legend title in plots
• Preserve frequency in DatetimeIndex when possible in boolean indexing operations
• Promote datetime.date values in data alignment operations (GH867)
• Add `order` method to Index classes (GH1028)
• Avoid hash table creation in large monotonic hash table indexes (GH1160)
• Store time zones in HDFStore (GH1232)
• Enable storage of sparse data structures in HDFStore (GH85)
• Enable Series.asof to work with arrays of timestamp inputs
• Cython implementation of DataFrame.corr speeds up by > 100x (GH1349, GH1354)
• Exclude “nuisance” columns automatically in GroupBy.transform (GH1364)
• Support functions-as-strings in GroupBy.transform (GH1362)
• Use index name as xlabel/ylabel in plots (GH1415)
• Add convert_dtype option to Series.apply to be able to leave data as dtype=object (GH1414)
• Can specify all index level names in concat (GH1419)
• Add dialect keyword to parsers for quoting conventions (GH1363)
• Enable DataFrame[bool_DataFrame] += value (GH1366)
• Add retries argument to get_data_yahoo to try to prevent Yahoo! API 404s (GH826)
• Improve performance of reshaping by using O(N) categorical sorting
• Series names will be used for index of DataFrame if no index passed (GH1494)
• Header argument in DataFrame.to_csv can accept a list of column names to use instead of the object’s columns (GH921)
• Add raise_conflict argument to DataFrame.update (GH1526)
• Support file-like objects in ExcelFile (GH1529)

38.32.3 API Changes

• Rename pandas._series to pandas.lib
• Rename Factor to Categorical and add improvements. Numerous Categorical bug fixes
• Frequency name overhaul, WEEKDAY/EOM and rules with @ deprecated. get_legacy_offset_name backwards compatibility function added
• Raise ValueError in DataFrame.__nonzero__, so “if df” no longer works (GH1073)
• Change BDay (business day) to not normalize dates by default (GH506)
• Remove deprecated DataMatrix name
• Default merge suffixes for overlap now have underscores instead of periods to facilitate tab completion, etc. (GH1239)
• Deprecation of offset, time_rule timeRule parameters throughout codebase
• Series.append and DataFrame.append no longer check for duplicate indexes by default, add verify_integrity parameter (GH1394)
• Refactor Factor class, old constructor moved to Factor.from_array
• Modified internals of MultiIndex to use less memory (no longer represented as array of tuples) internally, speed up construction time and many methods which construct intermediate hierarchical indexes (GH1467)

38.32.4 Bug Fixes

• Fix OverflowError from storing pre-1970 dates in HDFStore by switching to datetime64 (GH179)
• Fix logical error with February leap year end in YearEnd offset
• Series([False, nan]) was getting casted to float64 (GH1074)
• Fix binary operations between boolean Series and object Series with booleans and NAs (GH1074, GH1079)
• Couldn’t assign whole array to column in mixed-type DataFrame via .ix (GH1142)
• Fix label slicing issues with float index values (GH1167)
• Fix segfault caused by empty groups passed to groupby (GH1048)
• Fix occasionally misbehaved reindexing in the presence of NaN labels (GH522)
• Fix imprecise logic causing weird Series results from .apply (GH1183)
• Unstack multiple levels in one shot, avoiding empty columns in some cases. Fix pivot table bug (GH1181)
• Fix formatting of MultiIndex on Series/DataFrame when index name coincides with label (GH1217)
• Handle Excel 2003 #N/A as NaN from xld (GH1213, GH1225)
• Fix timestamp locale-related deserialization issues with HDFStore by moving to datetime64 representation (GH1081, GH809)
• Fix DataFrame.duplicated/drop_duplicates NA value handling (GH557)
• Actually raise exceptions in fast reducer (GH1243)
• Fix various timezone-handling bugs from 0.7.3 (GH969)
• GroupBy on level=0 discarded index name (GH1313)
• Better error message with unmergeable DataFrames (GH1307)
• Series.__repr__ alignment fix with unicode index values (GH1279)
• Better error message if nothing passed to reindex (GH1267)
• More robust NA handling in DataFrame.drop_duplicates (GH557)
• Resolve locale-based and pre-epoch HDF5 timestamp deserialization issues (GH973, GH1081, GH179)
• Implement Series.repeat (GH1229)
• Fix indexing with namedtuple and other tuple subclasses (GH1026)
• Fix float64 slicing bug (GH1167)
• Parsing integers with commas (GH796)
• Fix groupby improper data type when group consists of one value (GH1065)
• Fix negative variance possibility in nanvar resulting from floating point error (GH1090)
• Consistently set name on groupby pieces (GH184)
• Treat dict return values as Series in GroupBy.apply (GH823)
• Respect column selection for DataFrame in GroupBy.transform (GH1365)
• Fix MultiIndex partial indexing bug (GH1352)
• Enable assignment of rows in mixed-type DataFrame via .ix (GH1432)
• Reset index mapping when grouping Series in Cython (GH1423)
• Fix outer/inner DataFrame.join with non-unique indexes (GH1421)
• Fix MultiIndex groupby bugs with empty lower levels (GH1401)
• Calling fillna with a Series will have same behavior as with dict (GH1486)
• SparseSeries reduction bug (GH1375)
• Fix unicode serialization issue in HDFStore (GH1361)
• Pass keywords to pyplot.boxplot in DataFrame.boxplot (GH1493)
• Bug fixes in MonthBegin (GH1483)
- Preserve MultiIndex names in drop (GH1513)
- Fix Panel DataFrame slice-assignment bug (GH1533)
- Don’t use locals() in read_* functions (GH1547)

38.33 pandas 0.7.3

Release date: April 12, 2012

38.33.1 New Features

- Support for non-unique indexes: indexing and selection, many-to-one and many-to-many joins (GH1306)
- Added fixed-width file reader, read_fwf (GH952)
- Add group_keys argument to groupby to not add group names to MultiIndex in result of apply (GH938)
- DataFrame can now accept non-integer label slicing (GH946). Previously only DataFrame.ix was able to do so.
- DataFrame.apply now retains name attributes on Series objects (GH983)
- Numeric DataFrame comparisons with non-numeric values now raises proper TypeError (GH943). Previously raise “PandasError: DataFrame constructor not properly called!”
- Add kurt methods to Series and DataFrame (GH964)
- Can pass dict of column -> list/set NA values for text parsers (GH754)
- Allows users specified NA values in text parsers (GH754)
- Parsers checks for openpyxl dependency and raises ImportError if not found (GH1007)
- New factory function to create HDFStore objects that can be used in a with statement so users do not have to explicitly call HDFStore.close (GH1005)
- pivot_table is now more flexible with same parameters as groupby (GH941)
- Added stacked bar plots (GH987)
- scatter_matrix method in pandas/tools/plotting.py (GH935)
- DataFrame.boxplot returns plot results for ex-post styling (GH985)
- Short version number accessible as pandas.version.short_version (GH930)
- Additional documentation in panel.to_frame (GH942)
- More informative Series.apply docstring regarding element-wise apply (GH977)
- Notes on rpy2 installation (GH1006)
- Add rotation and font size options to hist method (GH1012)
- Use exogenous / X variable index in result of OLS.y_predict. Add OLS.predict method (GH1027, GH1008)

38.33.2 API Changes

- Calling apply on grouped Series, e.g. describe(), will no longer yield DataFrame by default. Will have to call unstack() to get prior behavior
- NA handling in non-numeric comparisons has been tightened up (GH933, GH953)
• No longer assign dummy names key_0, key_1, etc. to groupby index (GH1291)

38.33.3 Bug Fixes

• Fix logic error when selecting part of a row in a DataFrame with a MultiIndex index (GH1013)
• Series comparison with Series of differing length causes crash (GH1016).
• Fix bug in indexing when selecting section of hierarchically-indexed row (GH1013)
• DataFrame.plot(logy=True) has no effect (GH1011).
• Broken arithmetic operations between SparsePanel-Panel (GH1015)
• Unicode repr issues in MultiIndex with non-ASCII characters (GH1010)
• DataFrame.lookup() returns inconsistent results if exact match not present (GH1001)
• DataFrame arithmetic operations not treating None as NA (GH992)
• DataFrameGroupBy.apply returns incorrect result (GH991)
• Series.reshape returns incorrect result for multiple dimensions (GH989)
• Series.std and Series.var ignores ddof parameter (GH934)
• DataFrame.append loses index names (GH980)
• DataFrame.plot(kind='bar') ignores color argument (GH958)
• Inconsistent Index comparison results (GH948)
• Improper int dtype DataFrame construction from data with NaN (GH846)
• Removes default ‘result’ name in groupby results (GH995)
• DataFrame.from_records no longer mutate input columns (GH975)
• Use Index name when grouping by it (GH1313)

38.34 pandas 0.7.2

Release date: March 16, 2012

38.34.1 New Features

• Add additional tie-breaking methods in DataFrame.rank (GH874)
• Add ascending parameter to rank in Series, DataFrame (GH875)
• Add sort_columns parameter to allow unsorted plots (GH918)
• IPython tab completion on GroupBy objects

38.34.2 API Changes

• Series.sum returns 0 instead of NA when called on an empty series. Analogously for a DataFrame whose rows or columns are length 0 (GH844)
38.34.3 Improvements to existing features

- Don’t use groups dict in Grouper.size (GH860)
- Use khash for Series.value_counts, add raw function to algorithms.py (GH861)
- Enable column access via attributes on GroupBy (GH882)
- Enable setting existing columns (only) via attributes on DataFrame, Panel (GH883)
- Intercept __builtin__.sum in groupby (GH885)
- Can pass dict to DataFrame.fillna to use different values per column (GH661)
- Can select multiple hierarchical groups by passing list of values in .ix (GH134)
- Add level keyword to drop for dropping values from a level (GH159)
- Add coerce_float option on DataFrame.from_records (GH893)
- Raise exception if passed date_parser fails in read_csv
- Add axis option to DataFrame.fillna (GH174)
- Fixes to Panel to make it easier to subclass (GH888)

38.34.4 Bug Fixes

- Fix overflow-related bugs in groupby (GH850, GH851)
- Fix unhelpful error message in parsers (GH856)
- Better err msg for failed boolean slicing of dataframe (GH859)
- Series.count cannot accept a string (level name) in the level argument (GH869)
- Group index platform int check (GH870)
- concat on axis=1 and ignore_index=True raises TypeError (GH871)
- Further unicode handling issues resolved (GH795)
- Fix failure in multiindex-based access in Panel (GH880)
- Fix DataFrame boolean slice assignment failure (GH881)
- Fix combineAdd NotImplementedError for SparseDataFrame (GH887)
- Fix DataFrame.to_html encoding and columns (GH890, GH891, GH909)
- Fix na-filling handling in mixed-type DataFrame (GH910)
- Fix to DataFrame.set_value with non-existant row/col (GH911)
- Fix malformed block in groupby when excluding nuisance columns (GH916)
- Fix inconsistent NA handling in dtype=object arrays (GH925)
- Fix missing center-of-mass computation in ewmcov (GH862)
- Don’t raise exception when opening read-only HDF5 file (GH847)
- Fix possible out-of-bounds memory access in 0-length Series (GH917)
38.35 pandas 0.7.1

Release date: February 29, 2012

38.35.1 New Features

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard (GH774)
- Add `itertuples` method to DataFrame for iterating through the rows of a dataframe as tuples (GH818)
- Add ability to pass `fill_value` and method to DataFrame and Series align method (GH806, GH807)
- Add `fill_value` option to reindex, align methods (GH784)
- Enable concat to produce DataFrame from Series (GH787)
- Add `between` method to Series (GH802)
- Add HTML representation hook to DataFrame for the IPython HTML notebook (GH773)
- Support for reading Excel 2007 XML documents using openpyxl

38.35.2 Improvements to existing features

- Improve performance and memory usage of `fillna` on DataFrame
- Can concatenate a list of Series along axis=1 to obtain a DataFrame (GH787)

38.35.3 Bug Fixes

- Fix memory leak when inserting large number of columns into a single DataFrame (GH790)
- Appending length-0 DataFrame with new columns would not result in those new columns being part of the resulting concatenated DataFrame (GH782)
- Fixed groupby corner case when passing dictionary grouper and `as_index` is False (GH819)
- Fixed bug whereby bool array sometimes had object dtype (GH820)
- Fix exception thrown on `np.diff` (GH816)
- Fix to_records where columns are non-strings (GH822)
- Fix Index.intersection where indices have incomparable types (GH811)
- Fix `ExcelFile` throwing an exception for two-line file (GH837)
- Add clearer error message in csv parser (GH835)
- Fix loss of fractional seconds in HDFStore (GH513)
- Fix DataFrame join where columns have datetimes (GH787)
- Work around NumPy performance issue in `take` (GH817)
- Improve comparison operations for NA-friendliness (GH801)
- Fix indexing operation for floating point values (GH780, GH798)
- Fix groupby case resulting in malformed dataframe (GH814)
- Fix behavior of `reindex` of Series dropping name (GH812)
• Improve on redundant groupby computation (GH775)
• Catch possible NA assignment to int/bool series with exception (GH839)

38.36 pandas 0.7.0

Release date: 2/9/2012

38.36.1 New Features

• New `merge` function for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains (GH220, GH249, GH267)
• New `concat` function for concatenating DataFrame or Panel objects along an axis. Can form union or intersection of the other axes. Improves performance of `DataFrame.append` (GH468, GH479, GH273)
• Handle differently-indexed output values in `DataFrame.append` (GH498)
• Can pass list of dicts (e.g., a list of shallow JSON objects) to `DataFrame` constructor (GH526)
• Add `reorder_levels` method to `Series` and `DataFrame` (GH534)
• Add dict-like `get` function to `DataFrame` and `Panel` (GH521)
• `DataFrame.iterrows` method for efficiently iterating through the rows of a `DataFrame`
• Added `DataFrame.to_panel` with code adapted from `LongPanel.to_long`
• `reindex_axis` method added to `DataFrame`
• Add level option to binary arithmetic functions on `DataFrame` and `Series`
• Add level option to the `reindex` and `align` methods on `Series` and `DataFrame` for broadcasting values across a level (GH542, GH552, others)
• Add attribute-based item access to `Panel` and add IPython completion (PR GH554)
• Add logy option to `Series.plot` for log-scaling on the Y axis
• Add `index`, `header`, and `justify` options to `DataFrame.to_string`. Add option to (GH570, GH571)
• Can pass multiple DataFrames to `DataFrame.join` to join on index (GH115)
• Can pass multiple Panels to `Panel.join` (GH115)
• Can pass multiple DataFrames to `DataFrame.append` to concatenate (stack) and multiple Series to `Series.append` too
• Added justify argument to `DataFrame.to_string` to allow different alignment of column headers
• Add `verbose` option to `GroupBy` to allow disabling sorting of the group keys for potential speedups (GH595)
• Can pass `MaskedArray` to `Series` constructor (GH563)
• Add Panel item access via attributes and IPython completion (GH554)
• Implement `DataFrame.lookup`, fancy-indexing analogue for retrieving values given a sequence of row and column labels (GH338)
• Add `verbose` option to `read_csv` and `read_table` to show number of NA values inserted in non-numeric columns (GH614)
pandas: powerful Python data analysis toolkit, Release 0.23.3

- Can pass a list of dicts or Series to DataFrame.append to concatenate multiple rows (GH464)
- Add level argument to DataFrame.xs for selecting data from other MultiIndex levels. Can take one or more levels with potentially a tuple of keys for flexible retrieval of data (GH371, GH629)
- New crosstab function for easily computing frequency tables (GH170)
- Can pass a list of functions to aggregate with groupby on a DataFrame, yielding an aggregated result with hierarchical columns (GH166)
- Add integer-indexing functions iget in Series and irow/iget in DataFrame (GH628)
- Add new Series.unique function, significantly faster than numpy.unique (GH658)
- Add new cummin and cummax instance methods to Series and DataFrame (GH647)
- Add new value_range function to return min/max of a dataframe (GH288)
- Add drop parameter to reset_index method of DataFrame and added method to Series as well (GH699)
- Add isin method to Index objects, works just like Series.isin (GH GH657)
- Implement array interface on Panel so that ufuncs work (re: GH740)
- Add sort option to DataFrame.join (GH731)
- Improved handling of NAs (propagation) in binary operations with dtype=object arrays (GH737)
- Add abs method to Pandas objects
- Added algorithms module to start collecting central algos

### 38.36.2 API Changes

- Label-indexing with integer indexes now raises KeyError if a label is not found instead of falling back on location-based indexing (GH700)
- Label-based slicing via ix or [] on Series will now only work if exact matches for the labels are found or if the index is monotonic (for range selections)
- Label-based slicing and sequences of labels can be passed to [] on a Series for both getting and setting (GH86)
- __ operator (__getitem__ and __setitem__) will raise KeyError with integer indexes when an index is not contained in the index. The prior behavior would fall back on position-based indexing if a key was not found in the index which would lead to subtle bugs. This is now consistent with the behavior of .ix on DataFrame and friends (GH328)
- Rename DataFrame.delevel to DataFrame.reset_index and add deprecation warning
- Series.sort (an in-place operation) called on a Series which is a view on a larger array (e.g. a column in a DataFrame) will generate an Exception to prevent accidentally modifying the data source (GH316)
- Refactor to remove deprecated LongPanel class (GH552)
- Deprecated Panel.to_long, renamed to to_frame
- Deprecated colSpace argument in DataFrame.to_string, renamed to col_space
- Rename precision to accuracy in engineering float formatter (GH GH395)
- The default delimiter for read_csv is comma rather than letting csv.Sniffer infer it
- Rename col_or_columns argument in DataFrame.drop_duplicates (GH GH734)
38.36.3 Improvements to existing features

- Better error message in DataFrame constructor when passed column labels don’t match data (GH497)
- Substantially improve performance of multi-GroupBy aggregation when a Python function is passed, reuse ndarray object in Cython (GH496)
- Can store objects indexed by tuples and floats in HDFStore (GH492)
- Don’t print length by default in Series.to_string, add length option (GH GH489)
- Improve Cython code for multi-groupby to aggregate without having to sort the data (GH93)
- Improve MultiIndex reindexing speed by storing tuples in the MultiIndex, test for backwards unpickling compatibility
- Improve column reindexing performance by using specialized Cython take function
- Further performance tweaking of Series.__getitem__ for standard use cases
- Avoid Index dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions
- Friendlier error message in setup.py if NumPy not installed
- Use common set of NA-handling operations (sum, mean, etc.) in Panel class also (GH536)
- Default name assignment when calling reset_index on DataFrame with a regular (non-hierarchical) index (GH476)
- Use Cythonized groupers when possible in Series/DataFrame stat ops with level parameter passed (GH545)
- Ported skiplist data structure to C to speed up rolling_median by about 5-10x in most typical use cases (GH374)
- Some performance enhancements in constructing a Panel from a dict of DataFrame objects
- Made Index._get_duplicates a public method by removing the underscore
- Prettier printing of floats, and column spacing fix (GH395, GH571)
- Add bold_rows option to DataFrame.to_html (GH586)
- Improve the performance of DataFrame.sort_index by up to 5x or more when sorting by multiple columns
- Substantially improve performance of DataFrame and Series constructors when passed a nested dict or dict, respectively (GH540, GH621)
- Modified setup.py so that pip / setuptools will install dependencies (GH GH507, various pull requests)
- Unstack called on DataFrame with non-MultiIndex will return Series (GH GH477)
- Improve DataFrame.to_string and console formatting to be more consistent in the number of displayed digits (GH395)
- Use bottleneck if available for performing NaN-friendly statistical operations that it implemented (GH91)
- Monkey-patch context to traceback in DataFrame.apply to indicate which row/column the function application failed on (GH614)
- Improved ability of read_table and read_clipboard to parse console-formatted DataFrames (can read the row of index names, etc.)
- Can pass list of group labels (without having to convert to an ndarray yourself) to groupby in some cases (GH659)
- Use kind argument to Series.order for selecting different sort kinds (GH668)
• Add option to Series.to_csv to omit the index (GH684)
• Add delimiter as an alternative to sep in read_csv and other parsing functions
• Substantially improved performance of groupby on DataFrames with many columns by aggregating blocks of columns all at once (GH745)
• Can pass a file handle or StringIO to Series/DataFrame.to_csv (GH765)
• Can pass sequence of integers to DataFrame.irow(icol) and Series.iget, (GH GH654)
• Prototypes for some vectorized string functions
• Add float64 hash table to solve the Series.unique problem with NAs (GH714)
• Memoize objects when reading from file to reduce memory footprint
• Can get and set a column of a DataFrame with hierarchical columns containing “empty” (‘’) lower levels without passing the empty levels (PR GH768)

38.36.4 Bug Fixes

• Raise exception in out-of-bounds indexing of Series instead of seg-faulting, regression from earlier releases (GH495)
• Fix error when joining DataFrames of different dtypes within the same typeclass (e.g. float32 and float64) (GH486)
• Fix bug in Series.min/Series.max on objects like datetime.datetime (GH GH487)
• Preserve index names in Index.union (GH501)
• Fix bug in Index joining causing subclass information (like DateRange type) to be lost in some cases (GH500)
• Accept empty list as input to DataFrame constructor, regression from 0.6.0 (GH491)
• Can output DataFrame and Series with ndarray objects in a dtype=object array (GH490)
• Return empty string from Series.to_string when called on empty Series (GH GH488)
• Fix exception passing empty list to DataFrame.from_records
• Fix Index.format bug (excluding name field) with datetimes with time info
• Fix scalar value access in Series to always return NumPy scalars, regression from prior versions (GH510)
• Handle rows skipped at beginning of file in read_* functions (GH505)
• Handle improper dtype casting in set_value methods
• Unary ‘-’ / __neg__ operator on DataFrame was returning integer values
• Unbox 0-dim ndarrays from certain operators like all, any in Series
• Fix handling of missing columns (was combine_first-specific) in DataFrame.combine for general case (GH529)
• Fix type inference logic with boolean lists and arrays in DataFrame indexing
• Use centered sum of squares in R-square computation if entity_effects=True in panel regression
• Handle all NA case in Series.{corr, cov}, was raising exception (GH548)
• Aggregating by multiple levels with level argument to DataFrame, Series stat method, was broken (GH545)
• Fix Cython buf when converter passed to read_csv produced a numeric array (buffer dtype mismatch when passed to Cython type inference function) (GH GH546)
• Fix exception when setting scalar value using .ix on a DataFrame with a MultiIndex (GH551)
• Fix outer join between two DateRanges with different offsets that returned an invalid DateRange
• Cleanup DataFrame.from_records failure where index argument is an integer
• Fix Data.from_records failure when passed a dictionary
• Fix NA handling in {Series, DataFrame}.rank with non-floating point dtypes
• Fix bug related to integer type-checking in .ix-based indexing
• Handle non-string index name passed to DataFrame.from_records
• DataFrame.insert caused the columns name(s) field to be discarded (GH527)
• Fix erroneous in monotonic many-to-one left joins
• Fix DataFrame.to_string to remove extra column white space (GH571)
• Format floats to default to same number of digits (GH395)
• Added decorator to copy docstring from one function to another (GH449)
• Fix error in monotonic many-to-one left joins
• Fix __eq__ comparison between DateOffsets with different relativedelta keywords passed
• Fix exception caused by parser converter returning strings (GH583)
• Fix MultiIndex formatting bug with integer names (GH601)
• Fix bug in handling of non-numeric aggregates in Series.groupby (GH612)
• Fix TypeError with tuple subclasses (e.g. namedtuple) in DataFrame.from_records (GH611)
• Catch misreported console size when running IPython within Emacs
• Fix minor bug in pivot table margins, loss of index names and length-1 ‘All’ tuple in row labels
• Add support for legacy WidePanel objects to be read from HDFStore
• Fix out-of-bounds segfault in pad_object and backfill_object methods when either source or target array are empty
• Could not create a new column in a DataFrame from a list of tuples
• Fix bugs preventing SparseDataFrame and SparseSeries working with groupby (GH666)
• Use sort kind in Series.sort / argsort (GH668)
• Fix DataFrame operations on non-scalar, non-pandas objects (GH672)
• Don’t convert DataFrame column to integer type when passing integer to __setitem__ (GH669)
• Fix downstream bug in pivot_table caused by integer level names in MultiIndex (GH678)
• Fix SparseSeries.combine_first when passed a dense Series (GH687)
• Fix performance regression in HDFStore loading when DataFrame or Panel stored in table format with datetimes
• Raise Exception in DateRange when offset with n=0 is passed (GH683)
• Fix get/set inconsistency with .ix property and integer location but non-integer index (GH707)
• Use right dropna function for SparseSeries. Return dense Series for NA fill value (GH730)
• Fix Index.format bug causing incorrectly string-formatted Series with datetime indexes (GH726, GH758)
• Fix errors caused by object dtype arrays passed to ols (GH759)
• Fix error where column names lost when passing list of labels to DataFrame.__getitem__. (GH662)
• Fix error whereby top-level week iterator overwrote week instance
• Fix circular reference causing memory leak in sparse array / series / frame, (GH663)
• Fix integer-slicing from integers-as-floats (GH670)
• Fix zero division errors in nanops from object dtype arrays in all NA case (GH676)
• Fix csv encoding when using unicode (GH705, GH717, GH738)
• Fix assumption that each object contains every unique block type in concat, (GH708)
• Fix sortedness check of multiindex in to_panel (GH719, 720)
• Fix that None was not treated as NA in PyObjectHashtable
• Fix hashing dtype because of endianness confusion (GH747, GH748)
• Fix SparseSeries.dropna to return dense Series in case of NA fill value (GH GH730)
• Use map_infer instead of np.vectorize. handle NA sentinels if converter yields numeric array, (GH753)
• Fixes and improvements to DataFrame.rank (GH742)
• Fix catching AttributeError instead of NameError for bottleneck
• Try to cast non-MultiIndex to better dtype when calling reset_index (GH726 GH440)
• Fix #1.QNAN0’ float bug on 2.6/win64
• Allow subclasses of dicts in DataFrame constructor, with tests
• Fix problem whereby set_index destroys column multiindex (GH764)
• Hack around bug in generating DateRange from naive DateOffset (GH770)
• Fix bug in DateRange.intersection causing incorrect results with some overlapping ranges (GH771)

38.37 pandas 0.6.1

Release date: 12/13/2011

38.37.1 API Changes

• Rename names argument in DataFrame.from_records to columns. Add deprecation warning
• Boolean get/set operations on Series with boolean Series will reindex instead of requiring that the indexes be exactly equal (GH429)

38.37.2 New Features

• Can pass Series to DataFrame.append with ignore_index=True for appending a single row (GH430)
• Add Spearman and Kendall correlation options to Series.corr and DataFrame.corr (GH428)
• Add new get_value and set_value methods to Series, DataFrame, and Panel to very low-overhead access to scalar elements. df.get_value(row, column) is about 3x faster than df[column][row] by handling fewer cases (GH437, GH438). Add similar methods to sparse data structures for compatibility
• Add Qt table widget to sandbox (GH435)
• DataFrame.align can accept Series arguments, add axis keyword (GH461)
• Implement new SparseList and SparseArray data structures. SparseSeries now derives from SparseArray (GH463)
• max_columns / max_rows options in set_printoptions (GH453)
• Implement Series.rank and DataFrame.rank, fast versions of scipy.stats.rankdata (GH428)
• Implement DataFrame.from_items alternate constructor (GH444)
• DataFrame.convert_objects method for inferring better dtypes for object columns (GH302)
• Add rolling_corr_pairwise function for computing Panel of correlation matrices (GH189)
• Add margins option to pivot_table for computing subgroup aggregates (GH GH114)
• Add Series.from_csv function (GH482)

38.37.3 Improvements to existing features

• Improve memory usage of DataFrame.describe (do not copy data unnecessarily) (GH425)
• Use same formatting function for outputting floating point Series to console as in DataFrame (GH420)
• DataFrame.delevel will try to infer better dtype for new columns (GH440)
• Exclude non-numeric types in DataFrame.{corr, cov}
• Override Index.astype to enable dtype casting (GH412)
• Use same float formatting function for Series.__repr__ (GH420)
• Use available console width to output DataFrame columns (GH453)
• Accept ndarrays when setting items in Panel (GH452)
• Infer console width when printing __repr__ of DataFrame to console (PR GH453)
• Optimize scalar value lookups in the general case by 25% or more in Series and DataFrame
• Can pass DataFrame/DataFrame and DataFrame/Series to rolling_corr/rolling_cov (GH462)
• Fix performance regression in cross-sectional count in DataFrame, affecting DataFrame.dropna speed
• Column deletion in DataFrame copies no data (computes views on blocks) (GH GH158)
• MultiIndex.get_level_values can take the level name
• More helpful error message when DataFrame.plot fails on one of the columns (GH478)
• Improve performance of DataFrame.{index, columns} attribute lookup

38.37.4 Bug Fixes

• Fix O(K^2) memory leak caused by inserting many columns without consolidating, had been present since 0.4.0 (GH467)
• DataFrame.count should return Series with zero instead of NA with length-0 axis (GH423)
• Fix Yahoo! Finance API usage in pandas.io.data (GH419, GH427)
• Fix upstream bug causing failure in Series.align with empty Series (GH434)
• Function passed to DataFrame.apply can return a list, as long as it’s the right length. Regression from 0.4 (GH432)
• Don’t “accidentally” upcast scalar values when indexing using .ix (GH431)
• Fix groupby exception raised with as_index=False and single column selected (GH421)
• Implement DateOffset.__ne__ causing downstream bug (GH456)
• Fix __doc__-related issue when converting py -> pyo with py2exe
• Bug fix in left join Cython code with duplicate monotonic labels
• Fix bug when unstacking multiple levels described in GH451
• Exclude NA values in dtype=object arrays, regression from 0.5.0 (GH469)
• Use Cython map_infer function in DataFrame.applymap to properly infer output type, handle tuple return values and other things that were breaking (GH465)
• Handle floating point index values in HDFStore (GH454)
• Fixed stale column reference bug (cached Series object) caused by type change / item deletion in DataFrame (GH473)
• Index.get_loc should always raise Exception when there are duplicates
• Handle differently-indexed Series input to DataFrame constructor (GH475)
• Omit nuisance columns in multi-groupby with Python function
• Buglet in handling of single grouping in general apply
• Handle type inference properly when passing list of lists or tuples to DataFrame constructor (GH484)
• Preserve Index / MultiIndex names in GroupBy.apply concatenation step (GH481)

38.37.5 Thanks

• Chang She
• Ted Square
• Chris Uga
• Dieter Vandenbussche

38.38 pandas 0.6.0

Release date: 11/25/2011
38.38.1 API Changes

- Arithmetic methods like `sum` will attempt to sum `dtype=object` values by default instead of excluding them (GH382)

38.38.2 New Features

- Add `melt` function to `pandas.core.reshape`
- Add `level` parameter to group by level in Series and DataFrame descriptive statistics (GH313)
- Add `head` and `tail` methods to Series, analogous to DataFrame (PR GH296)
- Add `Series.isin` function which checks if each value is contained in a passed sequence (GH289)
- Add `float_format` option to `Series.to_string`
- Add `skip_footer` (GH291) and `converters` (GH343) options to `read_csv` and `read_table`
- Add proper, tested weighted least squares to standard and panel OLS (GH GH303)
- Add `drop_duplicates` and `duplicated` functions for removing duplicate DataFrame rows and checking for duplicate rows, respectively (GH319)
- Implement logical (boolean) operators `&`, `|`, `^` on DataFrame (GH347)
- Add `Series.mad`, mean absolute deviation, matching DataFrame
- Add `QuarterEnd` DateOffset (GH321)
- Add matrix multiplication function `dot` to DataFrame (GH65)
- Add `orient` option to `Panel.from_dict` to ease creation of mixed-type Panels (GH359, GH301)
- Add `DataFrame.from_dict` with similar `orient` option
- Can now pass list of tuples or list of lists to `DataFrame.from_records` for fast conversion to DataFrame (GH357)
- Can pass multiple levels to groupby, e.g. `df.groupby(level=[0, 1])` (GH GH103)
- Can sort by multiple columns in `DataFrame.sort_index` (GH92, GH362)
- Add fast `get_value` and `put_value` methods to DataFrame and micro-performance tweaks (GH360)
- Add `cov` instance methods to Series and DataFrame (GH194, GH362)
- Add bar plot option to `DataFrame.plot` (GH348)
- Add `idxmin` and `idxmax` functions to Series and DataFrame for computing index labels achieving maximum and minimum values (GH286)
- Add `read_clipboard` function for parsing DataFrame from OS clipboard, should work across platforms (GH300)
- Add `nunique` function to Series for counting unique elements (GH297)
- DataFrame constructor will use Series name if no columns passed (GH373)
- Support regular expressions and longer delimiters in `read_table/read_csv`, but does not handle quoted strings yet (GH364)
- Add `DataFrame.to_html` for formatting DataFrame to HTML (GH387)
- MaskedArray can be passed to DataFrame constructor and masked values will be converted to NaN (GH396)
- Add `DataFrame.boxplot` function (GH368, others)
- Can pass extra args, kwds to `DataFrame.apply` (GH376)
38.38.3 Improvements to existing features

- Raise more helpful exception if date parsing fails in DateRange (GH298)
- Vastly improved performance of GroupBy on axes with a MultiIndex (GH299)
- Print level names in hierarchical index in Series repr (GH305)
- Return DataFrame when performing GroupBy on selected column and as_index=False (GH308)
- Can pass vector to on argument in DataFrame.join (GH312)
- Don’t show Series name if it’s None in the repr, also omit length for short Series (GH317)
- Show legend by default in DataFrame.plot, add legend boolean flag (GH GH324)
- Significantly improved performance of Series.order, which also makes np.unique called on a Series faster (GH327)
- Faster cythonized count by level in Series and DataFrame (GH341)
- Raise exception if dateutil 2.0 installed on Python 2.x runtime (GH346)
- Significant GroupBy performance enhancement with multiple keys with many “empty” combinations
- New Cython vectorized function map_infer speeds up Series.apply and Series.map significantly when passed elementwise Python function, motivated by GH355
- Cythonized cache_readonly, resulting in substantial micro-performance enhancements throughout the codebase (GH361)
- Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than np.apply_along_axis (GH309)
- Add raw option to DataFrame.apply for getting better performance when the passed function only requires an ndarray (GH309)
- Improve performance of MultiIndex.from_tuples
- Can pass multiple levels to stack and unstack (GH370)
- Can pass multiple values columns to pivot_table (GH381)
- Can call DataFrame.delevel with standard Index with name set (GH393)
- Use Series name in GroupBy for result index (GH363)
- Refactor Series/DataFrame stat methods to use common set of NaN-friendly function
- Handle NumPy scalar integers at C level in Cython conversion routines

38.38.4 Bug Fixes

- Fix bug in DataFrame.to_csv when writing a DataFrame with an index name (GH290)
- DataFrame should clear its Series caches on consolidation, was causing “stale” Series to be returned in some corner cases (GH304)
- DataFrame constructor failed if a column had a list of tuples (GH293)
- Ensure that Series.apply always returns a Series and implement Series.round (GH314)
- Support boolean columns in Cythonized groupby functions (GH315)
- DataFrame.describe should not fail if there are no numeric columns, instead return categorical describe (GH323)
• Fixed bug which could cause columns to be printed in wrong order in DataFrame.to_string if specific list of columns passed (GH325)
• Fix legend plotting failure if DataFrame columns are integers (GH326)
• Shift start date back by one month for Yahoo! Finance API in pandas.io.data (GH329)
• Fix DataFrame.join failure on unconsolidated inputs (GH331)
• DataFrame.min/max will no longer fail on mixed-type DataFrame (GH337)
• Fix read_csv / read_table failure when passing list to index_col that is not in ascending order (GH349)
• Fix failure passing Int64Index to Index.union when both are monotonic
• Fix error when passing SparseSeries to (dense) DataFrame constructor
• Added missing bang at top of setup.py (GH352)
• Change is_monotonic on MultiIndex so it properly compares the tuples
• Fix MultiIndex outer join logic (GH351)
• Set index name attribute with single-key groupby (GH358)
• Bug fix in reflexive binary addition in Series and DataFrame for non-commutative operations (like string concatenation) (GH353)
• setupegg.py will invoke Cython (GH192)
• Fix block consolidation bug after inserting column into MultiIndex (GH366)
• Fix bug in join operations between Index and Int64Index (GH367)
• Handle min_periods=0 case in moving window functions (GH365)
• Fixed corner cases in DataFrame.apply/pivot with empty DataFrame (GH378)
• Fixed repr exception when Series name is a tuple
• Always return DateRange from asfreq (GH390)
• Pass level names to swaplevel (GH379)
• Don’t lose index names in MultiIndex.droplevel (GH394)
• Infer more proper return type in DataFrame.apply when no columns or rows depending on whether the passed function is a reduction (GH389)
• Always return NA/NaN from Series.min/max and DataFrame.min/max when all of a row/column/values are NA (GH384)
• Enable partial setting with .ix / advanced indexing (GH397)
• Handle mixed-type DataFrames correctly in unstack, do not lose type information (GH403)
• Fix integer name formatting bug in Index.format and in Series.__repr__
• Handle label types other than string passed to groupby (GH405)
• Fix bug in .ix-based indexing with partial retrieval when a label is not contained in a level
• Index name was not being pickled (GH408)
• Level name should be passed to result index in GroupBy.apply (GH416)

38.39 pandas 0.5.0

**Release date:** 10/24/2011

This release of pandas includes a number of API changes (see below) and cleanup of deprecated APIs from pre-0.4.0 releases. There are also bug fixes, new features, numerous significant performance enhancements, and includes a new ipython completer hook to enable tab completion of DataFrame columns accesses and attributes (a new feature).

In addition to the changes listed here from 0.4.3 to 0.5.0, the minor releases 4.1, 0.4.2, and 0.4.3 brought some significant new functionality and performance improvements that are worth taking a look at.

Thanks to all for bug reports, contributed patches and generally providing feedback on the library.

38.39.1 API Changes

- `read_table`, `read_csv`, and `ExcelFile.parse` default arguments for `index_col` is now None. To use one or more of the columns as the resulting DataFrame’s index, these must be explicitly specified now.
- Parsing functions like `read_csv` no longer parse dates by default (GH GH225)
- Removed `weights` option in panel regression which was not doing anything principled (GH155)
- Changed `buffer` argument name in `Series.to_string` to `buf`
- `Series.to_string` and `DataFrame.to_string` now return strings by default instead of printing to `sys.stdout`.
- Deprecated `nanRep` argument in various `to_string` and `to_csv` functions in favor of `na_rep`. Will be removed in 0.6 (GH275).
- Renamed `delimiter` to `sep` in `DataFrame.from_csv` for consistency.
- Changed order of `Series.clip` arguments to match those of `numpy.clip` and added (unimplemented) `out` argument so `numpy.clip` can be called on a Series (GH272).
- Series functions renamed (and thus deprecated) in 0.4 series have been removed:
  - `asOf`, use `asof`
  - `toDict`, use `to_dict`
  - `toString`, use `to_string`
  - `toCSV`, use `to_csv`
  - `merge`, use `map`
  - `applymap`, use `apply`
  - `combineFirst`, use `combine_first`
  - `_firstTimeWithValue` use `first_valid_index`
  - `_lastTimeWithValue` use `last_valid_index`
- DataFrame functions renamed / deprecated in 0.4 series have been removed:
  - `asMatrix` method, use `as_matrix` or `values` attribute
  - `combineFirst`, use `combine_first`
  - `getXS`, use `xs`
  - `merge`, use `join`
  - `fromRecords`, use `from_records`
  - `fromcsv`, use `from_csv`
  - `toRecords`, use `to_records`
  - `toDict`, use `to_dict`
  - `toString`, use `to_string`
  - `toCSV`, use `to_csv`
  - `_firstTimeWithValue` use `first_valid_index`
  - `_lastTimeWithValue` use `last_valid_index`
  - `DataMatrix` is no longer needed
  - `rows()` method, use `index` attribute
  - `cols()` method, use `columns` attribute
  - `dropEmptyRows()`, use `dropna(\texttt{how=\textquoteleft all\textquoteright})`
  - `dropIncompleteRows()`, use `dropna()`
  - `tapply(f)`, use `apply(f, axis=1)`
  - `tgroupby(keyfunc, aggfunc)`, use `groupby` with `axis=1`
38.39.2 Deprecations Removed

- `indexField` argument in `DataFrame.from_records`
- `missingAtEnd` argument in `Series.order`. Use `na_last` instead
- `Series.fromValue` class method, use regular `Series` constructor instead
- Functions `parseCSV`, `parseText`, and `parseExcel` methods in `pandas.io.parsers` have been removed
- `Index.asOfDate` function
- `Panel.getMinorXS` (use `minor_xs`) and `Panel.getMajorXS` (use `major_xs`)
- `Panel.toWide`, use `Panel.to_wide` instead

38.39.3 New Features

- Added `DataFrame.align` method with standard join options
- Added `parse_dates` option to `read_csv` and `read_table` methods to optionally try to parse dates in the index columns
- Add `nrows`, `chunksize`, and `iterator` arguments to `read_csv` and `read_table`. The last two return a new `TextParser` class capable of lazily iterating through chunks of a flat file (GH242)
- Added ability to join on multiple columns in `DataFrame.join` (GH214)
- Added private `_get_duplicates` function to `Index` for identifying duplicate values more easily
- Added column attribute access to `DataFrame`, e.g. `df.A` equivalent to `df[‘A’]` if ‘A’ is a column in the DataFrame (GH213)
- Added IPython tab completion hook for `DataFrame` columns. (GH233, GH230)
- Implement `Series.describe` for `Series` containing objects (GH241)
- Add inner join option to `DataFrame.join` when joining on key(s) (GH248)
- Can select set of `DataFrame` columns by passing a list to `__getitem__` (GH GH253)
- Can use `&` and `|` to intersection / union `Index` objects, respectively (GH GH261)
- Added `pivot_table` convenience function to `pandas` namespace (GH234)
- Implemented `Panel.rename_axis` function (GH243)
- `DataFrame` will show index level names in console output
- Implemented `Panel.take`
- Add `set_eng_float_format` function for setting alternate `DataFrame` floating point string formatting
- Add convenience `set_index` function for creating a `DataFrame` index from its existing columns

38.39.4 Improvements to existing features

- Major performance improvements in file parsing functions `read_csv` and `read_table`
- Added Cython function for converting tuples to `ndarray` very fast. Speeds up many MultiIndex-related operations
- File parsing functions like `read_csv` and `read_table` will explicitly check if a parsed index has duplicates and raise a more helpful exception rather than deferring the check until later
- Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
- Improved speed of DataFrame.xs on mixed-type DataFrame objects by about 5x, regression from 0.3.0 (GH215)
- With new DataFrame.align method, speeding up binary operations between differently-indexed DataFrame objects by 10-25%.
- Significantly sped up conversion of nested dict into DataFrame (GH212)
- Can pass hierarchical index level name to groupby instead of the level number if desired (GH223)
- Add support for different delimiters in DataFrame.to_csv (GH244)
- Add more helpful error message when importing pandas post-installation from the source directory (GH250)
- Significantly speed up DataFrame __repr__ and count on large mixed-type DataFrame objects
- Better handling of pyx file dependencies in Cython module build (GH271)

38.39.5 Bug Fixes

- read_csv / read_table fixes
  - Be less aggressive about converting float->int in cases of floating point representations of integers like 1.0, 2.0, etc.
  - “True”/”False” will not get correctly converted to boolean
  - Index name attribute will get set when specifying an index column
  - Passing column names should force header=None (GH257)
  - Don’t modify passed column names when index_col is not None (GH258)
  - Can sniff CSV separator in zip file (since seek is not supported, was failing before)
- Worked around matplotlib “bug” in which series[:, np.newaxis] fails. Should be reported upstream to matplotlib (GH224)
- DataFrame.iteritems was not returning Series with the name attribute set. Also neither was DataFrame._series
- Can store datetime.date objects in HDFStore (GH231)
- Index and Series names are now stored in HDFStore
- Fixed problem in which data would get upcasted to object dtype in GroupBy.apply operations (GH237)
- Fixed outer join bug with empty DataFrame (GH238)
- Can create empty Panel (GH239)
- Fix join on single key when passing list with 1 entry (GH246)
- Don’t raise Exception on plotting DataFrame with an all-NA column (GH251, GH254)
- Bug min/max errors when called on integer DataFrames (GH241)
- DataFrame.iteritems and DataFrame._series not assigning name attribute
- Panel.__repr__ raised exception on length-0 major/minor axes
- DataFrame.join on key with empty DataFrame produced incorrect columns
- Implemented MultiIndex.diff (GH260)
- Int64Index.take and MultiIndex.take lost name field, fix downstream issue GH262
• Can pass list of tuples to `Series` (GH270)
• Can pass level name to `DataFrame.stack`
• Support set operations between MultiIndex and Index
• Fix many corner cases in MultiIndex set operations - Fix MultiIndex-handling bug with GroupBy.apply when returned groups are not indexed the same
• Fix corner case bugs in DataFrame.apply
• Setting DataFrame index did not cause Series cache to get cleared
• Various int32 -> int64 platform-specific issues
• Don’t be too aggressive converting to integer when parsing file with MultiIndex (GH285)
• Fix bug when slicing Series with negative indices before beginning

### 38.39.6 Thanks

• Thomas Kluyver
• Daniel Fortunov
• Aman Thakral
• Luca Beltrame
• Wouter Overmeire

### 38.40 pandas 0.4.3

**Release date:** 10/9/2011

This is largely a bugfix release from 0.4.2 but also includes a handful of new and enhanced features. Also, pandas can now be installed and used on Python 3 (thanks Thomas Kluyver!).

#### 38.40.1 New Features

• Python 3 support using 2to3 (GH200, Thomas Kluyver)
• Add `name` attribute to `Series` and added relevant logic and tests. Name now prints as part of `Series.__repr__`
• Add `name` attribute to standard Index so that stacking / unstacking does not discard names and so that indexed DataFrame objects can be reliably round-tripped to flat files, pickle, HDF5, etc.
• Add `isnull` and `notnull` as instance methods on Series (GH209, GH203)

#### 38.40.2 Improvements to existing features

• Skip xldr-related unit tests if not installed
• `Index.append` and `MultiIndex.append` can accept a list of Index objects to concatenate together
• Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks (GH205)
• Refactored `Series.__repr__` to be a bit more clean and consistent
38.40.3 API Changes

- *Series.describe* and *DataFrame.describe* now bring the 25% and 75% quartiles instead of the 10% and 90% deciles. The other outputs have not changed

- *Series.toString* will print deprecation warning, has been de-camelCased to *to_string*

38.40.4 Bug Fixes

- Fix broken interaction between *Index* and *Int64Index* when calling intersection. Implement *Int64Index.intersection*

- *MultiIndex.sortlevel* discarded the level names (GH202)

- Fix bugs in groupby, join, and append due to improper concatenation of *MultiIndex* objects (GH201)

- Fix regression from 0.4.1, *isnull* and *notnull* ceased to work on other kinds of Python scalar objects like *datetime
datetime*

- Raise more helpful exception when attempting to write empty DataFrame or LongPanel to *HDFStore* (GH204)

- Use stdlib csv module to properly escape strings with commas in *DataFrame.to_csv* (GH206, Thomas Kluyver)

- Fix Python ndarray access in Cython code for sparse blocked index integrity check

- Fix bug writing Series to CSV in Python 3 (GH209)

- Miscellaneous Python 3 bugfixes

38.40.5 Thanks

- Thomas Kluyver

- rsamson

38.41 pandas 0.4.2

Release date: 10/3/2011

This is a performance optimization release with several bug fixes. The new *Int64Index* and new merging / joining Cython code and related Python infrastructure are the main new additions

38.41.1 New Features

- Added fast *Int64Index* type with specialized join, union, intersection. Will result in significant performance enhancements for int64-based time series (e.g. using NumPy’s datetime64 one day) and also faster operations on DataFrame objects storing record array-like data.

- Refactored *Index* classes to have a *join* method and associated data alignment routines throughout the codebase to be able to leverage optimized joining / merging routines.

- Added *Series.align* method for aligning two series with choice of join method

- Wrote faster Cython data alignment / merging routines resulting in substantial speed increases

- Added *is_monotonic* property to *Index* classes with associated Cython code to evaluate the monotonicity of the *Index* values
• Add method `get_level_values` to `MultiIndex`
• Implemented shallow copy of `BlockManager` object in `DataFrame` internals

### 38.41.2 Improvements to existing features

• Improved performance of `isnull` and `notnull`, a regression from v0.3.0 (GH187)
• Wrote templating / code generation script to auto-generate Cython code for various functions which need to be available for the 4 major data types used in pandas (float64, bool, object, int64)
• Refactored code related to `DataFrame.join` so that intermediate aligned copies of the data in each `DataFrame` argument do not need to be created. Substantial performance increases result (GH176)
• Substantially improved performance of generic `Index.intersection` and `Index.union`
• Improved performance of `DateRange.union` with overlapping ranges and non-cacheable offsets (like Minute). Implemented analogous fast `DateRange.intersection` for overlapping ranges.
• Implemented `BlockManager.take` resulting in significantly faster `take` performance on mixed-type `DataFrame` objects (GH104)
• Improved performance of `Series.sort_index`
• Significant groupby performance enhancement: removed unnecessary integrity checks in `DataFrame` internals that were slowing down slicing operations to retrieve groups
• Added informative Exception when passing dict to `DataFrame` groupby aggregation with axis != 0

### 38.41.3 API Changes

### 38.41.4 Bug Fixes

• Fixed minor unhandled exception in Cython code implementing fast groupby aggregation operations
• Fixed bug in unstacking code manifesting with more than 3 hierarchical levels
• Throw exception when step specified in label-based slice (GH185)
• Fix `isnull` to correctly work with `np.float32`. Fix upstream bug described in GH182
• Finish implementation of `as_index=False` in groupby for `DataFrame` aggregation (GH181)
• Raise SkipTest for pre-epoch HDFStore failure. Real fix will be sorted out via datetime64 dtype

### 38.41.5 Thanks

• Uri Laserson
• Scott Sinclair

### 38.42 pandas 0.4.1

**Release date:** 9/25/2011

This is primarily a bug fix release but includes some new features and improvements
38.42.1 New Features

- Added new DataFrame methods `get_dtype_counts` and property `dtypes`

- Setting of values using `.ix` indexing attribute in mixed-type DataFrame objects has been implemented (fixes GH135)

- `read_csv` can read multiple columns into a `MultiIndex`. DataFrame’s `to_csv` method will properly write out a `MultiIndex` which can be read back (GH151, thanks to Skipper Seabold)

- Wrote fast time series merging / joining methods in Cython. Will be integrated later into DataFrame.join and related functions

- Added `ignore_index` option to `DataFrame.append` for combining unindexed records stored in a DataFrame

38.42.2 Improvements to existing features

- Some speed enhancements with internal Index type-checking function

- `DataFrame.rename` has a new `copy` parameter which can rename a DataFrame in place

- Enable unstacking by level name (GH142)

- Enable sortlevel to work by level name (GH141)

- `read_csv` can automatically “sniff” other kinds of delimiters using `csv.Sniffer` (GH146)

- Improved speed of unit test suite by about 40%

- Exception will not be raised calling `HDFStore.remove` on non-existent node with where clause

- Optimized `_ensure_index` function resulting in performance savings in type-checking Index objects

38.42.3 API Changes

38.42.4 Bug Fixes

- Fixed DataFrame constructor bug causing downstream problems (e.g. `copy()` failing) when passing a Series as the values along with a column name and index

- Fixed single-key groupby on DataFrame with as_index=False (GH160)

- `Series.shift` was failing on integer Series (GH154)

- `unstack` methods were producing incorrect output in the case of duplicate hierarchical labels. An exception will now be raised (GH147)

- Calling `count` with level argument caused reduceat failure or segfault in earlier NumPy (GH169)

- Fixed `DataFrame.corrwith` to automatically exclude non-numeric data (GH GH144)

- Unicode handling bug fixes in `DataFrame.to_string` (GH138)

- Excluding OLS degenerate unit test case that was causing platform specific failure (GH149)

- Skip blosc-dependent unit tests for PyTables < 2.2 (GH137)

- Calling `copy` on `DateRange` did not copy over attributes to the new object (GH168)

- Fix bug in `HDFStore` in which Panel data could be appended to a Table with different item order, thus resulting in an incorrect result read back
38.42.5 Thanks

- Yaroslav Halchenko
- Jeff Reback
- Skipper Seabold
- Dan Lovell
- Nick Pentreath

38.43 pandas 0.4.0

Release date: 9/12/2011

38.43.1 New Features

- *pandas.core.sparse* module: “Sparse” (mostly-NA, or some other fill value) versions of *Series*, *DataFrame*, and *Panel*. For low-density data, this will result in significant performance boosts, and smaller memory footprint. Added to_sparse methods to *Series*, *DataFrame*, and *Panel*. See online documentation for more on these.

- Fancy indexing operator on *Series* / *DataFrame*, e.g. via .ix operator. Both getting and setting of values is supported; however, setting values will only currently work on homogeneously-typed *DataFrame* objects. Things like:
  - `series.ix[[d1, d2, d3]]`
  - `frame.ix[5:10, ['C', 'B', 'A']`, `frame.ix[5:10, 'A':'C']`
  - `frame.ix[date1:date2]`

- Significantly enhanced *groupby* functionality
  - Can groupby multiple keys, e.g. `df.groupby(['key1', 'key2'])`. Iteration with multiple groupings products a flattened tuple
  - “Nuisance” columns (non-aggregatable) will automatically be excluded from *DataFrame* aggregation operations
  - Added automatic “dispatching to *Series* / *DataFrame* methods to more easily invoke methods on groups. e.g. `s.groupby(crit).std()` will work even though `std` is not implemented on the *GroupBy* class

- Hierarchical / multi-level indexing
  - New the *MultiIndex* class. Integrated *MultiIndex* into *Series* and *DataFrame* fancy indexing, slicing, __getitem__, __setitem__, reindexing, etc. Added level keyword argument to *groupby* to enable grouping by a level of a *MultiIndex*

- New data reshaping functions: *stack* and *unstack* on *DataFrame* and *Series*
  - Integrate with *MultiIndex* to enable sophisticated reshaping of data

- *Index* objects (labels for axes) are now capable of holding tuples

- *Series.describe*, *DataFrame.describe*: produces an R-like table of summary statistics about each data column

- *DataFrame.quantile*, *Series.quantile* for computing sample quantiles of data across requested axis

- Added general *DataFrame.dropna* method to replace *dropIncompleteRows* and *dropEmptyRows*, deprecated those.
- Series arithmetic methods with optional fill_value for missing data, e.g. a.add(b, fill_value=0). If a location is missing for both it will still be missing in the result though.
- fill_value option has been added to DataFrame.{add, mul, sub, div} methods similar to Series
- Boolean indexing with DataFrame objects: data[data > 0.1] = 0.1 or data[data> other] = 1.
- pytz/tzinfo support in DateRange
  - tz_localize, tz_normalize, and tz_validate methods added
- Added ExcelFile class to pandas.io.parsers for parsing multiple sheets out of a single Excel 2003 document
- GroupBy aggregations can now optionally broadcast, e.g. produce an object of the same size with the aggregated value propagated
- Added select function in all data structures: reindex axis based on arbitrary criterion (function returning boolean value), e.g. frame.select(lambda x: ‘foo’ in x, axis=1)
- DataFrame.consolidate method, API function relating to redesigned internals
- DataFrame.insert method for inserting column at a specified location rather than the default __setitem__ behavior (which puts it at the end)
- HDFStore class in pandas.io.pytables has been largely rewritten using patches from Jeff Reback from others. It now supports mixed-type DataFrame and Series data and can store Panel objects. It also has the option to query DataFrame and Panel data. Loading data from legacy HDFStore files is supported explicitly in the code
- Added set_printoptions method to modify appearance of DataFrame tabular output
- rolling_quantile functions; a moving version of Series.quantile / DataFrame.quantile
- Generic rolling_apply moving window function
- New drop method added to Series, DataFrame, etc. which can drop a set of labels from an axis, producing a new object
- reindex methods now sport a copy option so that data is not forced to be copied then the resulting object is indexed the same
- Added sort_index methods to Series and Panel. Renamed DataFrame.sort to sort_index. Leaving DataFrame.sort for now.
- Added skipna option to statistical instance methods on all the data structures
- pandas.io.data module providing a consistent interface for reading time series data from several different sources

### 38.43.2 Improvements to existing features

- The 2-dimensional DataFrame and DataMatrix classes have been extensively redesigned internally into a single class DataFrame, preserving where possible their optimal performance characteristics. This should reduce confusion from users about which class to use.
  - Note that under the hood there is a new essentially “lazy evaluation” scheme within respect to adding columns to DataFrame. During some operations, like-typed blocks will be “consolidated” but not before.
- DataFrame accessing columns repeatedly is now significantly faster than DataMatrix used to be in 0.3.0 due to an internal Series caching mechanism (which are all views on the underlying data)
- Column ordering for mixed type data is now completely consistent in DataFrame. In prior releases, there was inconsistent column ordering in DataMatrix
- Improved console / string formatting of DataMatrix with negative numbers
- Improved tabular data parsing functions, read_table and read_csv:
- Added `skiprows` and `na_values` arguments to `pandas.io.parsers` functions for more flexible IO
- `parseCSV` / `read_csv` functions and others in `pandas.io.parsers` now can take a list of custom NA values, and also a list of rows to skip

- Can slice `DataFrame` and get a view of the data (when homogeneously typed), e.g. `frame.xs(idx, copy=False)` or `frame.ix[idx]`

- Many speed optimizations throughout `Series` and `DataFrame`

- Eager evaluation of groups when calling `groupby` functions, so if there is an exception with the grouping function it will raised immediately versus sometime later on when the groups are needed

- `datetools.WeekOfMonth` offset can be parameterized with `n` different than 1 or -1.

- Statistical methods on `DataFrame` like `mean`, `std`, `var`, `skew` will now ignore non-numerical data. Before a not very useful error message was generated. A flag `numeric_only` has been added to `DataFrame.sum` and `DataFrame.count` to enable this behavior in those methods if so desired (disabled by default)

- `DataFrame.pivot` generalized to enable pivoting multiple columns into a `DataFrame` with hierarchical columns

- `DataFrame` constructor can accept structured / record arrays

- `Panel` constructor can accept a dict of DataFrame-like objects. Do not need to use `from_dict` anymore (`from_dict` is there to stay, though).

### 38.43.3 API Changes

- The `DataMatrix` variable now refers to `DataFrame`, will be removed within two releases

- `WidePanel` is now known as `Panel`. The `WidePanel` variable in the pandas namespace now refers to the renamed `Panel` class

- `LongPanel` and `Panel / WidePanel` now no longer have a common subclass. `LongPanel` is now a subclass of `DataFrame` having a number of additional methods and a hierarchical index instead of the old `LongPanelIndex` object, which has been removed. Legacy `LongPanel` pickles may not load properly

- Cython is now required to build `pandas` from a development branch. This was done to avoid continuing to check in cythonized C files into source control. Builds from released source distributions will not require Cython

- Cython code has been moved up to a top level `pandas/src` directory. Cython extension modules have been renamed and promoted from the `lib` subpackage to the top level, i.e.

  - `pandas.lib.tseries -> pandas._tseries`
  - `pandas.lib.sparse -> pandas._sparse`

- `DataFrame` pickling format has changed. Backwards compatibility for legacy pickles is provided, but it’s recommended to consider PyTables-based `HDFStore` for storing data with a longer expected shelf life

- A `copy` argument has been added to the `DataFrame` constructor to avoid unnecessary copying of data. Data is no longer copied by default when passed into the constructor

- Handling of boolean dtype in `DataFrame` has been improved to support storage of boolean data with NA / NaN values. Before it was being converted to float64 so this should not (in theory) cause API breakage

- To optimize performance, Index objects now only check that their labels are unique when uniqueness matters (i.e. when someone goes to perform a lookup). This is a potentially dangerous tradeoff, but will lead to much better performance in many places (like `groupby`).

- Boolean indexing using Series must now have the same indices (labels)

- Backwards compatibility support for `begin/end/nPeriods` keyword arguments in `DateRange` class has been removed
• More intuitive / shorter filling aliases `ffill` (for `pad`) and `bfill` (for `backfill`) have been added to the functions that use them: `reindex`, `asfreq`, `fillna`.

• `pandas.core.mixins` code moved to `pandas.core.generic`

• `buffer` keyword arguments (e.g. `DataFrame.to_string`) renamed to `buf` to avoid using Python built-in name

• `DataFrame.rows()` removed (use `DataFrame.index`)

• Added deprecation warning to `DataFrame.cols()`, to be removed in next release

• `DataFrame` deprecations and de-camelCasing: `merge`, `asMatrix`, `toDataMatrix`, `_firstTimeWithValue`, `_lastTimeWithValue`, `toRecords`, `fromRecords`, `tgroupby`, `toString`

• `pandas.io.parsers` method deprecations
  – `parseCSV` is now `read_csv` and keyword arguments have been de-camelCased
  – `parseText` is now `read_table`
  – `parseExcel` is replaced by the `ExcelFile` class and its `parse` method

• `fillMethod` arguments (deprecated in prior release) removed, should be replaced with `method`

• `Series.fill`, `DataFrame.fill`, and `Panel.fill` removed, use `fillna` instead

• `groupby` functions now exclude NA / NaN values from the list of groups. This matches R behavior with NAs in factors e.g. with the `tapply` function

• Removed `parseText`, `parseCSV` and `parseExcel` from pandas namespace

• `Series.combineFunc` renamed to `Series.combine` and made a bit more general with a `fill_value` keyword argument defaulting to NaN

• Removed `pandas.core.pytools` module. Code has been moved to `pandas.core.common`

• Tacked on `groupName` attribute for groups in GroupBy renamed to `name`

• Panel/LongPanel `dims` attribute renamed to `shape` to be more conformant

• Slicing a `Series` returns a view now

• More `Series` deprecations / renaming: `toCSV` to `to_csv`, `asOf` to `asof`, `merge` to `map`, `applymap` to `apply`, `toDict` to `to_dict`, `combineFirst` to `combine_first`. Will print `FutureWarning`.

• `DataFrame.to_csv` does not write an “index” column label by default anymore since the output file can be read back without it. However, there is a new `index_label` argument. So you can do `index_label='index'` to emulate the old behavior

• `datetools.Week` argument renamed from `dayOfWeek` to `weekday`

• `timeRule` argument in `shift` has been deprecated in favor of using the `offset` argument for everything. So you can still pass a time rule string to `offset`

• Added optional `encoding` argument to `read_csv`, `read_table`, `to_csv`, `from_csv` to handle unicode in Python 2.x

### 38.43.4 Bug Fixes

• Column ordering in `pandas.io.parsers.parseCSV` will match CSV in the presence of mixed-type data

• Fixed handling of Excel 2003 dates in `pandas.io.parsers`

• `DateRange` caching was happening with high resolution `DateOffset` objects, e.g. `DateOffset(seconds=1)`. This has been fixed

• Fixed `__truediv__` issue in `DataFrame`
• Fixed `DataFrame.toCSV` bug preventing IO round trips in some cases
• Fixed bug in `Series.plot` causing matplotlib to barf in exceptional cases
• Disabled `Index` objects from being hashable, like ndarrays
• Added `__ne__` implementation to `Index` so that operations like `ts[ts != idx]` will work
• Added `__ne__` implementation to `DataFrame`
• Bug / unintuitive result when calling `fillna` on unordered labels
• Bug calling `sum` on boolean DataFrame
• Bug fix when creating a DataFrame from a dict with scalar values
• Series.{sum, mean, std, ...} now return NA/NaN when the whole Series is NA
• NumPy 1.4 through 1.6 compatibility fixes
• Fixed bug in bias correction in `rolling_cov`, was affecting `rolling_corr` too
• R-square value was incorrect in the presence of fixed and time effects in the `PanelOLS` classes
• `HDFStore` can handle duplicates in table format, will take

38.43.5 Thanks

38.44 pandas 0.3.0

Release date: February 20, 2011

38.44.1 New features

- `corrwith` function to compute column- or row-wise correlations between two DataFrame objects
- Can boolean-index DataFrame objects, e.g. `df[df > 2] = 2`, `px[px > last_px] = 0`
- Added comparison magic methods (`__lt__`, `__gt__`, etc.)
- Flexible explicit arithmetic methods (add, mul, sub, div, etc.)
- Added `reindex_like` method
- Added `reindex_like` method to WidePanel
- Convenience functions for accessing SQL-like databases in `pandas.io.sql` module
- Added (still experimental) HDFStore class for storing pandas data structures using HDF5 / PyTables in `pandas.io.pytables` module
- Added WeekOfMonth date offset
- `pandas.rpy` (experimental) module created, provide some interfacing / conversion between rpy2 and pandas

38.44.2 Improvements to existing features

- Unit test coverage: 100% line coverage of core data structures
- Speed enhancement to rolling_{median, max, min}
- Column ordering between DataFrame and DataMatrix is now consistent: before DataFrame would not respect column order
- Improved `{Series, DataFrame}.plot` methods to be more flexible (can pass matplotlib Axis arguments, plot DataFrame columns in multiple subplots, etc.)

38.44.3 API Changes

- Exponentially-weighted moment functions in `pandas.stats.moments` have a more consistent API and accept a `min_periods` argument like their regular moving counterparts.
- `fillMethod` argument in Series, DataFrame changed to `method`, `FutureWarning` added.
- `fill` method in Series, DataFrame/DataMatrix, WidePanel renamed to `fillna`, `FutureWarning` added to `fill`
- Renamed `DataFrame.getXS` to `xs`, `FutureWarning` added
- Removed `cap` and `floor` functions from DataFrame, renamed to `clip_upper` and `clip_lower` for consistency with NumPy
38.44.4 Bug Fixes

- Fixed bug in IndexableSkiplist Cython code that was breaking rolling_max function
- Numerous numpy.int64-related indexing fixes
- Several NumPy 1.4.0 NaN-handling fixes
- Bug fixes to pandas.io.parsers.parseCSV
- Fixed DateRange caching issue with unusual date offsets
- Fixed bug in DateRange.union
- Fixed corner case in IndexableSkiplist implementation
