pandas: powerful Python data analysis toolkit

Release 1.4.1

Wes McKinney and the Pandas Development Team

Feb 12, 2022
# CONTENTS

1 Getting started  
1.1 Installation ........................................ 3  
1.2 Intro to pandas .................................. 3  
1.3 Coming from... ................................ 5  
1.4 Tutorials ........................................ 5  
1.4.1 Installation ................................ 6  
1.4.2 Package overview ......................... 12  
1.4.3 Getting started tutorials .................. 15  
1.4.4 Comparison with other tools .......... 61  
1.4.5 Community tutorials ....................... 147  

2 User Guide  
2.1 10 minutes to pandas  
2.1.1 Object creation  
2.1.2 Viewing data  
2.1.3 Selection ................................ 153  
2.1.4 Missing data ................................ 158  
2.1.5 Operations ................................ 159  
2.1.6 Merge ........................................ 161  
2.1.7 Grouping .................................... 163  
2.1.8 Reshaping .................................. 165  
2.1.9 Time series ................................ 167  
2.1.10 Categoricals  
2.1.11 Plotting ................................... 171  
2.1.12 Getting data in/out ...................... 173  
2.1.13 Gotchas .................................... 174  

2.2 Intro to data structures  
2.2.1 Series ....................................... 175  
2.2.2 DataFrame .................................. 180  

2.3 Essential basic functionality  
2.3.1 Head and tail ................................ 198  
2.3.2 Attributes and underlying data ........ 199  
2.3.3 Accelerated operations ................... 201  
2.3.4 Flexible binary operations ............... 202  
2.3.5 Descriptive statistics .................... 211  
2.3.6 Function application ..................... 220  
2.3.7 Reindexing and altering labels .......... 233  
2.3.8 Iteration .................................... 243  
2.3.9 .dt accessor ................................ 247  
2.3.10 Vectorized string methods ............. 251
2.12 Categorical data .......................................................... 637
2.11 Duplicate Labels ......................................................... 629
2.10 Working with missing data ......................................... 599
2.9 Working with text data ................................................. 576
2.8 Reshaping and pivot tables ........................................... 543
2.7 Merge, join, concatenate and compare ......................... 508
2.6.3 Sorting a MultiIndex ................................................. 489
2.6.4 Take methods ........................................................ 492
2.6.5 Index types .......................................................... 494
2.6.6 Miscellaneous indexing FAQ .................................... 503
2.12.4 Working with categories ........................................ 645
2.12.3 Description .......................................................... 644
2.12.2 CategoricalDtype .................................................. 643
2.11.3 Disallowing Duplicate Labels ................................. 633
2.11.2 Duplicate Label Detection ...................................... 632
2.11.1 Consequences of Duplicate Labels ......................... 630
2.10.13 Experimental ....................................................... 618
2.10.11 String/regular expression replacement ................... 610
2.10.10 Replacing generic values ..................................... 609
2.10.9 Interpolation ......................................................... 603
2.10.8 Dropping axis labels with missing data: dropna .......... 602
2.10.7 Filling with a PandasObject .................................... 601
2.10.6 Filling missing values: fillna ................................ 599
2.10.5 NA values in GroupBy ........................................... 598
2.10.4 Sum/prod of empties/nans ..................................... 597
2.10.3 Calculations with missing data ............................... 595
2.10.2 Inserting missing data ............................................ 593
2.10.1 Values considered “missing” .................................... 592
2.9.9 Method summary .................................................... 591
2.9.8 Creating indicator variables .................................... 589
2.9.7 Testing for strings that match or contain a pattern ....... 587
2.9.6 Extracting substrings .............................................. 585
2.9.5 Indexing with .str .................................................. 583
2.9.4 Concatenation ....................................................... 581
2.9.3 Splitting and replacing strings ................................. 579
2.9.2 String methods ...................................................... 577
2.9.1 Text data types ...................................................... 576
2.8.11 Exploding a list-like column .................................. 571
2.8.10 Examples .......................................................... 570
2.8.9 Factorizing values .................................................. 568
2.8.8 Computing indicator / dummy variables ..................... 567
2.8.7 Tiling ................................................................. 565
2.8.6 Cross tabulations ................................................... 563
2.8.5 Pivot tables .......................................................... 561
2.8.4 Combining with stats and GroupBy ............................ 557
2.8.3 Reshaping by melt ................................................ 541
2.8.2 Reshaping by stacking and unstacking ....................... 541
2.8.1 Reshaping by pivoting DataFrame objects .................... 538
2.7.4 Comparing objects ................................................ 533
2.7.3 Timeseries friendly merging ..................................... 528
2.7.2 Database-style DataFrame or named Series joining/merging 527
2.7.1 Concatenating objects ............................................ 509
2.6.3 Sorting a MultiIndex ................................................. 492
2.6.4 Take methods ........................................................ 492
2.6.5 Index types .......................................................... 494
2.6.6 Miscellaneous indexing FAQ .................................... 503
2.7 Merge, join, concatenate and compare ......................... 508
2.8 Reshaping and pivot tables ........................................... 543
2.8.1 Reshaping by pivoting DataFrame objects .................... 543
2.8.2 Reshaping by stacking and unstacking ....................... 546
2.8.3 Reshaping by melt .................................................. 555
2.8.4 Combining with stats and GroupBy ............................ 557
2.8.5 Pivot tables .......................................................... 558
2.8.6 Cross tabulations ................................................... 563
2.8.7 Tiling ................................................................. 565
2.8.8 Computing indicator / dummy variables ..................... 566
2.8.9 Factorizing values .................................................. 569
2.8.10 Examples .......................................................... 571
2.8.11 Exploding a list-like column .................................. 574
2.9 Working with text data ................................................. 576
2.9.1 Text data types ...................................................... 576
2.9.2 String methods ...................................................... 579
2.9.3 Splitting and replacing strings ................................. 581
2.9.4 Concatenation ....................................................... 585
2.9.5 Indexing with .str .................................................. 591
2.9.6 Extracting substrings .............................................. 591
2.9.7 Testing for strings that match or contain a pattern ....... 595
2.9.8 Creating indicator variables .................................... 597
2.9.9 Method summary .................................................... 598
2.10 Working with missing data ......................................... 599
2.10.1 Values considered “missing” .................................... 599
2.10.2 Inserting missing data ............................................ 602
2.10.3 Calculations with missing data ............................... 603
2.10.4 Sum/prod of empties/nans ..................................... 605
2.10.5 NA values in GroupBy ........................................... 605
2.10.6 Filling missing values: fillna ................................ 606
2.10.7 Filling with a PandasObject .................................... 607
2.10.8 Dropping axis labels with missing data: dropna .......... 609
2.10.9 Interpolation ......................................................... 609
2.10.10 Replacing generic values ..................................... 618
2.10.11 String/regular expression replacement ................... 620
2.10.12 Numeric replacement ........................................... 622
2.10.13 Experimental NA scalar to denote missing values .... 625
2.11 Duplicate Labels ....................................................... 629
2.11.1 Consequences of Duplicate Labels ......................... 630
2.11.2 Duplicate Label Detection ...................................... 632
2.11.3 Disallowing Duplicate Labels ................................. 633
2.12 Categorical data ........................................................ 637
2.12.1 Object creation ...................................................... 638
2.12.2 CategoricalDtype .................................................. 643
2.12.3 Description .......................................................... 644
2.12.4 Working with categories ........................................ 645
2.12.5 Sorting and order .................................................. 649
2.12.6 Comparisons ......................................................... 652
2.12.7 Operations .......................................................... 655
2.12.8 Data munging ......................................................... 657
2.12.9 Getting data in/out ............................................... 665
2.12.10 Missing data ....................................................... 666
2.12.11 Differences to R’s factor ........................................ 667
2.12.12 Gotchas ............................................................. 667

2.13 Nullable integer data type ........................................... 671
2.13.1 Construction ......................................................... 672
2.13.2 Operations .......................................................... 673
2.13.3 Scalar NA Value ................................................... 675

2.14 Nullable Boolean data type .......................................... 675
2.14.1 Indexing with NA values ........................................ 675
2.14.2 Kleene logical operations ........................................ 676

2.15 Chart Visualization ................................................... 677
2.15.1 Basic plotting: plot .............................................. 678
2.15.2 Other plots .......................................................... 680
2.15.3 Plotting with missing data ..................................... 714
2.15.4 Plotting tools ......................................................... 715
2.15.5 Plot formatting ...................................................... 723
2.15.6 Plotting directly with matplotlib ............................... 749
2.15.7 Plotting backends ................................................ 750

2.16 Table Visualization ................................................... 751
2.16.1 Styler Object and HTML ....................................... 751
2.16.2 Formatting the Display .......................................... 752
2.16.3 Methods to Add Styles ......................................... 753
2.16.4 Table Styles ........................................................ 754
2.16.5 Setting Classes and Linking to External CSS ............... 755
2.16.6 Styler Functions .................................................... 756
2.16.7 Tooltips and Captions .......................................... 757
2.16.8 Finer Control with Slicing ..................................... 758
2.16.9 Optimization ........................................................ 759
2.16.10 Builtin Styles ....................................................... 762
2.16.11 Sharing styles ...................................................... 764
2.16.12 Limitations ........................................................ 765
2.16.13 Other Fun and Useful Stuff ................................. 765
2.16.14 Export to Excel .................................................. 767
2.16.15 Export to LaTeX ................................................ 768
2.16.16 More About CSS and HTML ................................. 768
2.16.17 Extensibility ....................................................... 770

2.17 Computational tools .................................................. 772
2.17.1 Statistical functions .............................................. 772

2.18 Group by: split-apply-combine ..................................... 777
2.18.1 Splitting an object into groups ............................... 778
2.18.2 Iterating through groups ....................................... 787
2.18.3 Selecting a group .................................................. 788
2.18.4 Aggregation ........................................................ 788
2.18.5 Transformation ...................................................... 796
2.18.6 Filtration ............................................................. 803
2.18.7 Dispatching to instance methods ............................. 804
2.18.8 Flexible apply ...................................................... 806
2.18.9 Numba Accelerated Routines .................................. 808
2.18.10 Other useful features .......................................... 808

3.3.3 Conversion .......................................................... 1444
3.3.4 Indexing, iteration ............................................. 1446
3.3.5 Binary operator functions .................................. 1446
3.3.6 Function application, GroupBy & window ............ 1447
3.3.7 Computations / descriptive stats ....................... 1448
3.3.8 Reindexing / selection / label manipulation ......... 1449
3.3.9 Missing data handling ...................................... 1450
3.3.10 Reshaping, sorting ......................................... 1450
3.3.11 Combining / comparing / joining / merging ........ 1451
3.3.12 Time Series-related ....................................... 1451
3.3.13 Accessors ..................................................... 1451
3.3.14 Plotting ....................................................... 1568
3.3.15 Serialization / IO / conversion ....................... 1615

3.4 DataFrame ......................................................... 1616
3.4.1 Constructor ................................................... 1616
3.4.2 Attributes and underlying data ....................... 1960
3.4.3 Conversion ................................................... 1960
3.4.4 Indexing, iteration ........................................ 1961
3.4.5 Binary operator functions ................................ 1961
3.4.6 Function application, GroupBy & window .......... 1963
3.4.7 Computations / descriptive stats .................... 1963
3.4.8 Reindexing / selection / label manipulation ......... 1964
3.4.9 Missing data handling ..................................... 1965
3.4.10 Reshaping, sorting, transposing ..................... 1965
3.4.11 Combining / comparing / joining / merging ....... 1966
3.4.12 Time Series-related ..................................... 1966
3.4.13 Flags .......................................................... 1967
3.4.14 Metadata .................................................... 1967
3.4.15 Plotting ...................................................... 1967
3.4.16 Sparse accessor ............................................ 2025
3.4.17 Serialization / IO / conversion ....................... 2026

3.5 pandas arrays, scalars, and data types ................ 2027
3.5.1 pandas.array ................................................ 2027
3.5.2 Datetime data ............................................... 2031
3.5.3 Timedelta data ............................................. 2063
3.5.4 Timespan data ............................................. 2073
3.5.5 Period ........................................................ 2073
3.5.6 Interval data ............................................... 2090
3.5.7 Nullable integer ............................................ 2104
3.5.8 Categorical data ........................................... 2109
3.5.9 Sparse data .................................................. 2115
3.5.10 Text data .................................................... 2117
3.5.11 Boolean data with missing values .................. 2120

3.6 Index objects .................................................... 2122
3.6.1 Index .......................................................... 2122
3.6.2 Numeric Index ............................................. 2189
3.6.3 CategoricalIndex ......................................... 2193
3.6.4 IntervalIndex ............................................... 2203
3.6.5 MultiIndex ................................................... 2214
3.6.6 DatetimeIndex ............................................. 2235
3.6.7 TimedeltaIndex ............................................ 2267
3.6.8 PeriodIndex ................................................ 2278

3.7 Date offsets ..................................................... 2285
3.7.1 DateTimeOffset ............................................. 2285

Bibliography ......................................................... 3701

Python Module Index ..................................................... 3703
pandas is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the Python programming language.

Getting started

New to pandas? Check out the getting started guides. They contain an introduction to pandas' main concepts and links to additional tutorials.

To the getting started guides

User guide

The user guide provides in-depth information on the key concepts of pandas with useful background information and explanation.

To the user guide

API reference

The reference guide contains a detailed description of the pandas API. The reference describes how the methods work and which parameters can be used. It assumes that you have an understanding of the key concepts.

To the reference guide

Developer guide

Saw a typo in the documentation? Want to improve existing functionalities? The contributing guidelines will guide you through the process of improving pandas.

To the development guide
1.1 Installation

Working with conda?

pandas is part of the Anaconda distribution and can be installed with Anaconda or Miniconda:

```
conda install pandas
```

Prefer pip?

pandas can be installed via pip from PyPI.

```
pip install pandas
```

In-depth instructions?

Installing a specific version? Installing from source? Check the advanced installation page.

1.2 Intro to pandas

*Straight to tutorial…*

When working with tabular data, such as data stored in spreadsheets or databases, pandas is the right tool for you. pandas will help you to explore, clean, and process your data. In pandas, a data table is called a `DataFrame`.

*To introduction tutorial*

*To user guide*

*Straight to tutorial…*

pandas supports the integration with many file formats or data sources out of the box (csv, excel, sql, json, parquet,…). Importing data from each of these data sources is provided by function with the prefix `read_*`. Similarly, the `to_*` methods are used to store data.

*To introduction tutorial*

*To user guide*

*Straight to tutorial…*
Selecting or filtering specific rows and/or columns? Filtering the data on a condition? Methods for slicing, selecting, and extracting the data you need are available in pandas.

pandas provides plotting your data out of the box, using the power of Matplotlib. You can pick the plot type (scatter, bar, boxplot,...) corresponding to your data.

There is no need to loop over all rows of your data table to do calculations. Data manipulations on a column work elementwise. Adding a column to a DataFrame based on existing data in other columns is straightforward.

Basic statistics (mean, median, min, max, counts...) are easily calculable. These or custom aggregations can be applied on the entire data set, a sliding window of the data, or grouped by categories. The latter is also known as the split-apply-combine approach.

Change the structure of your data table in multiple ways. You can melt() your data table from wide to long/tidy form or pivot() from long to wide format. With aggregations built-in, a pivot table is created with a single command.

Multiple tables can be concatenated both column wise and row wise as database-like join/merge operations are provided to combine multiple tables of data.

pandas has great support for time series and has an extensive set of tools for working with dates, times, and time-indexed data.
Datasets do not only contain numerical data. pandas provides a wide range of functions to clean textual data and extract useful information from it.

1.3 Coming from...

Are you familiar with other software for manipulating tabular data? Learn the pandas-equivalent operations compared to software you already know:

The R programming language provides the `data.frame` data structure and multiple packages, such as `tidyverse` use and extend `data.frame` for convenient data handling functionalities similar to pandas.

The `data set` included in the STATA statistical software suite corresponds to the pandas `DataFrame`. Many of the operations known from STATA have an equivalent in pandas.

Users of Excel or other spreadsheet programs will find that many of the concepts are transferrable to pandas.

The SAS statistical software suite also provides the `data set` corresponding to the pandas `DataFrame`. Also SAS vectorized operations, filtering, string processing operations, and more have similar functions in pandas.

1.4 Tutorials

For a quick overview of pandas functionality, see `10 Minutes to pandas`.

You can also reference the pandas cheat sheet for a succinct guide for manipulating data with pandas.

The community produces a wide variety of tutorials available online. Some of the material is enlisted in the community contributed `Community tutorials`.
1.4.1 Installation

The easiest way to install pandas is to install it as part of the Anaconda distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, PyPI, ActivePython, various Linux distributions, or a development version are also provided.

Python version support

Officially Python 3.8, 3.9 and 3.10.

Installing pandas

Installing with Anaconda

Installing pandas and the rest of the NumPy and SciPy stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the SciPy stack (IPython, NumPy, Matplotlib, ...) is with Anaconda, a cross-platform (Linux, macOS, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the SciPy stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for Anaconda can be found here.

A full list of the packages available as part of the Anaconda distribution can be found here.

Another advantage to installing Anaconda is that you don't need admin rights to install it. Anaconda can install in the user's home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

Installing with Miniconda

The previous section outlined how to get pandas installed as part of the Anaconda distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with Miniconda may be a better solution.

Conda is the package manager that the Anaconda distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

Miniconda allows you to create a minimal self contained Python installation, and then use the Conda command to install additional packages.

First you will need Conda to be installed and downloading and running the Miniconda will do this for you. The installer can be found here

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:
source activate name_of_my_env

On Windows the command is:

activate name_of_my_env

The final step required is to install pandas. This can be done with the following command:

conda install pandas

To install a specific pandas version:

conda install pandas=0.20.3

To install other packages, IPython for example:

conda install ipython

To install the full Anaconda distribution:

conda install anaconda

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

conda install pip
pip install django

**Installing from PyPI**

pandas can be installed via pip from PyPI.

**Note:** You must have pip>=19.3 to install from PyPI.

pip install pandas

**Installing with ActivePython**

Installation instructions for ActivePython can be found [here](#). Versions 2.7, 3.5 and 3.6 include pandas.

**Installing using your Linux distribution’s package manager.**

The commands in this table will install pandas for Python 3 from your distribution.
**pandas: powerful Python data analysis toolkit, Release 1.4.1**

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Status</th>

</tr>
</tbody>
</table>

However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it’s recommended to install using the pip or conda methods described above.

**Handling ImportErrors**

If you encounter an ImportError, it usually means that Python couldn’t find pandas in the list of available libraries. Python internally has a list of directories it searches through, to find packages. You can obtain these directories with:

```python
import sys
sys.path
```

One way you could be encountering this error is if you have multiple Python installations on your system and you don’t have pandas installed in the Python installation you’re currently using. In Linux/Mac you can run `which python` on your terminal and it will tell you which Python installation you are using. If it’s something like “/usr/bin/python”, you’re using the Python from the system, which is not recommended.

It is highly recommended to use `conda`, for quick installation and for package and dependency updates. You can find simple installation instructions for pandas in this document: [installation instructions](http://<getting_started.html>).

**Installing from source**

See the [contributing guide](http://) for complete instructions on building from the git source tree. Further, see [creating a development environment](http://) if you wish to create a pandas development environment.

**Running the test suite**

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest >= 6.0` and `Hypothesis >= 3.58`, then run:

```bash
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-packages\pandas
```

(continues on next page)
Dependencies

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>NumPy</td>
<td>1.18.5</td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.8.1</td>
</tr>
<tr>
<td>pytz</td>
<td>2020.1</td>
</tr>
</tbody>
</table>

Recommended dependencies

- **numexpr**: for accelerating certain numerical operations. `numexpr` uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.7.1 or higher.
- **bottleneck**: for accelerating certain types of `nan` evaluations. `bottleneck` uses specialized cython routines to achieve large speedups. If installed, must be Version 1.3.1 or higher.

**Note**: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

Optional dependencies

pandas has many optional dependencies that are only used for specific methods. For example, `pandas.read_hdf()` requires the `pytables` package, while `DataFrame.to_markdown()` requires the `tabulate` package. If the optional dependency is not installed, pandas will raise an `ImportError` when the method requiring that dependency is called.

Visualization

<table>

<tr>
<td>lxml</td>
<td>4.5.0</td>
<td>HTML parser for read_html</td>
</tr>
</tbody>
</table>

One of the following combinations of libraries is needed to use the top-level read_html() function:

- BeautifulSoup4 and html5lib
- BeautifulSoup4 and lxml
- BeautifulSoup4 and html5lib and lxml
- Only lxml, although see HTML Table Parsing gotchas for reasons as to why you should probably not take this approach.

Warning:

- if you install BeautifulSoup4 you must install either lxml or html5lib or both. read_html() will not work with only BeautifulSoup4 installed.
- You are highly encouraged to read HTML Table Parsing gotchas. It explains issues surrounding the installation and usage of the above three libraries.

1.4.2 Package overview

pandas is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, real-world data analysis in Python. Additionally, it has the broader goal of becoming the most powerful and flexible open source data analysis/manipulation tool available in any language. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, Series (1-dimensional) and DataFrame (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, DataFrame provides everything that R’s data.frame provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of missing data (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be inserted and deleted from DataFrame and higher dimensional objects
- Automatic and explicit data alignment: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let Series, DataFrame, etc. automatically align the data for you in computations
- Powerful, flexible group by functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it easy to convert ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based slicing, fancy indexing, and subsetting of large data sets
- Intuitive merging and joining data sets
- Flexible reshaping and pivoting of data sets

Chapter 1. Getting started
• **Hierarchical** labeling of axes (possible to have multiple labels per tick)

• Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**

• **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, date shifting, and lagging.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

• pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in Cython code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.

• pandas is a dependency of statsmodels, making it an important part of the statistical computing ecosystem in Python.

• pandas has been used extensively in production in financial applications.

### Data structures

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Series</td>
<td>1D labeled homogeneously-typed array</td>
</tr>
<tr>
<td>2</td>
<td>DataFrame</td>
<td>General 2D labeled, size-mutable tabular structure with potentially heterogeneous-typed column</td>
</tr>
</tbody>
</table>

### Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using the N-dimensional array (ndarrays) to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguousness matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set, there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```python
for col in df.columns:
    series = df[col]
    # do something with series
```
Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to favor immutability where sensible.

Getting support

The first stop for pandas issues and ideas is the Github Issue Tracker. If you have a general question, pandas community experts can answer through Stack Overflow.

Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to all of our contributors.

If you're interested in contributing, please visit the contributing guide.

pandas is a NumFOCUS sponsored project. This will help ensure the success of the development of pandas as a world-class open-source project and makes it possible to donate to the project.

Project governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in Project Governance documents. The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

Development team

The list of the Core Team members and more detailed information can be found on the people’s page of the governance repo.

Institutional partners

The information about current institutional partners can be found on pandas website page.

1.4.3 Getting started tutorials

What kind of data does pandas handle?

I want to start using pandas

```
In [1]: import pandas as pd
```

To load the pandas package and start working with it, import the package. The community agreed alias for pandas is pd, so loading pandas as pd is assumed standard practice for all of the pandas documentation.

**pandas data table representation**

I want to store passenger data of the Titanic. For a number of passengers, I know the name (characters), age (integers) and sex (male/female) data.

```
In [2]: df = pd.DataFrame(
    ...:     {  
    ...:         "Name": [  
    ...:             "Braund, Mr. Owen Harris",  
    ...:             "Allen, Mr. William Henry",  
    ...:             "Bonnell, Miss. Elizabeth",  
    ...:         ],
    ...:     })
```

(continues on next page)
...:    "Age": [22, 35, 58],
...:    "Sex": ["male", "male", "female"],
...:  }
...:

In [3]: df
Out[3]:
Name   Age  Sex
0   Braund, Mr. Owen Harris  22  male
1  Allen, Mr. William Henry  35  male
2  Bonnell, Miss. Elizabeth  58  female

To manually store data in a table, create a DataFrame. When using a Python dictionary of lists, the dictionary keys will be used as column headers and the values in each list as columns of the DataFrame.

A DataFrame is a 2-dimensional data structure that can store data of different types (including characters, integers, floating point values, categorical data and more) in columns. It is similar to a spreadsheet, a SQL table or the data frame in R.

- The table has 3 columns, each of them with a column label. The column labels are respectively Name, Age and Sex.
- The column Name consists of textual data with each value a string, the column Age are numbers and the column Sex is textual data.

In spreadsheet software, the table representation of our data would look very similar:
Each column in a DataFrame is a Series

I’m just interested in working with the data in the column `Age`

```
In [4]: df["Age"]
Out[4]:
0    22
1    35
2    58
Name: Age, dtype: int64
```

When selecting a single column of a pandas DataFrame, the result is a pandas Series. To select the column, use the column label in between square brackets `[]`.

**Note:** If you are familiar to Python dictionaries, the selection of a single column is very similar to selection of dictionary values based on the key.

You can create a Series from scratch as well:

```
In [5]: ages = pd.Series([22, 35, 58], name="Age")
In [6]: ages
Out[6]:
0    22
1    35
2    58
Name: Age, dtype: int64
```

A pandas Series has no column labels, as it is just a single column of a DataFrame. A Series does have row labels.

**Do something with a DataFrame or Series**

I want to know the maximum Age of the passengers

We can do this on the DataFrame by selecting the `Age` column and applying `max()`:

```
In [7]: df["Age"].max()
Out[7]: 58
```

Or to the Series:

```
In [8]: ages.max()
Out[8]: 58
```

As illustrated by the `max()` method, you can do things with a DataFrame or Series. pandas provides a lot of functionalities, each of them a method you can apply to a DataFrame or Series. As methods are functions, do not forget to use parentheses `()`.

I’m interested in some basic statistics of the numerical data of my data table

1.4. Tutorials
The `describe()` method provides a quick overview of the numerical data in a DataFrame. As the Name and Sex columns are textual data, these are by default not taken into account by the `describe()` method.

Many pandas operations return a DataFrame or a Series. The `describe()` method is an example of a pandas operation returning a pandas Series or a pandas DataFrame.

Check more options on `describe` in the user guide section about *aggregations with describe*

**Note:** This is just a starting point. Similar to spreadsheet software, pandas represents data as a table with columns and rows. Apart from the representation, also the data manipulations and calculations you would do in spreadsheet software are supported by pandas. Continue reading the next tutorials to get started!

- Import the package, aka `import pandas as pd`
- A table of data is stored as a pandas DataFrame
- Each column in a DataFrame is a Series
- You can do things by applying a method to a DataFrame or Series

A more extended explanation to DataFrame and Series is provided in the *introduction to data structures.*

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.
How do I read and write tabular data?

I want to analyze the Titanic passenger data, available as a CSV file.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

pandas provides the `read_csv()` function to read data stored as a csv file into a pandas DataFrame. pandas supports many different file formats or data sources out of the box (csv, excel, sql, json, parquet, ...), each of them with the prefix `read_*`.

Make sure to always have a check on the data after reading in the data. When displaying a DataFrame, the first and last 5 rows will be shown by default:

```python
In [3]: titanic
Out[3]:
          PassengerId  Survived  Pclass       Name                      ...
0            1          0         3  Braund, Mr. Owen Harris #... #... #...
1            2          1         1  Cumings, Mrs. John Bradley (Florence Briggs Th... #... #...
2            3          1         3  Heikkinen, Miss. Laina #... #... #...
3            4          1         1  Futrelle, Mrs. Jacques Heath (Lily May Peel) #... #... #...
4            5          0         3                  Allen, Mr. William Henry #... #... #...
5                      #... #... #... #... #... #... #... #...
886          886          0         2  Montvila, Rev. Juozas #... #... #...
887          887          1         0                  Graham, Miss. Margaret Edith #... #... #...
888          888          1         0  Johnston, Miss. Catherine Helen "Carrie" #... #... #...
889          889          1         0                  Behr, Mr. Karl Howell #... #... #...
890          891          0         3  Dooley, Mr. Patrick #... #... #...
891                      #... #... #... #... #... #... #... #...
```

I want to see the first 8 rows of a pandas DataFrame.

```python
In [4]: titanic.head(8)
Out[4]:
          PassengerId  Survived  Pclass       Name                      ...
0            1          0         3  Braund, Mr. Owen Harris #... #... #...
1            2          1         1  Cumings, Mrs. John Bradley (Florence Briggs Th... #... #...
2            3          1         3  Heikkinen, Miss. Laina #... #... #...
3            4          1         1  Futrelle, Mrs. Jacques Heath (Lily May Peel) #... #... #...
4            5          0         3                  Allen, Mr. William Henry #... #... #...
5                      #... #... #... #... #... #... #... #...
886          886          0         2  Montvila, Rev. Juozas #... #... #...
887          887          1         0                  Graham, Miss. Margaret Edith #... #... #...
888          888          1         0  Johnston, Miss. Catherine Helen "Carrie" #... #... #...
889          889          1         0                  Behr, Mr. Karl Howell #... #... #...
890          891          0         3  Dooley, Mr. Patrick #... #... #...
891                      #... #... #... #... #... #... #... #...
```

(continues on next page)
To see the first N rows of a DataFrame, use the `head()` method with the required number of rows (in this case 8) as argument.

**Note:** Interested in the last N rows instead? pandas also provides a `tail()` method. For example, `titanic.tail(10)` will return the last 10 rows of the DataFrame.

A check on how pandas interpreted each of the column data types can be done by requesting the pandas `dtypes` attribute:

```python
In [5]: titanic.dtypes
Out[5]:
PassengerId    int64
Survived       int64
Pclass         int64
Name           object
Sex            object
Age            float64
SibSp          int64
Parch          int64
Ticket         object
Fare           float64
Cabin          object
Embarked       object
dtype: object
```

For each of the columns, the used data type is enlisted. The data types in this DataFrame are integers (int64), floats (float64) and strings (object).

**Note:** When asking for the `dtypes`, no brackets are used! `dtypes` is an attribute of a DataFrame and Series. Attributes of DataFrame or Series do not need brackets. Attributes represent a characteristic of a DataFrame/Series, whereas a method (which requires brackets) *do* something with the DataFrame/Series as introduced in the *first tutorial*.

My colleague requested the Titanic data as a spreadsheet.

```python
In [6]: titanic.to_excel("titanic.xlsx", sheet_name="passengers", index=False)
```

Whereas `read_*` functions are used to read data to pandas, the `to_*` methods are used to store data. The `to_excel()`
method stores the data as an excel file. In the example here, the `sheet_name` is named `passengers` instead of the default `Sheet1`. By setting `index=False` the row index labels are not saved in the spreadsheet.

The equivalent read function `read_excel()` will reload the data to a DataFrame:

```python
In [7]: titanic = pd.read_excel("titanic.xlsx", sheet_name="passengers")
```

I'm interested in a technical summary of a DataFrame

```python
In [9]: titanic.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 891 entries, 0 to 890
Data columns (total 12 columns):
#    Column    Non-Null Count   Dtype
---  ------     --------------   ----
 0    PassengerId 891 non-null   int64
 1    Survived   891 non-null   int64
 2    Pclass     891 non-null   int64
 3    Name       891 non-null   object
 4    Sex        891 non-null   object
 5    Age        714 non-null   float64
 6    SibSp      891 non-null   int64
 7    Parch      891 non-null   int64
 8    Ticket     891 non-null   int64
 9    Fare       891 non-null   float64
10   Cabin      204 non-null   object
11   Embarked   889 non-null   object
dtypes: float64(2), int64(5), object(5)
memory usage: 83.7+ KB
```

The method `info()` provides technical information about a DataFrame, so let's explain the output in more detail:

- It is indeed a `DataFrame`.
- There are 891 entries, i.e. 891 rows.
- Each row has a row label (aka the index) with values ranging from 0 to 890.
- The table has 12 columns. Most columns have a value for each of the rows (all 891 values are non-null). Some columns do have missing values and less than 891 non-null values.
• The columns Name, Sex, Cabin and Embarked consists of textual data (strings, aka object). The other columns are numerical data with some of them whole numbers (aka integer) and others are real numbers (aka float).

• The kind of data (characters, integers,...) in the different columns are summarized by listing the dtypes.

• The approximate amount of RAM used to hold the DataFrame is provided as well.

• Getting data in to pandas from many different file formats or data sources is supported by read_* functions.

• Exporting data out of pandas is provided by different to_* methods.

• The head/tail/info methods and the dtypes attribute are convenient for a first check.

For a complete overview of the input and output possibilities from and to pandas, see the user guide section about reader and writer functions.

In [1]: import pandas as pd

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

• PassengerId: Id of every passenger.

• Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.

• Pclass: There are 3 classes: Class 1, Class 2 and Class 3.

• Name: Name of passenger.

• Sex: Gender of passenger.

• Age: Age of passenger.

• SibSp: Indication that passenger have siblings and spouse.

• Parch: Whether a passenger is alone or have family.

• Ticket: Ticket number of passenger.

• Fare: Indicating the fare.

• Cabin: The cabin of passenger.

• Embarked: The embarked category.

In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()
Out[3]:
      PassengerId  Survived  Pclass  Name     ...  Embarked  
   0        1          0        3  Braund, Mr. Owen Harris  ...        S 
   1        2          1        1  Cumings, Mrs. John Bradley (Florence Briggs Th...  ...        C 
   2        3          1        3  Heikkinen, Miss. Laina  ...  ...        C 
   3        4          1        1  Futrelle, Mrs. Jacques Heath (Lily May Peel)  ...  ...        S 
   4        5          0        3  Allen, Mr. William Henry  ...  ...        S 

[5 rows x 12 columns]
How do I select a subset of a DataFrame?

How do I select specific columns from a DataFrame?

I’m interested in the age of the Titanic passengers.

```python
In [4]: ages = titanic["Age"]

In [5]: ages.head()
Out[5]:
0   22.0
1   38.0
2   26.0
3   35.0
4   35.0
Name: Age, dtype: float64
```

To select a single column, use square brackets `[]` with the column name of the column of interest.

Each column in a DataFrame is a Series. As a single column is selected, the returned object is a pandas Series. We can verify this by checking the type of the output:

```python
In [6]: type(titanic["Age"])
Out[6]: pandas.core.series.Series
```

And have a look at the shape of the output:

```python
In [7]: titanic["Age"].shape
Out[7]: (891,)
```

DataFrame.shape is an attribute (remember tutorial on reading and writing, do not use parentheses for attributes) of a pandas Series and DataFrame containing the number of rows and columns: (nrows, ncolumns). A pandas Series is 1-dimensional and only the number of rows is returned.

I’m interested in the age and sex of the Titanic passengers.

```python
In [8]: age_sex = titanic[["Age", "Sex"]]

In [9]: age_sex.head()
Out[9]:
          Age  Sex
         0  22.0  male
         1  38.0 female
         2  26.0 female
         3  35.0 female
         4  35.0  male
```

To select multiple columns, use a list of column names within the selection brackets `[]`.

Note: The inner square brackets define a Python list with column names, whereas the outer brackets are used to select the data from a pandas DataFrame as seen in the previous example.

The returned data type is a pandas DataFrame:
In [10]: type(titanic["Age", "Sex"])
Out[10]: pandas.core.frame.DataFrame

In [11]: titanic["Age", "Sex"].shape
Out[11]: (891, 2)

The selection returned a DataFrame with 891 rows and 2 columns. Remember, a DataFrame is 2-dimensional with both a row and column dimension.

For basic information on indexing, see the user guide section on indexing and selecting data.

How do I filter specific rows from a DataFrame?

I'm interested in the passengers older than 35 years.

In [12]: above_35 = titanic[titanic["Age"] > 35]

In [13]: above_35.head()
Out[13]:
   PassengerId  Survived  Pclass  Name                  Sex ...  Parch  Ticket  Fare  Cabin  Embarked
   ---          -----      ----   -----                --- ...    ----    --     ----   ------
   1            2        1     1 Cumings, Mrs. John Bradley (Florence Briggs Th... female ... 0  PC 17599 71.2833 C85 C
   6            7        0     1 McCarthy, Mr. Timothy J female ... 0  17463 51.8625 E46 S
   11           12       1     1 Bonnell, Miss. Elizabeth male ... 0  113783 26.5500 C103 S
   13           14       0     3 Andersson, Mr. Anders Johan male ... 0  347082 31.2750 NaN S
   15           16       1     2 Hewlett, Mrs. (Mary D Kingcome) female ... 0  248706 16.0000 NaN S

[5 rows x 12 columns]

To select rows based on a conditional expression, use a condition inside the selection brackets [].

The condition inside the selection brackets `titanic["Age"] > 35` checks for which rows the `Age` column has a value larger than 35:

In [14]: titanic["Age"] > 35
Out[14]:
0  False
1   True
2  False
3  False
4  False
... 
886 False
887 False
888 False
889 False

(continues on next page)
The output of the conditional expression (>, but also ==, !=, <, <=...) would work) is actually a pandas Series of boolean values (either True or False) with the same number of rows as the original DataFrame. Such a Series of boolean values can be used to filter the DataFrame by putting it in between the selection brackets [ ]. Only rows for which the value is True will be selected.

We know from before that the original Titanic DataFrame consists of 891 rows. Let’s have a look at the number of rows which satisfy the condition by checking the shape attribute of the resulting DataFrame above_35:

```
In [15]: above_35.shape
Out[15]: (217, 12)
```

I’m interested in the Titanic passengers from cabin class 2 and 3.

```
In [16]: class_23 = titanic[titanic["Pclass""].isin([2, 3])]
```

```
In [17]: class_23.head()
Out[17]:
   PassengerId  Survived  Pclass  Name       Sex  Age  SibSp  ⦿
              ⦿

0           1   349909  21.0750     NaN       S
```

Similar to the conditional expression, the isin() conditional function returns a True for each row the values are in the provided list. To filter the rows based on such a function, use the conditional function inside the selection brackets [ ]. In this case, the condition inside the selection brackets titanic["Pclass""].isin([2, 3]) checks for which rows the Pclass column is either 2 or 3.

The above is equivalent to filtering by rows for which the class is either 2 or 3 and combining the two statements with an | (or) operator:

```
In [18]: class_23 = titanic[(titanic["Pclass"] == 2) | (titanic["Pclass"] == 3)]
```

```
In [19]: class_23.head()
Out[19]:
   PassengerId  Survived  Pclass  Name       Sex  Age  SibSp  ⦿
              ⦿
0           1          0      3  Braund, Mr. Owen Harris  male  22.0   1
0            A/5 21171   7.2500     NaN       S
2           3          1      3  Heikkinen, Miss. Laina  female  26.0   0
0           0  STON/O2.3101282  7.9250     NaN       S
4           5          0      3   Allen, Mr. William Henry  male  35.0   0
0           0    373450   8.0500     NaN       S
5           6          0      3   Moran, Mr. James       male  NaN    0
0           0  330877    8.4583     NaN       Q
```

(continues on next page)
Note: When combining multiple conditional statements, each condition must be surrounded by parentheses (). Moreover, you cannot use `or`/`and` but need to use the `or` operator `|` and the `and` operator `&`.

I want to work with passenger data for which the age is known.

```python
In [20]: age_no_na = titanic[titanic["Age"].notna()]
```

```python
In [21]: age_no_na.head()
Out[21]:
          PassengerId  Survived  Pclass        Name                      Ticket  
0           1          0       3    Braund, Mr. Owen Harris  A/5 21171  
1           2          1       1  Cumings, Mrs. John Bradley (Florence Briggs Th...  
2           3          1       3  Heikkinen, Miss. Laina  STON/O2. 3101282  
3           3          1       1    Futrelle, Mrs. Jacques Heath (Lily May Peel)  
4           4          1       3              Allen, Mr. William Henry  

[5 rows x 12 columns]
```

The `notna()` conditional function returns a `True` for each row the values are not an `Null` value. As such, this can be combined with the selection brackets `[]` to filter the data table.

You might wonder what actually changed, as the first 5 lines are still the same values. One way to verify is to check if the shape has changed:

```python
In [22]: age_no_na.shape
Out[22]: (714, 12)
```

For more dedicated functions on missing values, see the user guide section about handling missing data.

**How do I select specific rows and columns from a DataFrame?**

I’m interested in the names of the passengers older than 35 years.

```python
In [23]: adult_names = titanic.loc[titanic["Age"] > 35, "Name"]
```

```python
In [24]: adult_names.head()
Out[24]:
1  Cumings, Mrs. John Bradley (Florence Briggs Th...

(continues on next page)"
In this case, a subset of both rows and columns is made in one go and just using selection brackets \[\] is not sufficient anymore. The **loc/iloc** operators are required in front of the selection brackets \[\]. When using **loc/iloc**, the part before the comma is the rows you want, and the part after the comma is the columns you want to select.

When using the column names, row labels or a condition expression, use the **loc** operator in front of the selection brackets \[\]. For both the part before and after the comma, you can use a single label, a list of labels, a slice of labels, a conditional expression or a colon. Using a colon specifies you want to select all rows or columns.

I’m interested in rows 10 till 25 and columns 3 to 5.

```python
In [25]: titanic.iloc[9:25, 2:5]
Out[25]:
          Pclass     Name       Sex
9        2   Nasser, Mrs. Nicholas (Adele Achem) female
10       3  Sandstrom, Miss. Marguerite Rut female
11       1    Bonnell, Miss. Elizabeth female
12       3  Saundercoc, Mr. William Henry male
13       3  Andersson, Mr. Anders Johan male
   ... ... ... ... ...
20       2   Fynney, Mr. Joseph J male
21       2  Beesley, Mr. Lawrence male
22       3     McGowan, Miss. Anna "Annie" female
23       1     Sloper, Mr. William Thompson male
24       3  Palsson, Miss. Torborg Danira female

[16 rows x 3 columns]
```

Again, a subset of both rows and columns is made in one go and just using selection brackets \[\] is not sufficient anymore. When specifically interested in certain rows and/or columns based on their position in the table, use the **iloc** operator in front of the selection brackets \[\].

When selecting specific rows and/or columns with **loc** or **iloc**, new values can be assigned to the selected data. For example, to assign the name **anonymous** to the first 3 elements of the third column:

```python
In [26]: titanic.iloc[0:3, 3] = "anonymous"
In [27]: titanic.head()
Out[27]:
          PassengerId  Survived  Pclass     Name      ...     Cabin  Embarked
    0           1         0        3 anonymous      ...       NaN        S
    1          21171       1.0        3 anonymous      ...       NaN        S
    2          17599       1.0        3 anonymous      ...       NaN        C
    3       3101282.0       1.0        3 anonymous      ...       NaN        S
    4          113803       1.0        3 anonymous      ...       NaN        S
```

(continues on next page)
See the user guide section on different choices for indexing to get more insight in the usage of loc and iloc.

- When selecting subsets of data, square brackets [] are used.
- Inside these brackets, you can use a single column/row label, a list of column/row labels, a slice of labels, a conditional expression or a colon.
- Select specific rows and/or columns using loc when using the row and column names
- Select specific rows and/or columns using iloc when using the positions in the table
- You can assign new values to a selection based on loc/iloc.

A full overview of indexing is provided in the user guide pages on indexing and selecting data.

```
In [1]: import pandas as pd
In [2]: import matplotlib.pyplot as plt

For this tutorial, air quality data about NO₂ is used, made available by openaq and using the py-openaq package. The air_quality_no2.csv data set provides NO₂ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

In [3]: air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_...dates=True)

In [4]: air_quality.head()
Out[4]:
   station_antwerp  station_paris  station_london
datetime
2019-05-07 02:00:00        NaN       NaN        23.0
2019-05-07 03:00:00        50.5       25.0        19.0
2019-05-07 04:00:00        45.0       27.7        19.0
2019-05-07 05:00:00        NaN       50.4        16.0
2019-05-07 06:00:00        NaN       61.9        NaN
```

Note: The usage of the index_col and parse_dates parameters of the read_csv function to define the first (0th) column as index of the resulting DataFrame and convert the dates in the column to Timestamp objects, respectively.
How to create plots in pandas?

I want a quick visual check of the data.

```
In [5]: air_quality.plot()
Out[5]: <AxesSubplot:xlabel='datetime'>
```

With a DataFrame, pandas creates by default one line plot for each of the columns with numeric data.

I want to plot only the columns of the data table with the data from Paris.

```
In [6]: air_quality["station_paris"].plot()
Out[6]: <AxesSubplot:xlabel='datetime'>
```
To plot a specific column, use the selection method of the *subset data tutorial* in combination with the *plot()* method. Hence, the *plot()* method works on both *Series* and *DataFrame*.

I want to visually compare the $N_0$ values measured in London versus Paris.

```
In [7]: air_quality.plot.scatter(x="station_london", y="station_paris", alpha=0.5)
Out[7]: <AxesSubplot:xlabel='station_london', ylabel='station_paris'>
```
Apart from the default line plot when using the `plot` function, a number of alternatives are available to plot data. Let’s use some standard Python to get an overview of the available plot methods:

```python
In [8]:
    ...:   method_name
    ...:   for method_name in dir(air_quality.plot)
    ...:     if not method_name.startswith('_')
    ...:]
Out[8]:
    ['area',
     'bar',
     'barh',
     'box',
     'density',
     'hexbin',
     'hist',
     'kde',
     'line',
     'pie',
     'scatter']
```

Note: In many development environments as well as IPython and Jupyter Notebook, use the TAB button to get an
overview of the available methods, for example `air_quality.plot. + TAB.`

One of the options is `DataFrame.plot.box()`, which refers to a boxplot. The box method is applicable on the air quality example data:

```python
In [9]: air_quality.plot.box()
Out[9]: <AxesSubplot:>
```

For an introduction to plots other than the default line plot, see the user guide section about supported plot styles. I want each of the columns in a separate subplot.

```python
In [10]: axs = air_quality.plot.area(figsize=(12, 4), subplots=True)
```
Separate subplots for each of the data columns are supported by the `subplots` argument of the `plot` functions. The built-in options available in each of the pandas plot functions are worth reviewing.

Some more formatting options are explained in the user guide section on `plot formatting`.

I want to further customize, extend or save the resulting plot.

```
In [11]: fig, axs = plt.subplots(figsize=(12, 4))
In [12]: air_quality.plot.area(ax=axs)
Out[12]: <AxesSubplot:xlabel='datetime'>
In [13]: axs.set_ylabel("NO$_2$ concentration")
Out[13]: Text(0, 0.5, 'NO$_2$ concentration')
In [14]: fig.savefig("no2_concentrations.png")
```

Each of the plot objects created by pandas is a `matplotlib` object. As Matplotlib provides plenty of options to customize plots, making the link between pandas and Matplotlib explicit enables all the power of Matplotlib to the plot. This strategy is applied in the previous example:

```
fig, axs = plt.subplots(figsize=(12, 4))  # Create an empty matplotlib Figure and Axes
air_quality.plot.area(ax=axs)  # Use pandas to put the area plot on the prepared Figure/Axes
axs.set_ylabel("NO$_2$ concentration")  # Do any matplotlib customization you like
```

(continues on next page)
fig.savefig("no2_concentrations.png")  # Save the Figure/Axes using the
existing matplotlib method.

- The .plot.* methods are applicable on both Series and DataFrames
- By default, each of the columns is plotted as a different element (line, boxplot,..)
- Any plot created by pandas is a Matplotlib object.

A full overview of plotting in pandas is provided in the visualization pages.

In [1]: import pandas as pd

For this tutorial, air quality data about $NO_2$ is used, made available by openaq and using the py-openaq package. The air_quality_no2.csv data set provides $NO_2$ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

In [2]: air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_
dates=True)

In [3]: air_quality.head()

Out[3]:

<table>
<thead>
<tr>
<th>station_antwerp</th>
<th>station_paris</th>
<th>station_london</th>
<th>datetime</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>2019-05-07 02:00:00</td>
</tr>
<tr>
<td>50.5</td>
<td>25.0</td>
<td>19.0</td>
<td>2019-05-07 03:00:00</td>
</tr>
<tr>
<td>45.0</td>
<td>27.7</td>
<td>19.0</td>
<td>2019-05-07 04:00:00</td>
</tr>
<tr>
<td>NaN</td>
<td>50.4</td>
<td>16.0</td>
<td>2019-05-07 05:00:00</td>
</tr>
<tr>
<td>NaN</td>
<td>61.9</td>
<td>NaN</td>
<td>2019-05-07 06:00:00</td>
</tr>
</tbody>
</table>

How to create new columns derived from existing columns?

I want to express the $NO_2$ concentration of the station in London in mg/m³

(If we assume temperature of 25 degrees Celsius and pressure of 1013 hPa, the conversion factor is 1.882)

In [4]: air_quality["london_mg_per_cubic"] = air_quality["station_london"] * 1.882

In [5]: air_quality.head()

Out[5]:

<table>
<thead>
<tr>
<th>station_antwerp</th>
<th>station_paris</th>
<th>station_london</th>
<th>london_mg_per_cubic</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>23.0</td>
</tr>
<tr>
<td>50.5</td>
<td>25.0</td>
<td>19.0</td>
<td>43.286</td>
</tr>
<tr>
<td>45.0</td>
<td>27.7</td>
<td>19.0</td>
<td>35.758</td>
</tr>
<tr>
<td>NaN</td>
<td>50.4</td>
<td>16.0</td>
<td>30.112</td>
</tr>
<tr>
<td>NaN</td>
<td>61.9</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

To create a new column, use the [] brackets with the new column name at the left side of the assignment.

**Note:** The calculation of the values is done element_wise. This means all values in the given column are multiplied
by the value 1.882 at once. You do not need to use a loop to iterate each of the rows!

I want to check the ratio of the values in Paris versus Antwerp and save the result in a new column

```
In [6]: air_quality["ratio_paris_antwerp"] = (
    ...:     air_quality["station_paris"] / air_quality["station_antwerp"]
    ...: )
    ...
```

```
In [7]: air_quality.head()
Out[7]:
     station_antwerp  station_paris  station_london  london_mg_per_cubic  ratio_paris_antwerp  
date          2019-05-07 02:00:00, NaN, NaN, 23.0, 43.286, NaN, NaN,
              2019-05-07 03:00:00, 50.5, 25.0, 19.0, 35.758, 0.495050,
              2019-05-07 04:00:00, 45.0, 27.7, 19.0, 35.758, 0.615556,
              2019-05-07 05:00:00, NaN, 50.4, 16.0, 30.112, NaN,
              2019-05-07 06:00:00, NaN, 61.9, NaN, NaN, NaN,
```

The calculation is again element-wise, so the / is applied for the values in each row.

Also other mathematical operators (+, -, \*, /) or logical operators (<, >, =...) work element wise. The latter was already used in the subset data tutorial to filter rows of a table using a conditional expression.

If you need more advanced logic, you can use arbitrary Python code via apply().

I want to rename the data columns to the corresponding station identifiers used by openAQ

```
In [8]: air_quality_renamed = air_quality.rename(
    ...:     columns={
    ...:         "station_antwerp": "BETR801",
    ...:         "station_paris": "FR04014",
    ...:         "station_london": "London Westminster",
    ...:     } )
    ...
```

```
In [9]: air_quality_renamed.head()
Out[9]:
     BETR801  FR04014 London Westminster  london_mg_per_cubic  ratio_paris_antwerp  
date          2019-05-07 02:00:00, NaN, NaN, 23.0, 43.286, NaN, NaN,
              2019-05-07 03:00:00, 50.5, 25.0, 19.0, 35.758, 0.495050,
              2019-05-07 04:00:00, 45.0, 27.7, 19.0, 35.758, 0.615556,
              2019-05-07 05:00:00, NaN, 50.4, 16.0, 30.112, NaN,
              2019-05-07 06:00:00, NaN, 61.9, NaN, NaN, NaN,
```

(continues on next page)
The *rename()* function can be used for both row labels and column labels. Provide a dictionary with the keys the current names and the values the new names to update the corresponding names.

The mapping should not be restricted to fixed names only, but can be a mapping function as well. For example, converting the column names to lowercase letters can be done using a function as well:

```
In [10]: air_quality_renamed = air_quality_renamed.rename(columns=str.lower)
In [11]: air_quality_renamed.head()
Out[11]:
     datetime  betr801  fr04014  london_westminster  london_mg_per_cubic  ratio_
paris_antwerp
2019-05-07 02:00:00  NaN  NaN         23.0                  43.286
    NaN
2019-05-07 03:00:00  50.5  25.0         19.0                  35.758
    0.495050
2019-05-07 04:00:00  45.0  27.7         19.0                  35.758
    0.615556
2019-05-07 05:00:00  NaN  50.4         16.0                  30.112
    NaN
2019-05-07 06:00:00  NaN  61.9  NaN         NaN                  NaN
    NaN
```

Details about column or row label renaming is provided in the user guide section on *renaming labels*.  
- Create a new column by assigning the output to the DataFrame with a new column name in between the [].
- Operations are element-wise, no need to loop over rows.
- Use `rename` with a dictionary or function to rename row labels or column names.

The user guide contains a separate section on *column addition and deletion*.

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
• Parch: Whether a passenger is alone or have family.
• Ticket: Ticket number of passenger.
• Fare: Indicating the fare.
• Cabin: The cabin of passenger.
• Embarked: The embarked category.

In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()
Out[3]:
   PassengerId  Survived  Pclass  Name       ...   Cabin   Embarked
   0             1       3      1  Braund, Mr. Owen Harris ...  NaN      S
   1             1       1      1  Cumings, Mrs. John Bradley (Florence Briggs Th... ...  C85      C
   2             3       3      1       Heikkinen, Miss. Laina ...  NaN      S
   3             3       1      1       Futrelle, Mrs. Jacques Heath (Lily May Peel) ...      C123      S
   4             5       0      3       Allen, Mr. William Henry ...  NaN      S

[5 rows x 12 columns]

How to calculate summary statistics?

Aggregating statistics

What is the average age of the Titanic passengers?

In [4]: titanic["Age"].mean()
Out[4]: 29.69911764705882

Different statistics are available and can be applied to columns with numerical data. Operations in general exclude missing data and operate across rows by default.

What is the median age and ticket fare price of the Titanic passengers?

In [5]: titanic[["Age", "Fare"]].median()
Out[5]:
Age  28.0000
Fare  14.4542
dtype: float64

The statistic applied to multiple columns of a DataFrame (the selection of two columns return a DataFrame, see the subset data tutorial) is calculated for each numeric column.
The aggregating statistic can be calculated for multiple columns at the same time. Remember the *describe* function from *first tutorial*?

```python
In [6]: titanic["Age", "Fare"]).describe()
Out[6]:
               Age    Fare
    count   714.000000  891.000000
     mean   29.699118  32.204208
     std    14.526497  49.693429
    min     0.420000   0.000000
    25%    20.125000   7.910400
    50%    28.000000  14.454200
    75%    38.000000  31.000000
     max    80.000000  512.329200
```

Instead of the predefined statistics, specific combinations of aggregating statistics for given columns can be defined using the *DataFrame.agg()* method:

```python
In [7]: titanic.agg(
    ...:     
    ...:     "Age": ["min", "max", "median", "skew"],
    ...:     "Fare": ["min", "max", "median", "mean"],
    ...:     )
Out[7]:
               Age    Fare
     min     0.420000   0.000000
      max    80.000000  512.329200
   median   28.000000  14.454200
     skew   0.389108    NaN
     mean   NaN        32.204208
```

Details about descriptive statistics are provided in the user guide section on *descriptive statistics*.

**Aggregating statistics grouped by category**

What is the average age for male versus female Titanic passengers?

```python
In [8]: titanic["Sex", "Age"]).groupby("Sex").mean()
Out[8]:
     Age
     Sex  
   female  27.915709
      male  30.726645
```

As our interest is the average age for each gender, a subselection on these two columns is made first: *titanic["Sex", "Age"]*. Next, the *groupby()* method is applied on the *Sex* column to make a group per category. The average age for each gender is calculated and returned.

Calculating a given statistic (e.g. mean age) for each category in a column (e.g. male/female in the *Sex* column) is a common pattern. The *groupby* method is used to support this type of operations. More general, this fits in the more general split-apply-combine pattern:
• **Split** the data into groups

• **Apply** a function to each group independently

• **Combine** the results into a data structure

The apply and combine steps are typically done together in pandas.

In the previous example, we explicitly selected the 2 columns first. If not, the `mean` method is applied to each column containing numerical columns:

```python
In [9]: titanic.groupby("Sex").mean()
Out[9]:
   PassengerId  Survived  Pclass  Age  SibSp  Parch  Fare
Sex
female  431.028662   0.742038  2.159236 27.915709  0.694268  0.649682  44.479818
male    454.147314   0.188908  2.389948 30.726645  0.429809  0.235702  25.523893
```

It does not make much sense to get the average value of the `Pclass` if we are only interested in the average age for each gender; the selection of columns (rectangular brackets `[ ]` as usual) is supported on the grouped data as well:

```python
In [10]: titanic.groupby("Sex")["Age"].mean()
Out[10]:
   Sex
female  27.915709
male    30.726645
Name: Age, dtype: float64
```

**Note:** The `Pclass` column contains numerical data but actually represents 3 categories (or factors) with respectively the labels ‘1’, ‘2’ and ‘3’. Calculating statistics on these does not make much sense. Therefore, pandas provides a `Categorical` data type to handle this type of data. More information is provided in the user guide `Categorical data` section.

What is the mean ticket fare price for each of the sex and cabin class combinations?

```python
In [11]: titanic.groupby(["Sex", "Pclass"])["Fare"].mean()
Out[11]:
   Sex  Pclass  Fare
female  1  106.125798
         2  21.970121
         3  16.118810
male    1  67.226127
         2  19.741782
         3  12.661633
Name: Fare, dtype: float64
```

Grouping can be done by multiple columns at the same time. Provide the column names as a list to the `groupby()` method.

A full description on the split-apply-combine approach is provided in the user guide section on `groupby operations`. 

---

**1.4. Tutorials**
Count number of records by category

What is the number of passengers in each of the cabin classes?

```
In [12]: titanic["Pclass"].value_counts()
Out[12]:
3    491
1    216
2    184
Name: Pclass, dtype: int64
```

The `value_counts()` method counts the number of records for each category in a column. The function is a shortcut, as it is actually a groupby operation in combination with counting of the number of records within each group:

```
In [13]: titanic.groupby("Pclass")["Pclass"].count()
Out[13]:
Pclass
    1    216
   2    184
   3    491
Name: Pclass, dtype: int64
```

**Note:** Both `size` and `count` can be used in combination with `groupby`. Whereas `size` includes NaN values and just provides the number of rows (size of the table), `count` excludes the missing values. In the `value_counts` method, use the `dropna` argument to include or exclude the NaN values.

The user guide has a dedicated section on `value_counts`, see page on discretization.

- Aggregation statistics can be calculated on entire columns or rows
- `groupby` provides the power of the split-apply-combine pattern
- `value_counts` is a convenient shortcut to count the number of entries in each category of a variable

A full description on the split-apply-combine approach is provided in the user guide pages about `groupby operations`.

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
• Ticket: Ticket number of passenger.
• Fare: Indicating the fare.
• Cabin: The cabin of passenger.
• Embarked: The embarked category.

In [2]: `titanic = pd.read_csv("data/titanic.csv")`

In [3]: `titanic.head()`

Out[3]:

<table>

[5 rows x 12 columns]

This tutorial uses air quality data about $NO_2$ and Particulate matter less than 2.5 micrometers, made available by openaq and using the py-openaq package. The `air_quality_long.csv` data set provides $NO_2$ and $PM_{2.5}$ values for the measurement stations *FR04014, BETR801* and *London Westminster* in respectively Paris, Antwerp and London.

The air-quality data set has the following columns:

• city: city where the sensor is used, either Paris, Antwerp or London
• country: country where the sensor is used, either FR, BE or GB
• location: the id of the sensor, either *FR04014, BETR801* or *London Westminster*
• parameter: the parameter measured by the sensor, either $NO_2$ or Particulate matter
• value: the measured value
• unit: the unit of the measured parameter, in this case ‘µg/m$^3$’

and the index of the DataFrame is `datetime`, the datetime of the measurement.

Note: The air-quality data is provided in a so-called *long format* data representation with each observation on a separate row and each variable a separate column of the data table. The long/narrow format is also known as the *tidy data format*.

In [4]: `air_quality = pd.read_csv("data/air_quality_long.csv", index_col="date.utc", parse_dates=True)`

In [5]: `air_quality.head()`

(continues on next page)
How to reshape the layout of tables?

Sort table rows

I want to sort the Titanic data according to the age of the passengers.

```
In [6]: titanic.sort_values(by="Age").head()
```

```
Out[6]:
PASSENGERID  SURVIVED  PCLASS  NAME               SEX  AGE  SIBSP  PARCH  TICKET  FARE  CABS  EMBARKED
803         0  3  Thomas, Master. Assad Alexander  male  0.42  0  0 NaN  NaN
755         0  2  Hamalainen, Master. Viljo  male  0.67  1  0  NaN  NaN
644         0  3  Baclini, Miss. Eugenie  female  0.75  2  0  NaN  NaN
469         0  3  Baclini, Miss. Helene Barbara  female  0.75  2  0  NaN  NaN
78          0  2  Caldwell, Master. Alden Gates  male  0.83  0  0 NaN  NaN
```

I want to sort the Titanic data according to the cabin class and age in descending order.

```
In [7]: titanic.sort_values(by=['Pclass', 'Age'], ascending=False).head()
```

```
PASSENGERID  SURVIVED  PCLASS  NAME               SEX  AGE  SIBSP  PARCH  TICKET  FARE  CABS  EMBARKED
851         0  3  Svensson, Mr. Johan  male  74.0  0  0 NaN  NaN
116         0  3  Connors, Mr. Patrick  male  70.5  0  0 NaN  NaN
280         0  3  Duane, Mr. Frank  male  65.0  0  0 NaN  NaN
483         0  3  Turkula, Mrs. (Hedwig)  female  63.0  0  0 NaN  NaN
326         0  3  Nysveen, Mr. Johan Hansen  male  61.0  0  0 NaN  NaN
```

With `Series.sort_values()`, the rows in the table are sorted according to the defined column(s). The index will follow the row order.

More details about sorting of tables is provided in the using guide section on sorting data.
Long to wide table format

Let’s use a small subset of the air quality data set. We focus on NO₂ data and only use the first two measurements of each location (i.e. the head of each group). The subset of data will be called no2_subset.

```python
# filter for no2 data only
In [8]: no2 = air_quality[air_quality["parameter"] == "no2"]

# use 2 measurements (head) for each location (groupby)
In [9]: no2_subset = no2.sort_index().groupby(["location"]).head(2)

Out[10]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>city</th>
<th>country</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
<th>unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-04-09</td>
<td>Antwerpen</td>
<td>BE</td>
<td>BETR801</td>
<td>no2</td>
<td>22.5</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>24.4</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>London</td>
<td>GB</td>
<td>London Westminster</td>
<td>no2</td>
<td>67.0</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>Antwerpen</td>
<td>BE</td>
<td>BETR801</td>
<td>no2</td>
<td>53.5</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>27.4</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>London</td>
<td>GB</td>
<td>London Westminster</td>
<td>no2</td>
<td>67.0</td>
<td>µg/m³</td>
</tr>
</tbody>
</table>
```

I want the values for the three stations as separate columns next to each other.

```python
In [11]: no2_subset.pivot(columns="location", values="value")
Out[11]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-04-09</td>
<td>22.5</td>
<td>24.4</td>
<td>NaN</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>53.5</td>
<td>27.4</td>
<td>67.0</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>NaN</td>
<td>NaN</td>
<td>67.0</td>
</tr>
</tbody>
</table>
```

The `pivot()` function is purely reshaping of the data: a single value for each index/column combination is required.

As pandas support plotting of multiple columns (see plotting tutorial) out of the box, the conversion from long to wide table format enables the plotting of the different time series at the same time:

```python
In [12]: no2.head()
Out[12]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>city</th>
<th>country</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
<th>unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-06-21</td>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>20.0</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-06-20</td>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>21.8</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-06-20</td>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>26.5</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-06-20</td>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>24.9</td>
<td>µg/m³</td>
</tr>
<tr>
<td>2019-06-20</td>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>21.4</td>
<td>µg/m³</td>
</tr>
</tbody>
</table>
```

```python
In [13]: no2.pivot(columns="location", values="value").plot()
Out[13]: <AxesSubplot;xlabel='date.utc'>
Note: When the index parameter is not defined, the existing index (row labels) is used.

For more information about `pivot()`, see the user guide section on pivoting DataFrame objects.

**Pivot table**

I want the mean concentrations for \( NO_2 \) and \( PM_{2.5} \) in each of the stations in table form

```python
In [14]: air_quality.pivot_table(
    ....:     values="value", index="location", columns="parameter", aggfunc="mean"
    ....: )
```

```python
Out[14]:

<table>
<thead>
<tr>
<th>location</th>
<th>parameter</th>
<th>no2</th>
<th>pm25</th>
</tr>
</thead>
<tbody>
<tr>
<td>BETR801</td>
<td>NO2</td>
<td>26.950920</td>
<td>23.169492</td>
</tr>
<tr>
<td>FR04014</td>
<td>NO2</td>
<td>29.374284</td>
<td>NaN</td>
</tr>
<tr>
<td>London Westminster</td>
<td>NO2</td>
<td>29.740050</td>
<td>13.443568</td>
</tr>
<tr>
<td></td>
<td>PM2.5</td>
<td>26.950920</td>
<td>23.169492</td>
</tr>
<tr>
<td></td>
<td>PM2.5</td>
<td>29.374284</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>PM2.5</td>
<td>29.740050</td>
<td>13.443568</td>
</tr>
</tbody>
</table>
```

In the case of `pivot()`, the data is only rearranged. When multiple values need to be aggregated (in this specific case,
the values on different time steps) `pivot_table()` can be used, providing an aggregation function (e.g. mean) on how to combine these values.

Pivot table is a well known concept in spreadsheet software. When interested in summary columns for each variable separately as well, put the `margin` parameter to `True`:

```
In [15]: air_quality.pivot_table(
    ....:     values="value",
    ....:     index="location",
    ....:     columns="parameter",
    ....:     aggfunc="mean",
    ....:     margins=True,
    ....: )
```

```
Out[15]:
    parameter  no2     pm25     All
    location
    BETR801  26.950920  23.169492  24.982353
    FR04014  29.374284   NaN      29.374284
    All       29.430316  14.386849  24.222743
```

For more information about `pivot_table()`, see the user guide section on `pivot tables`.

**Note**: In case you are wondering, `pivot_table()` is indeed directly linked to `groupby()`. The same result can be derived by grouping on both `parameter` and `location`:

```
air_quality.groupby(["parameter", "location"]).mean()
```

Have a look at `groupby()` in combination with `unstack()` at the user guide section on `combining stats and groupby`.

### Wide to long format

Starting again from the wide format table created in the previous section:

```
In [16]: no2_pivoted = no2.pivot(columns="location", values="value").reset_index()
In [17]: no2_pivoted.head()
```

```
Out[17]:
    location       date.utc  BETR801  FR04014  London Westminster
    0   2019-04-09 01:00:00+00:00  22.5     24.4       NaN
    1   2019-04-09 02:00:00+00:00  53.5     27.4       67.0
    2   2019-04-09 03:00:00+00:00  54.5     34.2       67.0
    3   2019-04-09 04:00:00+00:00  34.5     48.5       41.0
    4   2019-04-09 05:00:00+00:00  46.5     59.5       41.0
```

I want to collect all air quality $NO_2$ measurements in a single column (long format)

```
In [18]: no_2 = no2_pivoted.melt(id_vars="date.utc")
```

(continues on next page)
The pandas.melt() method on a DataFrame converts the data table from wide format to long format. The column headers become the variable names in a newly created column.

The solution is the short version on how to apply pandas.melt(). The method will melt all columns NOT mentioned in id_vars together into two columns: A column with the column header names and a column with the values itself. The latter column gets by default the name value.

The pandas.melt() method can be defined in more detail:

```
In [20]: no_2 = no2_pivoted.melt(  
       ....:  id_vars="date.utc",  
       ....:  value_vars=["BETR801", "FR04014", "London Westminster"],  
       ....:  value_name="NO_2",  
       ....:  var_name="id_location",  
       ....:  )  
      
In [21]: no_2.head()  
```

The result in the same, but in more detail defined:

- value_vars defines explicitly which columns to melt together
- value_name provides a custom column name for the values column instead of the default column name value
- var_name provides a custom column name for the column collecting the column header names. Otherwise it takes the index name or a default variable

Hence, the arguments value_name and var_name are just user-defined names for the two generated columns. The columns to melt are defined by id_vars and value_vars.

Conversion from wide to long format with pandas.melt() is explained in the user guide section on reshaping by melt.

- Sorting by one or more columns is supported by sort_values
- The pivot function is purely restructuring of the data, pivot_table supports aggregations
- The reverse of pivot (long to wide format) is melt (wide to long format)

A full overview is available in the user guide on the pages about reshaping and pivoting.
In [1]: import pandas as pd

For this tutorial, air quality data about \( NO_2 \) is used, made available by openaq and downloaded using the `py-openaq` package.

The `air_quality_no2_long.csv` data set provides \( NO_2 \) values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

In [2]: air_quality_no2 = pd.read_csv("data/air_quality_no2_long.csv",  
...:     parse_dates=True)

In [3]: air_quality_no2 = air_quality_no2[["date.utc", "location",  
...:     "parameter", "value"]]

In [4]: air_quality_no2.head()

Out[4]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>

How to combine data from multiple tables?

Concatenating objects

I want to combine the measurements of $NO_2$ and $PM_{25}$, two tables with a similar structure, in a single table:

```python
In [8]: air_quality = pd.concat([air_quality_pm25, air_quality_no2], axis=0)
```

```python
In [9]: air_quality.head()
```

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>02019-06-18 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.0</td>

<td>BETR801</td>
<td>pm25</td>
<td>7.5</td>
</tr>
</tbody>
</table>

The `concat()` function performs concatenation operations of multiple tables along one of the axes (row-wise or column-wise).

By default concatenation is along axis 0, so the resulting table combines the rows of the input tables. Let’s check the shape of the original and the concatenated tables to verify the operation:

```python
In [10]: print('Shape of the "air_quality_pm25" table: ', air_quality_pm25.shape)
Shape of the "air_quality_pm25" table: (1110, 4)
```

```python
In [11]: print('Shape of the "air_quality_no2" table: ', air_quality_no2.shape)
Shape of the "air_quality_no2" table: (2068, 4)
```

```python
In [12]: print('Shape of the resulting "air_quality" table: ', air_quality.shape)
Shape of the resulting "air_quality" table: (3178, 4)
```

Hence, the resulting table has 3178 = 1110 + 2068 rows.

**Note:** The `axis` argument will return in a number of pandas methods that can be applied along an axis. A DataFrame has two corresponding axes: the first running vertically downwards across rows (axis 0), and the second running horizontally across columns (axis 1). Most operations like concatenation or summary statistics are by default across rows (axis 0), but can be applied across columns as well.

Sorting the table on the datetime information illustrates also the combination of both tables, with the parameter column defining the origin of the table (either `no2` from table `air_quality_no2` or `pm25` from table `air_quality_pm25`):

```python
In [13]: air_quality = air_quality.sort_values("date.utc")
```

```python
In [14]: air_quality.head()
```

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2067 2019-05-07 01:00:00+00:00</td>
<td>London Westminster</td>
<td>no2</td>
<td>23.0</td>
</tr>
<tr>
<td>1003 2019-05-07 01:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>25.0</td>
</tr>
<tr>
<td>100 2019-05-07 01:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>12.5</td>
</tr>
</tbody>
</table>

(continues on next page)
In this specific example, the parameter column provided by the data ensures that each of the original tables can be identified. This is not always the case. The `concat` function provides a convenient solution with the keys argument, adding an additional (hierarchical) row index. For example:

```python
In [15]: air_quality_ = pd.concat([air_quality_pm25, air_quality_no2], keys=['PM25', 'NO2'])
```

```python
In [16]: air_quality_.head()
```

```
Out[16]:
```
<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-06-18 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.0</td>
</tr>
<tr>
<td>2019-06-17 08:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>6.5</td>
</tr>
<tr>
<td>2019-06-17 07:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.5</td>
</tr>
<tr>
<td>2019-06-17 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>16.0</td>
</tr>
<tr>
<td>2019-06-17 05:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>7.5</td>
</tr>
</tbody>
</table>
```

**Note:** The existence of multiple row/column indices at the same time has not been mentioned within these tutorials. *Hierarchical indexing or MultiIndex* is an advanced and powerful pandas feature to analyze higher dimensional data.

Multi-indexing is out of scope for this pandas introduction. For the moment, remember that the function `reset_index` can be used to convert any level of an index to a column, e.g. `air_quality.reset_index(level=0)`

Feel free to dive into the world of multi-indexing at the user guide section on advanced indexing.

More options on table concatenation (row and column wise) and how `concat` can be used to define the logic (union or intersection) of the indexes on the other axes is provided at the section on *object concatenation*.

**Join tables using a common identifier**

Add the station coordinates, provided by the stations metadata table, to the corresponding rows in the measurements table.

**Warning:** The air quality measurement station coordinates are stored in a data file `air_quality_stations.csv`, downloaded using the `py-openaq` package.

```python
In [17]: stations_coord = pd.read_csv("data/air_quality_stations.csv")
```

```python
In [18]: stations_coord.head()
```

```
Out[18]:
```
<table>
<thead>
<tr>
<th>location</th>
<th>coordinates.latitude</th>
<th>coordinates.longitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>BELAL01</td>
<td>51.23619</td>
<td>4.38522</td>
</tr>
<tr>
<td>BELHB23</td>
<td>51.17030</td>
<td>4.34100</td>
</tr>
<tr>
<td>BELLD01</td>
<td>51.10998</td>
<td>5.00486</td>
</tr>
<tr>
<td>BELLD02</td>
<td>51.12038</td>
<td>5.02155</td>
</tr>
<tr>
<td>BELR833</td>
<td>51.32766</td>
<td>4.36226</td>
</tr>
</tbody>
</table>
```

1.4. Tutorials
Note: The stations used in this example (FR04014, BETR801 and London Westminster) are just three entries enlisted in the metadata table. We only want to add the coordinates of these three to the measurements table, each on the corresponding rows of the `air_quality` table.

```
In [19]: air_quality.head()
Out[19]:
      date.utc          location parameter  value
0 2019-05-07 01:00:00+00:00  London Westminster   no2    23.0
1 2019-05-07 01:00:00+00:00       FR04014   no2    25.0
100 2019-05-07 01:00:00+00:00    BETR801    pm25     12.5
1098 2019-05-07 01:00:00+00:00   BETR801    no2     50.5
1109 2019-05-07 01:00:00+00:00  London Westminster    pm25     8.0
```

```
In [20]: air_quality = pd.merge(air_quality, stations_coord, how="left", on="location")
In [21]: air_quality.head()
Out[21]:
      date.utc          location parameter  value  coordinates.latitude  coordinates.longitude
0 2019-05-07 01:00:00+00:00  London Westminster   no2    23.0          51.49467           -0.13193
1 2019-05-07 01:00:00+00:00       FR04014   no2    25.0           48.83724            2.39390
2 2019-05-07 01:00:00+00:00       FR04014    pm25     12.5           48.83722            2.39390
3 2019-05-07 01:00:00+00:00    BETR801    pm25     12.5          51.20966            4.43182
4 2019-05-07 01:00:00+00:00    BETR801    no2     50.5          51.20966            4.43182
```

Using the `merge()` function, for each of the rows in the `air_quality` table, the corresponding coordinates are added from the `air_quality_stations_coord` table. Both tables have the column `location` in common which is used as a key to combine the information. By choosing the `left` join, only the locations available in the `air_quality` (left) table, i.e. FR04014, BETR801 and London Westminster, end up in the resulting table. The `merge` function supports multiple join options similar to database-style operations.

Add the parameter full description and name, provided by the parameters metadata table, to the measurements table

```
Warning: The air quality parameters metadata are stored in a data file `air_quality_parameters.csv`, downloaded using the `py-openaq` package.
```

```
In [22]: air_quality_parameters = pd.read_csv("data/air_quality_parameters.csv")
In [23]: air_quality_parameters.head()
Out[23]:
     id  description      name
0   bc       Black Carbon    BC
1   co      Carbon Monoxide  CO
2  no2      Nitrogen Dioxide  NO2
3   o3            Ozone     03
```

<td>PM2.5</td>
<td>...</td>
<td>pm25</td>
</tr>
</tbody>
</table>
```

Compared to the previous example, there is no common column name. However, the `parameter` column in the `air_quality` table and the `id` column in the `air_quality_parameters` table both provide the measured variable in a common format. The `left_on` and `right_on` arguments are used here (instead of just `on`) to make the link between the two tables.

pandas supports also inner, outer, and right joins. More information on join/merge of tables is provided in the user guide section on *database style merging of tables*. Or have a look at the *comparison with SQL* page.

- Multiple tables can be concatenated both column-wise and row-wise using the `concat` function.

- For database-like merging/joining of tables, use the `merge` function.

See the user guide for a full description of the various facilities to combine data tables.

**In [1]:**
```
import pandas as pd
```

**In [2]:**
```
import matplotlib.pyplot as plt
```

For this tutorial, air quality data about $NO_2$ and Particulate matter less than 2.5 micrometers is used, made available by *openaq* and downloaded using the *py-openaq* package. The `air_quality_no2_long.csv` data set provides $NO_2$ values for the measurement stations *FR04014*, *BETR801* and *London Westminster* in respectively Paris, Antwerp and London.

**In [3]:**
```
air_quality = pd.read_csv("data/air_quality_no2_long.csv")
```

**In [4]:**
```
air_quality = air_quality.rename(columns={"date.utc": "datetime"})
```

**In [5]:**
```
air_quality.head()
```

**Out[5]:**

<td>µg/m³</td>
</tr>
</tbody>
</table>
```

(continues on next page)
**How to handle time series data with ease?**

**Using pandas datetime properties**

I want to work with the dates in the column `datetime` as datetime objects instead of plain text.

```python
In [7]: air_quality['datetime'] = pd.to_datetime(air_quality['datetime'])
```

```python
In [8]: air_quality['datetime']
```

```
0 2019-06-21 00:00:00+00:00
1 2019-06-20 23:00:00+00:00
2 2019-06-20 22:00:00+00:00
3 2019-06-20 21:00:00+00:00
4 2019-06-20 20:00:00+00:00
...
2063 2019-05-07 06:00:00+00:00
2064 2019-05-07 04:00:00+00:00
2065 2019-05-07 03:00:00+00:00
2066 2019-05-07 02:00:00+00:00
2067 2019-05-07 01:00:00+00:00
Name: datetime, Length: 2068, dtype: datetime64[ns, UTC]
```

Initially, the values in `datetime` are character strings and do not provide any datetime operations (e.g. extract the year, day of the week,...). By applying the `to_datetime` function, pandas interprets the strings and convert these to datetime (i.e. `datetime64[ns, UTC]`) objects. In pandas we call these datetime objects similar to `datetime.datetime` from the standard library as `pandas.Timestamp`.

**Note:** As many data sets do contain datetime information in one of the columns, pandas input function like `pandas.read_csv()` and `pandas.read_json()` can do the transformation to dates when reading the data using the `parse_dates` parameter with a list of the columns to read as `Timestamp`:

```python
pd.read_csv("../data/air_quality_no2_long.csv", parse_dates=['datetime'])
```

Why are these `pandas.Timestamp` objects useful? Let's illustrate the added value with some example cases.

What is the start and end date of the time series data set we are working with?

```python
In [9]: air_quality['datetime'].min(), air_quality['datetime'].max()
```

```
(Timestamp('2019-05-07 01:00:00+0000', tz='UTC'),
 Timestamp('2019-06-21 00:00:00+0000', tz='UTC'))
```
Using `pandas.Timestamp` for datetimes enables us to calculate with date information and make them comparable. Hence, we can use this to get the length of our time series:

```python
In [10]: air_quality["datetime"].max() - air_quality["datetime"].min()
Out[10]: Timedelta('44 days 23:00:00')
```

The result is a `pandas.Timedelta` object, similar to `datetime.timedelta` from the standard Python library and defining a time duration.

The various time concepts supported by pandas are explained in the user guide section on time related concepts.

I want to add a new column to the DataFrame containing only the month of the measurement

```python
In [11]: air_quality["month"] = air_quality["datetime"].dt.month
In [12]: air_quality.head()
```

<table>
<thead>
<tr>
<th>city</th>
<th>country</th>
<th>datetime</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
<th>unit</th>
<th>month</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paris</td>
<td>FR</td>
<td>2019-06-21 00:00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>20.0</td>
<td>µg/m³</td>
<td>6</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>2019-06-20 23:00:00</td>
<td>FR04014</td>

<td>6</td>
</tr>
</tbody>
</table>

By using Timestamp objects for dates, a lot of time-related properties are provided by pandas. For example the month, but also year, weekofyear, quarter,... All of these properties are accessible by the `dt` accessor.

An overview of the existing date properties is given in the time and date components overview table. More details about the `dt` accessor to return datetime like properties are explained in a dedicated section on the `dt accessor`.

What is the average $\text{NO}_2$ concentration for each day of the week for each of the measurement locations?

```python
In [13]: air_quality.groupby(    ....: [air_quality["datetime"].dt.weekday, "location"])["value"].mean()
```

<table>
<thead>

</tbody>
</table>

Remember the split-apply-combine pattern provided by `groupby` from the tutorial on statistics calculation? Here, we want to calculate a given statistic (e.g. mean $\text{NO}_2$) for each weekday and for each measurement location. To group on weekdays, we use the datetime property `weekday` (with Monday=0 and Sunday=6) of pandas Timestamp, which is also accessible by the `dt` accessor. The grouping on both locations and weekdays can be done to split the calculation of the mean on each of these combinations.
Danger: As we are working with a very short time series in these examples, the analysis does not provide a long-term representative result!

Plot the typical $NO_2$ pattern during the day of our time series of all stations together. In other words, what is the average value for each hour of the day?

```
In [14]: fig, axs = plt.subplots(figsize=(12, 4))
In [15]: air_quality.groupby(air_quality["datetime"].dt.hour)["value"].mean().plot(
    ....:     kind='bar', rot=0, ax=axs
    ....: )
Out[15]: <AxesSubplot:xlabel='datetime'>
In [16]: plt.xlabel("Hour of the day"); # custom x label using matplotlib
In [17]: plt.ylabel("$NO_2 (\mu g/m^3)$");
```

![Plot of NO2 pattern](image)

Similar to the previous case, we want to calculate a given statistic (e.g. mean $NO_2$) for each hour of the day and we can use the split-apply-combine approach again. For this case, we use the datetime property `hour` of pandas Timestamp, which is also accessible by the `dt` accessor.

**Datetime as index**

In the tutorial on reshaping, `pivot()` was introduced to reshape the data table with each of the measurements locations as a separate column:

```
In [18]: no_2 = air_quality.pivot(index="datetime", columns="location", values="value")
In [19]: no_2.head()
Out[19]:
<table>
<thead>
<tr>
<th>location</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td>datetime</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2019-05-07</td>
<td>01:00:00+00:00</td>
<td>50.5</td>
<td>25.0</td>
</tr>
<tr>
<td>2019-05-07</td>
<td>02:00:00+00:00</td>
<td>45.0</td>
<td>27.7</td>
</tr>
<tr>
<td>2019-05-07</td>
<td>03:00:00+00:00</td>
<td>NaN</td>
<td>50.4</td>
</tr>
<tr>
<td>2019-05-07</td>
<td>04:00:00+00:00</td>
<td>NaN</td>
<td>61.9</td>
</tr>
<tr>
<td>2019-05-07</td>
<td>05:00:00+00:00</td>
<td>NaN</td>
<td>72.4</td>
</tr>
</tbody>
</table>
```
Note: By pivoting the data, the datetime information became the index of the table. In general, setting a column as an index can be achieved by the `set_index` function.

Working with a datetime index (i.e. `DatetimeIndex`) provides powerful functionalities. For example, we do not need the `dt` accessor to get the time series properties, but have these properties available on the index directly:

```python
In [20]: no_2.index.year, no_2.index.weekday
Out[20]:
(Int64Index([2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019,
          ..., 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019],
           dtype='int64', name='datetime', length=1033),
Int64Index([1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
          ..., 3, 3, 3, 3, 3, 3, 3, 3, 3, 4],
           dtype='int64', name='datetime', length=1033))
```

Some other advantages are the convenient subsetting of time period or the adapted time scale on plots. Let’s apply this on our data.

Create a plot of the $NO_2$ values in the different stations from the 20th of May till the end of 21st of May

```python
In [21]: no_2["2019-05-20":"2019-05-21"].plot();
```
By providing a string that parses to a datetime, a specific subset of the data can be selected on a DatetimeIndex.

More information on the DatetimeIndex and the slicing by using strings is provided in the section on time series indexing.

### Resample a time series to another frequency

Aggregate the current hourly time series values to the monthly maximum value in each of the stations.

```python
In [22]: monthly_max = no_2.resample("M").max()
In [23]: monthly_max
Out[23]:
    location       BETR801   FR04014    London Westminster
   datetime
2019-05-31 00:00:00+00:00  74.5    97.0           97.0
2019-06-30 00:00:00+00:00  52.5    84.7           52.0
```

A very powerful method on time series data with a datetime index, is the ability to resample() time series to another frequency (e.g., converting secondly data into 5-minutely data).

The resample() method is similar to a groupby operation:

- it provides a time-based grouping, by using a string (e.g. M, 5H,...) that defines the target frequency
- it requires an aggregation function such as mean, max,...

An overview of the aliases used to define time series frequencies is given in the offset aliases overview table.

When defined, the frequency of the time series is provided by the freq attribute:

```python
In [24]: monthly_max.index.freq
Out[24]: <MonthEnd>
```

Make a plot of the daily mean NO\textsubscript{2} value in each of the stations.

```python
In [25]: no_2.resample("D").mean().plot(style="-o", figsize=(10, 5));
```
More details on the power of time series resampling is provided in the user guide section on resampling.

- Valid date strings can be converted to datetime objects using `to_datetime` function or as part of read functions.
- Datetime objects in pandas support calculations, logical operations and convenient date-related properties using the `dt` accessor.
- A `DatetimeIndex` contains these date-related properties and supports convenient slicing.
- `Resample` is a powerful method to change the frequency of a time series.

A full overview on time series is given on the pages on time series and date functionality.

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
- **Parch**: Whether a passenger is alone or have family.
- **Ticket**: Ticket number of passenger.
- **Fare**: Indicating the fare.
- **Cabin**: The cabin of passenger.
- **Embarked**: The embarked category.
In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()
Out[3]:
   PassengerId  Survived  Pclass  Name                                        ...
0              1       0        3  Braund, Mr. Owen Harris                  ...
1              2       1        1  Cumings, Mrs. John Bradley (Florence Briggs Th... ...
2              3       1        3  Heikkinen, Miss. Laina                   ...
3              4       1        3  Futrelle, Mrs. Jacques Heath (Lily May Peel) ...
4              5       0        3  Allen, Mr. William Henry                 ...
   Ticket     Fare     Cabin    Embarked
0      A/5 21171  7.2500  NaN       S

2  STON/O2. 3101282 7.9250  NaN       S
3          113803 53.1000  C123       S
4            373450 8.0500  NaN       S
[5 rows x 12 columns]

How to manipulate textual data?

Make all name characters lowercase.

In [4]: titanic["Name"].str.lower()
Out[4]:
0  braund, mr. owen harris
1  cumings, mrs. john bradley (florence briggs th...
2  heikkinen, miss. laina
3  futrelle, mrs. jacques heath (lily may peel)
4  allen, mr. william henry
   ... montvila, rev. juozas
886  graham, miss. margaret edith
887  johnston, miss. catherine helen "carrie"
889  behr, mr. karl howell
890  dooley, mr. patrick
Name: Name, Length: 891, dtype: object

To make each of the strings in the Name column lowercase, select the Name column (see the tutorial on selection of data), add the str accessor and apply the lower method. As such, each of the strings is converted element-wise.

Similar to datetime objects in the time series tutorial having a dt accessor, a number of specialized string methods are available when using the str accessor. These methods have in general matching names with the equivalent built-in string methods for single elements, but are applied element-wise (remember element-wise calculations?) on each of the values of the columns.

Create a new column Surname that contains the surname of the passengers by extracting the part before the comma.

In [5]: titanic["Name"].str.split(",")
Out[5]:
0  [Braund, Mr. Owen Harris]
1  [Cumings, Mrs. John Bradley (Florence Briggs ...]
2  [Heikkinen, Miss. Laina]

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.1

Using the `Series.str.split()` method, each of the values is returned as a list of 2 elements. The first element is the part before the comma and the second element is the part after the comma.

```python
In [6]: titanic["Surname"] = titanic["Name"].str.split(",").str.get(0)

In [7]: titanic["Surname"]
```

```
Out[7]:
0   Braund
1  Cumings
2  Heikkinen
3  Futrelle
4    Allen
   ...  
886  Montvila
887    Graham
888  Johnston
889     Behr
890     Dooley
Name: Surname, Length: 891, dtype: object
```

As we are only interested in the first part representing the surname (element 0), we can again use the `str` accessor and apply `Series.str.get()` to extract the relevant part. Indeed, these string functions can be concatenated to combine multiple functions at once!

More information on extracting parts of strings is available in the user guide section on *splitting and replacing strings.*

Extract the passenger data about the countesses on board of the Titanic.

```python
In [8]: titanic["Name"].str.contains("Countess")
```

```
Out[8]:
0   False
1   False
2   False
3   False
4   False
   ...  
886  False
887  False
888  False
889  False
890  False
Name: Name, Length: 891, dtype: bool
```
The string method `Series.str.contains()` checks for each of the values in the column `Name` if the string contains the word `Countess` and returns for each of the values `True` (`Countess` is part of the name) or `False` (`Countess` is not part of the name). This output can be used to subselect the data using conditional (boolean) indexing introduced in the subsetting of data tutorial. As there was only one countess on the Titanic, we get one row as a result.

Note: More powerful extractions on strings are supported, as the `Series.str.contains()` and `Series.str.extract()` methods accept regular expressions, but out of scope of this tutorial.

More information on extracting parts of strings is available in the user guide section on string matching and extracting.

Which passenger of the Titanic has the longest name?

To get the longest name we first have to get the lengths of each of the names in the `Name` column. By using pandas string methods, the `Series.str.len()` function is applied to each of the names individually (element-wise).

Next, we need to get the corresponding location, preferably the index label, in the table for which the name length is the largest. The `idxmax()` method does exactly that. It is not a string method and is applied to integers, so no `str` is used.

Based on the index name of the row (307) and the column (`Name`), we can do a selection using the `loc` operator, introduced in the tutorial on subsetting.
In the “Sex” column, replace values of “male” by “M” and values of “female” by “F”.

```
In [13]: titanic["Sex_short"] = titanic["Sex"].replace({"male": "M", "female": "F"})
In [14]: titanic["Sex_short"]
Out[14]:
0   M
1   F
2   F
3   F
4   M
   ...  
886  M
887  F
888  F
889  M
890  M
Name: Sex_short, Length: 891, dtype: object
```

Whereas `replace()` is not a string method, it provides a convenient way to use mappings or vocabularies to translate certain values. It requires a dictionary to define the mapping `{from : to}`.

**Warning:** There is also a `replace()` method available to replace a specific set of characters. However, when having a mapping of multiple values, this would become:

```
titanic["Sex_short"] = titanic["Sex"].str.replace("female", "F")
titanic["Sex_short"] = titanic["Sex_short"].str.replace("male", "M")
```

This would become cumbersome and easily lead to mistakes. Just think (or try out yourself) what would happen if those two statements are applied in the opposite order...

- String methods are available using the `str` accessor.
- String methods work element-wise and can be used for conditional indexing.
- The `replace` method is a convenient method to convert values according to a given dictionary.

A full overview is provided in the user guide pages on *working with text data*.

### 1.4.4 Comparison with other tools

**Comparison with R / R libraries**

Since pandas aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the R language and its many third party libraries as they relate to pandas. In comparisons with R and CRAN libraries, we care about the following things:

- **Functionality / flexibility**: what can/cannot be done with each tool
- **Performance**: how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use**: Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.
For transfer of DataFrame objects from pandas to R, one option is to use HDF5 files, see External compatibility for an example.

Quick reference

We’ll start off with a quick reference guide pairing some common R operations using dplyr with pandas equivalents.

Querying, filtering, sampling

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>dim(df)</td>
<td>df.shape</td>
</tr>
<tr>
<td>head(df)</td>
<td>df.head()</td>
</tr>
<tr>
<td>slice(df, 1:10)</td>
<td>df.iloc[:9]</td>
</tr>
<tr>
<td>filter(df, col1 == 1, col2 == 1)</td>
<td>df.query('col1 == 1 &amp; col2 == 1')</td>
</tr>
<tr>
<td>df[df$col1 == 1 &amp; df$col2 == 1]</td>
<td>df[(df.col1 == 1) &amp; (df.col2 == 1)]</td>
</tr>
<tr>
<td>select(df, col1, col2)</td>
<td>df[['col1', 'col2']]</td>
</tr>
<tr>
<td>select(df, col1:col3)</td>
<td>df.loc[:, 'col1':'col3']</td>
</tr>
<tr>
<td>select(df, -(col1:col3))</td>
<td>df.drop(cols_to_drop, axis=1) but see</td>
</tr>
<tr>
<td>distinct(select(df, col1))</td>
<td>df[['col1']].drop_duplicates()</td>
</tr>
<tr>
<td>distinct(select(df, col1, col2))</td>
<td>df[['col1', 'col2']].drop_duplicates()</td>
</tr>
<tr>
<td>sample_n(df, 10)</td>
<td>df.sample(n=10)</td>
</tr>
<tr>
<td>sample_frac(df, 0.01)</td>
<td>df.sample(frac=0.01)</td>
</tr>
</tbody>
</table>

Sorting

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>arrange(df, col1, col2)</td>
<td>df.sort_values(['col1', 'col2'])</td>
</tr>
<tr>
<td>arrange(df, desc(col1))</td>
<td>df.sort_values('col1', ascending=False)</td>
</tr>
</tbody>
</table>

Transforming

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>select(df, col_one = col1)</td>
<td>df.rename(columns={'col1': 'col_one'})['col_one']</td>
</tr>
<tr>
<td>rename(df, col_one = col1)</td>
<td>df.rename(columns={'col1': 'col_one'})</td>
</tr>
<tr>
<td>mutate(df, c=a-b)</td>
<td>df.assign(c=df['a']-df['b'])</td>
</tr>
</tbody>
</table>

1 R’s shorthand for a subrange of columns (select(df, col1:col3)) can be approached cleanly in pandas, if you have the list of columns, for example df[cols[1:3]] or df.drop(cols[1:3]), but doing this by column name is a bit messy.
Grouping and summarizing

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>summary(df)</code></td>
<td><code>df.describe()</code></td>
</tr>
<tr>
<td><code>gdf &lt;- group_by(df, col1)</code></td>
<td><code>gdf = df.groupby('col1')</code></td>
</tr>
<tr>
<td><code>summarise(gdf, avg=mean(col1, na.rm=TRUE))</code></td>
<td><code>gdf.groupby('col1').agg({'col1': 'mean'})</code></td>
</tr>
<tr>
<td><code>summarise(gdf, total=sum(col1))</code></td>
<td><code>gdf.groupby('col1').sum()</code></td>
</tr>
</tbody>
</table>

Base R

Slicing with R's c

R makes it easy to access data.frame columns by name

```r
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```r
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```python
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list("abc"))

In [2]: df["a", "c"]
Out[2]:
   a  c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892

In [3]: df.loc[:, ["a", "c"]]
Out[3]:
   a  c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
```

(continues on next page)
Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```
In [4]: named = list("abcdefg")

In [5]: n = 30

In [6]: columns = named + np.arange(len(named), n).tolist()

In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)

In [8]: df.iloc[:, np.r_[:10, 24:30]]
Out[8]:
    a     b     c     d     e     f   ...   24   25
   --- --- --- --- --- ---   ... --- ---
  0 -1.344312 0.844885 1.075770 -0.109050 1.643563 -1.469388 ... -1.170299 -0.226169
  1 -0.410835 0.813850 0.132003 -0.827317 0.619976 0.149748 ... 0.959726 -1.110336
  2 0.176444 0.403310 -0.154951 0.301624 -2.179861 -1.369849 ... 0.084844 0.432390
  3 -1.19970 -0.493662 0.600178 0.274230 0.132885 -0.023688 ... 2.484478 -0.281461
  4 0.030711 0.109121 1.126203 0.977349 1.474071 -0.064034 ... -1.197071 -1.066969

 11 0.332872 -2.013086 -1.602549 0.333109

[30 rows x 16 columns]
```
aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called df and splitting it into groups by1 and by2:

```r
df <- data.frame(
  v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),
  v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)
```

The `groupby()` method is similar to base R `aggregate` function.

```python
In [9]: df = pd.DataFrame(
    ...:     {
    ...:         "v1": [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
    ...:         "v2": [11, 33, 55, 77, 88, 33, 55, np.nan, 44, 55, 77, 99],
    ...:         "by1": ["red", "blue", 1, 2, np.nan, "big", 1, 2, "red", 1, np.nan, 12],
    ...:         "by2": ["wet", "dry", 99, 95, np.nan, "damp", 95, 99, "red", 99, np.nan, np.nan],
    ...:     },
    ...: )
    ...
In [10]: g = df.groupby(["by1", "by2"])
In [11]: g["v1", "v2"].mean()
Out[11]:
   v1   v2
by1 by2
1  95  5.0  55.0
   99  5.0  55.0
2  95  7.0  77.0
   99  NaN  NaN
big damp  3.0  33.0
blue dry  3.0  33.0
red red  4.0  44.0
   wet  1.0  11.0
```

For more details and examples see the groupby documentation.
match / %in%

A common way to select data in R is using %in% which is defined using the function \texttt{match}. The operator %in% is used to return a logical vector indicating if there is a match or not:

```
s <- 0:4
s %in% c(2,4)
```

The \texttt{isin()} method is similar to R %in% operator:

```
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)
In [13]: s.isin([2, 4])
Out[13]:
0    False
1    False
2    True
3    False
4    True
 dtype: bool
```

The \texttt{match} function returns a vector of the positions of matches of its first argument in its second:

```
s <- 0:4
match(s, c(2,4))
```

For more details and examples see \textit{the reshaping documentation}.

\textbf{tapply}

\texttt{tapply} is similar to \texttt{aggregate}, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a data.frame called \texttt{baseball}, and retrieving information based on the array \texttt{team}:

```
baseball <-
data.frame(team = gl(5, 5, labels = paste("Team", LETTERS[1:5])),
player = sample(letters, 25),
batting.average = runif(25, .200, .400))
tapply(baseball$batting.average, baseball.example$team, max)
```

In pandas we may use \texttt{pivot_table()} method to handle this:

```
In [14]: import random
In [15]: import string
In [16]: baseball = pd.DataFrame(
...:     {
...:         "team": ["team %d" % (x + 1) for x in range(5)] * 5,
...:         "player": random.sample(list(string.ascii_lowercase), 25),
...:         "batting avg": np.random.uniform(0.200, 0.400, 25),
...:     }
```
In [17]: baseball.pivot_table(values="batting avg", columns="team", aggfunc=np.max)

Out[17]:

<table>
<thead>
<tr>
<th></th>
<th>team 1</th>
<th>team 2</th>
<th>team 3</th>
<th>team 4</th>
<th>team 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>batting avg</td>
<td>0.352134</td>
<td>0.295327</td>
<td>0.397191</td>
<td>0.394457</td>
<td>0.396194</td>
</tr>
</tbody>
</table>

For more details and examples see the reshaping documentation.

subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column’s values are less than another column’s values:

```r
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a < b)
df[df$a < df$b,]  # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```python
In [18]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})

In [19]: df.query("a <= b")
Out[19]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.174950</td>
<td>0.552887</td>
</tr>
<tr>
<td>2</td>
<td>-0.023167</td>
<td>0.148084</td>
</tr>
<tr>
<td>3</td>
<td>-0.495291</td>
<td>-0.300218</td>
</tr>
<tr>
<td>4</td>
<td>-0.860736</td>
<td>0.197378</td>
</tr>
<tr>
<td>5</td>
<td>-1.134146</td>
<td>1.720780</td>
</tr>
<tr>
<td>7</td>
<td>-0.290098</td>
<td>0.083515</td>
</tr>
<tr>
<td>8</td>
<td>0.238636</td>
<td>0.946550</td>
</tr>
</tbody>
</table>

In [20]: df[df["a"] <= df["b"]]
Out[20]:

<table>
<thead>
<tr>
<th></th>

For more details and examples see the query documentation.

\textbf{with}

An expression using a data.frame called \texttt{df} in R with the columns \texttt{a} and \texttt{b} would be evaluated using \texttt{with} like so:

\begin{verbatim}
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b  # same as the previous expression
\end{verbatim}

In pandas the equivalent expression, using the \texttt{eval()} method, would be:

\begin{verbatim}
In [22]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})
In [23]: df.eval("a + b")
Out[23]:
       0    1        2
0 -0.091430 -2.483890
1 -0.252728 -0.261740
2 -0.626444  2.149503
3 -0.332214  0.799331
4  2.104677 -2.377245
5  0.799331  2.104677
dtype: float64

In [24]: df["a"] + df["b"]  # same as the previous expression
Out[24]:
       0    1        2
0 -0.091430 -2.483890
1 -0.252728 -0.261740
2 -0.626444  2.149503
3 -0.332214  0.799331
4  2.104677 -2.377245
5  0.799331  2.104677
dtype: float64
\end{verbatim}

In certain cases \texttt{eval()} will be much faster than evaluation in pure Python. For more details and examples see the \texttt{eval} documentation.
plyr

plyr is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, \(a\) for arrays, \(l\) for lists, and \(d\) for data.frame. The table below shows how these data structures could be mapped in Python.

<table>
<thead>
<tr>
<th>R</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>lists</td>
<td>dictionary or list of objects</td>
</tr>
<tr>
<td>data.frame</td>
<td>dataframe</td>
</tr>
</tbody>
</table>

ddply

An expression using a data.frame called \(df\) in R where you want to summarize \(x\) by \(month\):

```r
require(plyr)
df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5, 6, 7, 8), 30),
  week = sample(1:4, 120, TRUE)
)
ddply(df, .(month, week), summarize,
  mean = round(mean(x), 2),
  sd = round(sd(x), 2))
```

In pandas the equivalent expression, using the `groupby()` method, would be:

```python
In [25]: df = pd.DataFrame(
          ....:     
          ....:     {"x": np.random.uniform(1.0, 168.0, 120),
          ....:      "y": np.random.uniform(7.0, 334.0, 120),
          ....:      "z": np.random.uniform(1.7, 20.7, 120),
          ....:      "month": [5, 6, 7, 8] * 30,
          ....:      "week": np.random.randint(1, 4, 120),
          ....:     }
          ....:)
          ....:
In [26]: grouped = df.groupby(['month', 'week'])

In [27]: grouped['x'].agg([np.mean, np.std])
```

**Out[27]:**

<table>
<thead>
<tr>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>week</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>78.126605</td>
</tr>
<tr>
<td>3</td>
<td>92.091886</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>70.971205</td>
</tr>
</tbody>
</table>

3 73.936856 60.773900

For more details and examples see the groupby documentation.

**reshape / reshape2**

**meltarray**

An expression using a 3 dimensional array called `a` in R where you want to melt it into a data.frame:

```r
a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))
```

In Python, since `a` is a list, you can simply use list comprehension.

```
In [28]: a = np.array(list(range(1, 24)) + [np.NAN]).reshape(2, 3, 4)
```

```
In [29]: pd.DataFrame([tuple(list(x) + [val]) for x, val in np.ndenumerate(a)])
Out[29]:
      0  1  2  3
0  0  0  0  1.0
1  0  0  1  2.0
2  0  0  2  3.0
3  0  0  3  4.0
4  0  1  0  5.0
... ... ... ...
19 1  1  3 20.0
20 1  2  0 21.0
21 1  2  1 22.0
22 1  2  2 23.0
23 1  2  3  NaN
[24 rows x 4 columns]
```

**meltlist**

An expression using a list called `a` in R where you want to melt it into a data.frame:

```r
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NAN]))

In [31]: pd.DataFrame(a)
Out[31]:
   0  1
0  0  1.0
1  1  2.0
2  2  3.0
3  3  4.0
4  4  NaN

For more details and examples see the Into to Data Structures documentation.

**meltdf**

An expression using a data.frame called `cheese` in R where you want to reshape the data.frame:

```r
cheese <- data.frame(
  first = c('John', 'Mary'),
  last = c('Doe', 'Bo'),
  height = c(5.5, 6.0),
  weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```python
In [32]: cheese = pd.DataFrame(
    ....:     {
    ....:         "first": ["John", "Mary"],
    ....:         "last": ["Doe", "Bo"],
    ....:         "height": [5.5, 6.0],
    ....:         "weight": [130, 150],
    ....:     }
    ....: )
    ....:

In [33]: pd.melt(cheese, id_vars=["first", "last"])
Out[33]:
   first last variable  value
0  John  Doe    height  5.5
1  Mary   Bo    height  6.0
2  John  Doe     weight 130.0
3  Mary   Bo     weight 150.0

In [34]: cheese.set_index(["first", "last"]).stack()  # alternative way
Out[34]:
   first last
John  Doe  height  5.5
          weight 130.0
Mary  Bo   height  6.0
          weight 150.0
```

(continues on next page)
dtype: float64

For more details and examples see the reshaping documentation.

cast

In R acast is an expression using a data.frame called df in R to cast into a higher dimensional array:

df <- data.frame(
    x = runif(12, 1, 168),
    y = runif(12, 7, 334),
    z = runif(12, 1.7, 20.7),
    month = rep(c(5,6,7),4),
    week = rep(c(1,2), 6)
)
mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)

In Python the best way is to make use of pivot_table():

In [35]: df = pd.DataFrame(
    { ...
        "x": np.random.uniform(1.0, 168.0, 12),
        "y": np.random.uniform(7.0, 334.0, 12),
        "z": np.random.uniform(1.7, 20.7, 12),
        "month": [5, 6, 7] * 4,
        "week": [1, 2] * 6,
    }
)
In [36]: mdf = pd.melt(df, id_vars=["month", "week"])

In [37]: pd.pivot_table(
    mdf,
    values="value",
    index=["variable", "week"],
    columns=["month"],
    aggfunc=np.mean,
)

Out[37]:

<table>
<thead>
<tr>
<th></th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>93.888747</td>
<td>98.762034</td>
<td>55.219673</td>
</tr>
<tr>
<td>y</td>
<td>94.391427</td>
<td>38.112932</td>
<td>83.942781</td>
</tr>
<tr>
<td>z</td>
<td>11.016009</td>
<td>10.079307</td>
<td>16.170549</td>
</tr>
<tr>
<td></td>
<td>8.476111</td>
<td>17.638509</td>
<td>19.003494</td>
</tr>
</tbody>
</table>
Similarly for `dcast` which uses a data.frame called df in R to aggregate information based on Animal and FeedType:

```r
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
             'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```python
In [38]: df = pd.DataFrame(
       
    
       {  
    
       "Animal": [  
    
       "Animal1",
    
       "Animal2",
    
       "Animal3",
    
       "Animal2",
    
       "Animal1",
    
       "Animal2",
    
       "Animal3"],
    
       "FeedType": ["A", "B", "A", "A", "B", "B", "A"],
    
       "Amount": [10, 7, 4, 2, 5, 6, 2],
    
       }

Out[38]:
```

```python
In [39]: df.pivot_table(values="Amount", index="Animal", columns="FeedType", aggfunc="sum")
```

```text
FeedType A B
Animal Animal1 10.0 5.0
       Animal2 2.0 13.0
       Animal3 6.0 NaN
```

The second approach is to use the `groupby()` method:

```python
In [40]: df.groupby(["Animal", "FeedType"])['Amount'].sum()
```

```text
Animal FeedType
Animal1 A 10
       B 5
Animal2 A 2
       B 13
Animal3 A 6
Name: Amount, dtype: int64
```

For more details and examples see the reshaping documentation or the groupby documentation.
**factor**

pandas has a data type for categorical data.

```
cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))
```

In pandas this is accomplished with `pd.cut` and `astype("category")`:

```
In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
Out[41]:
0 (0.995, 2.667]
1 (0.995, 2.667]
2 (2.667, 4.333]
3 (2.667, 4.333]
4 (4.333, 6.0]
5 (4.333, 6.0]
dtype: category
Categories (3, interval[float64, right]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.0]]

In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
Out[42]:
0 1
1 2
2 3
3 2
4 2
5 3
dtype: category
Categories (3, int64): [1, 2, 3]
```

For more details and examples see *categorical introduction* and the API documentation. There is also a documentation regarding the *differences to R's factor*.

**Comparison with SQL**

Since many potential pandas users have some familiarity with SQL, this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Most of the examples will utilize the *tips* dataset found within pandas tests. We’ll read the data into a DataFrame called *tips* and assume we have a database table of the same name and structure.

```
In [3]: url = (...
   ...:  "https://raw.githubusercontent.com/pandas-dev" (continues on next page)
In [4]: tips = pd.read_csv(url)

In [5]: tips

Out[5]:
<table>
<thead>

</tr>
</tbody>
</table>

[244 rows x 7 columns]

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

**Note:** You will see an *inplace=True* keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```

Its use is discouraged. *More information.*
SELECT

In SQL, selection is done using a comma-separated list of columns you'd like to select (or a * to select all columns):

```sql
SELECT total_bill, tip, smoker, time
FROM tips;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```python
In [6]: tips["total_bill", "tip", "smoker", "time"]
Out[6]:
   total_bill  tip  smoker  time
0    16.99    1.01   No  Dinner
1    10.34    1.66   No  Dinner
2    21.01    3.50   No  Dinner
3    23.68    3.31   No  Dinner
4    24.59    3.61   No  Dinner
   ...    ...    ...    ...
239  29.03    5.92   No  Dinner
240  27.18    2.00   Yes Dinner
241  22.67    2.00   Yes Dinner
242  17.82    1.75   No  Dinner
243  18.78    3.00   No  Dinner
```

Calling the DataFrame without the list of column names would display all columns (akin to SQL’s *).

In SQL, you can add a calculated column:

```sql
SELECT *, tip/total_bill as tip_rate
FROM tips;
```

With pandas, you can use the `DataFrame.assign()` method of a DataFrame to append a new column:

```python
In [7]: tips.assign(tip_rate=tips["tip"] / tips["total_bill")
Out[7]:
   total_bill  tip  sex  smoker  day  time  size  tip_rate
0     16.99  1.01 Female   No  Sun  Dinner 2  0.059447
1     10.34  1.66  Male    No  Sun  Dinner 3  0.160542
2     21.01  3.50  Male    No  Sun  Dinner 3  0.166587
3     23.68  3.31  Male    No  Sun  Dinner 2  0.139780
4     24.59  3.61 Female   No  Sun  Dinner 4  0.146808
   ...    ...    ...    ...    ...    ...
239  29.03  5.92  Male    No  Sat  Dinner 3  0.203927
240  27.18  2.00 Female  Yes  Sat  Dinner 2  0.073584
241  22.67  2.00 Female  Yes  Sat  Dinner 2  0.088222
242  17.82  1.75  Male    No  Sat  Dinner 2  0.098204
243  18.78  3.00 Female   No  Thur  Dinner 2  0.159744
```

[244 rows x 8 columns]
WHERE

Filtering in SQL is done via a WHERE clause.

```
SELECT *
FROM tips
WHERE time = 'Dinner';
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```
In [8]: tips[tips["total_bill"] > 10]
Out[8]:

   total_bill  tip  sex  smoker  day  time  size
0    16.99   1.01  Female  No  Sun  Dinner   2
1    10.34   1.66    Male  No  Sun  Dinner   3
2    21.01   3.50    Male  No  Sun  Dinner   3
3    23.68   3.31    Male  No  Sun  Dinner   2
4    24.59   3.61  Female  No  Sun  Dinner   4
...    ...    ...     ...   ...    ...    ...  ...
239  29.03   5.92    Male  No  Sat  Dinner   3
240  27.18   2.00  Female  Yes  Sat  Dinner   2
241  22.67   2.60    Male  Yes  Sat  Dinner   2
242  17.82   1.75    Male  No  Sat  Dinner   2
243  18.78   3.00  Female  No  Thur  Dinner   2
```

[227 rows x 7 columns]

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with `True`.

```
In [9]: is_dinner = tips["time"] == "Dinner"

In [10]: is_dinner
Out[10]:

0   True
1   True
2   True
3   True
4   True
   ... 
239  True
240  True
241  True
242  True
243  True
Name: time, Length: 244, dtype: bool

In [11]: is_dinner.value_counts()
Out[11]:

    True    176
   False     68
Name: time, dtype: int64
```

(continues on next page)
In [12]: tips[is_dinner]
Out[12]:
    total_bill  tip  sex  smoker day  time  size
0   16.99      1.01 Female  No  Sun  Dinner  2
1   19.34      1.66   Male  No  Sun  Dinner  3
2   21.61      3.50   Male  No  Sun  Dinner  3
3   23.68      3.31   Male  No  Sun  Dinner  2
4   24.59      3.61 Female  No  Sun  Dinner  4
...  ...  ...  ...  ...  ...  ...  ...
239 29.03      5.92   Male  No  Sat  Dinner  3
240 27.18      2.00 Female  Yes  Sat  Dinner  2
241 22.67      2.00   Male  Yes  Sat  Dinner  2
242 17.82      1.75   Male  No  Sat  Dinner  2
243 18.78      3.00 Female  No  Thur  Dinner  4
[176 rows x 7 columns]

Just like SQL's OR and AND, multiple conditions can be passed to a DataFrame using | (OR) and & (AND).

Tips of more than $5 at Dinner meals:

SELECT *
FROM tips
WHERE time = 'Dinner' AND tip > 5.00;

In [13]: tips[(tips["time"] == "Dinner") & (tips["tip"] > 5.00)]
Out[13]:
    total_bill  tip  sex  smoker day  time  size
   23     39.42  7.58   Male  No  Sat  Dinner  4
   44     30.40  5.60   Male  No  Sun  Dinner  4
   47     32.40  6.00   Male  No  Sun  Dinner  4
   52     34.81  5.20 Female  No  Sun  Dinner  4
   59     48.27  6.73   Male  No  Sat  Dinner  4
   116    29.93  5.07   Male  No  Sun  Dinner  4
   155    29.85  5.14 Female  No  Sun  Dinner  5
   170    50.81 10.00   Male  Yes  Sat  Dinner  3
   172     7.25  5.15   Male  Yes  Sun  Dinner  2
   181    23.33  5.65   Male  Yes  Sun  Dinner  2
   183    23.17  6.50   Male  Yes  Sun  Dinner  4
   211    25.89  5.16   Male  Yes  Sat  Dinner  4
   212    48.33  9.00   Male  No  Sat  Dinner  4
   214    28.17  6.50 Female  Yes  Sat  Dinner  3
   239    29.03  5.92   Male  No  Sat  Dinner  3

Tips by parties of at least 5 diners OR bill total was more than $45:

SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;

In [14]: tips[(tips["size"] >= 5) | (tips["total_bill"] > 45)]
Out[14]:

(continues on next page)
NULL checking is done using the `notna()` and `isna()` methods.

Assume we have a table of the same structure as our DataFrame above. We can see only the records where `col2` IS NULL with the following query:

```
SELECT * 
FROM frame 
WHERE col2 IS NULL;
```

```
In [17]: frame[frame["col2"].isna()]
Out[17]:
     col1  col2
0     A     F
1     B  NaN
2  NaN     G
3     C     H
4     D     I
```

Getting items where `col1` IS NOT NULL can be done with `notna()`.

```
SELECT * 
FROM frame 
WHERE col1 IS NOT NULL;
```

```
In [18]: frame[frame["col1"].notna()]
Out[18]:
     col1  col2
0     A     F
1     B  NaN
```

(continues on next page)
GROUP BY

In pandas, SQL's GROUP BY operations are performed using the similarly named `groupby()` method. `groupby()` typically refers to a process where we'd like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```sql
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female 87
Male 157
*/
```

The pandas equivalent would be:

```python
In [19]: tips.groupby("sex").size()
Out[19]:
sex
Female 87
Male 157
dtype: int64
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of NOT NULL records within each.

```python
In [20]: tips.groupby("sex").count()
Out[20]:
total_bill  tip  smoker  day  time  size
text
sex
Female  87  87  87  87  87  87
Male    157 157 157 157 157 157
```

Alternatively, we could have applied the `count()` method to an individual column:

```python
In [21]: tips.groupby("sex")["total_bill"].count()
Out[21]:
sex
Female 87
Male  157
Name: total_bill, dtype: int64
```

Multiple functions can also be applied at once. For instance, say we'd like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.
```sql
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri  2.734737  19
Sat  2.993103  87
Sun  3.255132  76
Thu  2.771452  62
*/
```

In [22]: tips.groupby("day").agg({"tip": np.mean, "day": np.size})

Out[22]:

<table>
<thead>
<tr>
<th></th>
<th>tip</th>
<th>day</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2.734737</td>
<td>19</td>
</tr>
<tr>
<td></td>
<td>2.993103</td>
<td>87</td>
</tr>
<tr>
<td></td>
<td>3.255132</td>
<td>76</td>
</tr>
<tr>
<td></td>
<td>2.771452</td>
<td>62</td>
</tr>
</tbody>
</table>

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```sql
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
/*
smoker  day
No     Fri   4  2.812500
       Sat   45 3.102889
       Sun  57  3.167895
       Thu  45  2.673778
Yes    Fri  15 2.714000
       Sat  42  2.875476
       Sun  19  3.516842
       Thu  17  3.030000
*/
```

In [23]: tips.groupby(["smoker", "day"]).agg({"tip": [np.size, np.mean]})

Out[23]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>size</td>
<td>mean</td>
<td></td>
</tr>
</tbody>
</table>
| smoker day
No  | Fri   | 4   | 2.812500  
    | Sat   | 45  | 3.102889 
    | Sun   | 57  | 3.167895 
    | Thu   | 45  | 2.673778 
Yes | Fri   | 15  | 2.714000 
    | Sat   | 42  | 2.875476 
    | Sun   | 19  | 3.516842 
    | Thu   | 17  | 3.030000  

1.4. Tutorials
JOIN

JOINs can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

**Warning:** If both key columns contain rows where the key is a null value, those rows will be matched against each other. This is different from usual SQL join behaviour and can lead to unexpected results.

```python
In [24]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})
In [25]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})
```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let’s go over the various types of JOINs.

**INNER JOIN**

```sql
SELECT *
FROM df1
INNER JOIN df2
ON df1.key = df2.key;
```

```python
# merge performs an INNER JOIN by default
In [26]: pd.merge(df1, df2, on="key")
```

```python
Out[26]:
<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>B -0.282863  1.212112</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>D -1.135632  -0.173215</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>D -1.135632   0.119209</td>
<td></td>
</tr>
</tbody>
</table>
```

`merge()` also offers parameters for cases when you’d like to join one DataFrame’s column with another DataFrame’s index.

```python
In [27]: indexed_df2 = df2.set_index("key")
In [28]: pd.merge(df1, indexed_df2, left_on="key", right_index=True)
```

```python
Out[28]:
<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>B -0.282863  1.212112</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>D -1.135632  -0.173215</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>D -1.135632   0.119209</td>
<td></td>
</tr>
</tbody>
</table>
```
LEFT OUTER JOIN

Show all records from df1.

```
SELECT *
FROM df1
LEFT OUTER JOIN df2
  ON df1.key = df2.key;
```

```bash
In [29]: pd.merge(df1, df2, on="key", how="left")
Out[29]:
   key  value_x  value_y
0   A   0.469112   NaN
1   B  -0.282863  1.212112
2   C  -1.509059   NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
```

RIGHT JOIN

Show all records from df2.

```
SELECT *
FROM df1
RIGHT OUTER JOIN df2
  ON df1.key = df2.key;
```

```bash
In [30]: pd.merge(df1, df2, on="key", how="right")
Out[30]:
   key  value_x  value_y
0   B  -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209
3   E   NaN     -1.044236
```

FULL JOIN

pandas also allows for FULL JOINs, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINs are not supported in all RDBMS (MySQL).

Show all records from both tables.

```
SELECT *
FROM df1
FULL OUTER JOIN df2
  ON df1.key = df2.key;
```

```bash
In [31]: pd.merge(df1, df2, on="key", how="outer")
Out[31]:
   key  value_x  value_y
```

(continues on next page)
UNION

UNION ALL can be performed using `concat()`.

```python
In [32]: df1 = pd.DataFrame(
    ....:     {"city": ["Chicago", "San Francisco", "New York City"], "rank": range(1, 4)}
    ....:     )
    ....:

In [33]: df2 = pd.DataFrame(
    ....:     {"city": ["Chicago", "Boston", "Los Angeles"], "rank": [1, 4, 5]}
    ....:     )
    ....:
```

```sql
SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
   city rank
   Chicago   1
   San Francisco   2
   New York City   3
     Chicago   1
       Boston   4
   Los Angeles   5
*/
```

```python
In [34]: pd.concat([df1, df2])
Out[34]:
    city rank
0  Chicago    1
1 San Francisco    2
2 New York City    3
0  Chicago    1
1   Boston    4
2 Los Angeles    5
```

SQL's UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```sql
SELECT city, rank
FROM df1
```
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time

<table>
<thead>
<tr>
<th>city</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chicago</td>
<td>1</td>
</tr>
<tr>
<td>San Francisco</td>
<td>2</td>
</tr>
<tr>
<td>New York City</td>
<td>3</td>
</tr>
<tr>
<td>Boston</td>
<td>4</td>
</tr>
<tr>
<td>Los Angeles</td>
<td>5</td>
</tr>
</tbody>
</table>

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

```python
In [35]: pd.concat([df1, df2]).drop_duplicates()
Out[35]:
          city  rank
0   Chicago     1
1  San Francisco  2
2  New York City  3
1    Boston     4
2  Los Angeles   5
```

LIMIT

```sql
SELECT * FROM tips
LIMIT 10;
```

```python
In [36]: tips.head(10)
Out[36]:
          total_bill  tip sex smoker day       time size
0          16.99  1.01 Female    No Sun Dinner  2
1          10.34  1.66   Male    No Sun Dinner  3
2          21.01  3.50   Male    No Sun Dinner  3
3          23.68  3.31   Male    No Sun Dinner  2
4          24.59  3.61 Female    No Sun Dinner  4
5          25.29  4.71   Male    No Sun Dinner  4
6           8.77  2.00   Male    No Sun Dinner  2
7          26.88  3.12   Male    No Sun Dinner  4
8          15.04  1.96   Male    No Sun Dinner  2
9          14.78  3.23   Male    No Sun Dinner  2
```
pandas equivalents for some SQL analytic and aggregate functions

Top n rows with offset

```sql
-- MySQL
SELECT *
FROM tips
ORDER BY tip DESC
LIMIT 10 OFFSET 5;
```

```python
In [37]: tips.nlargest(10 + 5, columns="tip").tail(10)
Out[37]:
   total_bill  tip  sex  smoker  day    time  size
0   23.17    6.50  Male   Yes    Sun  Dinner    4
1   28.17    6.50 Female  Yes    Sat  Dinner    3
2   32.40    6.00  Male    No    Sun  Dinner    4
3   29.03    5.92  Male    No    Sat  Dinner    3
4   24.71    5.85  Male    No  Thur  Lunch    2
5   23.33    5.65  Male   Yes    Sun  Dinner    2
6   30.40    5.60  Male    No    Sun  Dinner    4
7   34.81    5.20 Female    No  Thur  Lunch    4
8   34.83    5.17 Female    No  Thur  Lunch    4
9   25.89    5.16  Male   Yes    Sat  Dinner    4
```

Top n rows per group

```sql
-- Oracle's ROW_NUMBER() analytic function
SELECT *
FROM (SELECT t.*, ROW_NUMBER() OVER(PARTITION BY day ORDER BY total_bill DESC) AS rn
FROM tips t)
WHERE rn < 3
ORDER BY day, rn;
```

```python
In [38]: (....: tips.assign(.....:   rn=tips.sort_values(["total_bill"], ascending=False).....:     .groupby(["day"])
.....:     .cumcount()).....:   + 1
.....: )
.....: .query("rn < 3")
.....: .sort_values(["day", "rn"])
.....: )
Out[38]:
   total_bill  tip  sex  smoker  day    time  size  rn
0     40.17    4.73  Male   Yes    Fri  Dinner    4   1
1     28.97    3.00  Male   Yes    Fri  Dinner    2   2
```
(continues on next page)
the same using `rank(method='first')` function

```python
In [39]:
    ...
    ...:   tips.assign(
    ...:     rnk=tips.groupby(["day"])["total_bill"].rank(
    ...:         method="first", ascending=False
    ...:     )
    ...:     )
    ...:     .query("rnk < 3")
    ...:     .sort_values(["day", "rnk"]
    ...:     )
    ...
Out[39]:
       total_bill  tip  sex  smoker  day  time  size  rnk
   95      40.17  4.73  Male   Yes  Fri  Dinner  4  1.0
   90      28.97  3.00  Male   Yes  Fri  Dinner  2  2.0
  170      50.81 10.00  Male   Yes  Sat  Dinner  3  1.0
  212      48.33  9.00  Male    No  Sat  Dinner  4  2.0
  156      48.17  5.00  Male    No  Sun  Dinner  6  1.0
  182      45.35  3.50  Male   Yes  Sun  Dinner  3  2.0
  197      43.11  5.00 Female   Yes  Thur Lunch  4  1.0
  142      41.19  5.00  Male    No  Thur Lunch  5  2.0
```

-- Oracle's `RANK()` analytic function

```sql
SELECT * FROM (  
    SELECT  
        t.*,  
        RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk  
    FROM tips t  
    WHERE tip < 2  
)
WHERE rnk < 3  
ORDER BY sex, rnk;
```

Let's find tips with `(rank < 3)` per gender group for `(tips < 2)`. Notice that when using `rank(method='min')` function `rnk_min` remains the same for the same `tip` (as Oracle's `RANK()` function)

```python
In [40]:
    ...
    ...:   tips[tips["tip"] < 2]
    ...:     .assign(rnk_min=tips.groupby(["sex"])["tip"].rank(method="min"))
    ...:     .query("rnk_min < 3")
    ...:     .sort_values(["sex", "rnk_min"]
    ...:     )
    ...
Out[40]:
```

(continues on next page)
UPDATE

```sql
UPDATE tips
SET tip = tip * 2
WHERE tip < 2;
```

```python
In [41]: tips.loc[tips["tip"] < 2, "tip"] *= 2
```

DELETE

```sql
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain instead of deleting them:

```python
In [42]: tips = tips.loc[tips["tip"] <= 9]
```

Comparison with spreadsheets

Since many potential pandas users have some familiarity with spreadsheet programs like Excel, this page is meant to provide some examples of how various spreadsheet operations would be performed using pandas. This page will use terminology and link to documentation for Excel, but much will be the same/similar in Google Sheets, LibreOffice Calc, Apple Numbers, and other Excel-compatible spreadsheet software.

If you’re new to pandas, you might want to first read through 10 Minutes to pandas to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```python
In [1]: import pandas as pd

In [2]: import numpy as np
```
Data structures

General terminology translation

<table>
<thead>
<tr>
<th>pandas</th>
<th>Excel</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame</td>
<td>worksheet</td>
</tr>
<tr>
<td>Series</td>
<td>column</td>
</tr>
<tr>
<td>Index</td>
<td>row headings</td>
</tr>
<tr>
<td>row</td>
<td>row</td>
</tr>
<tr>
<td>NaN</td>
<td>empty cell</td>
</tr>
</tbody>
</table>

**DataFrame**

A DataFrame in pandas is analogous to an Excel worksheet. While an Excel workbook can contain multiple worksheets, pandas DataFrames exist independently.

**Series**

A Series is the data structure that represents one column of a DataFrame. Working with a Series is analogous to referencing a column of a spreadsheet.

**Index**

Every DataFrame and Series has an Index, which are labels on the rows of the data. In pandas, if no index is specified, a RangeIndex is used by default (first row = 0, second row = 1, and so on), analogous to row headings/numbers in spreadsheets.

In pandas, indexes can be set to one (or multiple) unique values, which is like having a column that is used as the row identifier in a worksheet. Unlike most spreadsheets, these Index values can actually be used to reference the rows. (Note that this can be done in Excel with structured references.) For example, in spreadsheets, you would reference the first row as A1:Z1, while in pandas you could use `populations.loc['Chicago']`.

Index values are also persistent, so if you re-order the rows in a DataFrame, the label for a particular row don’t change. See the indexing documentation for much more on how to use an Index effectively.

**Copies vs. in place operations**

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

**Note:** You will see an inplace=True keyword argument available for some methods:
df.sort_values("col1", inplace=True)

Its use is discouraged. More information.

Data input / output

Constructing a DataFrame from values

In a spreadsheet, values can be typed directly into cells.

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```python
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})

In [4]: df
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

Reading external data

Both Excel and pandas can import data from various sources in various formats.

CSV

Let’s load and display the tips dataset from the pandas tests, which is a CSV file. In Excel, you would download and then open the CSV. In pandas, you pass the URL or local path of the CSV file to `read_csv()`:

```python
In [5]: url = (...: "https://raw.github.com/pandas-dev"...
      ...: "/pandas/main/pandas/tests/io/data/csv/tips.csv"
      ...: )
      ...

In [6]: tips = pd.read_csv(url)

In [7]: tips
Out[7]:
   total_bill   tip  sex smoker  day   time  size
0    16.99   1.01 Female    No  Sun  Dinner   2
1    10.34   1.66   Male    No  Sun  Dinner   3
2    21.01   3.50   Male    No  Sun  Dinner   3
3    23.68   3.31   Male    No  Sun  Dinner   2
4    24.59   3.61 Female    No  Sun  Dinner   4
...     ...     ...     ...    ...     ...     ...
239  29.03   5.92   Male    No   Sat  Dinner   3
```

(continues on next page)
Like Excel's Text Import Wizard, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```python
tips = pd.read_csv("tips.csv", sep="\t", header=None)
```

# alternatively, read_table is an alias to read_csv with tab delimiter
```
tips = pd.read_table("tips.csv", header=None)
```

### Excel files

Excel opens various Excel file formats by double-clicking them, or using the Open menu. In pandas, you use *special methods for reading and writing from/to Excel files.*

Let's first create a new Excel file based on the `tips` dataframe in the above example:

```python
tips.to_excel("./tips.xlsx")
```

Should you wish to subsequently access the data in the `tips.xlsx` file, you can read it into your module using

```python
tips_df = pd.read_excel("./tips.xlsx", index_col=0)
```

You have just read in an Excel file using pandas!

### Limiting output

Spreadsheet programs will only show one screenful of data at a time and then allow you to scroll, so there isn't really a need to limit output. In pandas, you'll need to put a little more thought into controlling how your `DataFrame`s are displayed.

By default, pandas will truncate output of large `DataFrame`s to show the first and last rows. This can be overridden by *changing the pandas options*, or using `DataFrame.head()` or `DataFrame.tail()`.

```python
In [8]: tips.head(5)
Out[8]:
       total_bill  tip  sex  smoker  day  time size
0  16.990000  1.01 Female  No  Sun  Dinner  2
1  10.340000  1.66  Male  No  Sun  Dinner  3
2  21.010000  3.50  Male  No  Sun  Dinner  3
3  23.680000  3.31  Male  No  Sun  Dinner  2
4  24.590000  3.61 Female  No  Sun  Dinner  4
```
Exporting data

By default, desktop spreadsheet software will save to its respective file format (.xlsx, .ods, etc). You can, however, save to other file formats.

*pandas can create Excel files, CSV, or a number of other formats.*

Data operations

Operations on columns

In spreadsheets, formulas are often created in individual cells and then dragged into other cells to compute them for other columns. In pandas, you’re able to do operations on whole columns directly.

pandas provides vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The DataFrame.drop() method drops a column from the DataFrame.

```
In [9]: tips["total_bill"] = tips["total_bill"] - 2
In [10]: tips["new_bill"] = tips["total_bill"] / 2
In [11]: tips
```

```
Out[11]:
      total_bill  tip    sex  smoker day  time  size  new_bill
0      14.99  1.01 Female  No  Sun   Dinner  2   7.495
1       8.34  1.66    Male  No  Sun   Dinner  3   4.170
2      19.01  3.50    Male  No  Sun   Dinner  3   9.505
3      21.68  3.31    Male  No  Sun   Dinner  2  10.840
4      22.59  3.61 Female  No  Sun   Dinner  4  11.295
...     ...    ...    ...    ...    ...    ...    ...
239   27.03  5.92    Male  No  Sat   Dinner  3  13.515
240   25.18  2.00 Female Yes  Sat   Dinner  2  12.590
241   20.67  2.00    Male Yes  Sat   Dinner  2  10.335
242   15.82  1.75    Male  No  Sat   Dinner  2   7.910
243   16.78  3.00 Female  No  Thur  Dinner  2   8.390
```

```
[244 rows x 8 columns]
```

```
In [12]: tips = tips.drop("new_bill", axis=1)
```

Note that we aren’t having to tell it to do that subtraction cell-by-cell — pandas handles that for us. See how to create new columns derived from existing columns.
Filtering

In Excel, filtering is done through a graphical menu.

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```python
In [13]: tips[tips["total_bill"] > 10]
Out[13]:
   total_bill  tip    sex  smoker  day  time  size
 0    17.81  2.54  Male      NO  Sat  Dinner
```

(continues on next page)
The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

In [14]: is_dinner = tips["time"] == "Dinner"

In [15]: is_dinner

Out[15]:
0   True
1   True
2   True
3   True
4   True
   ...
239  True
240  True
241  True
242  True
243  True
Name: time, Length: 244, dtype: bool

In [16]: is_dinner.value_counts()

Out[16]:
True    176
False    68
Name: time, dtype: int64

In [17]: tips[is_dinner]

Out[17]:
<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>14.99</td>
<td>1.01</td>
<td>Female</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>8.34</td>
<td>1.66</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>

</tr>
</tbody>
</table>

[204 rows x 7 columns]
If/then logic

Let’s say we want to make a bucket column with values of low and high, based on whether the total_bill is less or more than $10.

In spreadsheets, logical comparison can be done with conditional formulas. We’d use a formula of =IF(A2 < 10, "low", "high"), dragged to all cells in a new bucket column.

The same operation in pandas can be accomplished using the where method from numpy.

```
In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```
In [19]: tips
Out[19]:
         total_bill  tip    sex  smoker day  time  size  bucket
0   14.99   1.01  Female     No  Sun  Dinner     2  high
1   8.34   1.66    Male     No  Sun  Dinner     3  low
2  19.01   3.50    Male     No  Sun  Dinner     3  high
3  21.68   3.31    Male     No  Sun  Dinner     2  high
4  22.59   3.61  Female     No  Sun  Dinner     4  high
...     ...     ...     ...  ...     ...     ...  ...  ...
239 27.03   5.92    Male     No  Sat  Dinner     3  high
240 25.18   2.00  Female    Yes  Sat  Dinner     2  high
241 20.67   2.00    Male    Yes  Sat  Dinner     2  high
242 15.82   1.75    Male     No  Sat  Dinner     2  high
243 16.78   3.00  Female     No  Thur  Dinner     2  high
```

[244 rows x 8 columns]
Date functionality

This section will refer to “dates”, but timestamps are handled similarly.

We can think of date functionality in two parts: parsing, and output. In spreadsheets, date values are generally parsed automatically, though there is a `DATEVALUE` function if you need it. In pandas, you need to explicitly convert plain text to datetime objects, either while reading from a CSV or once in a DataFrame.

Once parsed, spreadsheets display the dates in a default format, though the format can be changed. In pandas, you’ll generally want to keep dates as datetime objects while you’re doing calculations with them. Outputting parts of dates (such as the year) is done through date functions in spreadsheets, and datetime properties in pandas.

Given `date1` and `date2` in columns A and B of a spreadsheet, you might have these formulas:

<table>
<thead>
<tr>
<th>column</th>
<th>formula</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>date1_year</code></td>
<td>=YEAR(A2)</td>
</tr>
<tr>
<td><code>date2_month</code></td>
<td>=MONTH(B2)</td>
</tr>
<tr>
<td><code>date1_next</code></td>
<td>=DATE(YEAR(A2),MONTH(A2)+1,1)</td>
</tr>
<tr>
<td><code>months_between</code></td>
<td>=DATEDIF(A2,B2,&quot;M&quot;)</td>
</tr>
</tbody>
</table>

The equivalent pandas operations are shown below.

```python
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"]
In [26]: tips["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]
Out[26]:
       date1       date2 date1_year  date2_month date1_next months_between
...          ...          ...          ...          ...          ...
(continues on next page)
```
Selection of columns

In spreadsheets, you can select columns you want by:

- Hiding columns
- Deleting columns
- Referencing a range from one worksheet into another

Since spreadsheet columns are typically named in a header row, renaming a column is simply a matter of changing the text in that first cell.

The same operations are expressed in pandas below.

Keep certain columns

In [27]: tips[['sex', 'total_bill', 'tip']]

Out[27]:

<table>
<thead>
<tr>
<th></th>
<th>sex</th>
<th>total_bill</th>
<th>tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Female</td>
<td>14.99</td>
<td>1.01</td>
</tr>
<tr>
<td>1</td>
<td>Male</td>
<td>8.34</td>
<td>1.66</td>
</tr>
<tr>
<td>2</td>
<td>Male</td>
<td>19.01</td>
<td>3.50</td>
</tr>
<tr>
<td>3</td>
<td>Male</td>
<td>21.68</td>
<td>3.31</td>
</tr>
<tr>
<td>4</td>
<td>Female</td>
<td>22.59</td>
<td>3.61</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>239</td>
<td>Male</td>
<td>27.03</td>
<td>5.92</td>
</tr>
<tr>
<td>240</td>
<td>Female</td>
<td>25.18</td>
<td>2.00</td>
</tr>
<tr>
<td>241</td>
<td>Male</td>
<td>20.67</td>
<td>2.00</td>
</tr>
<tr>
<td>242</td>
<td>Male</td>
<td>15.82</td>
<td>1.75</td>
</tr>
<tr>
<td>243</td>
<td>Female</td>
<td>16.78</td>
<td>3.00</td>
</tr>
</tbody>
</table>

[244 rows x 3 columns]

Drop a column

In [28]: tips.drop("sex", axis=1)

Out[28]:

<table>
<thead>
<tr>
<th></th>
<th>total_bill</th>
<th>tip</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>14.99</td>
<td>1.01</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>8.34</td>
<td>1.66</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>19.01</td>
<td>3.50</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>21.68</td>
<td>3.31</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>22.59</td>
<td>3.61</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>4</td>
</tr>
</tbody>
</table>
Rename a column

```
In [29]: tips.rename(columns={"total_bill": "total_bill_2"})
Out[29]:
     total_bill_2  tip  sex  smoker  day  time size
0    14.99      1.01 Female   No  Sun  Dinner   2
1     8.34      1.66  Male     No  Sun  Dinner   3
2    19.01      3.50  Male     No  Sun  Dinner   3
3    21.68      3.31  Male     No  Sun  Dinner   2
4    22.59      3.61 Female   No  Sun  Dinner   4
..        ...      ...     ...    ...    ...   ...
239   27.03      5.92  Male     No  Sat  Dinner   3
240   25.18      2.00 Female   Yes  Sat  Dinner   2
241   20.67      2.00  Male     Yes  Sat  Dinner   2
242   15.82      1.75  Male     No  Sat  Dinner   2
243   16.78      3.00 Female   No  Thur  Dinner   2
```

[244 rows x 7 columns]

Sorting by values

Sorting in spreadsheets is accomplished via the sort dialog.
pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [30]: tips = tips.sort_values(["sex", "total_bill"])

In [31]: tips
Out[31]:
    total_bill   tip  sex  smoker day time size
   67    1.07  1.00  Female   Yes  Sat Dinner  1
   92    3.75  1.00  Female   Yes  Fri Dinner  2
  111    5.25  1.00  Female    No  Sat Dinner  1
  145    6.35  1.50  Female    No  Thur  Lunch  2
  135    6.51  1.25  Female    No  Thur  Lunch  2
       ...   ...    ...     ...    ...    ...    ...
 182   43.35  3.50   Male    Yes  Sun Dinner  3
  156   46.17  5.00   Male    No  Sun Dinner  6
   59   46.27  6.73   Male    No  Sat Dinner  4
  212   46.33  9.00   Male    No  Sat Dinner  4
  170   48.81 10.00   Male    Yes  Sat Dinner  3

[244 rows x 7 columns]
```

**String processing**

**Finding length of string**

In spreadsheets, the number of characters in text can be found with the `LEN` function. This can be used with the `TRIM` function to remove extra whitespace.

```
=LEN(TRIM(A2))
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.
In [32]: tips["time"].str.len()
Out[32]:
67    6
92    6
111   6
145   5
135   5
   ..
182   6
156   6
59    6
212   6
170   6
Name: time, Length: 244, dtype: int64
In [33]: tips["time"].str.rstrip().str.len()
Out[33]:
67    6
92    6
111   6
145   5
135   5
   ..
182   6
156   6
59    6
212   6
170   6
Name: time, Length: 244, dtype: int64

Note this will still include multiple spaces within the string, so isn’t 100% equivalent.

**Finding position of substring**

The FIND spreadsheet function returns the position of a substring, with the first character being 1.
You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```
In [34]: tips["sex"].str.find("ale")
Out[34]:
67    3
92    3
111   3
145   3
135   3
   ...
182   1
156   1
  59   1
212   1
170   1
Name: sex, Length: 244, dtype: int64
```

**Extracting substring by position**

Spreadsheets have a `MID` formula for extracting a substring from a given position. To get the first character:

```
=MID(A2,1,1)
```

With pandas you can use `[ ]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [35]: tips["sex"].str[0:1]
Out[35]:
67    F
92    F
```

(continues on next page)
Extracting nth word

In Excel, you might use the Text to Columns Wizard for splitting text and retrieving a specific column. (Note it’s possible to do so through a formula as well.)

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```python
In [36]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})
In [37]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]
In [38]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[1]
In [39]: firstlast
Out[39]:
     String   First_Name   Last_Name
0  John Smith       John     Smith
1     Jane Cook  Jane       Cook
```

Changing case

Spreadsheets provide UPPER, LOWER, and PROPER functions for converting text to upper, lower, and title case, respectively.

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```python
In [40]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})
In [41]: firstlast["upper"] = firstlast["string"].str.upper()
In [42]: firstlast["lower"] = firstlast["string"].str.lower()
In [43]: firstlast["title"] = firstlast["string"].str.title()
In [44]: firstlast
Out[44]:
     string   upper   lower      title
0  John Smith  JOHN SMITH  john smith  John Smith
1     Jane Cook  JANE COOK  jane cook  Jane Cook
```
Merging

The following tables will be used in the merge examples:

```python
In [45]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'], 'value': np.random.randn(4)})

In [46]: df1
Out[46]:
   key  value
0   A   0.469112
1   B  -0.282863
2   C  -1.509059
3   D  -1.135632

In [47]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'], 'value': np.random.randn(4)})

In [48]: df2
Out[48]:
   key  value
0   B   1.212112
1   D  -0.173215
2   D   0.119209
3   E  -1.044236
```

In Excel, there are merging of tables can be done through a VLOOKUP.

![VLOOKUP Formula](image)

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```python
In [49]: inner_join = df1.merge(df2, on=['key'], how='inner')

In [50]: inner_join
Out[50]:
   key  value_x  value_y
0   B   -0.282863  1.212112
1   D  -1.135632 -0.173215
2   D  -1.135632  0.119209
```

(continues on next page)
In [51]: ```python
left_join = df1.merge(df2, on="key", how="left")
```  
In [52]: ```python
left_join
```

```
key  value_x  value_y  
0   A   0.469112   NaN   
1   B  -0.282863  1.212112  
2   C  -1.509059   NaN   
3   D  -1.135632  -0.173215  
4   D  -1.135632   0.119209  
```

In [53]: ```python
right_join = df1.merge(df2, on="key", how="right")
```  
In [54]: ```python
right_join
```

```
key  value_x  value_y  
0   B  -0.282863  1.212112  
1   D  -1.135632  -0.173215  
2   D  -1.135632   0.119209  
3   E    NaN  -1.044236  
```

In [55]: ```python
outer_join = df1.merge(df2, on="key", how="outer")
```  
In [56]: ```python
outer_join
```

```
key  value_x  value_y  
0   A   0.469112   NaN   
1   B  -0.282863  1.212112  
2   C  -1.509059   NaN   
3   D  -1.135632  -0.173215  
4   D  -1.135632   0.119209  
5   E    NaN  -1.044236  
```

merge has a number of advantages over VLOOKUP:

- The lookup value doesn’t need to be the first column of the lookup table
- If multiple rows are matched, there will be one row for each match, instead of just the first
- It will include all columns from the lookup table, instead of just a single specified column
- It supports more complex join operations

Other considerations

Fill Handle

Create a series of numbers following a set pattern in a certain set of cells. In a spreadsheet, this would be done by shift+drag after entering the first number or by entering the first two or three values and then dragging.

This can be achieved by creating a series and assigning it to the desired cells.
pandas: powerful Python data analysis toolkit, Release 1.4.1

```python
In [57]: df = pd.DataFrame({'AAA': [1] * 8, 'BBB': list(range(0, 8)))

In [58]: df
Out[58]:
   AAA  BBB
0  1.0  0.0
1  1.0  1.0
2  1.0  2.0
3  1.0  3.0
4  1.0  4.0
5  1.0  5.0
6  1.0  6.0
7  1.0  7.0

In [59]: series = list(range(1, 5))

In [60]: series
Out[60]: [1, 2, 3, 4]

In [61]: df.loc[2:5, 'AAA'] = series

In [62]: df
Out[62]:
   AAA  BBB
0  1.0  0.0
1  1.0  1.0
2  1.0  2.0
3  2.0  3.0
4  3.0  4.0
5  4.0  5.0
6  1.0  6.0
7  1.0  7.0

Drop Duplicates

Excel has built-in functionality for removing duplicate values. This is supported in pandas via `drop_duplicates()`.

```python
In [63]: df = pd.DataFrame(
    ...:
    ...:
    ...:
    ...:
    ...:
    ...:
    ...:
    ...:
    ...:
    ...
    ...
    ...
    ...
    ...
    ...

In [64]: df.drop_duplicates()
Out[64]:
       class  student_count  all_pass
0     A         42         Yes
1     A         35         Yes
```

(continues on next page)
In [65]: df.drop_duplicates(["class", "student_count"])

Out[65]:

<table>
<thead>
<tr>
<th>class</th>
<th>student_count</th>
<th>all_pass</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>42</td>
<td>Yes</td>
</tr>
<tr>
<td>A</td>
<td>35</td>
<td>Yes</td>
</tr>
<tr>
<td>B</td>
<td>50</td>
<td>No</td>
</tr>
<tr>
<td>C</td>
<td>47</td>
<td>No</td>
</tr>
<tr>
<td>D</td>
<td>45</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Pivot Tables

Pivot Tables from spreadsheets can be replicated in pandas through *Reshaping and pivot tables*. Using the tips dataset again, let's find the average gratuity by size of the party and sex of the server.

In Excel, we use the following configuration for the PivotTable:

![Excel PivotTable Configuration](image)

The equivalent in pandas:

In [66]: pd.pivot_table(
                   tips, values="tip", index=["size"], columns=["sex"],
                   aggfunc=np.average)

Out[66]:

<table>
<thead>
<tr>
<th>sex</th>
<th>Female</th>
<th>Male</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1.2766667</td>
<td>1.92</td>
</tr>
<tr>
<td>2</td>
<td>2.528448276</td>
<td>2.614183673</td>
</tr>
<tr>
<td>3</td>
<td>3.25</td>
<td>3.476666667</td>
</tr>
<tr>
<td>4</td>
<td>4.0211111111</td>
<td>4.172142857</td>
</tr>
<tr>
<td>5</td>
<td>5.14</td>
<td>3.75</td>
</tr>
<tr>
<td>6</td>
<td>4.6</td>
<td>5.85</td>
</tr>
<tr>
<td>(blank)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Grand Total</td>
<td>2.833448276</td>
<td>3.089617834</td>
</tr>
</tbody>
</table>

(continues on next page)
Adding a row

Assuming we are using a `RangeIndex` (numbered 0, 1, etc.), we can use `concat()` to add a row to the bottom of a DataFrame.

```python
In [67]: df
Out[67]:
          class  student_count  all_pass
0         A          42         Yes
1         A          35         Yes
2         A          42         Yes
3         B          50          No
4         C          47          No
5         D          45         Yes

In [68]: new_row = pd.DataFrame([["E", 51, True]],
                           columns=["class", "student_count", "all_pass"])

In [69]: pd.concat([df, new_row])
Out[69]:
          class  student_count  all_pass
0         A          42         Yes
1         A          35         Yes
2         A          42         Yes
3         B          50          No
4         C          47          No
5         D          45         Yes
6         E          51         True
```

Find and Replace

Excel’s Find dialog takes you to cells that match, one by one. In pandas, this operation is generally done for an entire column or DataFrame at once through conditional expressions.

```python
In [70]: tips
Out[70]:
       total_bill  tip  sex  smoker  day  time  size
       67   1.07  1.00  Female   Yes  Sat  Dinner  1
       92   3.75  1.00  Female   Yes  Fri  Dinner  2
      111   5.25  1.00  Female    No  Sat  Dinner  1
      145   6.35  1.50  Female    No  Thur  Lunch  2
      135   6.51  1.25  Female    No  Thur  Lunch  2
       ...    ...    ...       ...    ...    ...    ...
    182   43.35  3.50    Male   Yes  Sun  Dinner  3
    156   46.17  5.00    Male    No  Sun  Dinner  6
```
In [71]: tips == "Sun"

Out[71]:

<table>
<thead>
<tr>
<th></th>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>False</td>
<td>False</td>
<td>False</td>
<td>False</td>
<td>False</td>

(continues on next page)
Comparison with SAS

For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Data structures

**General terminology translation**

<table>
<thead>
<tr>
<th>pandas</th>
<th>SAS</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame</td>
<td>data set</td>
</tr>
<tr>
<td>column</td>
<td>variable</td>
</tr>
<tr>
<td>row</td>
<td>observation</td>
</tr>
<tr>
<td>groupby</td>
<td>BY-group</td>
</tr>
<tr>
<td>NaN</td>
<td>.</td>
</tr>
</tbody>
</table>

**DataFrame**

A **DataFrame** in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS’s **DATA** step, can also be accomplished in pandas.

**Series**

A **Series** is the data structure that represents one column of a **DataFrame**. SAS doesn’t have a separate data structure for a single column, but in general, working with a **Series** is analogous to referencing a column in the **DATA** step.
Index

Every DataFrame and Series has an Index - which are labels on the rows of the data. SAS does not have an exactly analogous concept. A data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed during the DATA step (_N_).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

**Note:** You will see an inplace=True keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```

Its use is discouraged. More information.

Data input / output

Constructing a DataFrame from values

A SAS data set can be built from specified values by placing the data after a datalines statement and specifying the column names.

```sas
data df;
  input x y;
datalines;
  1 2
  3 4
  5 6
;run;
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```python
In [1]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
In [2]: df
```
Reading external data

Like SAS, pandas provides utilities for reading in data from many formats. The tips dataset, found within the pandas tests (csv) will be used in many of the following examples.

SAS provides PROC IMPORT to read csv data into a data set.

```
proc import datafile='tips.csv' dbms=csv out=tips replace;
  getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```
In [3]: url = (
    ...:   "https://raw.github.com/pandas-dev/
    ...:   "pandas/main/pandas/tests/io/data/csv/tips.csv"
    ...: )
    ...

In [4]: tips = pd.read_csv(url)

In [5]: tips
Out[5]:
   total_bill  tip  sex  smoker  day   time  size
0     16.99  1.01  Female   No   Sun  Dinner    2
1     10.34  1.66  Male      No   Sun  Dinner    3
2     21.01  3.50  Male      No   Sun  Dinner    3
3     23.68  3.31  Male      No   Sun  Dinner    2
4     24.59  3.61  Female   No   Sun  Dinner    4
    ...   ...     ...    ...    ...     ...    ...
239   29.03  5.92  Male      No   Sat  Dinner    3
240   27.18  2.00  Female     Yes   Sat  Dinner    2
241   22.67  2.00  Male      Yes   Sat  Dinner    2
242   17.82  1.75  Male      No   Sat  Dinner    2
243   18.78  3.00  Female   No   Thur  Dinner    2
[244 rows x 7 columns]
```

Like PROC IMPORT, read_csv can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv("tips.csv", sep="\t", header=None)
```
In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a `pd.read_*` function. See the IO documentation for more details.

**Limiting output**

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using `DataFrame.head()` or `DataFrame.tail()`.

```python
In [1]: tips.head(5)
Out[1]:
   total_bill  tip  sex     smoker  day  time  size
0      16.99  1.01 Female     No  Sun  Dinner   2
1      10.34  1.66   Male      No  Sun  Dinner   3
2      21.01  3.50   Male      No  Sun  Dinner   3
3      23.68  3.31   Male      No  Sun  Dinner   2
4      24.59  3.61 Female     No  Sun  Dinner   4
```

The equivalent in SAS would be:

```sas
proc print data=df(obs=5); run;
```

**Exporting data**

The inverse of PROC IMPORT in SAS is PROC EXPORT

```sas
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of `read_csv` is `to_csv()`, and other data formats follow a similar api.

```python
tips.to_csv("tips2.csv")
```

**Data operations**

**Operations on columns**

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```python
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the DataFrame.
In [1]: tips["total_bill"] = tips["total_bill"] - 2

In [2]: tips["new_bill"] = tips["total_bill"] / 2

In [3]: tips

Out[3]:
   total_bill  tip  sex  smoker  day  time  size  new_bill
0    14.99  1.01  Female  No  Sun  Dinner  2   7.495
1     8.34  1.66   Male  No  Sun  Dinner  3   4.170
2    19.01  3.50   Male  No  Sun  Dinner  3   9.505
3    21.68  3.31   Male  No  Sun  Dinner  2  10.840
4    22.59  3.61  Female  No  Sun  Dinner  4  11.295
...     ...     ...     ...    ...    ...    ...   ...
239  27.03  5.92   Male  No  Sat  Dinner  3  13.515
240  25.18  2.00  Female  Yes  Sat  Dinner  2  12.590
241  20.67  2.00   Male  Yes  Sat  Dinner  2  10.335
242  15.82  1.75   Male  No  Sat  Dinner  2   7.910
243  16.78  3.00  Female  No  Thur  Dinner  2   8.390

[244 rows x 8 columns]

In [4]: tips = tips.drop("new_bill", axis=1)

Filtering

Filtering in SAS is done with an if or where statement, on one or more columns.

```plaintext
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
  /* equivalent in this case - where happens before the
     DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

In [1]: tips[tips["total_bill"] > 10]

Out[1]:
   total_bill  tip  sex  smoker  day  time  size
0    14.99  1.01  Female  No  Sun  Dinner  2
2    19.01  3.50   Male  No  Sun  Dinner  3
3    21.68  3.31   Male  No  Sun  Dinner  2
4    22.59  3.61  Female  No  Sun  Dinner  4
5    23.29  4.71   Male  No  Sun  Dinner  4
...     ...     ...     ...    ...    ...    ...
239  27.03  5.92   Male  No  Sat  Dinner  3
240  25.18  2.00  Female  Yes  Sat  Dinner  2

(continues on next page)
The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [1]: is_dinner = tips["time"] == "Dinner"

In [2]: is_dinner
Out[2]:
0   True
1   True
2   True
3   True
4   True
   ...  
239  True
240  True
241  True
242  True
243  True
Name: time, Length: 244, dtype: bool

In [3]: is_dinner.value_counts()
Out[3]:
True   176
False  68
Name: time, dtype: int64

In [4]: tips[is_dinner]
Out[4]:
   total_bill  tip  sex  smoker  day  time  size
0     14.99  1.01 Female   No  Sun  Dinner  2
1      8.34  1.66    Male   No  Sun  Dinner  3
2     19.01  3.50    Male   No  Sun  Dinner  3
3     21.68  3.31    Male   No  Sun  Dinner  2
4     22.59  3.61 Female   No  Sun  Dinner  4
   ...    ...     ...    ...   ...    ...   ...
239  27.03  5.92    Male   No  Sat  Dinner  3
240  25.18  2.00 Female   Yes  Sat  Dinner  2
241  20.67  2.00    Male   Yes  Sat  Dinner  2
242  15.82  1.75    Male   No  Sat  Dinner  2
243  16.78  3.00 Female   No  Thur  Dinner  2
[176 rows x 7 columns]
If/then logic

In SAS, if/then logic can be used to create new columns.

```sas
data tips;
  set tips;
  format bucket $4.;
  if total_bill < 10 then bucket = 'low';
  else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```python
In [1]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```python
In [2]: tips
Out[2]:
         total_bill  tip  sex   smoker  day    time  size  bucket
0       14.99  1.01 Female        No  Sun  Dinner   2    high
1        8.34  1.66      Male        No  Sun  Dinner   3      low
2       19.01  3.50      Male        No  Sun  Dinner   3    high
3       21.68  3.31      Male        No  Sun  Dinner   2    high
4       22.59  3.61 Female        No  Sun  Dinner   4    high
..        ...    ...      ...        ...  ...    ...    ...  ...
239      27.03  5.92      Male        No  Sat  Dinner   3    high
240      25.18  2.00 Female       Yes  Sat  Dinner   2    high
241      20.67  2.00      Male       Yes  Sat  Dinner   2    high
242      15.82  1.75      Male        No  Sat  Dinner   2    high
243      16.78  3.00 Female        No  Thur  Dinner   2    high
[244 rows x 8 columns]
```

Date functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```sas
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmddyy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  /* shift date to beginning of next interval; */
  date1_next = intnx('MONTH', date1, 1);
  /* count intervals between dates; */
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the `timeseries documentation` for more details.
In [1]: tips["date1"] = pd.Timestamp("2013-01-15")
In [2]: tips["date2"] = pd.Timestamp("2015-02-15")
In [3]: tips["date1_year"] = tips["date1"].dt.year
In [4]: tips["date2_month"] = tips["date2"].dt.month
In [5]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [6]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"][...].dt.to_period("M")
In [7]: tips["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]
Out[7]:
    date1    date2 date1_year date2_month  date1_next  months_between
   0 2013-01-15 2015-02-15  2013          2  2013-02-01       <25 * MonthEnds>

[244 rows x 6 columns]

Selection of columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

data tips;
    set tips;
    keep sex total_bill tip;
run;

data tips;
    set tips;
    drop sex;
run;
data tips;
The same operations are expressed in pandas below.

Keep certain columns

```python
In [1]: tips["sex", "total_bill", "tip"]
Out[1]:
   sex  total_bill  tip
0  Female    14.99  1.01
1      Male     8.34  1.66
2      Male    19.01  3.50
3      Male   21.68  3.31
4  Female    22.59  3.61
   ...     ...    ...  
239     Male   27.03  5.92
240    Female   25.18  2.00
241      Male   20.67  2.00
242      Male   15.82  1.75
243    Female   16.78  3.00
[244 rows x 3 columns]
```

Drop a column

```python
In [2]: tips.drop("sex", axis=1)
Out[2]:
   total_bill  tip  smoker  day  time  size
0     14.99  1.01   No  Sun  Dinner   2
1      8.34  1.66   No  Sun  Dinner   3
2     19.01  3.50   No  Sun  Dinner   3
3    21.68  3.31   No  Sun  Dinner   2
4    22.59  3.61   No  Sun  Dinner   4
   ...    ...    ...    ...    ...    ...
239  27.03  5.92   No  Sat  Dinner   3
240  25.18  2.00   Yes  Sat  Dinner   2
241  20.67  2.00   Yes  Sat  Dinner   2
242  15.82  1.75   No  Sat  Dinner   2
243  16.78  3.00   No  Thur  Dinner   2
[244 rows x 6 columns]
```
Rename a column

```python
In [1]: tips.rename(columns={"total_bill": "total_bill_2"})
Out[1]:
   total_bill_2  tip  sex  smoker day  time  size
0       14.99  1.01  Female  No  Sun  Dinner  2
1        8.34  1.66     Male  No  Sun  Dinner  3
2       19.01  3.50     Male  No  Sun  Dinner  3
3       21.68  3.31     Male  No  Sun  Dinner  2
4       22.59  3.61    Female  No  Sun  Dinner  4
   ...     ...     ...     ...   ...    ...    ...
239    27.03  5.92     Male  No  Sat  Dinner  3
240    25.18  2.00    Female  Yes  Sat  Dinner  2
241    20.67  2.00     Male  Yes  Sat  Dinner  2
242    15.82  1.75     Male  No  Sat  Dinner  2
243    16.78  3.00    Female  No  Thur  Dinner  2
```

[244 rows x 7 columns]

Sorting by values

Sorting in SAS is accomplished via PROC SORT

```sas
proc sort data=tips;
   by sex total_bill;
run;
```

pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```python
In [1]: tips = tips.sort_values(["sex", "total_bill"])
In [2]: tips
Out[2]:
   total_bill  tip  sex  smoker day  time  size
67        1.07  1.00  Female  Yes  Sat  Dinner  1
92        3.75  1.00  Female  Yes  Fri  Dinner  2
111       5.25  1.00  Female  No  Sat  Dinner  1
145       6.35  1.50  Female  No  Thur  Lunch  2
135       6.51  1.25  Female  No  Thur  Lunch  2
   ...     ...     ...     ...   ...    ...    ...
192        3.50  5.50     Male  Yes  Sun  Dinner  3
156       4.17  5.00     Male  No  Sun  Dinner  6
59        4.27  6.73     Male  No  Sat  Dinner  4
212       4.33  9.00     Male  No  Sat  Dinner  4
170       4.81 10.00     Male  Yes  Sat  Dinner  3
```

[244 rows x 7 columns]
**String processing**

**Finding length of string**

SAS determines the length of a character string with the `LENGTHN` and `LENGTHC` functions. `LENGTHN` excludes trailing blanks and `LENGTHC` includes trailing blanks.

```sas
data _null_;
set tips;
put(LENGTHN(time));
put(LENGTHC(time));
run;
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```python
In [1]: tips["time"].str.len()
Out[1]:
   67    6
   92    6
  111    6
  145    5
  135    5
   ... 
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64

In [2]: tips["time"].str.rstrip().str.len()
Out[2]:
   67    6
   92    6
  111    6
  145    5
  135    5
   ... 
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64
```
Finding position of substring

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```python
data _null_;
set tips;
put(FINDW(sex,'ale'));
run;
```

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```
In [1]: tips["sex"].str.find("ale")
Out[1]:
       67      92     111     145     135      ..     182     156      59     212     170
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```python
data _null_;
set tips;
put(substr(sex,1,1));
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [1]: tips["sex"][0:1]
Out[1]:
       67      92     111     145     135      ..     182     156      59
Name: sex, Length: 244, dtype: object
```

(continues on next page)
Extracting nth word

The SAS SCAN function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```sas
data firstlast;
  input String $60.;
  First_Name = scan(string, 1);
  Last_Name = scan(string, -1);
datalines2;
  John Smith;
  Jane Cook;
 run;
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```python
In [1]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})

In [2]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]

In [3]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[1]

In [4]: firstlast
Out[4]:
```
```
<table>
<thead>
<tr>
<th>String</th>
<th>First_Name</th>
<th>Last_Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>John Smith</td>
<td>John</td>
<td>Smith</td>
</tr>
<tr>
<td>Jane Cook</td>
<td>Jane</td>
<td>Cook</td>
</tr>
</tbody>
</table>
```

Changing case

The SAS UPCASE LOWCASE and PROPCASE functions change the case of the argument.

```sas
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
  John Smith;
  Jane Cook;
 run;
```

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.
In [1]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})

In [2]: firstlast["upper"] = firstlast["string"].str.upper()

In [3]: firstlast["lower"] = firstlast["string"].str.lower()

In [4]: firstlast["title"] = firstlast["string"].str.title()

In [5]: firstlast

Out[5]:
<table>
<thead>
<tr>
<th></th>
<th>string</th>
<th>upper</th>
<th>lower</th>
<th>title</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>John Smith</td>
<td>JOHN SMITH</td>
<td>john smith</td>
<td>John Smith</td>
</tr>
<tr>
<td>1</td>
<td>Jane Cook</td>
<td>JANE COOK</td>
<td>jane cook</td>
<td>Jane Cook</td>
</tr>
</tbody>
</table>

**Merging**

The following tables will be used in the merge examples:

In [1]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})

In [2]: df1

Out[2]:
<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.469112</td>
</tr>
<tr>
<td>B</td>
<td>-0.282863</td>
</tr>
<tr>
<td>C</td>
<td>-1.509059</td>
</tr>
<tr>
<td>D</td>
<td>-1.135632</td>
</tr>
</tbody>
</table>

In [3]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})

In [4]: df2

Out[4]:
<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>1.212112</td>
</tr>
<tr>
<td>D</td>
<td>-0.173215</td>
</tr>
<tr>
<td>D</td>
<td>0.119209</td>
</tr>
<tr>
<td>E</td>
<td>-1.044236</td>
</tr>
</tbody>
</table>

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the in= dummy variables to track whether a match was found in one or both input frames.

```python
proc sort data=df1;
  by key;
run;

proc sort data=df2;
  by key;
run;

data left_join inner_join right_join outer_join;
  merge df1(in=a) df2(in=b);
```

(continues on next page)
if a and b then output inner_join;
if a then output left_join;
if b then output right_join;
if a or b then output outer_join;
run;

Pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```python
In [1]: inner_join = df1.merge(df2, on="key", how="inner")
In [2]: inner_join
Out[2]:
   key  value_x  value_y
0  B -0.282863  1.212112
1  D -1.135632 -0.173215
2  D -1.135632  0.119209

In [3]: left_join = df1.merge(df2, on="key", how="left")
In [4]: left_join
Out[4]:
   key  value_x  value_y
0  A  0.469112   NaN
1  B -0.282863  1.212112
2  C -1.509059  NaN
3  D -1.135632 -0.173215
4  D -1.135632  0.119209

In [5]: right_join = df1.merge(df2, on="key", how="right")
In [6]: right_join
Out[6]:
   key  value_x  value_y
0  B -0.282863  1.212112
1  D -1.135632 -0.173215
2  D -1.135632  0.119209
3  E   NaN    -1.044236

In [7]: outer_join = df1.merge(df2, on="key", how="outer")
In [8]: outer_join
Out[8]:
   key  value_x  value_y
0  A  0.469112   NaN
1  B -0.282863  1.212112
2  C -1.509059  NaN
3  D -1.135632 -0.173215
4  D -1.135632  0.119209
5  E   NaN    -1.044236
```
Missing data

Both pandas and SAS have a representation for missing data. pandas represents missing data with the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [1]: outer_join
Out[1]:
   key  value_x  value_y
0   A    0.469112     NaN
1   B  -0.282863  1.212112
2   C   -1.509059     NaN
3   D   -1.135632 -0.173215
4   D   -1.135632  0.119209
5   E     NaN      -1.044236

In [2]: outer_join["value_x"] + outer_join["value_y"]
Out[2]:
   0    NaN
1  0.929249
2     NaN
3 -1.016424
4    NaN
dtype: float64

In [3]: outer_join["value_x"].sum()
Out[3]:    -3.5940742896293765
```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```
data outer_join_nulls;
  set outer_join;
  if value_x = .;
run;

data outer_join_no_nulls;
  set outer_join;
  if value_x ^= .;
run;
```

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

```
In [1]: outer_join[outer_join["value_x"].isna()]
Out[1]:
   key  value_x  value_y
5   E     NaN      -1.044236

In [2]: outer_join[outer_join["value_x"].notna()]
Out[2]:
   key  value_x  value_y
0   A    0.469112     NaN
```

(continues on next page)
pandas provides a variety of methods to work with missing data. Here are some examples:

### Drop rows with missing values

```python
In [3]: outer_join.dropna()
Out[3]:
     key  value_x  value_y
  1    B   -0.282863   1.212112
  3    D   -1.135632  -0.173215
  4    D   -1.135632    0.119209
```

### Forward fill from previous rows

```python
In [4]: outer_join.fillna(method="ffill")
Out[4]:
     key  value_x  value_y
  0    A    0.469112     NaN
  1    B   -0.282863   1.212112
  2    C   -1.509059   1.212112
  3    D   -1.135632  -0.173215
  4    D   -1.135632    0.119209
  5    E   -1.135632 -1.044236
```

### Replace missing values with a specified value

Using the mean:

```python
In [1]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
Out[1]:
0    0.469112
1   -0.282863
2  -1.509059
3  -1.135632
4  -1.135632
5   -0.718815
Name: value_x, dtype: float64
```
**GroupBy**

**Aggregation**

SAS’s PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```sas
proc summary data=tips nway;
    class sex smoker;
    var total_bill tip;
    output out=tips_summed sum=;
run;
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the groupby documentation for more details and examples.

In [1]: tips_summed = tips.groupby(["sex", "smoker"])[["total_bill", "tip"]].sum()

In [2]: tips_summed

Out[2]:
<table>
<thead>
<tr>
<th>sex</th>
<th>smoker</th>
<th>total_bill</th>
<th>tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>No</td>
<td>869.68</td>
<td>149.77</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>527.27</td>
<td>96.74</td>
</tr>
<tr>
<td>Male</td>
<td>No</td>
<td>1725.75</td>
<td>302.00</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>1217.07</td>
<td>183.07</td>
</tr>
</tbody>
</table>

**Transformation**

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```sas
proc summary data=tips missing nway;
    class smoker;
    var total_bill;
    output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
    by smoker;
run;

data tips;
    merge tips(in=a) smoker_means(in=b);
    by smoker;
    adj_total_bill = total_bill - group_bill;
    if a and b;
run;
```

pandas provides a Transformation mechanism that allows these type of operations to be succinctly expressed in one operation.
In [1]: gb = tips.groupby("smoker")["total_bill"]

In [2]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")

In [3]: tips

Out[3]:

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>adj_total_bill</th>
</tr>
</thead>
<tbody>
<tr>

<td>3</td>
<td>30.053656</td>
</tr>
</tbody>
</table>

[244 rows x 8 columns]

By group processing

In addition to aggregation, pandas groupby can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```
proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;
```

In pandas this would be written as:

```
In [4]: tips.groupby(["sex", "smoker"]).first()

Out[4]:

<table>
<thead>
<tr>
<th>sex</th>
<th>smoker</th>
<th>total_bill</th>
<th>tip</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>adj_total_bill</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>No</td>
<td>5.25</td>
<td>1.00</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
<td>-11.938278</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>1.07</td>
<td>1.00</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
<td>-17.686344</td>
</tr>
<tr>
<td>Male</td>
<td>No</td>
<td>5.51</td>
<td>2.00</td>
<td>Thur</td>
<td>Lunch</td>
<td>2</td>
<td>-11.678278</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>5.25</td>
<td>5.15</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
<td>-13.506344</td>
</tr>
</tbody>
</table>
```
Other considerations

Disk vs memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine’s memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the dask.dataframe library (currently in development) which provides a subset of pandas functionality for an on-disk DataFrame.

Data interop

pandas provides a read_sas() method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```python
libname xportout xport 'transport-file.xpt';
data xportout.tips;
  set tips(rename=(total_bill=tbill));
  * xport variable names limited to 6 characters;
run;

df = pd.read_sas("transport-file.xpt")
df = pd.read_sas("binary-file.sas7bdat")
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```python
df = pd.read_sas("transport-file.xpt", format="xport")
df = pd.read_sas("binary-file.sas7bdat", format="sas7bdat")
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```text
# version 0.17, 10M rows
In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s
In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

Comparison with Stata

For potential users coming from Stata this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you’re new to pandas, you might want to first read through 10 Minutes to pandas to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```
Data structures

General terminology translation

</table>

DataFrame

A DataFrame in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

Series

A Series is the data structure that represents one column of a DataFrame. Stata doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column of a data set in Stata.

Index

Every DataFrame and Series has an Index – labels on the rows of the data. Stata does not have an exactly analogous concept. In Stata, a data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed with _n.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

Note: You will see an inplace=True keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```
Data input / output

Constructing a DataFrame from values

A Stata data set can be built from specified values by placing the data after an input statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
```

```
In [4]: df
Out[4]:
x y
0 1 2
1 3 4
2 5 6
```

Reading external data

Like Stata, pandas provides utilities for reading in data from many formats. The tips data set, found within the pandas tests (csv) will be used in many of the following examples.

Stata provides import delimited to read csv data into a data set in memory. If the tips.csv file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is read_csv(), which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = (  
...:     "https://raw.github.com/pandas-dev"  
...:     "/pandas/main/pandas/tests/io/data/csv/tips.csv"  
...: )  
...:  
In [6]: tips = pd.read_csv(url)
```

```
In [7]: tips
Out[7]:
total_bill  tip  sex smoker  day  time  size
```
Like `import delimited, read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```python
# alternatively, read_table is an alias to read_csv with tab delimiter
```

```
tips = pd.read_table("tips.csv", header=None)
```

Pandas can also read Stata data sets in `.dta` format with the `read_stata()` function.

```
df = pd.read_stata("data.dta")
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the IO documentation for more details.

### Limiting output

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using `DataFrame.head()` or `DataFrame.tail()`.

```
In [8]: tips.head(5)
```

```
Out[8]:
    total_bill  tip  sex  smoker  day  time  size
 0   16.990  1.01  Female   No   Sun  Dinner   2
 1   10.340  1.66   Male   No   Sun  Dinner   3
 2   21.010  3.50   Male   No   Sun  Dinner   3
 3   23.680  3.31   Male   No   Sun  Dinner   2
 4   24.590  3.61  Female   No   Sun  Dinner   4
```

The equivalent in Stata would be:

```
list in 1/5
```
**Exporting data**

The inverse of `import delimited` in Stata is `export delimited`

Syntax: `export delimited tips2.csv`

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```python
tips.to_csv("tips2.csv")
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```python
tips.to_stata("tips2.dta")
```

**Data operations**

**Operations on columns**

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

Pandas provides vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.

```
In [9]: tips["total_bill"] = tips["total_bill"] - 2
In [10]: tips["new_bill"] = tips["total_bill"] / 2
In [11]: tips
Out[11]:
       total_bill  tip  sex  smoker  day  time  size  new_bill
0       14.99  1.01  Female       No  Sun  Dinner  2  7.495
1       8.34  1.66   Male       No  Sun  Dinner  3  4.170
2      19.01  3.50   Male       No  Sun  Dinner  3  9.505
3      21.68  3.31   Male       No  Sun  Dinner  2 10.840
4      22.59  3.61  Female       No  Sun  Dinner  4 11.295
...     ...   ...     ...     ...     ...     ...     ...
239    27.03  5.92   Male       No  Sat  Dinner  3 13.515
240    25.18  2.00  Female      Yes  Sat  Dinner  2 12.590
241    20.67  2.00   Male      Yes  Sat  Dinner  2 10.335
242    15.82  1.75   Male       No  Sat  Dinner  2  7.910
243    16.78  3.00  Female       No  Thur  Dinner  2  8.390

[244 rows x 8 columns]
```

```
In [12]: tips = tips.drop("new_bill", axis=1)
```
Filtering

Filtering in Stata is done with an \texttt{if} clause on one or more columns.

\begin{verbatim}
list if total_bill > 10
\end{verbatim}

DataFrames can be filtered in multiple ways; the most intuitive of which is using \textit{boolean indexing}.

\begin{verbatim}
In [13]: tips[tips["total_bill"] > 10]
Out[13]:
  total_bill   tip    sex smoker day time size
0     14.99  1.01  Female       No  Sun Dinner  2
2     19.01  3.50    Male       No  Sun Dinner  3
3     21.68  3.31    Male       No  Sun Dinner  2
4     22.59  3.61  Female       No  Sun Dinner  4
5     23.29  4.71    Male       No  Sun Dinner  4
...        ...      ...        ...  ...  ... ...
239  27.03  5.92    Male       No  Sat Dinner  3
240  25.18  2.00  Female       Yes  Sat Dinner  2
241  20.67  2.00    Male       Yes  Sat Dinner  2
242  15.82  1.75    Male       No  Sat Dinner  2
243  16.78  3.00  Female       No  Thur Dinner  2
[204 rows x 7 columns]
\end{verbatim}

The above statement is simply passing a \texttt{Series} of \texttt{True}/\texttt{False} objects to the DataFrame, returning all rows with \texttt{True}.

\begin{verbatim}
In [14]: is_dinner = tips["time"] == "Dinner"

In [15]: is_dinner
Out[15]:
0    True
1    True
2    True
3    True
4    True
...  ...
239   True
240   True
241   True
242   True
243   True
Name: time, Length: 244, dtype: bool

In [16]: is_dinner.value_counts()
Out[16]:
True    176
False     68
Name: time, dtype: int64

In [17]: tips[is_dinner]
Out[17]:
\end{verbatim}
total_bill  tip  sex  smoker  day  time  size  bucket
0   14.99  1.01  Female  No  Sun  Dinner  2   high
1    8.34  1.66   Male  No  Sun  Dinner  3   low
2   19.01  3.50   Male  No  Sun  Dinner  3   high
3   21.68  3.31   Male  No  Sun  Dinner  2   high
4   22.59  3.61  Female  No  Sun  Dinner  4   high
..   ...  ...     ...  ...  ...  ...  ...  ...
239  27.03  5.92   Male  No  Sat  Dinner  3   high
240  25.18  2.00  Female   Yes  Sat  Dinner  2   high
241  20.67  2.00   Male   Yes  Sat  Dinner  2   high
242  15.82  1.75   Male  No  Sat  Dinner  2   high
243  16.78  3.00  Female  No  Thur  Dinner  2   high
[176 rows x 8 columns]

**If/then logic**

In Stata, an if clause can also be used to create new columns.

```
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```
In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
In [19]: tips
Out[19]:
      total_bill  tip  sex  smoker  day  time  size  bucket
     0      14.99  1.01  Female   No  Sun  Dinner  2      high
     1       8.34  1.66    Male   No  Sun  Dinner  3       low
     2      19.01  3.50    Male   No  Sun  Dinner  3      high
     3      21.68  3.31    Male   No  Sun  Dinner  2      high
     4      22.59  3.61  Female   No  Sun  Dinner  4      high
     ..    ...     ...     ...   ...     ...     ...   ...
239    27.03  5.92    Male   No  Sat  Dinner  3      high
240    25.18  2.00  Female    Yes  Sat  Dinner  2      high
241    20.67  2.00    Male    Yes  Sat  Dinner  2      high
242    15.82  1.75    Male   No  Sat  Dinner  2      high
243    16.78  3.00  Female   No  Thur  Dinner  2      high
[244 rows x 8 columns]
Date functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```stata
* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the timeseries documentation for more details.

```python
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"].dt.to_period("M")
```

```
Out[26]:
   date1    date2  date1_year  date2_month  date1_next  months_between
0 2013-01-15 2015-02-15  2013     2  2013-02-01 <25 * MonthEnds>
   ...     ...       ...       ...       ...       ...
```

(continues on next page)
Selection of columns

Stata provides keywords to select, drop, and rename columns.

```plaintext
keep sex total_bill tip
drop sex
rename total_bill total_bill_2
```

The same operations are expressed in pandas below.

Keep certain columns

```python
In [27]: tips["sex", "total_bill", "tip"]
Out[27]:
      sex  total_bill  tip
   0  Female     14.99  1.01
   1   Male       8.34  1.66
   2   Male      19.01  3.50
   3   Male      21.68  3.31
   4  Female      22.59  3.61
   ..     ...      ...  ...
  239  Male      27.03  5.92
  240  Female     25.18  2.00
  241   Male      20.67  2.00
  242   Male      15.82  1.75
  243  Female     16.78  3.00
[244 rows x 3 columns]
```

Drop a column

```python
In [28]: tips.drop("sex", axis=1)
Out[28]:
       total_bill  tip  smoker  day  time  size
   0    14.99  1.01  No  Sun  Dinner   2
   1     8.34  1.66  No  Sun  Dinner   3
   2    19.01  3.50  No  Sun  Dinner   3
   3    21.68  3.31  No  Sun  Dinner   2
   4    22.59  3.61  No  Sun  Dinner   4
   ...    ...    ...    ...    ...    ...
  239   27.03  5.92  Yes  Sat  Dinner   3
  240  25.18  2.00   Yes  Sat  Dinner   2
[244 rows x 6 columns]
```
Rename a column

```
In [29]: tips.rename(columns={"total_bill": "total_bill_2"})
Out[29]:
   total_bill_2  tip  sex  smoker  day  time  size
0      14.99  1.01  Female   No   Sun  Dinner  2
1       8.34  1.66    Male   No   Sun  Dinner  3
2      19.01  3.50    Male   No   Sun  Dinner  3
3      21.68  3.31    Male   No   Sun  Dinner  2
4      22.59  3.61  Female   No   Sun  Dinner  4
...     ...     ...     ...     ...     ...     ...
239  27.03  5.92    Male   No  Sat  Dinner  3
240  25.18  2.00  Female   Yes  Sat  Dinner  2
241  20.67  2.00    Male   Yes  Sat  Dinner  2
242  15.82  1.75    Male   No  Sat  Dinner  2
243  16.78  3.00  Female   No  Thur  Dinner  2
[244 rows x 7 columns]
```

Sorting by values

Sorting in Stata is accomplished via `sort`:

```
sort sex total_bill
```

Pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [30]: tips = tips.sort_values(["sex", "total_bill"])
In [31]: tips
Out[31]:
   total_bill  tip  sex  smoker  day  time  size
67     1.07  1.00  Female   Yes   Sat  Dinner  1
92     3.75  1.00  Female   Yes   Fri  Dinner  2
111    5.25  1.00  Female   No  Sat  Dinner  1
145    6.35  1.50  Female   No  Thur  Lunch  2
135    6.51  1.25  Female   No  Thur  Lunch  2
...     ...     ...     ...     ...     ...     ...
182    4.35  3.50    Male   Yes   Sun  Dinner  3
156    4.67  5.00    Male   No  Sun  Dinner  6
159    4.26  6.73    Male   No  Sat  Dinner  4
212    4.63  9.00    Male   No  Sat  Dinner  4
170    4.81  10.00   Female   Yes  Sat  Dinner  3
[182 rows x 7 columns]
```
String processing

Finding length of string

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```plaintext
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```plaintext
In [32]: tips["time"].str.len()
Out[32]:
67    6
92    6
111   6
145   5
135   5
   ...
182   6
156   6
59    6
212   6
170   6
Name: time, Length: 244, dtype: int64

In [33]: tips["time"].str.rstrip().str.len()
Out[33]:
67    6
92    6
111   6
145   5
135   5
   ...
182   6
156   6
59    6
212   6
170   6
Name: time, Length: 244, dtype: int64
```
Finding position of substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```python
generate str_position = strpos(sex, "ale")
```

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```python
In [34]: tips["sex"].str.find("ale")
Out[34]:
67   3
92   3
111  3
145  3
135  3
   ...
182  1
156  1
59   1
212  1
170  1
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

Stata extracts a substring from a string based on its position with the `substr()` function.

```python
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```python
In [35]: tips["sex"][0:1]
Out[35]:
67   F
92   F
111  F
145  F
135  F
   ...
182  M
156  M
59   M
212  M
170  M
Name: sex, Length: 244, dtype: object
```
Extracting nth word

The Stata `word()` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```stata
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```python
In [36]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})
In [37]: firstlast['First_Name'] = firstlast['String'].str.split(' ', expand=True)[0]
In [38]: firstlast['Last_Name'] = firstlast['String'].str.rsplit(' ', expand=True)[1]
In [39]: firstlast
Out[39]:
<table>
<thead>
<tr>
<th>String</th>
<th>First_Name</th>
<th>Last_Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 John Smith</td>
<td>John</td>
<td>Smith</td>
</tr>
<tr>
<td>1 Jane Cook</td>
<td>Jane</td>
<td>Cook</td>
</tr>
</tbody>
</table>
```

Changing case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```stata
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list
```

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```python
In [40]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})
In [41]: firstlast['upper'] = firstlast['string'].str.upper()
In [42]: firstlast['lower'] = firstlast['string'].str.lower()
(continues on next page)
In [43]: `firstlast["title"] = firstlast["string"] . str . title()`

In [44]: `firstlast`

Out[44]:

<table>
<thead>
<tr>
<th>string</th>
<th>upper</th>
<th>lower</th>
<th>title</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>John Smith</td>
<td>JOHN SMITH</td>
<td>John Smith</td>
</tr>
<tr>
<td>1</td>
<td>Jane Cook</td>
<td>JANE COOK</td>
<td>Jane Cook</td>
</tr>
</tbody>
</table>

**Merging**

The following tables will be used in the merge examples:

In [45]: `df1 = pd.DataFrame("key": ["A", "B", "C", "D"], "value": np.random.randn(4))`

In [46]: `df1`

Out[46]:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.469112</td>
</tr>
<tr>
<td>1</td>
<td>-0.282863</td>
</tr>
<tr>
<td>2</td>
<td>-1.509059</td>
</tr>
<tr>
<td>3</td>
<td>-1.135632</td>
</tr>
</tbody>
</table>

In [47]: `df2 = pd.DataFrame("key": ["B", "D", "D", "E"], "value": np.random.randn(4))`

In [48]: `df2`

Out[48]:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.212112</td>
</tr>
<tr>
<td>1</td>
<td>-0.173215</td>
</tr>
<tr>
<td>2</td>
<td>0.119209</td>
</tr>
<tr>
<td>3</td>
<td>-1.044236</td>
</tr>
</tbody>
</table>

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both **DataFrames** already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the `_merge` variable.

* First create `df2` and save to disk

```stata
clear
input str1 key
  B
  D
  D
  E
end
generate value = rnormal()
save df2.dta
```

(continues on next page)
* Now create df1 in memory

```
clear
input str1 key
A
B
C
D
end
generate value = rnormal()
preserve
```

* Left join

```
merge 1:n key using df2.dta
keep if _merge == 1
```

* Right join

```
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2
```

* Inner join

```
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3
```

* Outer join

```
restore
merge 1:n key using df2.dta
```

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [49]: inner_join = df1.merge(df2, on="key", how="inner")

In [50]: inner_join
Out[50]:
     key   value_x  value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209

In [51]: left_join = df1.merge(df2, on="key", how="left")

In [52]: left_join
Out[52]:
     key   value_x  value_y
0   A  0.469112    NaN
1   B -0.282863  1.212112
2   C -1.509059    NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
```

(continues on next page)
In [53]: right_join = df1.merge(df2, on="key", how="right")

In [54]: right_join
Out[54]:
   key  value_x  value_y
0  B  -0.282863  1.212112
1  D  -1.135632 -0.173215
2  D  -1.135632  0.119209
3  E    NaN     -1.044236

In [55]: outer_join = df1.merge(df2, on="key", how="outer")

In [56]: outer_join
Out[56]:
   key  value_x  value_y
0  A   0.469112     NaN
1  B  -0.282863  1.212112
2  C  -1.509059     NaN
3  D  -1.135632 -0.173215
4  D  -1.135632  0.119209
5  E    NaN     -1.044236

Missing data

Both pandas and Stata have a representation for missing data.
pandas represents missing data with the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

In [57]: outer_join
Out[57]:
   key  value_x  value_y
0  A   0.469112     NaN
1  B  -0.282863  1.212112
2  C  -1.509059     NaN
3  D  -1.135632 -0.173215
4  D  -1.135632  0.119209
5  E    NaN     -1.044236

In [58]: outer_join["value_x"] + outer_join["value_y"]
Out[58]:
   0    NaN
   1  0.929249
   2    NaN
   3 -1.308847
   4 -1.016424
   5    NaN
dtype: float64

In [59]: outer_join["value_x"].sum()

(continues on next page)
One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```plaintext
* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .
```

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

```plaintext
In [60]: outer_join[outer_join["value_x"].isna()]
Out[60]:
   key  value_x  value_y
0   E        NaN   -1.044236

In [61]: outer_join[outer_join["value_x"].notna()]
Out[61]:
   key  value_x  value_y
0   A    0.469112   NaN
1   B   -0.282863  1.212112
2   C   -1.509059   NaN
3   D  -1.135632  -0.173215
4   D  -1.135632   0.119209
```

pandas provides a variety of methods to work with missing data. Here are some examples:

**Drop rows with missing values**

```plaintext
In [62]: outer_join.dropna()
Out[62]:
   key  value_x  value_y
0   A    0.469112   NaN
1   B   -0.282863  1.212112
2   C   -1.509059   NaN
3   D  -1.135632  -0.173215
4   D  -1.135632   0.119209
```

**Forward fill from previous rows**

```plaintext
In [63]: outer_join.fillna(method="ffill")
Out[63]:
   key  value_x  value_y
0   A    0.469112   NaN
1   B   -0.282863  1.212112
2   C   -1.509059  1.212112
3   D  -1.135632  -0.173215
4   D  -1.135632   0.119209
5   E  -1.135632  -1.044236
```
Replace missing values with a specified value

Using the mean:

```python
In [64]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
Out[64]:
0   0.469112
1  -0.282863
2  -1.509059
3  -1.135632
4  -1.135632
5  -0.718815
Name: value_x, dtype: float64
```

**GroupBy**

**Aggregation**

Stata's `collapse` can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the `groupby documentation` for more details and examples.

```python
In [65]: tips_summed = tips.groupby(["sex", "smoker"])["total_bill", "tip"].sum()
In [66]: tips_summed
Out[66]:
          total_bill  tip
   sex smoker         869.68  149.77
        Female  No     527.27   96.74
        Yes                   1725.75  302.00
        Male  No     1217.07  183.07
        Yes                   
```

**Transformation**

In Stata, if the group aggregations need to be used with the original data set, one would usually use `bysort with egen()`. For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas provides a `Transformation` mechanism that allows these type of operations to be succinctly expressed in one operation.

```python
In [67]: gb = tips.groupby("smoker")["total_bill"]
In [68]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")
```
In [69]: tips
Out[69]:

    total_bill  tip  sex  smoker  day  time  size  adj_total_bill
67       1.07  1.00 Female  Yes  Sat  Dinner  1   -17.686344
92       3.75  1.00 Female  Yes  Fri  Dinner  2   -15.006344
111      5.25  1.00 Female  Yes  Sat  Dinner  1   -11.938278
145      6.35  1.50 Female  No   Thur Lunch  2   -10.838278
135      6.51  1.25 Female  No   Thur Lunch  2   -10.678278
         ... ... ... ... ...     ...     ... ... ... ... ...
182      43.35 3.50 Male   Yes  Sun  Dinner  3   24.593656
156      46.17 5.00 Male   No   Sun  Dinner  6   28.981722
59       46.27 6.73 Male   No   Sat  Dinner  4   29.081722
212      46.33 9.00 Male   No   Sat  Dinner  4   29.141722
170      48.81 10.00 Male  Yes  Sat  Dinner  3   30.053656
[244 rows x 8 columns]

By group processing

In addition to aggregation, pandas `groupby` can be used to replicate most other `bysort` processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

    bysort sex smoker: list if _n == 1

In pandas this would be written as:

In [70]: tips.groupby(["sex", "smoker"]).first()
Out[70]:

    total_bill  tip  day  time  size  adj_total_bill
    sex  smoker
    Female No  5.25  1.00  Sat  Dinner  1   -11.938278
    Yes      1.07  1.00  Sat  Dinner  1   -17.686344
    Male No  5.51  2.00  Thur Lunch  2   -11.678278
    Yes      5.25  5.15  Sun  Dinner  2   -13.506344

Other considerations

Disk vs memory

pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine’s memory. If out of core processing is needed, one possibility is the `dask.dataframe` library, which provides a subset of pandas functionality for an on-disk DataFrame.
1.4.5 Community tutorials

This is a guide to many pandas tutorials by the community, geared mainly for new users.

pandas cookbook by Julia Evans

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the pandas-cookbook GitHub repository.

pandas workshop by Stefanie Molin

An introductory workshop by Stefanie Molin designed to quickly get you up to speed with pandas using real-world datasets. It covers getting started with pandas, data wrangling, and data visualization (with some exposure to matplotlib and seaborn). The pandas-workshop GitHub repository features detailed environment setup instructions (including a Binder environment), slides and notebooks for following along, and exercises to practice the concepts. There is also a lab with new exercises on a dataset not covered in the workshop for additional practice.

Learn pandas by Hernan Rojas

A set of lesson for new pandas users: https://bitbucket.org/hrojas/learn-pandas

Practical data analysis with Python

This guide is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as munging data, aggregating data, visualizing data and time series.

Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main repository.

Modern pandas

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository TomAugspurger/effective-pandas.

- Pandas and Python: Top 10, by Manish Amde
- Pandas DataFrames Tutorial, by Karlijn Willems
- A concise tutorial with real life examples
The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10min. For a high level summary of the pandas fundamentals, see *Intro to data structures* and *Essential basic functionality*. Further information on any specific method can be obtained in the *API reference*.

### 2.1 10 minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*. Customarily, we import as follows:

```python
In [1]: import numpy as np
In [2]: import pandas as pd
```

#### 2.1.1 Object creation

See the *Intro to data structures section*.

Creating a *Series* by passing a list of values, letting pandas create a default integer index:

```python
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])
In [4]: s
Out[4]:
0    1.0
1    3.0
2    5.0
3  NaN
4    6.0
5    8.0
dtype: float64
```

Creating a *DataFrame* by passing a NumPy array, with a datetime index and labeled columns:
In [5]: dates = pd.date_range("20130101", periods=6)

In [6]: dates
Out[6]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
              '2013-01-05', '2013-01-06'], dtype='datetime64[ns]', freq='D')

In [7]: df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list("ABCD"))

In [8]: df
Out[8]:
A   B    C     D
2013-01-01 -1.325591 -0.336537 0.401489 0.752909
2013-01-02 -0.942121 -0.758401 -0.052704 0.282167
2013-01-03 -0.733393 -0.335276 -2.004442 0.363065
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420
2013-01-05 -0.128739  0.040554  0.514148  1.588288
2013-01-06 -0.486114  0.557386 -0.476266  1.107157

Creating a DataFrame by passing a dictionary of objects that can be converted into a series-like structure:

In [9]: df2 = pd.DataFrame({
...:     "A": 1.0,
...:     "B": pd.Timestamp("20130102"),
...:     "C": pd.Series(1, index=list(range(4)), dtype="float32"),
...:     "D": np.array([3] * 4, dtype="int32"),
...:     "E": pd.Categorical(["test", "train", "test", "train"]),
...:     "F": "foo",
...: })

In [10]: df2
Out[10]:
   A     B         C    D   E     F
0  1.0 2013-01-02  1.0  3  test  foo
1  1.0 2013-01-02  1.0  3  train foo
2  1.0 2013-01-02  1.0  3  test  foo
3  1.0 2013-01-02  1.0  3  train foo

The columns of the resulting DataFrame have different dtypes:

In [11]: df2.dtypes
Out[11]:
A    float64
B    datetime64[ns]
C    float32
D    int32
E    category
F    object
dtype: object
If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here’s a subset of the attributes that will be completed:

```{raw}
In [12]: df2.<TAB>  # noqa: E225, E999
   df2.A df2.bool
   df2.abs df2.boxplot
   df2.add df2.C
   df2.add_prefix df2.clip
   df2.add_suffix df2.columns
   df2.align df2.copy
   df2.all df2.count
   df2.any df2.combine
   df2.append df2.D
   df2.apply df2.describe
   df2.applymap df2.diff
   df2.B df2.duplicated
```

As you can see, the columns A, B, C, and D are automatically tab completed. E and F are there as well; the rest of the attributes have been truncated for brevity.

### 2.1.2 Viewing data

See the Basics section.

Here is how to view the top and bottom rows of the frame:

```{raw}
In [13]: df.head()
   Out[13]:
     A   B   C   D
2013-01-01 -1.325591 -0.336537 0.401489 0.752909
2013-01-02 -0.942121 -0.758401 -0.052704 0.282167
2013-01-03 -0.733393 -0.335276 -2.004442 0.363065
2013-01-04 0.770212 -1.936564 -0.065106 -1.720420
2013-01-05 -0.128739 0.040554 0.514148 1.588288

In [14]: df.tail(3)
   Out[14]:
     A   B   C   D
2013-01-04 0.770212 -1.936564 -0.065106 -1.720420
2013-01-05 -0.128739 0.040554 0.514148 1.588288
2013-01-06 -0.486114 0.557386 -0.476266 1.107157
```

Display the index, columns:

```{raw}
In [15]: df.index
   Out[15]:
   DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
                '2013-01-05', '2013-01-06'],
               dtype='datetime64[ns]', freq='D')

In [16]: df.columns
   Out[16]: Index(['A', 'B', 'C', 'D'], dtype='object')
```

DataFrame.to_numpy() gives a NumPy representation of the underlying data. Note that this can be an expensive
operation when your DataFrame has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: **NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column.** When you call DataFrame.to_numpy(), pandas will find the NumPy dtype that can hold all of the dtypes in the DataFrame. This may end up being object, which requires casting every value to a Python object.

For `df`, our DataFrame of all floating-point values, DataFrame.to_numpy() is fast and doesn’t require copying data:

```python
In [17]: df.to_numpy()
Out[17]:
array([[-1.32559115, -0.33653728, 0.40148882, 0.75290939],
       [-0.94212136, -0.75840071, -0.05270426, 0.2821667 ],
       [-0.73339346, -0.33527577, -2.00444171, 0.36306547],
       [ 0.77021181, -1.93656374, -0.06510639, -1.72042006],
       [-0.12873947, 0.04055377, 0.51414829, 1.58828791],
       [-0.48611421, 0.55738613, -0.47626626, 1.10715709]])
```

For `df2`, the DataFrame with multiple dtypes, DataFrame.to_numpy() is relatively expensive:

```python
In [18]: df2.to_numpy()
Out[18]:
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']],
      dtype=object)
```

**Note:** DataFrame.to_numpy() does not include the index or column labels in the output.

describe() shows a quick statistic summary of your data:

```python
In [19]: df.describe()
Out[19]:
            A          B          C          D
count 6.000000 6.000000 6.000000 6.000000
mean  -0.474291 -0.461473 -0.280480  0.395528
std   0.731990  0.846841  0.917078  1.144374
min  -1.325591 -1.936564 -2.004442 -1.720420
25%   -0.889939 -0.652935 -0.373476  0.302391
50%   -0.609754 -0.335907  0.287941  1.018595

max   -0.486114  0.557386  0.514148  1.107157
```

Transposing your data:

```python
In [20]: df.T
Out[20]:
A    -1.325591  -0.942121  -0.7333933  0.770212  -0.128739  -0.486114
B    -0.336537  -0.758401  -0.3352766  1.936564  0.405554  0.557386
C     0.401489  -0.052764  -2.004442  0.514148  -0.476266
D     0.752909  0.282167  0.3630656  1.720420  1.588288  1.107157
```

Sorting by an axis:
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
          D   C   B   A
2013-01-01  0.752909  0.401489 -0.336537 -1.325591
2013-01-02  0.282167 -0.052704 -0.758401 -0.942121
2013-01-03  0.363065 -2.004442 -0.335276 -0.733393
2013-01-04 -1.720420 -0.065106 -1.936564  0.770212
2013-01-05  1.588288  0.514148  0.040554 -0.128739
2013-01-06  1.107157 -0.476266  0.557386 -0.486114

Sorting by values:

In [22]: df.sort_values(by="B")
Out[22]:
         A     B     C       D
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167
2013-01-01 -1.325591 -0.336537  0.401489  0.752909
2013-01-03  0.733393 -0.335276 -2.004442  0.363065
2013-01-05  0.128739  0.514148  0.040554  1.588288
2013-01-06 -0.486114  0.557386 -0.476266  1.107157

2.1.3 Selection

Note: While standard Python / NumPy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, .at, .iat, .loc and .iloc.

See the indexing documentation Indexing and Selecting Data and MultiIndex / Advanced Indexing.

Getting

Selecting a single column, which yields a Series, equivalent to df.A:

In [23]: df["A"]
Out[23]:
2013-01-01    -1.325591
2013-01-02     -0.942121
2013-01-03     -0.733393
2013-01-04     0.770212
2013-01-05    -0.128739
2013-01-06    -0.486114
Freq: D, Name: A, dtype: float64

Selecting via [], which slices the rows:

In [24]: df[0:3]
Out[24]:
          A   B   C   D
2013-01-01 -1.325591 -0.336537  0.401489  0.752909
(continues on next page)
2013-01-02 -0.942121 -0.758401 -0.052704 0.282167
2013-01-03 -0.733393 -0.335276 -2.004442 0.363065

**In [25]:** df["20130102":"20130104"]

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-02</td>
<td>-0.942121</td>
<td>-0.758401</td>
<td>-0.052704</td>
<td>0.282167</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.733393</td>
<td>-0.335276</td>
<td>-2.004442</td>
<td>0.363065</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.770212</td>
<td>-1.936564</td>
<td>-0.065106</td>
<td>-1.720420</td>
</tr>
</tbody>
</table>

**Selection by label**

See more in *Selection by Label*.

For getting a cross section using a label:

**In [26]:** df.loc[dates[0]]

**Out [26]:**

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-1.325591</td>
<td>-0.336537</td>
<td>0.401489</td>
<td>0.752909</td>
</tr>
</tbody>
</table>

Name: 2013-01-01 00:00:00, dtype: float64

Selecting on a multi-axis by label:

**In [27]:** df.loc[:, ["A", "B"]]

**Out [27]:**

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-1.325591</td>
<td>-0.336537</td>
</tr>
<tr>
<td></td>
<td>-0.942121</td>
<td>-0.758401</td>
</tr>
<tr>
<td></td>
<td>-0.335276</td>
<td>0.401489</td>
</tr>
<tr>
<td></td>
<td>0.770212</td>
<td>-1.936564</td>
</tr>
<tr>
<td></td>
<td>-0.128739</td>
<td>0.040554</td>
</tr>
<tr>
<td></td>
<td>-0.486114</td>
<td>0.557386</td>
</tr>
</tbody>
</table>

Showing label slicing, both endpoints are *included*:

**In [28]:** df.loc["20130102":"20130104", ["A", "B"]]

**Out [28]:**

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-02</td>
<td>-0.942121</td>
<td>-0.758401</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.733393</td>
<td>-0.335276</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.770212</td>
<td>-1.936564</td>
</tr>
</tbody>
</table>

Reduction in the dimensions of the returned object:

**In [29]:** df.loc["20130102", ["A", "B"]]

**Out [29]:**

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-0.942121</td>
<td>-0.758401</td>
</tr>
</tbody>
</table>
For getting a scalar value:

```
In [30]: df.loc[dates[0], "A"]
Out[30]: -1.32559115465652
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], "A"]
Out[31]: -1.32559115465652
```

**Selection by position**

See more in *Selection by Position*.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
A   0.770212
B  -1.936564
C  -0.065106
D  -1.720420
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to NumPy/Python:

```
In [33]: df.iloc[3:5, 0:2]
Out[33]:
2013-01-04  0.770212  -1.936564
2013-01-05  -0.128739   0.040554
```

By lists of integer position locations, similar to the NumPy/Python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
     A      C
2013-01-02 -0.942121 -0.052704
2013-01-03 -0.733393 -2.004442
2013-01-05 -0.128739  0.514148
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out[35]:
         A      B      C      D
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167
2013-01-03 -0.733393 -0.335276 -2.004442  0.363065
```

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out[36]:
         B      C
```

(continues on next page)
For getting a value explicitly:

```python
In [37]: df.iloc[1, 1]
Out[37]: -0.7584007081724556
```

For getting fast access to a scalar (equivalent to the prior method):

```python
In [38]: df.iat[1, 1]
Out[38]: -0.7584007081724556
```

**Boolean indexing**

Using a single column's values to select data:

```python
In [39]: df[df["A"] > 0]
Out[39]:
   A    B    C    D
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420
```

Selecting values from a DataFrame where a boolean condition is met:

```python
In [40]: df[df > 0]
Out[40]:
   A    B    C    D
2013-01-01  NaN   NaN  0.401489  0.752909
2013-01-02  NaN   NaN  NaN     0.282167
2013-01-03  NaN   NaN  NaN     0.363065
2013-01-04  0.770212 NaN     NaN     NaN
2013-01-05  NaN  0.040554  0.514148  1.588288
2013-01-06  NaN  0.557386  NaN     1.107157
```

Using the `isin()` method for filtering:

```python
In [41]: df2 = df.copy()
In [42]: df2["E"] = ["one", "one", "two", "three", "four", "three"]
In [43]: df2
Out[43]:
   A    B    C    D    E
2013-01-01 -1.325591 -0.336537  0.401489  0.752909   one
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167   one
2013-01-03 -0.733393 -0.335276 -2.004442  0.363065   two
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420 three
2013-01-05 -0.128739  0.040554  0.514148  1.588288 four
```
2013-01-06 -0.486114 0.557386 -0.476266 1.107157 three

```
In [44]: df2[df2["E"].isin(["two", "four")]
Out[44]:
     A         B         C         D         E
2013-01-03 -0.733393 -0.335276 -2.004442 0.363065  two
2013-01-05 -0.128739 0.040554 0.514148 1.588288  four
```

### Setting

Setting a new column automatically aligns the data by the indexes:

```
In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range("20130102", periods=6))
In [46]: s1
Out[46]:
2013-01-02    1
2013-01-03    2
2013-01-04    3
2013-01-05    4
2013-01-06    5
2013-01-07    6
Freq: D, dtype: int64
In [47]: df["F"] = s1
```

Setting values by label:

```
In [48]: df.at[dates[0], "A"] = 0
```

Setting values by position:

```
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, "D"] = np.array([5] * len(df))
```

The result of the prior setting operations:

```
In [51]: df
Out[51]:
     A         B         C         D         E         F
2013-01-01  0.000000  0.000000  0.401489  5.000000  NaN
2013-01-02 -0.942121 -0.758401 -0.052704  5.000000  1.000000
2013-01-03 -0.733393 -0.335276 -2.004442  5.000000  2.000000
2013-01-04  0.770212 -1.936564 -0.065106  5.000000  3.000000
2013-01-05 -0.128739  0.040554  0.514148  5.000000  4.000000
2013-01-06 -0.486114  0.557386 -0.476266  5.000000  5.000000
```

A where operation with setting:

```
In [52]: df2[df2["E"].isin(["two", "four")]
Out[52]:
     A         B         C         D         E
2013-01-03 -0.733393 -0.335276 -2.004442 0.363065  two
2013-01-05 -0.128739 0.040554 0.514148 1.588288  four
```

2.1. 10 minutes to pandas
2.1.4 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the Missing Data section.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data:

```python
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])

In [56]: df1.loc[dates[0] : dates[1], "E"] = 1

In [57]: df1
```

```
Out[57]:
   A      B       C       D       F   E
0  2013-01-01  0.000000  0.000000 -0.401489  5.0  1.0
1  2013-01-02 -0.942121 -0.758401 -0.052704  5.0  1.0
2  2013-01-03 -0.733393 -0.335276 -2.001442  5.0  2.0
3  2013-01-04 -0.770212 -1.365564 -0.065166  5.0  3.0
```

To drop any rows that have missing data:

```python
In [58]: df1.dropna(how="any")
```

```
Out[58]:
   A      B       C       D       F   E
0  2013-01-02 -0.942121 -0.758401 -0.052704  5.0  1.0
```

Filling missing data:

```python
In [59]: df1.fillna(value=5)
```

```
Out[59]:
   A      B       C       D       F   E
0  2013-01-01  0.000000  0.000000  0.401489  5.0  1.0
1  2013-01-02 -0.942121 -0.758401 -0.052704  5.0  1.0
2  2013-01-03 -0.733393 -0.335276 -2.001442  5.0  2.0
3  2013-01-04 -0.770212 -1.365564 -0.065166  5.0  3.0
```

To get the boolean mask where values are `nan`:
2.1.5 Operations

See the Basic section on Binary Ops.

Stats

Operations in general exclude missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
A   -0.253359
B   -0.405383
C   -0.280480
D    5.000000
F    3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01  1.350372
2013-01-02  0.849355
2013-01-03  0.785378
2013-01-04  1.353708
2013-01-05  1.885193
2013-01-06  1.919001
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension:

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)

In [64]: s
Out[64]:
2013-01-01    NaN
2013-01-02    NaN
2013-01-03     1.0
2013-01-04     3.0
2013-01-05     5.0
2013-01-06    NaN
```

(continues on next page)
Freq: D, dtype: float64

In [65]: df.sub(s, axis="index")
Out[65]:
         A    B    C    D    F
2013-01-01 NaN  NaN  NaN  NaN  NaN
2013-01-02 NaN  NaN  NaN  NaN  NaN
2013-01-03 -1.733393 -1.335276 -3.004442 4.0  1.0
2013-01-04 -2.229788 -4.936564 -3.065106 2.0  0.0
2013-01-05 -5.128739 -4.959446 -4.485852 0.0 -1.0
2013-01-06 NaN  NaN  NaN  NaN  NaN

Apply

Applying functions to the data:

In [66]: df.apply(np.cumsum)
Out[66]:
         A    B    C    D    F
2013-01-01  0.000000  0.000000  0.401489  5.0  NaN
2013-01-02 -0.942121 -0.758401  0.348785 10.0  1.0
2013-01-03 -1.675515 -1.093676 -1.655657 15.0  3.0
2013-01-04 -0.905303 -3.030240 -1.720764 20.0  6.0
2013-01-05 -1.034042 -2.989686 -1.206615 25.0 10.0
2013-01-06 -1.520157 -2.432300 -1.682882 30.0 15.0

In [67]: df.apply(lambda x: x.max() - x.min())
Out[67]:
     A    B    C    D    F
dtype: float64
         1.712333  2.493950  2.518590  0.000000  4.000000

dtype: float64

Histogramming

See more at Histogramming and Discretization.

In [68]: s = pd.Series(np.random.randint(0, 7, size=10))

In [69]: s
Out[69]:
0   2
1   5
2   1
3   1
4   2
5   5
6   4
(continues on next page)
String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at Vectorized String Methods.

```python
In [72]: s.str.lower()
Out[72]:
0    a
1    b
2    c
3    aaba
4    baca
5   NaN
6    caba
7    dog
8    cat
dtype: object
```

2.1.6 Merge

**Concat**

pandas provides various facilities for easily combining together Series and DataFrame objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the Merging section.

Concatenating pandas objects together with `concat()`:

```python
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
In [74]: df
Out[74]:
```

2.1. 10 minutes to pandas
# break it into pieces
In [75]: pieces = [df[:3], df[3:7], df[7:]]

In [76]: pd.concat(pieces)

Out[76]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

<td>9</td>
<td>0.912028</td>
<td>0.687391</td>
<td>-0.067812</td>
</tr>
</tbody>
</table>

Note: Adding a column to a DataFrame is relatively fast. However, adding a row requires a copy, and may be expensive. We recommend passing a pre-built list of records to the DataFrame constructor instead of building a DataFrame by iteratively appending records to it.

## Join

SQL style merges. See the Database style joining section.

In [77]: left = pd.DataFrame({"key": ["foo", "foo"], "lval": [1, 2]})

In [78]: right = pd.DataFrame({"key": ["foo", "foo"], "rval": [4, 5]})

In [79]: left
Out[79]:

<table>
<thead>
<tr>
<th></th>
<th>key</th>
<th>lval</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>foo</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>foo</td>
<td>2</td>
</tr>
</tbody>
</table>

In [80]: right
Out[80]:

(continues on next page)
Another example that can be given is:

```python
In [81]: left = pd.DataFrame({"key": ["foo", "bar"], "lval": [1, 2]})
In [82]: right = pd.DataFrame({"key": ["foo", "bar"], "rval": [4, 5]})
In [83]: pd.merge(left, right, on="key")
Out[83]:
   key  lval  rval
0  foo    1    4
1  bar    2    5
2  foo    2    4
3  foo    2    5
```

2.1.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the Grouping section.

```python
In [87]: df = pd.DataFrame(
    ....:     {"A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
    ....:       "B": ["one", "one", "two", "three", "two", "two", "one", "three"],
    ....:       "C": np.random.randn(8),
)```
Grouping and then applying the \texttt{sum()} function to the resulting groups:

\begin{verbatim}
In [89]: df.groupby("A").sum()
Out[89]:
A     C       D
bar  2.143344 -1.875030
foo  3.114396  2.941453
\end{verbatim}

Grouping by multiple columns forms a hierarchical index, and again we can apply the \texttt{sum()} function:

\begin{verbatim}
In [90]: df.groupby(["A", "B"]).sum()
Out[90]:
   C       D
A B
bar one -0.420989  0.552912
      three  1.807672  0.024979
      two  0.756661 -1.347097
foo one -1.666853  1.932404
      three -1.709692  0.731181
      two  0.262149  0.277868
\end{verbatim}
2.1.8 Reshaping

See the sections on Hierarchical Indexing and Reshaping.

Stack

```python
In [91]: tuples = list(
    ....:     zip(
    ....:         "bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"),
    ....:         "one", "two", "one", "two", "one", "two", "one", "two"),
    ....:     )

In [92]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [93]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [94]: df2 = df[:4]

In [95]: df2
Out[95]:
    A    B
first second
bar one 1.622853 -0.232267
  two  0.686548 -1.534020
baz one 0.925424  1.387692
  two -1.247546  1.146858

The stack() method “compresses” a level in the DataFrame’s columns:

In [96]: stacked = df2.stack()

In [97]: stacked
Out[97]:
    first second
    bar one A  1.622853
    B  -0.232267
    two A  0.686548
    B  -1.534020
    baz one A  0.925424
    B  1.387692
    two A  1.247546
    B  1.146858

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack() is unstack(), which by default unstacks the last level:

In [98]: stacked.unstack()
Out[98]:
(continues on next page)
```
Pivot tables

See the section on Pivot Tables.

In [101]: df = pd.DataFrame(
.....:
    .....:
    "A": ["one", "one", "two", "three"] * 3,
    .....:
    "B": ["A", "B", "C"] * 4,
    .....:
    "C": ["foo", "foo", "foo", "bar", "bar", "bar"] * 2,
    .....:
    "D": np.random.randn(12),
    .....:
    "E": np.random.randn(12),
    .....:
)

In [102]: df

Out[102]:
    A  B  C       D        E
  0  one A  foo  0.571303 -0.283694
  1  one B  foo  0.597649 -0.344110
  2  two C  foo -0.348892  0.993136
  3  three A  bar -1.088158 -0.649614
  4  one B  bar  2.032043 -0.625472
  5  one C  bar -0.983588 -1.754765
  6  two A  foo  0.796674 -0.954840
  7  three B  foo -0.663216  1.149934
We can produce pivot tables from this data very easily:

```python
In [103]: pd.pivot_table(df, values="D", index=['A', 'B'], columns=['C'])
Out[103]:
     C     bar    foo
   A  B
one  A -0.216001  0.571303
     B  2.032043  0.597649
     C -0.983588 -1.258631
two  A      NaN -0.663216
     B  0.078620      NaN
     C  0.869189      NaN
three A  -1.088158     NaN
        B  0.869189      NaN
       C  0.348892      NaN
```

### 2.1.9 Time series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the Time Series section.

```python
In [104]: rng = pd.date_range("1/1/2012", periods=100, freq="S")
In [105]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [106]: ts.resample("5Min").sum()
Out[106]:
2012-01-01    20462
Freq: 5T, dtype: int64
```

Time zone representation:

```python
In [107]: rng = pd.date_range("3/6/2012 00:00", periods=5, freq="D")
In [108]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [109]: ts
Out[109]:
2012-03-06   -1.674564
2012-03-07    0.750881
2012-03-08    0.475429
2012-03-09    0.671150
2012-03-10   -2.616932
Freq: D, dtype: float64
```

(continues on next page)
In [110]: ts_utc = ts.tz_localize("UTC")

In [111]: ts_utc
Out[111]:

2012-03-06 00:00:00+00:00    -1.674564
2012-03-07 00:00:00+00:00     0.750881
2012-03-08 00:00:00+00:00     0.475429
2012-03-09 00:00:00+00:00     0.671150
2012-03-10 00:00:00+00:00    -2.616932
Freq: D, dtype: float64

Converting to another time zone:

In [112]: ts_utc.tz_convert("US/Eastern")
Out[112]:

2012-03-05 19:00:00-05:00    -1.674564
2012-03-06 19:00:00-05:00     0.750881
2012-03-07 19:00:00-05:00     0.475429
2012-03-08 19:00:00-05:00     0.671150
2012-03-09 19:00:00-05:00    -2.616932
Freq: D, dtype: float64

Converting between time span representations:

In [113]: rng = pd.date_range("1/1/2012", periods=5, freq="M")

In [114]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [115]: ts
Out[115]:

2012-01-31  -0.246723
2012-02-29   0.714166
2012-03-31   1.903492
2012-04-30  -0.890850
2012-05-31  -1.220504
Freq: M, dtype: float64

In [116]: ps = ts.to_period()

In [117]: ps
Out[117]:

2012-01   -0.246723
2012-02    0.714166
2012-03    1.903492
2012-04   -0.890850
2012-05   -1.220504
Freq: M, dtype: float64

In [118]: ps.to_timestamp()
Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [119]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")
In [120]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [121]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9
In [122]: ts.head()
Out[122]:
1990-03-01 09:00 1.374209
1990-06-01 09:00 0.701162
1990-09-01 09:00 0.734917
1990-12-01 09:00 -1.715392
1991-03-01 09:00 -0.216692
Freq: H, dtype: float64
```

### 2.1.10 Categoricals

pandas can include categorical data in a `DataFrame`. For full docs, see the categorical introduction and the API documentation.

```
In [123]: df = pd.DataFrame(
       .....:     {"id": [1, 2, 3, 4, 5, 6], "raw_grade": ["a", "b", "b", "a", "a", "e"]
       .....:     }
)  

Converting the raw grades to a categorical data type:

```
In [124]: df["grade"] = df["raw_grade"].astype("category")
```

```
In [125]: df["grade"]
```

```
Out[125]:
0  a
1  b
2  b
3  a
4  a
5  e
Name: grade, dtype: category
Categories (3, object): ['a', 'b', 'e']
```

Rename the categories to more meaningful names (assigning to `Series.cat.categories()` is in place!):
In [126]: df["grade"].cat.categories = ["very good", "good", "very bad"]

Reorder the categories and simultaneously add the missing categories (methods under `Series.cat()` return a new `Series` by default):

In [127]: df["grade"] = df["grade"].cat.set_categories(  
    .....:   ["very bad", "bad", "medium", "good", "very good"]  
    .....: )  
    .....:

In [128]: df["grade"]
Out[128]:
0   very good
1      good
2      good
3    very good
4    very good
5    very bad
Name: grade, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

Sorting is per order in the categories, not lexical order:

In [129]: df.sort_values(by="grade")
Out[129]:
   id  raw_grade  grade
5   6       e    very bad
1   2       b     good
2   3       b     good
0   1       a    very good
3   4       a    very good
4   5       a    very good

Grouping by a categorical column also shows empty categories:

In [130]: df.groupby("grade").size()
Out[130]:
grade
very bad    1
bad         0
medium      0
good        2
very good   3
dtype: int64
2.1.11 Plotting

See the *Plotting* docs.

We use the standard convention for referencing the matplotlib API:

```python
In [131]: import matplotlib.pyplot as plt
In [132]: plt.close("all")
```

The `close()` method is used to close a figure window:

```python
In [133]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
In [134]: ts = ts.cumsum()
In [135]: ts.plot();
```

If running under Jupyter Notebook, the plot will appear on `plot()`. Otherwise use `matplotlib.pyplot.show` to show it or `matplotlib.pyplot.savefig` to write it to a file.

```python
In [136]: plt.show();
```

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:
In [137]: df = pd.DataFrame(
    .....:     np.random.randn(1000, 4), index=ts.index, columns=["A", "B", "C", "D"]
    .....: )
    .....:

In [138]: df = df.cumsum()

In [139]: plt.figure();

In [140]: df.plot();

In [141]: plt.legend(loc='best');
### 2.1.12 Getting data in/out

#### CSV

Writing to a csv file:

```python
In [142]: df.to_csv("foo.csv")
```

Reading from a csv file:

```python
In [143]: pd.read_csv("foo.csv")
Out[143]:
```

<table>
<thead>
<tr>
<th>Unnamed: 0</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 2000-01-01</td>
<td>-0.044747</td>
<td>-0.830584</td>
<td>0.518126</td>
<td>0.117110</td>

</tr>
</tbody>
</table>

[1000 rows x 5 columns]

#### HDF5

Reading and writing to HDFStores.

Writing to a HDF5 Store:

```python
In [144]: df.to_hdf("foo.h5", "df")
```

Reading from a HDF5 Store:

```python
In [145]: pd.read_hdf("foo.h5", "df")
Out[145]:
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.044747</td>
<td>-0.830584</td>
<td>0.518126</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.931010</td>
<td>-0.188137</td>
<td>0.590739</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.253205</td>
<td>0.494730</td>
<td>1.894239</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>0.651105</td>
<td>-0.061714</td>
<td>1.923508</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-0.874070</td>
<td>-0.335711</td>
<td>0.720719</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2002-09-22</td>
<td>2.370770</td>
<td>-5.894657</td>
<td>9.157599</td>
</tr>

<td>8.342926</td>
</tr>
<tr>
<td>2002-09-26</td>
<td>1.692620</td>
<td>-5.858142</td>
<td>8.402035</td>
</tr>
</tbody>
</table>

[1000 rows x 4 columns]
Excel

Reading and writing to *MS Excel*.

Writing to an excel file:

```python
In [146]: df.to_excel("foo.xlsx", sheet_name="Sheet1")
```

Reading from an excel file:

```python
In [147]: pd.read_excel("foo.xlsx", "Sheet1", index_col=None, na_values=["NA")
Out[147]:
         A       B       C       D
0  2000-01-01 -0.044747 -0.830584  0.518126  0.117110
1  2000-01-02 -0.931010 -0.188137  0.590739 -0.065270

```

### 2.1.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```python
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...     ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See *Comparisons* for an explanation and what to do.

See *Gotchas* as well.

### 2.2 Intro to data structures

We’ll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```python
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic**. The link between labels and data will not be broken unless done so explicitly by you.
We’ll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

### 2.2.1 Series

*Series* is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the *index*. The basic method to create a Series is to call:

```python
>>> s = pd.Series(data, index=index)
```

Here, *data* can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed *index* is a list of axis labels. Thus, this separates into a few cases depending on what *data* is:

#### From ndarray

If *data* is an ndarray, *index* must be the same length as *data*. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```python
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [4]: s
Out[4]:
   a    0.469112
   b   -0.282863
   c   -1.509059
   d  -1.135632
   e    1.212112
Name: 1, dtype: float64

In [5]: s.index
Out[5]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
```

```python
In [6]: pd.Series(np.random.randn(5))
Out[6]:
   0   -0.173215
   1    0.119209
   2   -1.044236
   3    0.861849
   4   -2.104569
Name: 1, dtype: float64
```

**Note:** pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

#### From dict

Series can be instantiated from dicts:

2.2. Intro to data structures
In [7]: d = {"b": 1, "a": 0, "c": 2}

In [8]: pd.Series(d)

Out[8]:
   b  1
   a  0
   c  2
dtype: int64

Note: When the data is a dict, and an index is not passed, the Series index will be ordered by the dict's insertion order, if you're using Python version >= 3.6 and pandas version >= 0.23.

If you're using Python < 3.6 or pandas < 0.23, and an index is not passed, the Series index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a pandas version lower than 0.23, the Series would be ordered by the lexical order of the dict keys (i.e. ['a', 'b', 'c'] rather than ['b', 'a', 'c']).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

In [9]: d = {"a": 0.0, "b": 1.0, "c": 2.0}

In [10]: pd.Series(d)

Out[10]:
   a  0.0
   b  1.0
   c  2.0
dtype: float64

In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])

Out[11]:
   b  1.0
   c  2.0
d   NaN
   a  0.0
dtype: float64

Note: NaN (not a number) is the standard missing data marker used in pandas.

From scalar value

If data is a scalar value, an index must be provided. The value will be repeated to match the length of index.

In [12]: pd.Series(5.0, index=['a', 'b', 'c', 'd', 'e'])

Out[12]:
   a  5.0
   b  5.0
c  5.0
d  5.0
e  5.0
dtype: float64
Series is ndarray-like

Series acts very similarly to a ndarray, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.4691122999071863

In [14]: s[:3]
Out[14]:
   a    0.469112
   b  -0.282863
   c  -1.509059
dtype: float64

In [15]: s[s > s.median()]
Out[15]:
   a    0.469112
   e    1.212112
dtype: float64

In [16]: s[[4, 3, 1]]
Out[16]:
   e    1.212112
   d  -1.135632
   b  -0.282863
dtype: float64

In [17]: np.exp(s)
Out[17]:
   a    1.598575
   b    0.753623
   c    0.221118
   d    0.321219
   e    3.360575
dtype: float64
```

**Note:** We will address array-based indexing like `s[[4, 3, 1]]` in section on indexing.

Like a NumPy array, a pandas Series has a `dtype`.

```
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy dtype. However, pandas and 3rd-party libraries extend NumPy’s type system in a few places, in which case the dtype would be an `ExtensionDtype`. Some examples within pandas are `Categorical data` and `Nulllable integer data type`. See `dtypes` for more.

If you need the actual array backing a Series, use `Series.array`.

```
In [19]: s.array
Out[19]:
<PandasArray>
```

(continues on next page)
Accessing the array can be useful when you need to do some operation without the index (to disable automatic alignment, for example).

`Series.array` will always be an `ExtensionArray`. Briefly, an `ExtensionArray` is a thin wrapper around one or more concrete arrays like a `numpy.ndarray`. pandas knows how to take an `ExtensionArray` and store it in a `Series` or a column of a DataFrame. See `dtypes` for more.

While Series is ndarray-like, if you need an actual `ndarray`, then use `Series.to_numpy()`.

```python
In [20]: s.to_numpy()
Out[20]: array([ 0.4691, -0.2829, -1.5091, -1.1356, 1.2121])
```

Even if the Series is backed by a `ExtensionArray`, `Series.to_numpy()` will return a NumPy ndarray.

**Series is dict-like**

A Series is like a fixed-size dict in that you can get and set values by index label:

```python
In [21]: s["a"]
Out[21]: 0.4691122999071863

In [22]: s["e"] = 12.0

In [23]: s
Out[23]:
   a    0.469112
   b  -0.282863
   c  -1.509059
   d -1.135632
   e   12.000000
   dtype: float64

In [24]: "e" in s
Out[24]: True

In [25]: "f" in s
Out[25]: False
```

If a label is not contained, an exception is raised:

```python
>>> s["f"]
KeyError: 'f'
```

Using the `get` method, a missing label will return None or specified default:

```python
In [26]: s.get("f")
In [27]: s.get("f", np.nan)
Out[27]: nan
```
See also the section on attribute access.

Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [28]: s + s
Out[28]:
   a    0.938225
   b   -0.565727
   c   -3.018117
   d  -2.271265
   e   24.000000
   dtype: float64

In [29]: s * 2
Out[29]:
   a    0.938225
   b   -0.565727
   c   -3.018117
   d  -2.271265
   e   24.000000
   dtype: float64

In [30]: np.exp(s)
Out[30]:
   a     1.598575
   b     0.753623
   c     0.221118
   d     0.321219
   e  162754.791419
   dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [31]: s[1:] + s[:-1]
Out[31]:
   a       NaN
   b  -0.565727
   c   -3.018117
   d  -2.271265
   e       NaN
   dtype: float64
```

The result of an operation between unaligned Series will have the union of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.
Note: In general, we chose to make the default result of operations between differently indexed objects yield the union of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the `dropna` function.

**Name attribute**

Series can also have a `name` attribute:

```python
In [32]: s = pd.Series(np.random.randn(5), name="something")

In [33]: s
Out[33]:
0   -0.494929
1    1.071804
2    0.721555
3   -0.706771
4   -1.039575
Name: something, dtype: float64
```

```python
In [34]: s.name
Out[34]: 'something'
```

The Series `name` will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

You can rename a Series with the `pandas.Series.rename()` method.

```python
In [35]: s2 = s.rename("different")

In [36]: s2.name
Out[36]: 'different'
```

Note that `s` and `s2` refer to different objects.

### 2.2.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D `numpy.ndarray`
- Structured or record `ndarray`
- A Series
- Another DataFrame

Along with the data, you can optionally pass `index` (row labels) and `columns` (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.
If axis labels are not passed, they will be constructed from the input data based on common sense rules.

**Note:** When the data is a dict, and columns is not specified, the DataFrame columns will be ordered by the dict's insertion order, if you are using Python version >= 3.6 and pandas >= 0.23.

If you are using Python < 3.6 or pandas < 0.23, and columns is not specified, the DataFrame columns will be the lexically ordered list of dict keys.

### From dict of Series or dicts

The resulting *index* will be the *union* of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [37]: d = {
    ....:     "one": pd.Series([1.0, 2.0, 3.0], index=["a", "b", "c"],
    ....:     "two": pd.Series([1.0, 2.0, 3.0, 4.0], index=["a", "b", "c", "d"],
    ....:     }
    ....:

In [38]: df = pd.DataFrame(d)

In [39]: df
Out[39]:
    one  two
  a  1.0  1.0
  b  2.0  2.0
  c  3.0  3.0
  d  NaN  4.0

In [40]: pd.DataFrame(d, index=["d", "b", "a"])
Out[40]:
    one  two
  d  NaN  4.0
  b  2.0  NaN
  a  1.0  1.0

In [41]: pd.DataFrame(d, index=["d", "b", "a"], columns=["two", "three"])
Out[41]:
    two  three
  d  4.0  NaN
  b  2.0  NaN
  a  1.0  NaN
```

The row and column labels can be accessed respectively by accessing the *index* and *columns* attributes:

**Note:** When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [42]: df.index
Out[42]: Index(['a', 'b', 'c', 'd'], dtype='object')
```

(continues on next page)
From dict of ndarrays/lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be `range(n)`, where `n` is the array length.

```
In [44]: d = {"one": [1.0, 2.0, 3.0, 4.0], "two": [4.0, 3.0, 2.0, 1.0]}
In [45]: pd.DataFrame(d)
Out[45]:
   one  two
0  1.0  4.0
1  2.0  3.0
2  3.0  2.0
3  4.0  1.0
```

```
In [46]: pd.DataFrame(d, index=["a", "b", "c", "d")
Out[46]:
   one  two
  a  1.0  4.0
  b  2.0  3.0
  c  3.0  2.0
  d  4.0  1.0
```

From structured or record array

This case is handled identically to a dict of arrays.

```
In [47]: data = np.zeros((2,), dtype=[("A", "i4"), ("B", "f4"), ("C", "a10")])
In [48]: data[:]= [(1, 2.0, "Hello"), (2, 3.0, "World")]
In [49]: pd.DataFrame(data)
Out[49]:
   A  B       C
0  1  2.0 b'Hello'
1  2  3.0 b'World'
```

```
In [50]: pd.DataFrame(data, index=["first", "second")
Out[50]:
   A  B       C
first 1  2.0 b'Hello'
second 2  3.0 b'World'
```

```
In [51]: pd.DataFrame(data, columns=["C", "A", "B")
Out[51]:
   C  A  B
```
From a list of dicts

```
In [52]: data2 = [{"a": 1, "b": 2}, {"a": 5, "b": 10, "c": 20}]

In [53]: pd.DataFrame(data2)
Out[53]:
   a  b     c
0  1  2  NaN
1  5 10  20.0

In [54]: pd.DataFrame(data2, index=['first', 'second'])
Out[54]:
   a  b     c
first 1  2  NaN
second 5 10  20.0

In [55]: pd.DataFrame(data2, columns=['a', 'b'])
Out[55]:
   a  b
0  1  2
1  5 10
```

From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```
In [56]: pd.DataFrame(
   ....:   {
   ....:     ("a", "b") : {("A", "B") : 1, ("A", "C") : 2},
   ....:     ("a", "a") : {("A", "C") : 3, ("A", "B") : 4},
   ....:     ("a", "c") : {("A", "B") : 5, ("A", "C") : 6},
   ....:     ("b", "a") : {("A", "C") : 7, ("A", "B") : 8},
   ....:     ("b", "b") : {("A", "D") : 9, ("A", "B") : 10},
   ....:   })
   ....:)

Out[56]:
   a  b
   b a c a b
A B  1.0  4.0  5.0  8.0  10.0
C  2.0  3.0  6.0  7.0  NaN
D NaN NaN NaN NaN  9.0
```
From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

From a list of namedtuples

The field names of the first namedtuple in the list determine the columns of the DataFrame. The remaining namedtuples (or tuples) are simply unpacked and their values are fed into the rows of the DataFrame. If any of those tuples is shorter than the first namedtuple then the later columns in the corresponding row are marked as missing values. If any are longer than the first namedtuple, a ValueError is raised.

```python
In [57]: from collections import namedtuple

In [58]: Point = namedtuple("Point", "x y")

In [59]: pd.DataFrame([Point(0, 0), Point(0, 3), (2, 3)])
Out[59]:
          x   y
     0  0  0
     1  0  3
     2  2  3

In [60]: Point3D = namedtuple("Point3D", "x y z")

In [61]: pd.DataFrame([Point3D(0, 0, 0), Point3D(0, 3, 5), Point(2, 3)])
Out[61]:
         x   y   z
     0  0  0  0.0
     1  0  3  5.0
     2  2  3  NaN
```

From a list of dataclasses

New in version 1.1.0.

Data Classes as introduced in PEP557, can be passed into the DataFrame constructor. Passing a list of dataclasses is equivalent to passing a list of dictionaries.

Please be aware, that all values in the list should be dataclasses, mixing types in the list would result in a TypeError.

```python
In [62]: from dataclasses import make_dataclass

In [63]: Point = make_dataclass("Point", [('x', int), ('y', int)])

In [64]: pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
Out[64]:
         x   y
     0  0  0
     1  0  3
     2  2  3
```

Missing data
Much more will be said on this topic in the Missing data section. To construct a DataFrame with missing data, we use np.nan to represent missing values. Alternatively, you may pass a numpy.MaskedArray as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

Alternate constructors

DataFrame.from_dict

DataFrame.from_dict takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the orient parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```
In [65]: pd.DataFrame.from_dict(dict([("A", [1, 2, 3]), ("B", [4, 5, 6])]))
Out[65]:
        A  B
0  1.0  4.0
1  2.0  5.0
2  3.0  6.0
```

If you pass orient='index', the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [66]: pd.DataFrame.from_dict(
    ....:     dict([("A", [1, 2, 3]), ("B", [4, 5, 6])]),
    ....:     orient="index",
    ....:     columns=["one", "two", "three"],
    ....: )
Out[66]:
       one  two  three
A  1.0  2.0  3.0
B  4.0  5.0  6.0
```

DataFrame.from_records

DataFrame.from_records takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```
In [67]: data
Out[67]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])
In [68]: pd.DataFrame.from_records(data, index="C")
Out[68]:
       A  B
C  b'Hello'  1  2.0
    b'World'  2  3.0
```
Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [69]: df["one"]
Out[69]:
a  1.0
b  2.0
c  3.0
d  NaN
Name: one, dtype: float64

In [70]: df["three"] = df["one"] * df["two"]

In [71]: df["flag"] = df["one"] > 2

In [72]: df
Out[72]:
     one  two  three  flag
a  1.0  1.0   1.0  False
b  2.0  2.0   4.0  False
c  3.0  3.0   9.0   True
d  NaN  4.0   NaN  False
```

Columns can be deleted or popped like with a dict:

```
In [73]: del df["two"]

In [74]: three = df.pop("three")

In [75]: df
Out[75]:
     one   flag
a  1.0  False
b  2.0  False
c  3.0   True
d  NaN  False
```

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [76]: df["foo"] = "bar"

In [77]: df
Out[77]:
     one  flag  foo
a  1.0  False   bar
b  2.0  False   bar
c  3.0   True   bar
d  NaN  False   bar
```

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:
In [78]: df["one_trunc"] = df["one"][2]

In [79]: df

Out[79]:
   one  flag  foo  one_trunc
  a  1.0  False  bar  1.0
  b  2.0  False  bar  2.0
  c  3.0  True   bar  NaN
d  NaN  NaN     bar  NaN

You can insert raw ndarrays but their length must match the length of the DataFrame’s index.

By default, columns get inserted at the end. The *insert* function is available to insert at a particular location in the columns:

In [80]: df.insert(1, "bar", df["one"])

In [81]: df

Out[81]:
   one  bar  flag  foo  one_trunc

Assigning new columns in method chains

Inspired by *dplyr*'s *mutate* verb, DataFrame has an *assign()* method that allows you to easily create new columns that are potentially derived from existing columns.

In [82]: iris = pd.read_csv("data/iris.data")

In [83]: iris.head()

Out[83]:
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
</tbody>
</table>

In [84]: iris.assign(sepal_ratio=iris["SepalWidth"] / iris["SepalLength"]).head()

Out[84]:
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.686275</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.612245</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.680851</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.673913</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.720000</td>
</tr>
</tbody>
</table>

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.
assign always returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don’t have a reference to the DataFrame at hand. This is common when using `assign` in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:
Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that’s been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn’t have a reference to the filtered DataFrame available.

The function signature for assign is simply **kwargs. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a Series or NumPy array), or a function of one argument to be called on the DataFrame. A copy of the original DataFrame is returned, with the new values inserted.

Starting with Python 3.6 the order of **kwargs is preserved. This allows for dependent assignment, where an expression later in **kwargs can refer to a column created earlier in the same assign().

```
In [87]: dfa = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})

In [88]: dfa.assign(C=lambda x: x['A'] + x['B'], D=lambda x: x['A'] + x['C'])
Out[88]:
     A  B  C  D
0   1  4  5  6
1   2  5  7  9
2   3  6  9 12
```

In the second expression, x['C'] will refer to the newly created column, that’s equal to dfa['A'] + dfa['B'].

2.2. Intro to data structures 189
Indexing / selection

The basics of indexing are as follows:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select column</td>
<td>df[col]</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by label</td>
<td>df.loc[label]</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by integer location</td>
<td>df.iloc[loc]</td>
<td>Series</td>
</tr>
<tr>
<td>Slice rows</td>
<td>df[5:10]</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Select rows by boolean vector</td>
<td>df[bool_vec]</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```
In [89]: df.loc["b"]
Out[89]:
one    2.0
bar    2.0
flag   False
foo    bar
Name: b, dtype: object
```

```
In [90]: df.iloc[2]
Out[90]:
one    3.0
bar    3.0
flag   True
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the section on indexing. We will address the fundamentals of reindexing / conforming to new sets of labels in the section on reindexing.

Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on both the columns and the index (row labels). Again, the resulting object will have the union of the column and row labels.

```
In [91]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
In [92]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
In [93]: df + df2
Out[93]:
   A         B         C        D
0 0.045691  -0.014138  1.380871  NaN
1 -0.955398  -1.501007  0.037181  NaN
2 -0.662690   1.534833 -0.859691  NaN
3 -2.452949   1.237274 -2.320422  NaN
4  1.414490  -1.951676 -2.320422  NaN
5 -0.494922  -1.649727 -1.084601  NaN
```
When doing an operation between DataFrame and Series, the default behavior is to align the Series index on the DataFrame columns, thus broadcasting row-wise. For example:

```
In [94]: df - df.iloc[0]
Out[94]:
   A    B    C    D
0  0.000000 0.000000 0.000000 0.000000
1  1.359261 0.248717 0.453276 -1.754609
2  0.253128 0.829678 0.999676 -1.991234
3  0.111280 0.534325 0.726540 -1.620544
4  0.573025 0.500742 0.767384 1.367331
5  1.714128 0.781993 -1.241620 -2.053136
6  1.240774 0.869551 -0.153282 0.000430
7  0.743894 0.411013 -0.929563 -0.282386
8 -0.194921 1.320690 0.238224 -1.482644
9  2.293786 1.856228 0.773289 -1.446531
```

For explicit control over the matching and broadcasting behavior, see the section on flexible binary operations.

Operations with scalars are just as you would expect:

```
In [95]: df * 5 + 2
Out[95]:
   A    B    C    D
0  3.359299 -0.124862 4.835102 3.381160
1 -3.437003 -1.368449 2.568242 -5.392133
2  4.624938 4.023526 4.885230 -6.575010
3 -3.196342 0.146766 -3.789461 -4.721559
4  6.224426 7.378849 1.454750 10.217815
5 -5.346940 3.785103 -1.373001 -6.884519
6  0.743894 0.411013 -0.929563 -0.282386
7 -0.194921 1.320690 0.238224 -1.482644
8  2.293786 1.856228 0.773289 -1.446531
9  14.828230 9.156280 8.701544 -3.851494
```

```
In [96]: 1 / df
Out[96]:
   A    B    C    D
0  3.678365 -2.353094 1.763605 3.620145
1 -0.919624 -1.483463 8.799067 -0.676395
2  1.904807 2.470934 1.732964 -0.583090
3  0.962215 -2.697986 -0.863638 -0.743875
4  1.183593 0.929567 -0.170188 0.608434
5 -0.680555 2.800959 -1.482360 -0.562777
6 -1.032084 -0.772485 2.416988 3.614523
7 -2.118489 -71.634509 -2.758294 -162.507295
8 -1.083352 1.116424 1.241860 -0.828964
9  0.389765 0.698687 0.746097 -0.854483
```

(continues on next page)
In [97]: df ** 4
Out[97]:
   A        B            C            D
0 0.005462  3.261689e-02  0.103370  5.822320e-03
1 1.398165  2.059869e-01  0.000167  4.777482e+00
2 0.075962  2.682596e-02  0.110877  8.650845e+00
3 1.166571  1.887302e-02  1.797515  3.265879e+00
4 0.509555  1.339298e+00  0.000141  7.297019e+00
5 4.661717  1.624699e-02  0.207103  9.969092e+00
6 0.881334  2.808277e+00  0.029302  5.858632e-03
7 0.049647  3.797614e-08  0.017276  1.433866e-09
8 0.725974  6.437005e-01  0.420446  2.118275e+00
9 43.329821  4.196326e+00  3.227153  1.875802e+00

Boolean operators work as well:

In [98]: df1 = pd.DataFrame({'a': [1, 0, 1], 'b': [0, 1, 1]}, dtype=bool)
In [99]: df2 = pd.DataFrame({'a': [0, 1, 1], 'b': [1, 1, 0]}, dtype=bool)
In [100]: df1 & df2
Out[100]:
   a  b
0  False  False
1  False  True
2  True  False

In [101]: df1 | df2
Out[101]:
   a  b
0  True  True
1  True  True
2  True  True

In [102]: df1 ^ df2
Out[102]:
   a  b
0  True  True
1  True  False
2  False  True

In [103]: -df1
Out[103]:
   a  b
0  False  True
1  True  False
2  False  False
Transposing

To transpose, access the T attribute (also the `transpose` function), similar to an ndarray:

```python
# only show the first 5 rows
In [104]: df[:5].T
Out[104]:
    0      1      2      3      4
A  0.271860 -1.087401  0.524988 -1.039268  0.844885
B -0.424972 -0.673690  0.404705 -0.370647  1.075770
C  0.567020  0.113648  0.577046 -1.157892 -0.109050
D  0.276232 -1.478427 -1.715002 -1.344312  1.643563
```

DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on Series and DataFrame, assuming the data within are numeric:

```python
In [105]: np.exp(df)
Out[105]:
    A       B       C       D
0  1.312403  0.653788  1.763006  1.318154
1  0.337092  0.509824  1.120358  0.227996
2  1.690438  1.498861  1.780770  0.179963
3  0.353713  0.690288  0.314148  0.260719
4  2.327710  2.932249  0.896686  5.173571
5  0.230066  1.429065  0.509360  0.169161
6  0.379495  0.274028  1.512461  1.318720
7  0.623732  0.986137  0.695904  0.993865
8  0.397301  2.449092  2.237242  0.299269
9 13.009059  4.183951  3.820223  0.310274
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics and data model are quite different in places from an n-dimensional array.

A `Series` implements `__array_ufunc__`, which allows it to work with NumPy’s universal functions.

The ufunc is applied to the underlying array in a Series.

```python
In [107]: ser = pd.Series([1, 2, 3, 4])
```

---

2.2. Intro to data structures 193
In [108]: np.exp(ser)
Out[108]:
0   2.718282
1   7.389056
2  20.085537
3  54.598150
dtype: float64

Changed in version 0.25.0: When multiple Series are passed to a ufunc, they are aligned before performing the operation.

Like other parts of the library, pandas will automatically align labeled inputs as part of a ufunc with multiple inputs. For example, using numpy remainder() on two Series with differently ordered labels will align before the operation.

In [109]: ser1 = pd.Series([1, 2, 3], index=["a", "b", "c"])
In [110]: ser2 = pd.Series([1, 3, 5], index=["b", "a", "c"])
In [111]: ser1
Out[111]:
a    1
b    2
c    3
dtype: int64
In [112]: ser2
Out[112]:
b    1
a    3
c    5
dtype: int64
In [113]: np.remainder(ser1, ser2)
Out[113]:
a    1
b    0
c    3
dtype: int64

As usual, the union of the two indices is taken, and non-overlapping values are filled with missing values.

In [114]: ser3 = pd.Series([2, 4, 6], index=["b", "c", "d"])
In [115]: ser3
Out[115]:
b    2
c    4
d    6
dtype: int64
In [116]: np.remainder(ser1, ser3)
Out[116]:
a    NaN
(continues on next page)
When a binary ufunc is applied to a `Series` and `Index`, the Series implementation takes precedence and a Series is returned.

```python
In [117]: ser = pd.Series([1, 2, 3])
In [118]: idx = pd.Index([4, 5, 6])
In [119]: np.maximum(ser, idx)
Out[119]:
0 4
1 5
2 6
dtype: int64
```

NumPy ufuncs are safe to apply to `Series` backed by non-ndarray arrays, for example `arrays.SparseArray` (see Sparse calculation). If possible, the ufunc is applied without converting the underlying data to an ndarray.

### Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`.

(Here I am reading a CSV version of the `baseball` dataset from the `plyr` R package):

```python
In [120]: baseball = pd.read_csv("data/baseball.csv")
In [121]: print(baseball)
```

```
id player year stint team lg g ab r h x2b x3b hr rbi sb cs bb so ibb hbp sh sf gidp
0 88641 womacto01 2006 2 CHN NL 19 50 6 14 1 0 1 2.0 1.0 1.0 4.0 0.0 0.0 3.0 0.0 0.0
1 88643 schilcu01 2006 1 BOS AL 31 2 0 1 0 0 0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0
...
98 89533 aloumo01 2007 1 NYN NL 87 328 51 112 19 1 13 49.0 3.0 0.0 27.0 5.0 2.0 3.0 3.0
99 89534 alomasa02 2007 1 NYN NL 8 22 1 3 1 0 0 0.0 0.0 0.0 0.0 0.0 0.0 3.0 0.0 0.0

[100 rows x 23 columns]
```

```python
In [122]: baseball.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 100 entries, 0 to 99
Data columns (total 23 columns):
 # Column  Non-Null Count  Dtype
----- ------  -------------- ----
 0 id  100 non-null  int64
```

(continues on next page)
However, using `to_string` will return a string representation of the DataFrame in tabular form, though it won’t always fit the console width:

```
In [123]: print(baseball.iloc[-20:, :12].to_string())
```

<table>

</tbody>
</table>

Wide DataFrames will be printed across multiple rows by default:
In [124]: pd.DataFrame(np.random.randn(3, 12))
Out[124]:
     0       1       2       3       4       5       6       7
0 -1.226825 0.769804 -1.281247 -0.727707 -0.121306 -0.097883 0.695775 0.341734
1 -0.732339 0.687738 0.176444 0.403310 -0.154951 0.301624 -2.179861 -1.369849
2 -0.345352 1.314232 0.690579 0.995761 2.396780 0.014871 3.357427 -0.317441

You can change how much to print on a single row by setting the `display.width` option:

In [125]: pd.set_option("display.width", 40)  # default is 80

In [126]: pd.DataFrame(np.random.randn(3, 12))
Out[126]:
     0       1       2       3       4       5       6       7
0 -2.182937 0.380396 0.084844 0.432390 1.519970 -0.493662 0.600178 0.274230
1 0.206053 -0.251905 -2.213588 1.063327 1.266143 0.299368 -0.863838 0.408204
2 1.262731 1.289997 0.082423 -0.055758 0.536580 -0.489682 0.369374 -0.034571

You can adjust the max width of the individual columns by setting `display.max_colwidth`:

In [127]: datafile = {
               .....:     "filename": ["filename_01", "filename_02"],
               .....:     "path": [
               .....:         "media/user_name/storage/folder_01/filename_01",
               .....:         "media/user_name/storage/folder_02/filename_02",
               .....:     ],
               .....: }

In [128]: pd.set_option("display.max_colwidth", 30)

In [129]: pd.DataFrame(datafile)
Out[129]:
 filename path
0  filename_01 media/user_name/storage/fo...
1  filename_02 media/user_name/storage/fo...

In [130]: pd.set_option("display.max_colwidth", 100)

In [131]: pd.DataFrame(datafile)
Out[131]:
 filename path
0  filename_01 media/user_name/storage/folder_01/filename_01
1  filename_02 media/user_name/storage/folder_02/filename_02

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

2.2. Intro to data structures
DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```
In [132]: df = pd.DataFrame({"foo1": np.random.randn(5), "foo2": np.random.randn(5)})

In [133]: df
Out[133]:
foo1  foo2
0  1.126203  0.781836
1 -0.977349 -1.071357
2  1.474071  0.441153
3 -0.064034  2.353925
4 -1.282782  0.583787

In [134]: df.foo1
Out[134]:
0  1.126203
1 -0.977349
2  1.474071
3 -0.064034
4 -1.282782
Name: foo1, dtype: float64
```

The columns are also connected to the IPython completion mechanism so they can be tab-completed:

```
In [5]: df.fo<TAB>  # noqa: E225, E999
df.fo1 df.fo2
```

2.3 Essential basic functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. To begin, let’s create some example objects like we did in the 10 minutes to pandas section:

```
In [1]: index = pd.date_range("1/1/2000", periods=8)
In [2]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=["A", "B", "C"])
```

2.3.1 Head and tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [4]: long_series = pd.Series(np.random.randn(1000))
In [5]: long_series.head()
Out[5]:
0  -1.157892
```

(continues on next page)
1 -1.344312
2 0.844885
3 1.075770
4 -0.109050
dtype: float64

In [6]: long_series.tail(3)
Out[6]:
997 -0.289388
998 -1.020544
999 0.589993
dtype: float64

2.3.2 Attributes and underlying data

pandas objects have a number of attributes enabling you to access the metadata

- shape: gives the axis dimensions of the object, consistent with ndarray

- Axis labels
  - Series: index (only axis)
  - DataFrame: index (rows) and columns

Note, these attributes can be safely assigned to!

In [7]: df[:2]
Out[7]:
       A       B       C
2000-01-01 -0.173215  0.119209 -1.044236
2000-01-02 -0.861849 -2.104569 -0.494929

In [8]: df.columns = [x.lower() for x in df.columns]

In [9]: df
Out[9]:
       a       b       c
2000-01-01 -0.173215  0.119209 -1.044236
2000-01-02 -0.861849 -2.104569 -0.494929
2000-01-03  1.071804  0.721555 -0.706771
2000-01-04 -1.039575  0.271860 -0.424972
2000-01-05  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427
2000-01-07  0.524988  0.404705  0.577046
2000-01-08 -1.715002 -1.039268 -0.370647

pandas objects (Index, Series, DataFrame) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a numpy.ndarray. However, pandas and 3rd party libraries may extend NumPy’s type system to add support for custom arrays (see dtypes).

To get the actual data inside a Index or Series, use the .array property
array will always be an ExtensionArray. The exact details of what an ExtensionArray is and why pandas uses them are a bit beyond the scope of this introduction. See dtypes for more.

If you know you need a NumPy array, use to_numpy() or numpy.asarray().

When the Series or Index is backed by an ExtensionArray, to_numpy() may involve copying data and coercing values. See dtypes for more.

to_numpy() gives some control over the dtype of the resulting numpy.ndarray. For example, consider datetimes with timezones. NumPy doesn’t have a dtype to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-dtype numpy.ndarray with Timestamp objects, each with the correct tz
2. A datetime64[ns]-dtype numpy.ndarray, where the values have been converted to UTC and the timezone discarded

Timezones may be preserved with dtype=object

Getting the “raw data” inside a DataFrame is possibly a bit more complex. When your DataFrame only has a single data type for all the columns, DataFrame.to_numpy() will return the underlying data:
If a DataFrame contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame’s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

**Note:** When working with heterogeneous data, the dtype of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a Series or DataFrame. You’ll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your Series contains an extension type, it’s unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an `ExtensionArray`, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.

2. When your DataFrame contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the DataFrame.

### 2.3.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have nans.

Here is a sample (using 100 column x 100,000 row DataFrames):

<table>
<thead>
<tr>
<th>Operation</th>
<th>0.11.0 (ms)</th>
<th>Prior Version (ms)</th>
<th>Ratio to Prior</th>
</tr>
</thead>
<tbody>
<tr>
<td>df1 &gt; df2</td>
<td>13.32</td>
<td>125.35</td>
<td>0.1063</td>
</tr>
<tr>
<td>df1 * df2</td>
<td>21.71</td>
<td>36.63</td>
<td>0.5928</td>
</tr>
<tr>
<td>df1 + df2</td>
<td>22.04</td>
<td>36.50</td>
<td>0.6039</td>
</tr>
</tbody>
</table>

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:
2.3.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

Matching / broadcasting behavior

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

```
In [18]: df = pd.DataFrame(
        ....:     {
        ....:         "one": pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
        ....:         "two": pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
        ....:         "three": pd.Series(np.random.randn(3), index=['b', 'c', 'd']),
        ....:     }
        ....: )

In [19]: df
Out[19]:
   one   two   three
  a  1.394981  1.772517   NaN
  b  0.343054  1.912123 -0.050390
  c  0.695246  1.478369  1.227435
  d  NaN     0.279344 -0.613172

In [20]: row = df.iloc[1]

In [21]: column = df["two"]

In [22]: df.sub(row, axis="columns")
Out[22]:
   one   two   three
  a  1.051928 -0.139606   NaN
  b  0.000000  0.000000 -0.050390
  c  0.352192 -0.433754  1.277825
  d  NaN     -1.632779 -0.562782

In [23]: df.sub(row, axis=1)
Out[23]:
   one   two   three
  a  1.051928 -0.139606   NaN
```

(continues on next page)
Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

```python
In [26]: dfmi = df.copy()

In [27]: dfmi.index = pd.MultiIndex.from_tuples(
            [(1, "a"), (1, "b"), (1, "c"), (2, "a")], names=["first", "second"]

In [28]: dfmi.sub(column, axis=0, level="second")
```

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```python
In [29]: s = pd.Series(np.arange(10))

In [30]: s
```

(continues on next page)
In [31]: div, rem = divmod(s, 3)

In [32]: div
Out[32]:
0 0
1 0
2 0
3 1
4 1
5 1
6 2
7 2
8 2
9 3
dtype: int64

In [33]: rem
Out[33]:
0 0
1 1
2 2
3 0
4 1
5 2
6 0
7 1
8 2
9 0
dtype: int64

In [34]: idx = pd.Index(np.arange(10))

In [35]: idx
Out[35]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')

In [36]: div, rem = divmod(idx, 3)

In [37]: div
Out[37]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')

In [38]: rem
Out[38]: Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')

We can also do elementwise `divmod()`:

In [39]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])

(continues on next page)
In [40]: div
Out[40]:
0   0
1   0
2   0
3   1
4   1
5   1
6   1
7   1
8   1
9   1
dtype: int64

In [41]: rem
Out[41]:
0   0
1   1
2   2
3   0
4   0
5   1
6   1
7   2
8   2
9   3
dtype: int64

Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a fill_value, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using fillna if you wish).

In [42]: df
Out[42]:
   one   two   three
a  1.394981  1.772517    NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d   NaN    0.279344 -0.613172

In [43]: df2
Out[43]:
   one   two   three
a  1.394981  1.772517  1.000000
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d   NaN    0.279344 -0.613172

(continues on next page)
Flexible comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

### In [46]: df.gt(df2)

#### Out[46]:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>b</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>c</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>d</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

### In [47]: df2.ne(df)

#### Out[47]:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>False</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>b</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>c</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>d</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on *Boolean indexing*.

Boolean reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

### In [48]: (df > 0).all()

#### Out[48]:

<table>
<thead>
<tr>
<th>one</th>
<th>False</th>
</tr>
</thead>
<tbody>
<tr>
<td>two</td>
<td>True</td>
</tr>
<tr>
<td>three</td>
<td>False</td>
</tr>
</tbody>
</table>

dtype: bool

(continues on next page)
In [49]: (df > 0).any()
Out[49]:
one    True
two    True
three   True
dtype: bool

You can reduce to a final boolean value.

In [50]: (df > 0).any().any()
Out[50]: True

You can test if a pandas object is empty, via the `empty` property.

In [51]: df.empty
Out[51]: False

In [52]: pd.DataFrame(columns=list("ABC")).empty
Out[52]: True

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

In [53]: pd.Series([True]).bool()
Out[53]: True

In [54]: pd.Series([False]).bool()
Out[54]: False

In [55]: pd.DataFrame([[True]]).bool()
Out[55]: True

In [56]: pd.DataFrame([[False]]).bool()
Out[56]: False

Warning: You might be tempted to do the following:

```python
>>> if df:
...    pass
```

Or

```python
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.:

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See `gotchas` for a more detailed discussion.
Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider \( \text{df + df} \) and \( \text{df * 2} \). To test that these two computations produce the same result, given the tools shown above, you might imagine using \((\text{df + df} == \text{df * 2}).\text{all()}\). But in fact, this expression is False:

```python
In [57]: df + df == df * 2
Out[57]:
   one  two  three
  a   True  True   False
  b   True  True   True
  c   True  True   True
  d   False  True   True

In [58]: (df + df == df * 2).all()
Out[58]:
   one   False
  two   True
  three   False
dtype: bool
```

Notice that the boolean DataFrame \( \text{df + df} == \text{df * 2} \) contains some False values! This is because NaNs do not compare as equals:

```python
In [59]: np.nan == np.nan
Out[59]: False
```

So, NDFrames (such as Series and DataFrames) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```python
In [60]: (df + df).equals(df * 2)
Out[60]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```python
In [61]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})
In [62]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
In [63]: df1.equals(df2)
Out[63]: False
In [64]: df1.equals(df2.sort_index())
Out[64]: True
```
Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [65]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[65]:
0   True
1  False
2  False
dtype: bool
```

```
In [66]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[66]: array([ True, False, False])
```

Pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [67]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[67]:
0   True
1   True
2  False
dtype: bool
```

```
In [68]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[68]:
0   True
1   True
2  False
dtype: bool
```

Trying to compare Index or Series objects of different lengths will raise a ValueError:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare
```

```
In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series('foo')
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([2])
Out[69]: array([False,  True, False])
```

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```
Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of "higher quality". However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

In [71]: df1 = pd.DataFrame(  
...:     {"A": [1.0, np.nan, 3.0, 5.0, np.nan], "B": [np.nan, 2.0, 3.0, np.nan, 6.0]}  
...: )

In [72]: df2 = pd.DataFrame(  
...:     {  
...:         "A": [5.0, 2.0, 4.0, np.nan, 3.0, 7.0],  
...:         "B": [np.nan, np.nan, 3.0, 4.0, 6.0, 8.0],  
...:     }  
...: )

In [73]: df1
Out[73]:
A   B
0 1.0  NaN
1 NaN  2.0
2 3.0  3.0
3 5.0  NaN
4 NaN  6.0

In [74]: df2
Out[74]:
A   B
0 5.0  NaN
1 NaN  2.0
2 4.0  3.0
3 NaN  4.0
4 3.0  6.0
5 7.0  8.0

In [75]: df1.combine_first(df2)
Out[75]:
A   B
0 1.0  NaN
1 2.0  2.0
2 3.0  3.0
3 5.0  4.0
4 3.0  6.0
5 7.0  8.0
General DataFrame combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```python
In [76]: def combiner(x, y):
    ....:     return np.where(pd.isna(x), y, x)
    ....:

In [77]: df1.combine(df2, combiner)
Out[77]:
   A  B
0  1.0 NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0
```

2.3.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on `Series`, `DataFrame`. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsun()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an `axis` argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)

For example:

```python
In [78]: df
Out[78]:
  one    two    three
a  1.394981  1.772517  NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d  NaN      0.279344 -0.613172

In [79]: df.mean(0)
Out[79]:
  one   0.811094
two   1.360588
three  0.187958
dtype: float64

In [80]: df.mean(1)
Out[80]:
a   1.583749
```

(continues on next page)
All such methods have a skipna option signaling whether to exclude missing data (True by default):

```python
In [81]: df.sum(0, skipna=False)
Out[81]:
        one        two        three
    NaN       5.442353         NaN
 dtype: float64

In [82]: df.sum(axis=1, skipna=True)
Out[82]:
   a   3.167498
   b   2.204786
   c   3.401050
   d  -0.333828
 dtype: float64
```

Combined with the broadcasting/arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation of 1), very concisely:

```python
In [83]: ts_stand = (df - df.mean()) / df.std()
In [84]: ts_stand.std()
Out[84]:
   one   two   three
  1.0   1.0   1.0
 dtype: float64

In [85]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)
In [86]: xs_stand.std(1)
Out[86]:
   a   b   c   d
  1.0 1.0 1.0 1.0
 dtype: float64
```

Note that methods like cumsum() and cumprod() preserve the location of NaN values. This is somewhat different from expanding() and rolling() since NaN behavior is furthermore dictated by a min_periods parameter.

```python
In [87]: df.cumsum()
Out[87]:
     one    two    three
   NaN   NaN    NaN
   NaN   NaN    NaN
   NaN   NaN    NaN
```

(continues on next page)
Here is a quick reference summary table of common functions. Each also takes an optional \texttt{level} parameter which applies only if the object has a \textit{hierarchical index}.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>Number of non-NA observations</td>
</tr>
<tr>
<td>sum</td>
<td>Sum of values</td>
</tr>
<tr>
<td>mean</td>
<td>Mean of values</td>
</tr>
<tr>
<td>mad</td>
<td>Mean absolute deviation</td>
</tr>
<tr>
<td>median</td>
<td>Arithmetic median of values</td>
</tr>
<tr>
<td>min</td>
<td>Minimum</td>
</tr>
<tr>
<td>max</td>
<td>Maximum</td>
</tr>
<tr>
<td>mode</td>
<td>Mode</td>
</tr>
<tr>
<td>abs</td>
<td>Absolute Value</td>
</tr>
<tr>
<td>prod</td>
<td>Product of values</td>
</tr>
<tr>
<td>std</td>
<td>Bessel-corrected sample standard deviation</td>
</tr>
<tr>
<td>var</td>
<td>Unbiased variance</td>
</tr>
<tr>
<td>sem</td>
<td>Standard error of the mean</td>
</tr>
<tr>
<td>skew</td>
<td>Sample skewness (3rd moment)</td>
</tr>
<tr>
<td>kurt</td>
<td>Sample kurtosis (4th moment)</td>
</tr>
<tr>
<td>quantile</td>
<td>Sample quantile (value at %</td>
</tr>
<tr>
<td>cumsum</td>
<td>Cumulative sum</td>
</tr>
<tr>
<td>cumprod</td>
<td>Cumulative product</td>
</tr>
<tr>
<td>cummax</td>
<td>Cumulative maximum</td>
</tr>
<tr>
<td>cummin</td>
<td>Cumulative minimum</td>
</tr>
</tbody>
</table>

Note that by chance some NumPy methods, like \texttt{mean}, \texttt{std}, and \texttt{sum}, will exclude NAs on Series input by default:

```python
In [88]: np.mean(df["one"])
Out[88]: 0.8110935116651192

In [89]: np.mean(df["one"].to_numpy())
Out[89]: nan
```

\texttt{Series.nunique()} will return the number of unique non-NA values in a Series:

```python
In [90]: series = pd.Series(np.random.randn(500))

In [91]: series[20:500] = np.nan

In [92]: series[10:20] = 5

In [93]: series.nunique()
Out[93]: 11
```
### Summarizing data: `describe`

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```python
In [94]: series = pd.Series(np.random.randn(1000))

In [95]: series[::2] = np.nan

In [96]: series.describe()
```

```
Out[96]:
count 500.000000
mean -0.021292
std 1.015906
min -2.683763
25% -0.699070
50% -0.069718
75% 0.714483
max 3.160915
dtype: float64
```

```python
In [97]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e'])

In [98]: frame.iloc[::2] = np.nan

In [99]: frame.describe()
```

```
Out[99]:
a   b   c   d   e
   count 500.000000 500.000000 500.000000 500.000000 500.000000
   mean  0.033387  0.030045 -0.043719 -0.051686  0.005979
   std  1.017152  0.978743  1.025270  1.015988  1.006695
   25% -0.647623 -0.576449 -0.712369 -0.691338 -0.691115
   50%  0.047578 -0.021499 -0.023888 -0.032652 -0.025363
   75%  0.729907  0.775880  0.618896  0.670047  0.649748
   max  2.740139  2.752332  3.004229  2.728702  3.240991
```

You can select specific percentiles to include in the output:

```python
In [100]: series.describe(percentiles=[0.05, 0.25, 0.75, 0.95])
```

```
Out[100]:
count 500.000000
mean -0.021292
std 1.015906
min -2.683763
5% -1.645423
25% -0.699070
50% -0.069718
75% 0.714483
95% 1.711409
max 3.160915
dtype: float64
```
By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```python
In [101]: s = pd.Series(["a", "a", "b", "b", "a", "a", np.nan, "c", "d", "a"])
In [102]: s.describe()
Out[102]:
   count 9
   unique 4
top     a
   freq  5
dtype: object
```

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```python
In [103]: frame = pd.DataFrame({"a": ["Yes", "Yes", "No", "No"], "b": range(4)})
In [104]: frame.describe()
Out[104]:
          b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000
```

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```python
In [105]: frame.describe(include=["object"])
Out[105]:
      a
count  4
unique 2
top   Yes
freq   2

In [106]: frame.describe(include=["number"])
Out[106]:
     b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000
```

(continues on next page)
In [107]: frame.describe(include="all")

Out[107]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>4</td>
<td>4.000000</td>
</tr>
<tr>
<td>unique</td>
<td>2</td>
<td>NaN</td>
</tr>
<tr>
<td>top</td>
<td>Yes</td>
<td>NaN</td>
</tr>
<tr>
<td>freq</td>
<td>2</td>
<td>NaN</td>
</tr>
<tr>
<td>mean</td>
<td>NaN</td>
<td>1.500000</td>
</tr>
<tr>
<td>std</td>
<td>NaN</td>
<td>1.290994</td>
</tr>
<tr>
<td>min</td>
<td>NaN</td>
<td>0.000000</td>
</tr>
<tr>
<td>25%</td>
<td>NaN</td>
<td>0.750000</td>
</tr>
<tr>
<td>50%</td>
<td>NaN</td>
<td>1.500000</td>
</tr>
<tr>
<td>75%</td>
<td>NaN</td>
<td>2.250000</td>
</tr>
<tr>
<td>max</td>
<td>NaN</td>
<td>3.000000</td>
</tr>
</tbody>
</table>

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

### Index of min/max values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

In [108]: s1 = pd.Series(np.random.randn(5))

In [109]: s1

Out[109]:

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.118076</td>
<td>-0.352051</td>
<td>-1.242883</td>
<td>-1.277155</td>
<td>-0.641184</td>
</tr>
<tr>
<td>dtype: float64</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In [110]: s1.idxmin(), s1.idxmax()

Out[110]:

(3, 0)

In [111]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])

In [112]: df1

Out[112]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-0.327863</td>
<td>-0.946180</td>
<td>-0.137570</td>
</tr>
<tr>
<td>1</td>
<td>-0.186235</td>
<td>-0.257213</td>
<td>-0.486567</td>
</tr>
<tr>
<td>2</td>
<td>-0.507027</td>
<td>-0.871259</td>
<td>-0.111110</td>
</tr>
<tr>
<td>3</td>
<td>2.006339</td>
<td>-2.430505</td>
<td>0.089759</td>
</tr>
<tr>
<td>4</td>
<td>-0.321434</td>
<td>-0.033695</td>
<td>0.096271</td>
</tr>
</tbody>
</table>

In [113]: df1.idxmin(axis=0)

Out[113]:

<table>
<thead>
<tr>
<th>A</th>
<th>2</th>
</tr>
</thead>
</table>
When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```python
In [115]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=["A"], index=list("edcba"))
In [116]: df3
Out[116]:
     A
    e  2.0
    d  1.0
    c  1.0
    b  3.0
    a  NaN

In [117]: df3["A"].idxmin()
Out[117]: 'd'
```

Note: `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

### Value counts (histogramming) / mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```python
In [118]: data = np.random.randint(0, 7, size=50)
In [119]: data
Out[119]:
array([6, 6, 2, 3, 5, 3, 2, 5, 4, 5, 4, 3, 4, 5, 0, 2, 0, 4, 2, 0, 3, 2,
       2, 5, 6, 5, 3, 4, 6, 4, 3, 5, 6, 4, 3, 6, 2, 6, 6, 2, 3, 4, 2, 1,
       6, 2, 6, 1, 5, 4])

In [120]: s = pd.Series(data)
In [121]: s.value_counts()
Out[121]:
    6    10
```

(continues on next page)
New in version 1.1.0.

The `value_counts()` method can be used to count combinations across multiple columns. By default all columns are used but a subset can be selected using the `subset` argument.

```python
In [123]: data = {"a": [1, 2, 3, 4], "b": ["x", "x", "y", "y"]}

In [124]: frame = pd.DataFrame(data)

In [125]: frame.value_counts()
```

```
Out[125]:
          a  b
    1  x  1
    2  x  1
    3  y  1
    4  y  1
dtype: int64
```

Similarly, you can get the most frequently occurring value(s), i.e. the mode, of the values in a Series or DataFrame:

```python
In [126]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])

In [127]: s5.mode()
```

```
Out[127]:
0  3
1  7
dtype: int64
```

```python
In [128]: df5 = pd.DataFrame(
    ....:     {  
    ....:         "A": np.random.randint(0, 7, size=50),
    ....:         "B": np.random.randint(-10, 15, size=50),
    ....:     }
    ....: )
```
In [129]: df5.mode()
Out[129]:
   A  B
0   1.0 -9
1  NaN 10
2  NaN 13

Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

In [130]: arr = np.random.randn(20)
In [131]: factor = pd.cut(arr, 4)
In [132]: factor
Out[132]:
[(-0.251, 0.464], (-0.968, -0.251], (0.464, 1.179], (-0.251, 0.464], ...
   ...,
(-0.251, 0.464], (-0.968, -0.251], (-0.968, -0.251], (-0.968, -0.251], (-0.968, -0.251)]
Length: 20
Categories (4, interval[float64, right]): 
   (-0.968, -0.251] < (-0.251, 0.464] < (0.464, 1.179] <
   (1.179, 1.893]]
In [133]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])
In [134]: factor
Out[134]:
[(0, 1], (-1, 0], (0, 1], (-1, 0], ..., (-1, 0], (-1, 0], (-1, 0], (-1, 0],
   ...,-0)
Length: 20
Categories (4, interval[int64, right]): 
   (-5, -1] < (-1, 0] < (0, 1] < (1, 5]]

dcut() computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

In [135]: arr = np.random.randn(30)
In [136]: factor = pd.qcut(arr, [0, 0.25, 0.5, 0.75, 1])
In [137]: factor
Out[137]:
[(0.569, 1.184], (-2.278, -0.301], (-2.278, -0.301], (0.569, 1.184], (0.569, 1.184], ...
   ...,-(-0.301, 0.569], (1.184, 2.346], (1.184, 2.346], (-0.301, 0.569], (-2.278, -0.301]
Length: 30
Categories (4, interval[float64, right]): 
   (-2.278, -0.301] < (-0.301, 0.569] < (0.569, 1.184] <
   (1.184, 2.346] <

(continues on next page)
We can also pass infinite values to define the bins:

```python
In [139]: arr = np.random.randn(20)
In [140]: factor = pd.cut(arr, [-np.inf, 0, np.inf])
In [141]: factor
Out[141]:
[(-inf, 0.0], (0.0, inf], (0.0, inf], (-inf, 0.0], (-inf, 0.0], ..., (-inf, 0.0], (-inf, 0.0], (0.0, inf], (0.0, inf]
Length: 20
Categories (2, interval[float64, right]): [(-inf, 0.0] < (0.0, inf]]
```

### 2.3.6 Function application

To apply your own or another library’s functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. **Tablewise Function Application**: `pipe()`
2. **Row or Column-wise Function Application**: `apply()`
3. **Aggregation API**: `agg()` and `transform()`
4. **Applying Elementwise Functions**: `applymap()`

#### Tablewise function application

DataFrames and Series can be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method.

First some setup:

```python
In [142]: def extract_city_name(df):
    ....:     
    ....:     "Chicago, IL -> Chicago for city_name column"
    ....:     
    ....:     df["city_name"] = df["city_and_code"].str.split("","").str.get(0)
    ....:     return df
    ....:
In [143]: def add_country_name(df, country_name=None):
```
In [144]: df_p = pd.DataFrame({"city_and_code": ["Chicago, IL"]})

extract_city_name and add_country_name are functions taking and returning DataFrames.

Now compare the following:

In [145]: add_country_name(extract_city_name(df_p), country_name="US")
Out[145]:
   city_and_code  city_name  city_and_country
0  Chicago, IL    Chicago    ChicagoUS

Is equivalent to:

In [146]: df_p.pipe(extract_city_name).pipe(add_country_name, country_name="US")
Out[146]:
   city_and_code  city_name  city_and_country
0  Chicago, IL    Chicago    ChicagoUS

pandas encourages the second style, which is known as method chaining. pipe makes it easy to use your own or another library’s functions in method chains, alongside pandas’ methods.

In the example above, the functions extract_city_name and add_country_name each expected a DataFrame as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide pipe with a tuple of (callable, data_keyword). .pipe will route the DataFrame to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a DataFrame as the second argument, data. We pass in the function, keyword pair (sm.ols, 'data') to pipe:

In [147]: import statsmodels.formula.api as sm

In [148]: bb = pd.read_csv("data/baseball.csv", index_col="id")

In [149]: (  
......:     bb.query("h > 0")  
......:     .assign(ln_h=lambda df: np.log(df.h))  
......:     .pipe((sm.ols, "data"), "hr ~ ln_h + year + g + C(lg)")  
......:     .fit()  
......:     .summary()  
......: )

Out[149]:
<class 'statsmodels.iolib.summary.Summary'>

    OLS Regression Results

==============================================================================
### Regression Results

- **Dep. Variable:** hr  
- **Model:** OLS  
- **Method:** Least Squares  
- **Date:** Sat, 12 Feb 2022  
- **Time:** 09:26:55  
- **R-squared:** 0.685  
- **Adj. R-squared:** 0.665  
- **F-statistic:** 34.28  
- **Prob (F-statistic):** 3.48e-15  
- **Log-Likelihood:** -205.92  
- **AIC:** 421.8  
- **BIC:** 432.9  
- **Df Residuals:** 63  
- **Df Model:** 4  
- **Covariance Type:** nonrobust  

|            | coef   | std err | t     | P>|t|   | [0.025  | 0.975] |
|------------|--------|---------|-------|-------|---------|---------|
| Intercept  | -8484.772 | 4664.146 | -1.819 | 0.074 | -1.78e+04 | 835.780 |
| C(lg)[T.NL]| -2.2736   | 1.325   | -1.716 | 0.091 | -4.922  | 0.375   |
| ln_h       | -1.3542   | 0.875   | -1.547 | 0.127 | -3.103  | 0.395   |
| year       | 4.2277    | 2.324   | 1.819  | 0.074 | -0.417  | 8.872   |
| g          | 0.1841    | 0.029   | 6.258  | 0.000 | 0.125   | 0.243   |

- **Omnibus:** 10.875  
- **Durbin-Watson:** 1.999  
- **Prob(Omnibus):** 0.004  
- **Jaque-Bera (JB):** 17.298  
- **Skew:** 0.537  
- **Prob(JB):** 0.000175  
- **Kurtosis:** 5.225  
- **Cond. No.:** 1.49e+07

**Notes:**

1. Standard Errors assume that the covariance matrix of the errors is correctly specified.
2. The condition number is large, 1.49e+07. This might indicate that there are strong multicollinearity or other numerical problems.

---

The pipe method is inspired by unix pipes and more recently dplyr and magrittr, which have introduced the popular `%>%` (read pipe) operator for R. The implementation of pipe here is quite clean and feels right at home in Python. We encourage you to view the source code of `pipe()`.

### Row or column-wise function application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```python
In [150]: df.apply(np.mean)
Out[150]:
one  0.811094
two  1.360588
three 0.187958
dtype: float64

In [151]: df.apply(np.mean, axis=1)
Out[151]:
a  1.583749
b  0.734929
```

(continues on next page)
In [152]: df.apply(lambda x: x.max() - x.min())
Out[152]:
   one  1.051928
   two  1.632779
   three 1.840607
dtype: float64

In [153]: df.apply(np.cumsum)
Out[153]:
   one  two  three
  a 1.394981 1.772517 NaN
  b 1.738035 3.684640 -0.050390
  c 2.433281 5.163008 1.177045
d  NaN 5.442353 0.563873

In [154]: df.apply(np.exp)
Out[154]:
   one  two  three
  a 4.034899 5.885648 NaN
  b 1.409244 6.767440 0.950858
c 2.004201 4.385785 3.412466
  d  NaN 1.322262 0.541630

The apply() method will also dispatch on a string method name.

In [155]: df.apply("mean")
Out[155]:
   one  0.811094
   two  1.360588
   three 0.187958
dtype: float64

In [156]: df.apply("mean", axis=1)
Out[156]:
   a  1.583749
   b  0.734929
c  1.133683
d -0.166914
dtype: float64

The return type of the function passed to apply() affects the type of the final output from DataFrame.apply for the default behaviour:

- If the applied function returns a Series, the final output is a DataFrame. The columns match the index of the Series returned by the applied function.
- If the applied function returns any other type, the final output is a Series.

This default behaviour can be overridden using the result_type, which accepts three options: reduce, broadcast, and expand. These will determine how list-likes return values expand (or not) to a DataFrame.
apply() combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```python
In [157]: tsdf = pd.DataFrame(
    .....:     np.random.randn(1000, 3),
    .....:     columns=['A', 'B', 'C'],
    .....:     index=pd.date_range("1/1/2000", periods=1000),
    .....:     )
    .....:
In [158]: tsdf.apply(lambda x: x.idxmax())
Out[158]:
A  2000-08-06
B  2001-01-18
C  2001-07-18
dtype: datetime64[ns]
```

You may also pass additional arguments and keyword arguments to the apply() method. For instance, consider the following function you would like to apply:

```python
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```python
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

```python
In [159]: tsdf.apply(pd.Series.interpolate)
Out[159]:
A  B  C
2000-01-01 -0.158131 -0.232466 0.321604
2000-01-02 -1.810340 -3.105758 0.433834
2000-01-03 -1.209847 -1.156793 -0.136794
2000-01-04 NaN NaN NaN
2000-01-05 NaN NaN NaN
2000-01-06 NaN NaN NaN
2000-01-07 NaN NaN NaN
2000-01-08 -0.653602 0.178875 1.008298
2000-01-09 1.007996 0.462824 0.254472
2000-01-10 0.307473 0.600337 1.643950
(continues on next page)
```
Finally, `apply()` takes an argument `raw` which is False by default, which converts each row or column into a Series before applying the function. When set to True, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

### Aggregation API

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see the `groupby API`, the `window API`, and the `resample API`. The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [161]: tsdf = pd.DataFrame(
              ....:     np.random.randn(10, 3),
              ....:     columns=["A", "B", "C"],
              ....:     index=pd.date_range("1/1/2000", periods=10),
              ....:     
              ....: )
```

```
In [162]: tsdf.iloc[3:7] = np.nan
```

```
In [163]: tsdf
```

```
Out[163]:
```

```
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>1.257606</td>
<td>1.004194</td>
<td>0.167574</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.749892</td>
<td>0.288112</td>
<td>-0.757304</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-0.207550</td>
<td>-0.298599</td>
<td>0.116018</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>0.814347</td>
<td>-0.257623</td>
<td>0.869226</td>
</tr>
<tr>
<td>2000-01-09</td>
<td>-0.250663</td>
<td>-1.206601</td>
<td>0.896839</td>
</tr>
<tr>
<td>2000-01-10</td>
<td>2.169758</td>
<td>-1.333632</td>
<td>0.283157</td>
</tr>
</tbody>
</table>
```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```
In [164]: tsdf.agg(np.sum)
```

```
Out[164]:
```

```
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>3.033606</td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>-1.803879</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>1.575510</td>
<td></td>
</tr>
</tbody>
</table>
```

```
In [165]: tsdf.agg("sum")
```

```
Out[165]:
```

```
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>3.033606</td>
</tr>
<tr>
<td>B</td>
<td>-1.803879</td>
</tr>
</tbody>
</table>
```

(continues on next page)
C 1.575510
dtype: float64

# these are equivalent to a `.sum()` because we are aggregating
# on a single function
In [166]: tsdf.sum()
Out[166]:
A  3.033606
B -1.803879
C  1.575510
dtype: float64

Single aggregations on a Series this will return a scalar value:

In [167]: tsdf["A"].agg("sum")
Out[167]: 3.033606102414146

Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

In [168]: tsdf.agg(['sum'])
Out[168]:
   A   B   C
sum 3.033606 -1.803879  1.575510

Multiple functions yield multiple rows:

In [169]: tsdf.agg(['sum', 'mean'])
Out[169]:
   A   B   C
sum 3.033606 -1.803879  1.575510
   mean 0.505601  0.300647  0.262585

On a Series, multiple functions return a Series, indexed by the function names:

In [170]: tsdf["A"].agg(['sum', 'mean'])
Out[170]:
   sum  3.033606
   mean 0.505601
Name: A, dtype: float64

Passing a lambda function will yield a <lambda> named row:

In [171]: tsdf["A"].agg(['sum', lambda x: x.mean()])
Out[171]:
   sum  3.033606
<lambda> 0.505601
Name: A, dtype: float64

Passing a named function will yield that name for the row:
In [172]: def mymean(x):
       ....:     return x.mean()
       ....:

In [173]: tsdf["A"].agg(["sum", mymean])
Out[173]:
sum    3.033606
mymean 0.505601
Name: A, dtype: float64

Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

In [174]: tsdf.agg({"A": "mean", "B": "sum"})
Out[174]:
A   0.505601
B  -1.803879
dtype: float64

Passing a list-like will generate a `DataFrame` output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be `NaN`:

In [175]: tsdf.agg({"A": ["mean", "min"], "B": "sum"})
Out[175]:
   A     B
  mean 0.505601 NaN
  min -0.749892 NaN
  sum  NaN -1.803879

Mixed dtypes

Deprecated since version 1.4.0: Attempting to determine which columns cannot be aggregated and silently dropping them from the results is deprecated and will be removed in a future version. If any portion of the columns or operations provided fail, the call to `.agg` will raise.

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `.groupby.agg` works.

In [176]: mdf = pd.DataFrame({
       ....:     "A": [1, 2, 3],
       ....:     "B": [1.0, 2.0, 3.0],
       ....:     "C": ["foo", "bar", "baz"],
       ....:     "D": pd.date_range("20130101", periods=3),
       ....: })

2.3. Essential basic functionality
In [177]: mdf.dtypes
Out[177]:
   A  int64
   B  float64
   C    object
   D  datetime64[ns]
dtype: object

In [178]: mdf.agg(["min", "sum"])
Out[178]:
       A  B      C     D
  min   1  1.0     bar 2013-01-01
  sum   6  6.0   foobarbaz       NaT

Custom describe

With .agg() it is possible to easily create a custom describe function, similar to the built in `describe` function.

In [179]: from functools import partial

In [180]: q_25 = partial(pd.Series.quantile, q=0.25)

In [181]: q_25.__name__ = "25%"

In [182]: q_75 = partial(pd.Series.quantile, q=0.75)

In [183]: q_75.__name__ = "75%"

In [184]: tsdf.agg(["count", "mean", "std", "min", q_25, "median", q_75, "max"])
Out[184]:
       A   B    C
count 6.000000 6.000000 6.000000
mean  0.505601 -0.300647 0.262585
std   1.103362 0.887508 0.606860
min  -0.749892 -1.333363 -0.757304
25%   -0.239885 -0.979600 0.128907
median 0.303398 -0.278111 0.225365
75%   1.146791 0.151678 0.722709
max   2.169758 1.004194 0.896839

Transform API

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide multiple operations at the same time rather than one-by-one. Its API is quite similar to the .agg API.

We create a frame similar to the one used in the above sections.

In [185]: tsdf = pd.DataFrame(
       ......:    np.random.randn(10, 3),
       ......:    columns=["A", "B", "C"],
       (continues on next page)
In [186]: todf.iloc[3:7] = np.nan

In [187]: todf

Out[187]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.428759</td>
<td>-0.864890</td>
<td>-0.675341</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.168731</td>
<td>1.338144</td>
<td>1.279321</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-1.621034</td>
<td>0.438107</td>
<td>0.903794</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>0.254374</td>
<td>-1.240447</td>
<td>-0.201052</td>
</tr>
<tr>
<td>2000-01-09</td>
<td>-0.157795</td>
<td>0.791197</td>
<td>1.144209</td>
</tr>
<tr>
<td>2000-01-10</td>
<td>-0.030876</td>
<td>0.371900</td>
<td>0.061932</td>
</tr>
</tbody>
</table>

Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

In [188]: todf.transform(np.abs)

Out[188]:

<table>
<thead>

</table>

In [190]: todf.transform(lambda x: x.abs())
Here `transform()` received a single function; this is equivalent to a `ufunc` application.

Passing a single function to `.transform()` with a `Series` will yield a single `Series` in return.
Transform with multiple functions

Passing multiple functions will yield a column MultiIndexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```
In [193]: tsdf.transform([np.abs, lambda x: x + 1])
Out[193]:
           A       B       C
2000-01-01 0.428759 0.571241 0.864890
2000-01-02 0.168731 0.831269 1.338144
2000-01-03 1.621034 -0.621034 0.438107
2000-01-04  NaN     NaN     NaN
2000-01-05  NaN     NaN     NaN
2000-01-06  NaN     NaN     NaN
2000-01-07  NaN     NaN     NaN
2000-01-08 0.254374 1.254374 2.40447 0.201052
2000-01-09 0.157795 0.842205 0.791197 1.791197
2000-01-10 0.030876 0.969124 0.371900 1.371900
```

Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```
In [194]: tsdf["A"].transform([np.abs, lambda x: x + 1])
Out[194]:
         absolute <lambda>
2000-01-01 0.428759 0.571241
2000-01-02 0.168731 0.831269
2000-01-03 1.621034 -0.621034
2000-01-04  NaN     NaN
2000-01-05  NaN     NaN
2000-01-06  NaN     NaN
2000-01-07  NaN     NaN
2000-01-08 0.254374 1.254374

```

Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```
In [195]: tsdf.transform({"A": np.abs, "B": lambda x: x + 1})
Out[195]:
           A       B
2000-01-01 0.428759 0.135110
2000-01-02 0.168731 2.338144
2000-01-03 1.621034 1.438107
2000-01-04  NaN     NaN
2000-01-05  NaN     NaN
2000-01-06  NaN     NaN
2000-01-07  NaN     NaN
2000-01-08 0.254374 -0.240447
```

(continues on next page)
Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```
In [196]: tsdf.transform({"A": np.abs, "B": [lambda x: x + 1, "sqrt"]})
Out[196]:
     A  B
    absolute <lambda>    sqrt
2000-01-01  0.428759  0.135110  NaN
2000-01-02  0.168731  2.338144  1.156782
2000-01-03  1.621034  1.438107  0.661897
2000-01-04  NaN  NaN  NaN
2000-01-05  NaN  NaN  NaN
2000-01-06  NaN  NaN  NaN
2000-01-07  NaN  NaN  NaN
2000-01-08  0.254374 -0.240447  NaN
2000-01-09  0.157795  1.791197  0.889493
2000-01-10  0.030876  1.371900  0.609836
```

### Applying elementwise functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```
In [197]: df4
Out[197]:
     one   two   three
   a  1.394981  1.772517  NaN
   b  0.343054  1.912123 -0.050390
   c  0.695246  1.478369  1.227435
   d   NaN  0.279344 -0.613172

In [198]: def f(x):
       .....:     return len(str(x))
       .....:

In [199]: df4["one"].map(f)
Out[199]:
     a  18
     b  19
     c  18
     d   3
Name: one, dtype: int64

In [200]: df4.applymap(f)
Out[200]:
     one   two   three
   a  18   17   3
   b  19   18  20
```

(continues on next page)
Series.map() has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to merging/joining functionality:

In [201]: s = pd.Series(
       ....:     ["six", "seven", "six", "seven", "six"], index=["a", "b", "c", "d", "e"]
       ....: )
       ....:
In [202]: t = pd.Series({"six": 6.0, "seven": 7.0})

In [203]: s
Out[203]:
   a    six
   b    seven
   c    six
   d    seven
   e    six
   dtype: object

In [204]: s.map(t)
Out[204]:
   a   6.0
   b   7.0
   c   6.0
   d   7.0
   e   6.0
   dtype: float64

### 2.3.7 Reindexing and altering labels

**reindex()** is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To **reindex** means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, **fill** data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

In [205]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e")

In [206]: s
Out[206]:
   a   1.695148
   b   1.328614
   c   1.234686
   d   -0.385845
   e   0.385845
   dtype: float64

... (continues on next page)
In [207]: s.reindex(["e", "b", "f", "d"])
Out[207]:
e -1.326508
b  1.328614
f  NaN
d  -0.385845
dtype: float64

Here, the f label was not contained in the Series and hence appears as NaN in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

In [208]: df
Out[208]:
one   two   three  
a  1.394981  1.772517  NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d  NaN      0.279344 -0.613172

In [209]: df.reindex(index=["c", "f", "b"], columns=["three", "two", "one"])
Out[209]:
three  two   one
  c  1.227435  1.478369  0.695246
  f  NaN      NaN      NaN
  b -0.050390  1.912123  0.343054

You may also use reindex with an axis keyword:

In [210]: df.reindex(["c", "f", "b"], axis="index")
Out[210]:
one   two   three  
a  1.394981  1.772517  NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d  NaN      0.279344 -0.613172

Note that the Index objects containing the actual axis labels can be shared between objects. So if we have a Series and a DataFrame, the following can be done:

In [211]: rs = s.reindex(df.index)

In [212]: rs
Out[212]:
a  1.695148
b  1.328614
c  1.234686
d -0.385845
dtype: float64

In [213]: rs.index is df.index

(continues on next page)
This means that the reindexed Series’s index is the same Python object as the DataFrame’s index. 

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single `labels` argument and the `axis` it applies to.

```
In [214]: df.reindex(['c', 'f', 'b'], axis='index')
Out[214]:
   one     two     three
  c  0.695246  1.478369  1.227435
  f       NaN         NaN
  b  0.343054  1.912123 -0.050390
```

```
In [215]: df.reindex(['three', 'two', 'one'], axis='columns')
Out[215]:
     three     two     one
  a  NaN  1.772517  1.394981
  b -0.050390  1.912123  0.343054
  c  1.227435  1.478369  0.695246
  d -0.061317  0.279344  NaN
```

See also:

`MultiIndex / Advanced Indexing` is an even more concise way of doing reindexing.

**Note:** When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: many operations are faster on pre-aligned data. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

### Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```
In [216]: df2
Out[216]:
     one     two
  a  1.394981  1.772517
  b  0.343054  1.912123
  c  0.695246  1.478369
```

```
In [217]: df3
Out[217]:
     one     two
  a  0.583888  0.051514
  b -0.468040  0.191120
  c -0.115848  0.242634
```

(continues on next page)
Aligning objects with each other with `align`

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to joining and merging):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```python
In [218]: df.reindex_like(df2)
Out[218]:
      one       two
a  1.394981  1.772517
b  0.343054  1.912123
c  0.695246  1.478369
```

```python
In [219]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
In [220]: s1 = s[:4]
In [221]: s2 = s[1:]
In [222]: s1.align(s2)
Out[222]:
(a  -0.186646
 b  -1.692424
 c  -0.303893
 d  -1.425662
e       NaN
dtype: float64,
a       NaN
b  -1.692424
c  -0.303893
d  -1.425662
e  1.114285
dtype: float64)
```

```python
In [223]: s1.align(s2, join="inner")
Out[223]:
(b  -1.692424
c  -0.303893
d  -1.425662
dtype: float64,
b  -1.692424
c  -0.303893
d  -1.425662
dtype: float64)
```
In [224]: s1.align(s2, join="left")
Out[224]:
(a -0.186646  
| b -1.692424  
| c -0.303893  
| d -1.425662  
dtype: float64,  
| a NaN  
| b -1.692424  
| c -0.303893  
| d -1.425662  
dtype: float64)

For DataFrames, the join method will be applied to both the index and the columns by default:

In [225]: df.align(df2, join="inner")
Out[225]:
( one two
| a 1.394981 1.772517  
| b 0.343054 1.912123  
| c 0.695246 1.478369,  
| one two
| a 1.394981 1.772517  
| b 0.343054 1.912123  
| c 0.695246 1.478369)

You can also pass an axis option to only align on the specified axis:

In [226]: df.align(df2, join="inner", axis=0)
Out[226]:
( one two three
| a 1.394981 NaN 1.772517  
| b 0.343054 -0.050390 1.912123  
| c 0.695246 1.227435 1.478369,  
| one two
| a 1.394981 1.772517  
| b 0.343054 1.912123  
| c 0.695246 1.478369)

If you pass a Series to DataFrame.align(), you can choose to align both objects either on the DataFrame’s index or columns using the axis argument:

In [227]: df.align(df2.iloc[0], axis=1)
Out[227]:
( one three two
| a 1.394981 NaN 1.772517  
| b 0.343054 -0.050390 1.912123  
| c 0.695246 1.227435 1.478369  
| one three two
| a 1.394981 1.772517  
| b NaN 1.912123  
| c 0.695246 1.279344  
| d NaN -0.613172 0.279344)

(continues on next page)
two  1.772517
Name: a, dtype: float64)

Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
<tr>
<td>nearest</td>
<td>Fill from the nearest index value</td>
</tr>
</tbody>
</table>

We illustrate these fill methods on a simple Series:

```
In [228]: rng = pd.date_range("1/3/2000", periods=8)
In [229]: ts = pd.Series(np.random.randn(8), index=rng)
In [230]: ts2 = ts[[0, 3, 6]]

In [231]: ts
Out[231]:
2000-01-03   0.183051
2000-01-04   0.400528
2000-01-05  -0.015083
2000-01-06   2.395489
2000-01-07   1.414806
2000-01-08   0.118428
2000-01-09   0.733639
2000-01-10  -0.936077
Freq: D, dtype: float64

In [232]: ts2
Out[232]:
2000-01-03   0.183051
2000-01-06   2.395489
2000-01-09   0.733639
Freq: 3D, dtype: float64

In [233]: ts2.reindex(ts.index)
Out[233]:
2000-01-03   0.183051
2000-01-04     NaN
2000-01-05     NaN
2000-01-06   2.395489
2000-01-07     NaN
2000-01-08     NaN
2000-01-09   0.733639
2000-01-10     NaN
Freq: D, dtype: float64
```

(continues on next page)
These methods require that the indexes are ordered increasing or decreasing.

Note that the same result could have been achieved using `fillna` (except for method='nearest') or `interpolate`:

```
In [237]: ts2.reindex(ts.index).fillna(method="ffill")
Out[237]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  0.183051
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  2.395489
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```
reindex() will raise a ValueError if the index is not monotonically increasing or decreasing. fillna() and interpolate() will not perform any checks on the order of the index.

**Limits on filling while reindexing**

The limit and tolerance arguments provide additional control over filling while reindexing. Limit specifies the maximum count of consecutive matches:

```
In [238]: ts2.reindex(ts.index, method="ffill", limit=1)
Out[238]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05   NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08   NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

In contrast, tolerance specifies the maximum distance between the index and indexer values:

```
In [239]: ts2.reindex(ts.index, method="ffill", tolerance="1 day")
Out[239]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05   NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08   NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

Notice that when used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, tolerance will coerced into a Timedelta if possible. This allows you to specify tolerance with appropriate strings.

**Dropping labels from an axis**

A method closely related to reindex is the drop() function. It removes a set of labels from an axis:

```
In [240]: df
Out[240]:
   one  two  three
a  1.394981  1.772517   NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d   NaN  0.279344 -0.613172

In [241]: df.drop(["a", "d"], axis=0)
Out[241]:
   one  two  three
    a  1.394981  1.772517   NaN
    b  0.343054  1.912123 -0.050390
    c  0.695246  1.478369  1.227435
```

(continues on next page)
Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

### In [244]:

```python
s
```

```bash
Out[244]:
da  0.186464
d  -1.694242
c  0.303893
d  1.425662
e  1.114285
dtype: float64
```

### In [245]:

```python
s.rename(str.upper)
```

```bash
Out[245]:
A  0.186464
B  -1.694242
C  0.303893
D  1.425662
E  1.114285
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

### In [246]:

```python
def rename(
    columns={"one": "foo", "two": "bar"},
    index={"a": "apple", "b": "banana", "d": "durian"},
)
```

```bash
Out[246]:
```

(continues on next page)
If the mapping doesn’t include a column/index label, it isn’t renamed. Note that extra labels in the mapping don’t throw an error.

*DataFrame.rename()* also supports an “axis-style” calling convention, where you specify a single *mapper* and the *axis* to apply that mapping to.

```
In [247]: df.rename({"one": "foo", "two": "bar"}, axis="columns")
Out[247]:
   foo   bar   three
    a 1.394981 1.772517  NaN
    b 0.343054 1.912123 -0.050390
    c 0.695246 1.478369  1.227435
    d  NaN 0.279344 -0.613172
```

```
In [248]: df.rename({"a": "apple", "b": "banana", "d": "durian"}, axis="index")
Out[248]:
one   two   three
apple 1.394981 1.772517  NaN
banana 0.343054 1.912123 -0.050390
     c 0.695246 1.478369  1.227435
     d  NaN 0.279344 -0.613172
```

The *rename()* method also provides an *inplace* named parameter that is by default *False* and copies the underlying data. Pass *inplace=True* to rename the data in place.

Finally, *rename()* also accepts a scalar or list-like for altering the *Series.name* attribute.

```
In [249]: s.rename("scalar-name")
Out[249]:
da   -1.425662
    e    1.114285
Name: scalar-name, dtype: float64
```

The methods *DataFrame.rename_axis()* and *Series.rename_axis()* allow specific names of a *MultiIndex* to be changed (as opposed to the labels).

```
In [250]: df = pd.DataFrame(
.....:     {"x": [1, 2, 3, 4, 5, 6], "y": [10, 20, 30, 40, 50, 60]},
.....:     index=pd.MultiIndex.from_product(
.....:         [["a", "b", "c"], [1, 2]], names=["let", "num"]
.....:     ))
.....:
In [251]: df
Out[251]:
```

(continues on next page)
2.3.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. DataFrames follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (for i in object) produces:

• Series: values

• DataFrame: column labels

Thus, for example, iterating over a DataFrame gives you the column names:

In [254]: df = pd.DataFrame( .....:     {"col1": np.random.randn(3), "col2": np.random.randn(3)}, index=['a', 'b', "c"] .....: ) .....:

In [255]: for col in df:
.....:     print(col)
pandas objects also have the dict-like `items()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.

- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning:** Iterating through pandas objects is generally slow. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a vectorized solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, …

- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on function application.

- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the enhancing performance section for some examples of this approach.

**Warning:** You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```python
In [256]: df = pd.DataFrame( {"a": [1, 2, 3], "b": ["a", "b", "c"]})
In [257]: for index, row in df.iterrows():
    .....:
    row["a"] = 10
    .....:
In [258]: df
Out[258]:
a b
0 1 a
1 2 b
2 3 c
```
items

Consistent with the dict-like interface, `items()` iterates through key-value pairs:

- **Series**: (index, scalar value) pairs
- **DataFrame**: (column, Series) pairs

For example:

```python
In [259]: for label, ser in df.items():
     ....:   print(label)
     ....:   print(ser)
     ....:
a 0 1
1 2
2 3
Name: a, dtype: int64
b 0 a
1 b
2 c
Name: b, dtype: object
```

iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```python
In [260]: for row_index, row in df.iterrows():
     ....:   print(row_index, row, sep="\n")
     ....:
0 a 1
   b a
Name: 0, dtype: object
1 a 2
   b b
Name: 1, dtype: object
2 a 3
   b c
Name: 2, dtype: object
```

**Note:** Because `iterrows()` returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
In [261]: df_orig = pd.DataFrame([[1, 1.5]], columns=["int", "float"])
In [262]: df_orig.dtypes
Out[262]:
```

(continues on next page)
int     int64
float   float64
dtype: object

In [263]: row = next(df_orig.iterrows())[1]

In [264]: row
Out[264]:
int  1.0
float 1.5
Name: 0, dtype: float64

All values in row, returned as a Series, are now upcasted to floats, also the original integer value in column x:

In [265]: row["int"].dtype
Out[265]: dtype('float64')

In [266]: df_orig["int"].dtype
Out[266]: dtype('int64')

To preserve dtypes while iterating over the rows, it is better to use itertuples() which returns namedtuples of the values and which is generally much faster than iterrows().

For instance, a contrived way to transpose the DataFrame would be:

In [267]: df2 = pd.DataFrame({"x": [1, 2, 3], "y": [4, 5, 6]})

In [268]: print(df2)
   
   x  y
0  1  4
1  2  5
2  3  6

In [269]: print(df2.T)
   
   0  1  2
   x  1  2  3
   y  4  5  6

In [270]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})

In [271]: print(df2_t)
   
   0  1  2
   x  1  2  3
   y  4  5  6
**itertuples**

The `itertuples()` method will return an iterator yielding a named tuple for each row in the DataFrame. The first element of the tuple will be the row’s corresponding index value, while the remaining values are the row values.

For instance:

```python
In [272]: for row in df.itertuples():
    print(row)
   ...
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a named tuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

**Note:** The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

### 2.3.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the values of the Series, if it is a datetime/period like Series. This will return a Series, indexed like the existing Series.

```python
# datetime
In [273]: s = pd.Series(pd.date_range("20130101 09:10:12", periods=4))

In [274]: s
Out[274]:
0   2013-01-01 09:10:12
1   2013-01-02 09:10:12
2   2013-01-03 09:10:12
3   2013-01-04 09:10:12
dtype: datetime64[ns]

In [275]: s.dt.hour
Out[275]:
0     9
1     9
2     9
3     9
dtype: int64

In [276]: s.dt.second
Out[276]:
0    12
1    12
2    12
3    12
dtype: int64
```

(continues on next page)
In [277]: s.dt.day
Out[277]:
0    1
1    2
2    3
3    4
dtype: int64

This enables nice expressions like this:

In [278]: s[s.dt.day == 2]
Out[278]:
1   2013-01-02 09:10:12
dtype: datetime64[ns]

You can easily produce tz aware transformations:

In [279]: stz = s.dt.tz_localize("US/Eastern")
In [280]: stz
Out[280]:
0 2013-01-01 09:10:12-05:00
1 2013-01-02 09:10:12-05:00
2 2013-01-03 09:10:12-05:00
3 2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]

In [281]: stz.dt.tz
Out[281]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

You can also chain these types of operations:

In [282]: s.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")
Out[282]:
0 2013-01-01 04:10:12-05:00
1 2013-01-02 04:10:12-05:00
2 2013-01-03 04:10:12-05:00
3 2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

# DatetimeIndex

In [283]: s = pd.Series(pd.date_range("20130101", periods=4))
In [284]: s
Out[284]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: datetime64[ns]
In [285]: s.dt.strftime("%Y/%m/%d")
Out[285]:
0  2013/01/01
1  2013/01/02
2  2013/01/03
3  2013/01/04
dtype: object

# PeriodIndex
In [286]: s = pd.Series(pd.period_range("20130101", periods=4))
In [287]: s
Out[287]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04
dtype: period[D]
In [288]: s.dt.strftime("%Y/%m/%d")
Out[288]:
0  2013/01/01
1  2013/01/02
2  2013/01/03
3  2013/01/04
dtype: object

The `.dt` accessor works for period and timedelta dtypes.

# period
In [289]: s = pd.Series(pd.period_range("20130101", periods=4, freq="D"))
In [290]: s
Out[290]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04
dtype: period[D]
In [291]: s.dt.year
Out[291]:
0  2013
1  2013
2  2013
3  2013
dtype: int64
In [292]: s.dt.day
Out[292]:
0  1

(continues on next page)
# timedelta

In [293]: s = pd.Series(pd.timedelta_range("1 day 00:00:05", periods=4, freq="s"))

In [294]: s
Out[294]:
0  1 days 00:00:05
1  1 days 00:00:06
2  1 days 00:00:07
3  1 days 00:00:08
dtype: timedelta64[ns]

In [295]: s.dt.days
Out[295]:
0  1
1  1
2  1
3  1
dtype: int64

In [296]: s.dt.seconds
Out[296]:
0   5
1   6
2   7
3   8
dtype: int64

In [297]: s.dt.components
Out[297]:
   days  hours  minutes  seconds  milliseconds microseconds nanoseconds
0   1       0        0       5          0          0           0
1   1       0        0       6          0          0           0
2   1       0        0       7          0          0           0
3   1       0        0       8          0          0           0

Note: Series.dt will raise a TypeError if you access with a non-datetime-like values.
2.3.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series’s `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [298]: s = pd.Series(.....:
    .......: ['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
    .......: dtype='string'
    .......: )
    .......:
In [299]: s.str.lower()
Out[299]:
  0 a
  1 b
  2 c
  3 aaba
  4 baca
  5 <NA>
  6 caba
  7 dog
  8 cat
dtype: string
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

**Note:** Prior to pandas 1.0, string methods were only available on `object`-dtype Series. pandas 1.0 added the `StringDtype` which is dedicated to strings. See Text data types for more.

Please see Vectorized String Methods for a complete description.

2.3.11 Sorting

pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

By index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [300]: df = pd.DataFrame(.....:
    .......: {.....:
    .......:     "one": pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
    .......:     "two": pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
    .......:     "three": pd.Series(np.random.randn(3), index=['b', 'c', 'd']),
    .......: }
    .......: )
    .......:
```

(continues on next page)
In [301]: unsorted_df = df.reindex(
        ....:     index=["a", "d", "c", "b"], columns=["three", "two", "one"]
        ....: )
        ....:

In [302]: unsorted_df

Out[302]:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>NaN</td>
<td>-1.152244</td>
<td>0.562973</td>
</tr>
<tr>
<td>d</td>
<td>-0.252916</td>
<td>-0.109597</td>
<td>NaN</td>
</tr>
<tr>
<td>c</td>
<td>1.273388</td>
<td>-0.167123</td>
<td>0.640382</td>
</tr>
<tr>
<td>b</td>
<td>-0.098217</td>
<td>0.009797</td>
<td>-1.299504</td>
</tr>
</tbody>
</table>

# DataFrame

In [303]: unsorted_df.sort_index()

Out[303]:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>NaN</td>
<td>-1.152244</td>
<td>0.562973</td>
</tr>
<tr>
<td>d</td>
<td>-0.252916</td>
<td>-0.109597</td>
<td>NaN</td>
</tr>
<tr>
<td>c</td>
<td>1.273388</td>
<td>-0.167123</td>
<td>0.640382</td>
</tr>
<tr>
<td>b</td>
<td>-0.098217</td>
<td>0.009797</td>
<td>-1.299504</td>
</tr>
</tbody>
</table>

In [304]: unsorted_df.sort_index(ascending=False)

Out[304]:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>NaN</td>
<td>-0.252916</td>
<td>-0.109597</td>
</tr>
<tr>
<td>c</td>
<td>1.273388</td>
<td>-0.167123</td>
<td>0.640382</td>
</tr>
<tr>
<td>b</td>
<td>-0.098217</td>
<td>0.009797</td>
<td>-1.299504</td>
</tr>
<tr>
<td>a</td>
<td>NaN</td>
<td>-1.152244</td>
<td>0.562973</td>
</tr>
</tbody>
</table>

In [305]: unsorted_df.sort_index(axis=1)

Out[305]:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>three</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.562973</td>
<td>NaN</td>
<td>-1.152244</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
<td>-0.252916</td>
<td>-0.109597</td>
</tr>
<tr>
<td>c</td>
<td>0.640382</td>
<td>1.273388</td>
<td>-0.167123</td>
</tr>
<tr>
<td>b</td>
<td>-1.299504</td>
<td>-0.098217</td>
<td>0.009797</td>
</tr>
</tbody>
</table>

# Series

In [306]: unsorted_df["three"].sort_index()

Out[306]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>NaN</td>
</tr>
<tr>
<td>b</td>
<td>-0.098217</td>
</tr>
<tr>
<td>c</td>
<td>1.273388</td>
</tr>
<tr>
<td>d</td>
<td>-0.252916</td>
</tr>
</tbody>
</table>

Name: three, dtype: float64

New in version 1.1.0.

Sorting by index also supports a key parameter that takes a callable function to apply to the index being sorted. For MultiIndex objects, the key is applied per-level to the levels specified by level.
In [307]: s1 = pd.DataFrame({'a': ['B', 'a', 'C'], 'b': [1, 2, 3], 'c': [2, 3, 4]}).set_index(list('ab'))

In [308]: s1
Out[308]:
   c  
  a  b
B 1 2
a 2 3
C 3 4

In [309]: s1.sort_index(level='a')
Out[309]:
   c  
  a  b
B 1 2
a 2 3
C 3 4

In [310]: s1.sort_index(level='a', key=lambda idx: idx.str.lower())
Out[310]:
   c  
  a  b
a 2 3
B 1 2
C 3 4

For information on key sorting by value, see value sorting.

By values

The Series.sort_values() method is used to sort a Series by its values. The DataFrame.sort_values() method is used to sort a DataFrame by its column or row values. The optional by parameter to DataFrame.sort_values() may used to specify one or more columns to use to determine the sorted order.

In [311]: df1 = pd.DataFrame(
   ....:   {'one': [2, 1, 1, 1], 'two': [1, 3, 2, 4], 'three': [5, 4, 3, 2]}
   ....: )

In [312]: df1.sort_values(by='two')
Out[312]:
   one  two  three
0 2  1  5
2 1  2  3
1 1  3  4
3 1  4  2

The by parameter can take a list of column names, e.g.:
These methods have special treatment of NA values via the `na_position` argument:

```python
In [314]: s[2] = np.nan
In [315]: s.sort_values()
Out[315]:
   0  A
   3  Aaba
   1  B
   4  Baca
   6  CABA
   8  cat
   7  dog
   2  <NA>
   5  <NA>
dtype: string
```

```python
In [316]: s.sort_values(na_position="first")
Out[316]:
   2  <NA>
   5  <NA>
   0  A
   3  Aaba
   1  B
   4  Baca
   6  CABA
   8  cat
   7  dog
dtype: string
```

New in version 1.1.0.
Sorting also supports a `key` parameter that takes a callable function to apply to the values being sorted.

```python
In [317]: s1 = pd.Series(['B', 'a', 'C'])
In [318]: s1.sort_values()
Out[318]:
   0  B
   2  C
   1  a
dtype: object
```

```python
In [319]: s1.sort_values(key=lambda x: x.str.lower())
Out[319]:
(continues on next page)
key will be given the Series of values and should return a Series or array of the same shape with the transformed values. For DataFrame objects, the key is applied per column, so the key should still expect a Series and return a Series, e.g.

```
In [320]: df = pd.DataFrame({"a": ["B", "a", "C"], "b": [1, 2, 3]})
```

```
In [321]: df.sort_values(by="a")
Out[321]:
   a b
0 B 1
1 a 2
2 C 3
```

```
In [322]: df.sort_values(by="a", key=lambda col: col.str.lower())
Out[322]:
   a b
1 a 2
0 B 1
2 C 3
```

The name or type of each column can be used to apply different functions to different columns.

**By indexes and values**

Strings passed as the by parameter to DataFrame.sort_values() may refer to either columns or index level names.

```
# Build MultiIndex
In [323]: idx = pd.MultiIndex.from_tuples(
       .....:     [("a", 1), ("a", 2), ("a", 2), ("b", 2), ("b", 1), ("b", 1)]
       .....:)

In [324]: idx.names = ["first", "second"]
```

```
# Build DataFrame
In [325]: df_multi = pd.DataFrame{"A": np.arange(6, 0, -1)}, index=idx)

In [326]: df_multi
Out[326]:
         A
first  second
  a     1    6
    2    5
    2    4
  b     2    3
    1    2
    1    1
```

2.3. Essential basic functionality
Sort by ‘second’ (index) and ‘A’ (column)

```
In [327]: df_multi.sort_values(by=['second', 'A'])
Out[327]:
   A
first second
b  1  1
   1  2
a  1  6
b  2  3
a  2  4
   2  5
```

**Note:** If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

**searchsorted**

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [328]: ser = pd.Series([1, 2, 3])
In [329]: ser.searchsorted([0, 3])
Out[329]: array([0, 2])
In [330]: ser.searchsorted([0, 4])
Out[330]: array([0, 3])
In [331]: ser.searchsorted([1, 3], side="right")
Out[331]: array([1, 3])
In [332]: ser.searchsorted([1, 3], side="left")
Out[332]: array([0, 2])
In [333]: ser = pd.Series([3, 1, 2])
In [334]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[334]: array([0, 2])
```

**smallest / largest values**

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest n values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```
In [335]: s = pd.Series(np.random.permutation(10))
In [336]: s
Out[336]:
0    2
1    0
```

(continues on next page)
In [337]: s.sort_values()
Out[337]:
1 0
4 1
0 2
2 3
9 4
5 5
7 6
3 7
8 8
6 9
dtype: int64

In [338]: s.nsmallest(3)
Out[338]:
1 0
4 1
0 2
dtype: int64

In [339]: s.nlargest(3)
Out[339]:
6 9
8 8
3 7
dtype: int64

DataFrames also have the `nlargest` and `nsmallest` methods.

In [340]: df = pd.DataFrame(
   ...:       {
   ...:           "a": [-2, -1, 1, 10, 8, 11, -1],
   ...:           "b": list("abdceff"),
   ...:           "c": [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0],
   ...:       }
   ...:     )

In [341]: df.nlargest(3, "a")
Out[341]:
a  b  c
---
   ---
1  0  1
4  1  1
11  0  1

(continues on next page)
In [342]: df.nlargest(5, ["a", "c"])  
Out[342]:  
   a  b  c  
0  5  11 f  3.0  
1  3  10 c  3.2  
2  4  8  e  NaN  
6  6  1  d  4.0  
3  6  (  f  4.0

In [343]: df.nsmallest(3, "a")  
Out[343]:  
   a  b  c  
0 -2  a  1.0  
1  1  b  2.0  
6  6  f  4.0

In [344]: df.nsmallest(5, ["a", "c"])  
Out[344]:  
   a  b  c  
0 -2  a  1.0  
1 -1  b  2.0  
6  6  f  4.0  
2  1  d  4.0  
4  8  e  NaN

Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to by.

In [345]: df1.columns = pd.MultiIndex.from_tuples(  
......:       ["a", "one"], ("a", "two"), ("b", "three")  
......: )  
......:  

In [346]: df1.sort_values(by="a", "two")  
Out[346]:  
   a  b  
one two three  
0  2  1  5  
2  1  2  3  
1  1  3  4  
3  1  4  2
2.3.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that it is seldom necessary to copy objects. For example, there are only a handful of ways to alter a DataFrame in-place:

- Inserting, deleting, or modifying a column.
- Assigning to the index or columns attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

2.3.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for `float`, `int`, `bool`, `timedelta64[ns]` and `datetime64[ns]` (note that NumPy does not support timezone-aware datetimes).

Pandas and third-party libraries extend NumPy’s type system in a few places. This section describes the extensions pandas has made internally. See Extension types for how to write your own extension that works with pandas. See ecosystem.extensions for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. For methods requiring `dtype` arguments, strings can be specified as indicated. See the respective documentation sections for more on each type.

<table>
<thead>
<tr>
<th>Kind of Data</th>
<th>Data Type</th>
<th>Scalar</th>
<th>Array</th>
<th>String Aliases</th>
</tr>
</thead>
<tbody>
<tr>
<td>tz-aware date-time</td>
<td>DatetimeTZDtype</td>
<td>Timestamp</td>
<td>arrays. DatetimeArray</td>
<td>'datetime64[ns, &lt;tz&gt;]'</td>
</tr>
<tr>
<td>Categorical period</td>
<td>CategoricalDtype</td>
<td>(none)</td>
<td>CategoricalArray</td>
<td>'category'</td>
</tr>
<tr>
<td>(time spans)</td>
<td>PeriodDtype</td>
<td>Period</td>
<td>arrays. PeriodArray</td>
<td>'period[&lt;freq&gt;],'</td>
</tr>
<tr>
<td>sparse</td>
<td>SparseDtype</td>
<td>(none)</td>
<td>SparseArray</td>
<td>'Sparse', 'Sparse[int]', 'Sparse[float]'</td>
</tr>
<tr>
<td>intervals</td>
<td>IntervalDtype</td>
<td>Interval</td>
<td>arrays. IntervalArray</td>
<td>'interval', 'Interval[&lt;numpy_dtype&gt;]', 'Interval[datetime64[ns, &lt;tz&gt;]]', 'Interval[timedelta64[&lt;freq&gt;]]'</td>
</tr>
<tr>
<td>nullable integer</td>
<td>Int64Dtype</td>
<td>(none)</td>
<td>IntegerArray</td>
<td>'Int8', 'Int16', 'Int32', 'Int64', 'UInt8', 'UInt16', 'UInt32', 'UInt64'</td>
</tr>
<tr>
<td>Strings</td>
<td>StringDtype</td>
<td>(none)</td>
<td>StringArray</td>
<td>'string'</td>
</tr>
<tr>
<td>Boolean (with NA)</td>
<td>BooleanDtype</td>
<td>(none)</td>
<td>BooleanArray</td>
<td>'boolean'</td>
</tr>
</tbody>
</table>
pandas has two ways to store strings.

1. **object dtype**, which can hold any Python object, including strings.

2. **StringDtype**, which is dedicated to strings.

Generally, we recommend using **StringDtype**. See Text data types for more.

Finally, arbitrary objects may be stored using the object dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See object conversion).

A convenient **dtypes** attribute for DataFrame returns a Series with the data type of each column.

```python
In [347]: dft = pd.DataFrame(
    ...:     {
    ...:         "A": np.random.rand(3),
    ...:         "B": 1,
    ...:         "C": "foo",
    ...:         "D": pd.Timestamp("20010102"),
    ...:         "E": pd.Series([1.0] * 3).astype("float32"),
    ...:         "F": False,
    ...:         "G": pd.Series([1] * 3, dtype="int8")
    ...:     }
    ...: )
In [348]: dft
Out[348]:
   A     B     C       D       E  F     G
0 0.035962 1  foo 2001-01-02 1.0 False 1
1 0.701379 1  foo 2001-01-02 1.0 False 1
2 0.281885 1  foo 2001-01-02 1.0 False 1

In [349]: dft.dtypes
Out[349]:
A    float64
B    int64
C   object
D  datetime64[ns]
E   float32
F      bool
G    int8
dtype: object
```

On a Series object, use the **dtype** attribute.

```python
In [350]: dft["A"].dtype
Out[350]: dtype('float64')
```

If a pandas object contains data with multiple dtypes in a single column, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

```python
# these ints are coerced to floats
In [351]: pd.Series([1, 2, 3, 4, 5, 6.0])
Out[351]:
0    1.0
```

(continues on next page)
In [352]: pd.Series([1, 2, 3, 6.0, "foo"])
Out[352]:
0  1
1  2
2  3
3  6.0
4  foo
dtype: object

The number of columns of each type in a DataFrame can be found by calling DataFrame.dtypes.value_counts().

In [353]: dft.dtypes.value_counts()
Out[353]:
float64  1
int64    1
object   1
datetime64[ns]  1
float32  1
bool     1
int8     1
dtype: int64

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the dtype keyword, a passed ndarray, or a passed Series), then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will NOT be combined. The following example will give you a taste.

In [354]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=["A"], dtype="float32")

In [355]: df1
Out[355]:
     A
0  0.224364
1  1.890546
2  0.182879
3  0.787847
4 -0.188449
5  0.667715
6 -0.011736
7 -0.399073

In [356]: df1.dtypes
Out[356]:
A  float32
dtype: object

(continues on next page)
In [357]: df2 = pd.DataFrame(
        .....:     {
        .....:         "A": pd.Series(np.random.randn(8), dtype="float16"),
        .....:         "B": pd.Series(np.random.randn(8)),
        .....:         "C": pd.Series(np.array(np.random.randn(8), dtype="uint8")),
        .....:     }
        .....: )
In [358]: df2
Out[358]:
A B C
0 0.823242 0.256090 0
1 1.607422 1.426469 0
2 -0.333740 -0.416203 255
3 -0.063477 1.139976 0
4 -1.014648 -1.193477 0
5 0.678711 0.096706 0
6 -0.040863 -1.956850 1
7 -0.357422 -0.714337 0
In [359]: df2.dtypes
Out[359]:
A float16
B float64
C uint8
dtype: object

defaults

By default integer types are int64 and float types are float64, regardless of platform (32-bit or 64-bit). The following will all result in int64 dtypes.

In [360]: pd.DataFrame([1, 2], columns=["a"]).dtypes
Out[360]:
a int64
dtype: object

In [361]: pd.DataFrame({"a": [1, 2]}).dtypes
Out[361]:
a int64
dtype: object

In [362]: pd.DataFrame({"a": 1}, index=list(range(2))).dtypes
Out[362]:
a int64
dtype: object

Note that Numpy will choose platform-dependent types when creating arrays. The following WILL result in int32 on 32-bit platform.
Types can potentially be upcasted when combined with other types, meaning they are promoted from the current type (e.g. int to float).

```
In [364]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
In [365]: df3
Out[365]:
     A    B    C
0  1.05  0.26  0.0
1  3.49  1.42  0.0
2 -0.15 -0.41  255
3  0.72  1.14  0.0
4 -1.20 -1.19  0.0
5  1.34  0.09  0.0
6 -0.05 -1.96  1.0
7 -0.76 -0.71  0.0
```

```
In [366]: df3.dtypes
Out[366]:
     A    B    C
dtype: float32
```

DataFrame.to_numpy() will return the lower-common-denominator of the dtypes, meaning the dtype that can accommodate ALL of the types in the resulting homogeneous dtyped NumPy array. This can force some upcasting.

```
In [367]: df3.to_numpy().dtype
Out[367]:
dtype('float64')
```

You can use the astype() method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass copy=False to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the NumPy rules. If two different dtypes are involved in an operation, then the more general one will be used as the result of the operation.

```
In [368]: df3
Out[368]:
     A    B    C
0  1.05  0.26  0.0
1  3.49  1.42  0.0
2 -0.15 -0.41  255
3  0.72  1.14  0.0
4 -1.20 -1.19  0.0
(continues on next page)```
5  1.346426  0.096706  0.0
6  -0.052599 -1.956850  1.0
7  -0.756495 -0.714337  0.0

In [369]: df3.dtypes
Out[369]:
A   float32
B   float64
C   float64
dtype: object

# conversion of dtypes
In [370]: df3.astype("float32").dtypes
Out[370]:
A   float32
B   float32
C   float32
dtype: object

Convert a subset of columns to a specified type using `astype()`.

In [371]: dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})

In [372]: dft[['a', 'b']] = dft[['a', 'b']].astype(np.uint8)

In [373]: dft
Out[373]:
a  b  c
0  1  4  7
1  2  5  8
2  3  6  9

In [374]: dft.dtypes
Out[374]:
a   uint8
b   uint8
c   int64
dtype: object

Convert certain columns to a specific dtype by passing a dict to `astype()`.

In [375]: dft1 = pd.DataFrame({"a": [1, 0, 1], "b": [4, 5, 6], "c": [7, 8, 9]})

In [376]: dft1 = dft1.astype({"a": np.bool_, "c": np.float64})

In [377]: dft1
Out[377]:
a  b  c
0  True  4  7.0
1  False  5  8.0
2  True  6  9.0
pandas: powerful Python data analysis toolkit, Release 1.4.1

In [378]: dft1.dtypes
Out[378]:
  a  bool
  b  int64
  c  float64
dtype: object

Note: When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. 
`loc()` tries to fit in what we are assigning to the current dtypes, while [] will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

In [379]: dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})
In [380]: dft.loc[:, ["a", "b"]].astype(np.uint8).dtypes
Out[380]:
  a  uint8
  b  uint8
dtype: object
In [381]: dft.loc[:, ["a", "b"]].astype(np.uint8)
In [382]: dft.dtypes
Out[382]:
  a  int64
  b  int64
  c  int64
dtype: object

**object conversion**

pandas offers various functions to try to force conversion of types from the object dtype to other types. In cases where the data is already of the correct type, but stored in an object array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

In [383]: import datetime
In [384]: df = pd.DataFrame(
.....: [1, 2],
.....: ["a", "b"],
.....: [datetime.datetime(2016, 3, 2), datetime.datetime(2016, 3, 2)],
.....: )
In [385]: df = df.T
In [386]: df

2.3. Essential basic functionality
Because the data was transposed the original inference stored all columns as object, which infer_objects will correct.

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- **to_numeric()** (conversion to numeric dtypes)

  ```python
  In [389]: m = ['1.1', 2, 3]
  In [390]: pd.to_numeric(m)
  Out[390]: array([1.1, 2., 3.])
  ```

- **to_datetime()** (conversion to datetime objects)

  ```python
  In [391]: import datetime
  In [392]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]
  In [393]: pd.to_datetime(m)
  Out[393]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns], freq=None)
  ```

- **to_timedelta()** (conversion to timedelta objects)

  ```python
  In [394]: m = ['5us', pd.Timedelta("1day")]
  In [395]: pd.to_timedelta(m)
  Out[395]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype='timedelta64[ns], freq=None)
  ```

To force a conversion, we can pass in an errors argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, errors='raise', meaning that any errors encountered will be raised during the conversion process. However, if errors='coerce', these errors will be ignored and pandas will convert problematic elements to pd.NaT (for datetime and timedelta) or np.nan (for numeric). This might be
useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

In [396]: import datetime
In [397]: m = ['apple', datetime.datetime(2016, 3, 2)]
In [398]: pd.to_datetime(m, errors='coerce')
Out[398]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)
In [399]: m = ['apple', 2, 3]
In [400]: pd.to_numeric(m, errors='coerce')
Out[400]: array([nan, 2., 3.])
In [401]: m = ['apple', pd.Timedelta('1day')]
In [402]: pd.to_timedelta(m, errors='coerce')
Out[402]: TimedeltaIndex(['NaT', '1 days'], dtype='timedelta64[ns]', freq=None)

The errors parameter has a third option of errors='ignore', which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

In [403]: import datetime
In [404]: m = ['apple', datetime.datetime(2016, 3, 2)]
In [405]: pd.to_datetime(m, errors='ignore')
Out[405]: Index(['apple', 2016-03-02 00:00:00], dtype=object)
In [406]: m = ['apple', 2, 3]
In [407]: pd.to_numeric(m, errors='ignore')
Out[407]: array(['apple', 2, 3], dtype=object)
In [408]: m = ['apple', pd.Timedelta('1day')]
In [409]: pd.to_timedelta(m, errors='ignore')
Out[409]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)

In addition to object conversion, to_numeric() provides another argument downcast, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

In [410]: m = ['1', 2, 3]
In [411]: pd.to_numeric(m, downcast='integer')  # smallest signed int dtype
Out[411]: array([1, 2, 3], dtype=int8)
In [412]: pd.to_numeric(m, downcast='signed')  # same as 'integer'
Out[412]: array([1, 2, 3], dtype=int8)
In [413]: pd.to_numeric(m, downcast='unsigned')  # smallest unsigned int dtype
Out[413]: array([1, 2, 3], dtype=uint8)

(continues on next page)
As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```
In [415]: import datetime

In [416]: df = pd.DataFrame([["2016-07-09", datetime.datetime(2016, 3, 2)] * 2, dtype="O")

In [417]: df
Out[417]:
      0          1
0  2016-07-09  2016-03-02
1  2016-07-09  2016-03-02

In [418]: df.apply(pd.to_datetime)
Out[418]:
      0          1
0  2016-07-09  2016-03-02
1  2016-07-09  2016-03-02

In [419]: df = pd.DataFrame([["1.1", 2, 3]] * 2, dtype="O")

In [420]: df
Out[420]:
  0 1 2
0 1.1 2 3
1 1.1 2 3

In [421]: df.apply(pd.to_numeric)
Out[421]:
  0 1 2
0 1.1 2 3
1 1.1 2 3

In [422]: df = pd.DataFrame([["5us", pd.Timedelta("1day")]] * 2, dtype="O")

In [423]: df
Out[423]:
    0          1
0  5us  1 days
1  5us  1 days

In [424]: df.apply(pd.to_timedelta)
Out[424]:
    0          1
0  0 days  00:00:00.000005  1 days
1  0 days  00:00:00.000005  1 days
```
gotchas

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also Support for integer NA.

```
In [425]: dfi = df3.astype("int32")
In [426]: dfi["E"] = 1
In [427]: dfi
Out[427]:
    A  B  C  E
0  1  0  0  1
1  3  1  0  1
2  0  0  255 1
3  0  1  0  1
4  0  1  0  1
5  0  1  0  1
6  0  1  1  1
7  0  0  0  1
In [428]: dfi.dtypes
Out[428]:
    A    int32
    B    int32
    C    int32
    E    int64
dtype: object
In [429]: casted = dfi[dfi > 0]
In [430]: casted
Out[430]:
    A  B  C  E
0  1.0 NaN  NaN  1
1  3.0 1.0  NaN  1
2  NaN  NaN  255.0 1

7 NaN  NaN  NaN

In [437]: casted.dtypes
Out[437]:
A float32
B float64
C float64
dtype: object

### 2.3.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their dtype.

First, let’s create a `DataFrame` with a slew of different dtypes:

```python
In [438]: df = pd.DataFrame(
    ...:     {
    ...:         "string": list("abc"),
    ...:         "int64": list(range(1, 4)),
    ...:         "uint8": np.arange(3, 6).astype("u1"),
    ...:         "float64": np.arange(4.0, 7.0),
    ...:         "bool1": [True, False, True],
    ...:         "bool2": [False, True, False],
    ...:         "dates": pd.date_range("now", periods=3),
    ...:         "category": pd.Series(list("ABC")).astype("category"),
    ...:     }
    ...: )
```

...
In [439]: df["tdeltas"] = df.dates.diff()

In [440]: df["uint64"] = np.arange(3, 6).astype("u8")

In [441]: df["other_dates"] = pd.date_range("20130101", periods=3)

In [442]: df["tz_aware_dates"] = pd.date_range("20130101", periods=3, tz="US/Eastern")

In [443]: df

Out[443]:

</tr>
</tbody>
</table>

[3 rows x 12 columns]

And the dtypes:

In [444]: df.dtypes

Out[444]:

<table>
<thead>
<tr>
<th>string</th>
<th>object</th>
</tr>
</thead>
<tbody>
<tr>
<td>int64</td>
<td>int64</td>
</tr>
<tr>
<td>uint8</td>
<td>uint8</td>
</tr>
<tr>
<td>float64</td>
<td>float64</td>
</tr>
<tr>
<td>bool</td>
<td>bool</td>
</tr>
<tr>

</tr>
<tr>
<td>tz_aware_dates</td>
<td>datetime64[ns, US/Eastern]</td>
</tr>
<tr>
<td>dtype: object</td>
<td>object</td>
</tr>
</tbody>
</table>

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns with these dtypes” (include) and/or “give the columns without these dtypes” (exclude).

For example, to select bool columns:

In [445]: df.select_dtypes(include=[bool])

Out[445]:

<table>
<thead>
<tr>
<th>bool1</th>
<th>bool2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>True</td>
</tr>
<tr>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>False</td>
</tr>
</tbody>
</table>

You can also pass the name of a dtype in the NumPy dtype hierarchy:
In [446]: df.select_dtypes(include="bool")
Out[446]:
   bool1  bool2  
0   True  False
1  False   True
2   True  False

select_dtypes() also works with generic dtypes as well.  

For example, to select all numeric and boolean columns while excluding unsigned integers:

In [447]: df.select_dtypes(include=["number", "bool"], exclude=["unsignedinteger"])
Out[447]:
   int64  float64  bool1  bool2  tdeltas
0   1.0       4.0   True  False  NaT
1   2.0       5.0  False   True  1 days
2   3.0       6.0   True  False  1 days

To select string columns you must use the object dtype:

In [448]: df.select_dtypes(include=["object"])
Out[448]:
   string
0   a
1   b
2   c

To see all the child dtypes of a generic dtype like numpy.number you can define a function that returns a tree of child dtypes:

In [449]: def subdtypes(dtype):
   ....:     subs = dtype.__subclasses__()
   ....:     if not subs:
   ....:         return dtype
   ....:     return [dtype, [subdtypes(dt) for dt in subs]]

All NumPy dtypes are subclasses of numpy.generic:

In [450]: subdtypes(np.generic)
Out[450]:
[numpy.generic,
 [[numpy.number,
   [[numpy.integer,
     [[numpy.signedinteger,
       [numpy.int8,
         numpy.int16,
         numpy.int32,
         numpy.int64,
         numpy.longlong,
         numpy.timedelta64]],
     [numpy.unsignedinteger,
       [numpy.uint8,
         numpy.uint16,
         numpy.uint32,
         numpy.uint64,
         numpy.uint16]]]]]]
(continues on next page)
numpy.uint32,
numpy.uint64,
numpy.ulonglong]],
[numpy.inexact,
[[numpy.float64,
[numpy.float32, numpy.float64, numpy.float128]],
[numpy.complex128, numpy.complex256]]]],
numpy.flexible,
[[numpy.character, [numpy.bytes_, numpy.str_]],
numpy.bool_,
numpy.datetime64,
numpy.object_]]

Note: pandas also defines the types category and datetime64[ns, tz], which are not integrated into the normal NumPy hierarchy and won't show up with the above function.

## 2.4 IO tools (text, CSV, HDF5, ...)  

The pandas I/O API is a set of top level reader functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding writer functions are object methods that are accessed like `DataFrame.to_csv()`.

Below is a table containing available readers and writers.

<table>
<thead>
<tr>
<th>Format Type</th>
<th>Data Description</th>
<th>Reader</th>
<th>Writer</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>CSV</td>
<td>read_csv</td>
<td>to_csv</td>

<td>to_sql</td>
</tr>
<tr>
<td>SQL</td>
<td>Google BigQuery</td>
<td>read_gbq</td>
<td>to_gbq</td>
</tr>
</tbody>
</table>

Here is an informal performance comparison for some of these IO methods.
2.4.1 CSV & text files

The workhorse function for reading text files (a.k.a. flat files) is \texttt{read_csv()}. See the cookbook for some advanced strategies.

Parsing options

\texttt{read_csv()} accepts the following common arguments:

Basic

- \texttt{filepath_or_buffer} [various] Either a path to a file (a \texttt{str}, \texttt{pathlib.Path}, or \texttt{py:py._path.local.LocalPath}), URL (including http, ftp, and S3 locations), or any object with a \texttt{read()} method (such as an open file or \texttt{StringIO}).
- \texttt{sep} [str, defaults to ', ' for \texttt{read_csv()}, \t for \texttt{read_table()}] Delimiter to use. If \texttt{sep} is \texttt{None}, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, \texttt{csv.Sniffer}. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.
- \texttt{delimiter} [str, default \texttt{None}] Alternative argument name for \texttt{sep}.
- \texttt{delim_whitespace} [boolean, default False] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the delimiter. Equivalent to setting \texttt{sep='\s+'}. If this option is set to \texttt{True}, nothing should be passed in for the \texttt{delimiter} parameter.

Column and index locations and names

- \texttt{header} [int or list of ints, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to \texttt{header=0} and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to \texttt{header=None}. Explicitly pass \texttt{header=0} to be able to replace existing names.

  The header can be a list of ints that specify row locations for a MultiIndex on the columns e.g. \texttt{[0,1,3]}. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if \texttt{skip_blank_lines=True}, so \texttt{header=0} denotes the first line of data rather than the first line of the file.

- \texttt{names} [array-like, default \texttt{None}] List of column names to use. If file contains no header row, then you should explicitly pass \texttt{header=None}. Duplicates in this list are not allowed.

- \texttt{index_col} [int, str, sequence of int / str, or False, optional, default \texttt{None}] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

  Note: \texttt{index_col=False} can be used to force pandas to \texttt{not} use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.
The default value of `None` instructs pandas to guess. If the number of fields in the column header row is equal to
the number of fields in the body of the data file, then a default index is used. If it is larger, then the first columns
are used as index so that the remaining number of fields in the body are equal to the number of fields in the
header.

The first row after the header is used to determine the number of columns, which will go into the index. If the
subsequent rows contain less columns than the first row, they are filled with `NaN`.

This can be avoided through `usecols`. This ensures that the columns are taken as is and the trailing data are
ignored.

`usecols` [list-like or callable, default `None`] Return a subset of the columns. If list-like, all elements must either be
positional (i.e. integer indices into the document columns) or strings that correspond to column names provided
either by the user in `names` or inferred from the document header row(s). If `names` are given, the document
header row(s) are not taken into account. For example, a valid list-like `usecols` parameter would be `[0, 1, 2] or ['foo', 'bar', 'baz']`.

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from data
with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in
`['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable
function evaluates to True:

```python
In [1]: import pandas as pd
In [2]: from io import StringIO
In [3]: data = "col1,col2,col3\n    :a,b,1\n    :a,b,2\n    :c,d,3"
In [4]: pd.read_csv(StringIO(data))
Out[4]:
     col1  col2  col3
0     a     b     1
1     a     b     2
2     c     d     3
In [5]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COL1', 'COL3'])
Out[5]:
     col1  col3
0     a     1
1     a     2
2     c     3
```

Using this parameter results in much faster parsing time and lower memory usage when using the c engine. The
Python engine loads the data first before deciding which columns to drop.

`squeeze` [boolean, default `False`] If the parsed data only contains one column then return a `Series`.

Deprecated since version 1.4.0: Append `.squeeze("columns")` to the call to `{func_name}` to squeeze the
data.

`prefix` [str, default `None`] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

Deprecated since version 1.4.0: Use a list comprehension on the DataFrame’s columns after calling `read_csv`.
```
In [6]: data = "col1,col2,col3\na,b,1"
In [7]: df = pd.read_csv(StringIO(data))
In [8]: df.columns = [f"pre_{col}" for col in df.columns]
In [9]: df
Out[9]:
   pre_col1  pre_col2  pre_col3
0        a        b        1
```

**mangle_dupe_cols** [boolean, default True] Duplicate columns will be specified as ‘X’, ‘X.1’…’X.N’, rather than ‘X’…’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**General parsing configuration**

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use str or object together with suitable na_values settings to preserve and not interpret dtype.

**engine** [{'c', 'python', 'pyarrow'}] Parser engine to use. The C and pyarrow engines are faster, while the python engine is currently more feature-complete. Multithreading is currently only supported by the pyarrow engine.

New in version 1.4.0: The “pyarrow” engine was added as an experimental engine, and some features are unsupported, or may not work correctly, with this engine.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, default None] Values to consider as True.

**false_values** [list, default None] Values to consider as False.

**skipinitialspace** [boolean, default False] Skip spaces after delimiter.

**skiprows** [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:

```
In [10]: data = "col1,col2,col3\na,b,1\nb,a,2\nc,d,3"
In [11]: pd.read_csv(StringIO(data))
Out[11]:
   col1  col2  col3
0    a    b     1
1    b    a     2
2    c    d     3
In [12]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out[12]:
   col1  col2  col3
0    a    b     2
```

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').
nrows  [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

low_memory  [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)

memory_map  [boolean, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

NA and missing data handling

na_values  [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See na values const below for a list of the values interpreted as NaN by default.

keep_default_na  [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

  • If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.
  • If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.
  • If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.
  • If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter  [boolean, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

verbose  [boolean, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines  [boolean, default True] If True, skip over blank lines rather than interpreting as NaN values.

Datetime handling

parse_dates  [boolean or list of ints or names or list of lists or dict, default False.]

  • If True -> try parsing the index.
  • If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
  • If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
  • If {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’. A fast-path exists for iso8601-formatted dates.

infer_datetime_format  [boolean, default False] If True and parse_dates is enabled for a column, attempt to infer the datetime format to speed up the processing.

keep_date_col  [boolean, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.
pandas: powerful Python data analysis toolkit, Release 1.4.1

**date_parser** [function, default None] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [boolean, default False] DD/MM format dates, international and European format.

**cache_dates** [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets. New in version 0.25.0.

**Iteration**

**iterator** [boolean, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

**chunksize** [int, default None] Return `TextFileReader` object for iteration. See *iterating and chunking* below.

**Quoting, compression, and file format**

**compression** [{'infer', 'gzip', 'bz2', 'zip', 'xz', 'zstd', None, dict}, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip, xz, or zstandard if `filepath_or_buffer` is path-like ending in '.gz', '.bz2', '.zip', '.xz', '.zst', respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}.

Changed in version 1.1.0: dict option extended to support gzip and bz2.

Changed in version 1.2.0: Previous versions forwarded dict entries for 'gzip' to gzip.open.

**thousands** [str, default None] Thousands separator.

**decimal** [str, default ','] Character to recognize as decimal point. E.g. use ',', for European data.

**float_precision** [string, default None] Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.

**lineterminator** [str (length 1), default None] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

**doublequote** [boolean, default True] When `quotechar` is specified and `quoting` is not QUOTE_NONE, indicate whether or not to interpret two consecutive `quotechar` elements inside a field as a single `quotechar` element.

**escapechar** [str (length 1), default None] One-character string used to escape delimiter when quoting is QUOTE_NONE.

**comment** [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`. 

278 Chapter 2. User Guide
For example, if `comment='#'`, parsing ‘#empty
a,b,c
1,2,3’ with `header=0` will result in ‘a,b,c’ being treated as the header.

**encoding** [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). List of Python standard encodings.

**dialect** [str or csv.Dialect instance, default None] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

### Error handling

**error_bad_lines** [boolean, optional, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned. See bad lines below.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

**warn_bad_lines** [boolean, optional, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

**on_bad_lines** [(‘error’, ‘warn’, ‘skip’), default ‘error’] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are :

- ‘error’, raise an ParserError when a bad line is encountered.
- ‘warn’, print a warning when a bad line is encountered and skip that line.
- ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0.

### Specifying column data types

You can indicate the data type for the whole DataFrame or individual columns:

```python
In [13]: import numpy as np

In [14]: data = "a,b,c,d\n1,2,3,4\n5,6,7,8\n9,10,11"

In [15]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11

In [16]: df = pd.read_csv(StringIO(data), dtype=object)

In [17]: df
Out[17]:
a   b   c   d
0 1   2   3   4

(continues on next page)```
Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you're unfamiliar with these concepts, you can see [here](#) to learn more about dtypes, and [here](#) to learn more about object conversion in pandas.

For instance, you can use the **converters** argument of **read_csv()**:

```python
In [21]: data = "col_1
\n1
\n2
\nA
\n4.22"

In [22]: df = pd.read_csv(StringIO(data), converters={"col_1": str})

In [23]: df
Out[23]:
   col_1
0   1
1   2
2   A
3  4.22

In [24]: df["col_1"].apply(type).value_counts()
Out[24]:
<class 'str'>    4
Name: col_1, dtype: int64
```

Or you can use the **to_numeric()** function to coerce the dtypes after reading in the data.

```python
In [25]: df2 = pd.read_csv(StringIO(data))

In [26]: df2["col_1"] = pd.to_numeric(df2["col_1"], errors="coerce")

In [27]: df2
Out[27]:
   col_1
0    1.00
1    2.00
2     NaN
3    4.22
```
which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then \texttt{to_numeric()} is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the \texttt{converters} argument of \texttt{read_csv()} would certainly be worth trying.

\textbf{Note:} In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

\begin{verbatim}
In [29]: col_1 = list(range(500000)) + ["a", "b"] + list(range(500000))
In [30]: df = pd.DataFrame({"col_1": col_1})
In [31]: df.to_csv("foo.csv")
In [32]: mixed_df = pd.read_csv("foo.csv")
In [33]: mixed_df["col_1"].apply(type).value_counts()
Out[33]:
<class 'int'>    737858
<class 'str'>    262144
Name: col_1, dtype: int64
In [34]: mixed_df["col_1"].dtype
Out[34]: dtype('O')
\end{verbatim}

will result with \texttt{mixed_df} containing an \texttt{int} dtype for certain chunks of the column, and \texttt{str} for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a \texttt{dtype} of \texttt{object}, which is used for columns with mixed dtypes.

\section*{Specifying categorical dtype}

Categorical columns can be parsed directly by specifying \texttt{dtype='category'} or \texttt{dtype=CategoricalDtype(categories, ordered)}.

\begin{verbatim}
In [35]: data = "col1,col2,col3\na,b,1\nb,a,2\nc,d,3"
In [36]: pd.read_csv(StringIO(data))
Out[36]:
col1  col2  col3
0   a   b   1
1   a   b   2
\end{verbatim}

(continues on next page)
In 

```
In [37]: pd.read_csv(StringIO(data)).dtypes
Out[37]:
        col1       object
        col2       object
        col3      int64
dtype: object
```

```
In [38]: pd.read_csv(StringIO(data), dtype="category").dtypes
Out[38]:
        col1      category
        col2      category
        col3      category
dtype: object
```

Individual columns can be parsed as a Categorical using a dict specification:

```
In [39]: pd.read_csv(StringIO(data), dtype="col1": "category").dtypes
Out[39]:
        col1      category
        col2       object
        col3      int64
dtype: object
```

Specifying `dtype='category'` will result in an unordered Categorical whose categories are the unique values observed in the data. For more control on the categories and order, create a `CategoricalDtype` ahead of time, and pass that for that column's `dtype`.

```
In [40]: from pandas.api.types import CategoricalDtype
In [41]: dtype = CategoricalDtype(['a', 'b', 'd'], ordered=True)
In [42]: pd.read_csv(StringIO(data), dtype={"col1": dtype}).dtypes
Out[42]:
        col1      category
        col2       object
        col3      int64
dtype: object
```

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.

```
In [43]: dtype = CategoricalDtype(['a', 'b', 'd'])  # No 'c'
In [44]: pd.read_csv(StringIO(data), dtype={"col1": dtype}).col1
Out[44]:
0    a
1    a
2  NaN
Name: col1, dtype: category
Categories (3, object): ['a', 'b', 'd']
```
This matches the behavior of `Categorical.set_categories()`.

**Note:** With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

```python
In [45]: df = pd.read_csv(StringIO(data), dtype="category")

In [46]: df.dtypes
Out[46]:
col1 category
col2 category
col3 category
dtype: object

In [47]: df["col3"]
Out[47]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, object): ['1', '2', '3']

In [48]: df["col3"].cat.categories = pd.to_numeric(df["col3"].cat.categories)

In [49]: df["col3"]
Out[49]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]
```

## Naming and using columns

### Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```python
In [50]: data = "a,b,c\n1,2,3\n4,5,6\n7,8,9"

In [51]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [52]: pd.read_csv(StringIO(data))
(continues on next page)
```
By specifying the names argument in conjunction with header you can indicate other names to use and whether or not to throw away the header row (if any):

Note: Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to header=None.
Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```python
In [58]: data = "a,b,a\n0,1,2\n3,4,5"

In [59]: pd.read_csv(StringIO(data))
Out[59]:
   a  b  a.1
0  0  1  2
1  3  4  5
```

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns ‘X’, ‘X.1’, ‘X.2’, ‘X.N’. If `mangle_dupe_cols=False`, duplicate data can arise:

```python
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a  b  a
0  2  1  2
1  5  4  5
```

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```python
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
...  
ValueError: Setting mangle_dupe_cols=False is not supported yet
```

Filtering columns (usecols)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

```python
In [60]: data = "a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz"

In [61]: pd.read_csv(StringIO(data))
Out[61]:
   a  b  c  d
0  1  2  3  foo
1  4  5  6  bar
2  7  8  9  baz

In [62]: pd.read_csv(StringIO(data), usecols=["b", "d"])
Out[62]:
   b  d
0  2  foo
1  5  bar
2  8  baz
```

(continues on next page)
In [63]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
Out[63]:
   a  c  d
0  1  3  foo
1  4  6  bar
2  7  9  baz

In [64]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
Out[64]:
   a  c
0  1  3
1  4  6
2  7  9

The `usecols` argument can also be used to specify which columns not to use in the final result:

In [65]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[65]:
   b  d
0  2  foo
1  5  bar
2  8  baz

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

Comments and empty lines

Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

In [66]: data = "

# commented line
1,2,3
4,5,6"

In [67]: print(data)
a,b,c
# commented line
1,2,3
4,5,6

In [68]: pd.read_csv(StringIO(data), comment="#")
Out[68]:
   a  b  c
0  1  2  3
1  4  5  6

If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:
In [69]: data = "a,b,c\n1,2,3\n4,5,6"

In [70]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[70]:
   a  b  c
0  NaN  NaN  NaN
1  1.0  2.0  3.0
2  NaN  NaN  NaN
3  NaN  NaN  NaN
4  4.0  5.0  6.0

Warning: The presence of ignored lines might create ambiguities involving line numbers; the parameter header uses row numbers (ignoring commented/empty lines), while skiprows uses line numbers (including commented/empty lines):

In [71]: data = "#comment\na,b,c\nA,B,C\n1,2,3"

In [72]: pd.read_csv(StringIO(data), comment="#", header=1)
Out[72]:
   A  B  C
0  1  2  3

In [73]: data = "A,B,C\n#comment\na,b,c\n1,2,3"

In [74]: pd.read_csv(StringIO(data), comment="#", skiprows=2)
Out[74]:
   a  b  c
0  1  2  3

If both header and skiprows are specified, header will be relative to the end of skiprows. For example:

In [75]: data = (  ....:     "# empty\n  ....:     "# second empty line\n  ....:     "# third emptyline\n  ....:     "X,Y,Z\n  ....:     "1,2,3\n  ....:     "A,B,C\n  ....:     "1,2.,4.\n  ....:     "5.\n  ....:     NaN,10.0\n    ....: )
    ....:

In [76]: print(data)
# empty
# second empty line
# third emptyline
X,Y,Z
1,2,3
A,B,C
1,2.,4.

(continues on next page)
5.0, NaN, 10.0

```
In [77]: pd.read_csv(StringIO(data), comment='#', skiprows=4, header=1)
Out[77]:
   A    B    C
0  1.0  2.0  4.0
1  5.0  NaN 10.0
```

## Comments

Sometimes comments or meta data may be included in a file:

```
In [78]: print(open("tmp.csv").read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome
```

By default, the parser includes the comments in the output:

```
In [79]: df = pd.read_csv("tmp.csv")
```

```
In [80]: df
Out[80]:
   ID  level category
0  Patient1 123000    x # really unpleasant
1  Patient2 23000    y # wouldn't take his medicine
2  Patient3 1234018  z # awesome
```

We can suppress the comments using the `comment` keyword:

```
In [81]: df = pd.read_csv("tmp.csv", comment="#")
```

```
In [82]: df
Out[82]:
   ID  level category
0  Patient1 123000      x
1  Patient2 23000      y
2  Patient3 1234018    z
```

## Dealing with Unicode data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```
In [83]: from io import BytesIO
```

```
In [84]: data = b"word,length
Tr\xc3\xa4umen,7\nGr\xc3\xbcc3\xc9fe,5"
```

(continues on next page)
In [85]: data = data.decode("utf8").encode("latin-1")

In [86]: df = pd.read_csv(BytesIO(data), encoding="latin-1")

In [87]: df
Out[87]:
word length
0 Träumen 7
1 Grüße 5

In [88]: df["word"]
Out[88]: 'Grüße'

Some formats which encode all characters as multiple bytes, like UTF-16, won’t parse correctly at all without specifying the encoding. Full list of Python standard encodings.

**Index columns and trailing delimiters**

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame’s row names:

```
In [89]: data = "a,b,c\n4,apple,bat,5.7\n8,orange,cow,10"

In [90]: pd.read_csv(StringIO(data))
Out[90]:
a  b  c
4  apple  bat  5.7
8  orange  cow  10.0
```

```
In [91]: data = "index,a,b,c\n4,apple,bat,5.7\n8,orange,cow,10"

In [92]: pd.read_csv(StringIO(data), index_col=0)
Out[92]:
a  b  c
index
4  apple  bat  5.7
8  orange  cow  10.0
```

Ordinarily, you can achieve this behavior using the index_col option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass index_col=False:

```
In [93]: data = "a,b,c\n4,apple,bat,\n8,orange,cow,"

In [94]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [95]: pd.read_csv(StringIO(data))
Out[95]:
```
a b c  
4 apple bat NaN  
8 orange cow NaN  

In [96]: pd.read_csv(StringIO(data), index_col=False)  
Out[96]:  
        a  b  c  
0  4 apple bat  
1  8 orange cow  

If a subset of data is being parsed using the usecols option, the index_col specification is based on that subset, not the original data.

In [97]: data = "a,b,c
   4,apple,bat,
   8,orange,cow,"  
In [98]: print(data)  
a,b,c
4,apple,bat,  
8,orange,cow,  
In [99]: pd.read_csv(StringIO(data), usecols=["b", "c"])  
Out[99]:  
        b  c  
4  bat NaN  
8  cow NaN  
In [100]: pd.read_csv(StringIO(data), usecols=["b", "c"], index_col=0)  
Out[100]:  
        b  c  
4  bat NaN  
8  cow NaN  

Date Handling

Specifying date columns

To better facilitate working with datetime data, read_csv() uses the keyword arguments parse_dates and date_parser to allow users to specify a variety of columns and date/time formats to turn the input text data into datetime objects.

The simplest case is to just pass in parse_dates=True:

# Use a column as an index, and parse it as dates.  
In [101]: df = pd.read_csv("foo.csv", index_col=0, parse_dates=True)  
In [102]: df  
Out[102]:  
       A  B  C  
date  
2009-01-01 a 1 2  
2009-01-02 b 3 4  
(continues on next page)
# These are Python datetime objects

```python
In [103]: df.index
Out[103]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]', name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. The `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```python
In [104]: print(open("tmp.csv").read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900

In [105]: df = pd.read_csv("tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]])

In [106]: df
```

```
Out[106]:
          1_2   1_3         0         4
0  1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1  1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
2  1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3  1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4  1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5  1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```python
In [107]: df = pd.read_csv("tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]], keep_date_col=True)

In [108]: df
```

```
Out[108]:
          1_2   1_3   0   1   2    3    4
0  1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 19990127 19:00:00 18:56:00 0.81
1  1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 19990127 20:00:00 19:56:00 0.01
2  1999-01-27 21:00:00 1999-01-27 20:56:00 KORD 19990127 21:00:00 20:56:00 -0.59
3  1999-01-27 21:00:00 1999-01-27 21:18:00 KORD 19990127 21:00:00 21:18:00 -0.99
4  1999-01-27 22:00:00 1999-01-27 21:56:00 KORD 19990127 22:00:00 21:56:00 -0.59
5  1999-01-27 23:00:00 1999-01-27 22:56:00 KORD 19990127 23:00:00 22:56:00 -0.59
```

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[[1, 2]]` indicates that the second and third columns should each be parsed as separate date columns.

### 2.4. IO tools (text, CSV, HDF5, ...)

291
while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

```python
In [109]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}
In [110]: df = pd.read_csv("tmp.csv", header=None, parse_dates=date_spec)
In [111]: df
Out[111]:
   nominal    actual  0  4
0  1999-01-27  19:00:00  1999-01-27  18:56:00    KORD  0.81
1  1999-01-27  20:00:00  1999-01-27  19:56:00    KORD  0.01
2  1999-01-27  21:00:00  1999-01-27  20:56:00    KORD -0.59
3  1999-01-27  21:00:00  1999-01-27  21:18:00    KORD -0.99
4  1999-01-27  22:00:00  1999-01-27  21:56:00    KORD -0.59
5  1999-01-27  23:00:00  1999-01-27  22:56:00    KORD -0.59
```

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

```python
In [112]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}
In [113]: df = pd.read_csv("tmp.csv", header=None, parse_dates=date_spec, index_col=0)
In [114]: df
Out[114]:
    actual    0  4
nominal
1999-01-27  19:00:00  1999-01-27  18:56:00    KORD  0.81
1999-01-27  20:00:00  1999-01-27  19:56:00    KORD  0.01
1999-01-27  21:00:00  1999-01-27  20:56:00    KORD -0.59
1999-01-27  21:00:00  1999-01-27  21:18:00    KORD -0.99
1999-01-27  22:00:00  1999-01-27  21:56:00    KORD -0.59
1999-01-27  23:00:00  1999-01-27  22:56:00    KORD -0.59
```

**Note:** If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

**Note:** `read_csv` has a fast path for parsing datetimestrings in iso8601format, e.g “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.
Date parsing functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```
In [115]: df = pd.read_csv(
        ....:     "tmp.csv", header=None, parse_dates=date_spec, date_parser=pd.to_datetime
        ....:     )
        ....:
In [116]: df
```

```
  nominal   actual  0   4
0  1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1  1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2  1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3  1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4  1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5  1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(["2013", "2013"], ["1", "2"])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])`).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime()`: `date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

Parsing a CSV with mixed timezones

pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with `parse_dates`.

```
In [117]: content = """
        ....: a
        ....: 2000-01-01T00:00:00+05:00
        ....: 2000-01-01T00:00:00+06:00"
        ....:
In [118]: df = pd.read_csv(StringIO(content), parse_dates=["a"])

In [119]: df["a"]
```

```
  0  2000-01-01 00:00:00+05:00
  1  2000-01-01 00:00:00+06:00
Name: a, dtype: object
```

2.4. IO tools (text, CSV, HDF5, …)
To parse the mixed-timezone values as a datetime column, pass a partially-applied `to_datetime()` with `utc=True` as the `date_parser`.

```python
In [120]: df = pd.read_csv(
       ....:     StringIO(content),
       ....:     parse_dates=['a'],
       ....:     date_parser=lambda col: pd.to_datetime(col, utc=True),
       ....: )

In [121]: df['a']
Out[121]:
0  1999-12-31 19:00:00+00:00
1  1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```

**Inferring datetime format**

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```python
# Try to infer the format for the index column
In [122]: df = pd.read_csv(
       ....:     "foo.csv",
       ....:     index_col=0,
       ....:     parse_dates=True,
       ....:     infer_datetime_format=True,
       ....: )

In [123]: df
Out[123]:
   A  B  C
date
2009-01-01  a  1  2
```

(continues on next page)
International date formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

```python
In [124]: print(open("tmp.csv").read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

In [125]: pd.read_csv("tmp.csv", parse_dates=[0])
Out[125]:
date value cat
0 2000-01-06 5 a
1 2000-02-06 10 b
2 2000-03-06 15 c

In [126]: pd.read_csv("tmp.csv", dayfirst=True, parse_dates=[0])
Out[126]:
date value cat
0 2000-06-01 5 a
1 2000-06-02 10 b
2 2000-06-03 15 c
```

Writing CSVs to binary file objects

New in version 1.2.0.

df.to_csv(..., mode="wb") allows writing a CSV to a file object opened binary mode. In most cases, it is not necessary to specify `mode` as Pandas will auto-detect whether the file object is opened in text or binary mode.

```python
In [127]: import io

In [128]: data = pd.DataFrame([0, 1, 2])

In [129]: buffer = io.BytesIO()

In [130]: data.to_csv(buffer, encoding="utf-8", compression="gzip")
```
Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```python
In [131]: val = "0.306610199380709547156698135950136927504425048828125"

In [132]: data = "a,b,c

1,2,...

".format(val)

In [133]: def read_csv(data, engine="c", float_precision=None):
       ...:     return pd.read_csv(StringIO(data), engine=engine,
       ...:                       float_precision=float_precision)["c"]

In [133]: abs(read_csv(data, engine="c", float_precision=None) - float(val))
Out[133]: 5.551115123125783e-17

In [134]: abs(read_csv(data, engine="c", float_precision="high") - float(val))
Out[134]: 5.551115123125783e-17

In [135]: abs(read_csv(data, engine="c", float_precision="round_trip") - float(val))
Out[135]: 0.0
```

Thousand separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```python
In [136]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [137]: df = pd.read_csv("tmp.csv", sep="|")
```

(continues on next page)
In [138]: df
Out[138]:
   ID   level  category
0  123,000   x
1   23,000   y
2 1,234,018  z

In [139]: df.level.dtype
Out[139]:
dtype('O')

The thousands keyword allows integers to be parsed correctly:

In [140]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [141]: df = pd.read_csv("tmp.csv", sep="|", thousands="\",")

In [142]: df
Out[142]:
   ID   level  category
0  123000   x
1   23000   y
2 1234018   z

In [143]: df.level.dtype
Out[143]:
dtype('int64')

NA values

To control which values are parsed as missing values (which are signified by NaN), specify a string in na_values. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify keep_default_na=False.

The default NaN recognized values are ['\-1.IND', '1.\QNAN', '1.IND', '\-1.\QNAN', '\N/A', 'N/A', 'n/a', 'NA', '<\NA>', '\#NA', 'NULL', 'null', 'NaN', '\-NaN', 'nan', '\-nan', ''].

Let us consider some examples:

pd.read_csv("path_to_file.csv", na_values=[5])

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=[''])

Above, only an empty field will be recognized as NaN.

2.4. IO tools (text, CSV, HDF5, …)
pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=['NA', '0'])

Above, both NA and 0 as strings are NaN.

pd.read_csv("path_to_file.csv", na_values=['Nope'])

The default values, in addition to the string "Nope" are recognized as NaN.

**Infinity**

inf like values will be parsed as np.inf (positive infinity), and -inf as -np.inf (negative infinity). These will ignore the case of the value, meaning Inf, will also be parsed as np.inf.

**Returning Series**

Using the *squeeze* keyword, the parser will return output with a single column as a Series:

Deprecated since version 1.4.0: Users should append .squeeze("columns") to the DataFrame returned by read_csv instead.

```python
In [144]: print(open("tmp.csv").read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [145]: output = pd.read_csv("tmp.csv", squeeze=True)

In [146]: output
Out[146]:
Patient1     123000
Patient2     23000
Patient3    1234018
Name: level, dtype: int64

In [147]: type(output)
Out[147]: pandas.core.series.Series
```

**Boolean values**

The common values True, False, TRUE, and FALSE are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the true_values and false_values options as follows:

```python
In [148]: data = "a,b,c\n1,Yes,2\n3,No,4"

In [149]: print(data)
a,b,c
1,Yes,2
3,No,4

In [150]: pd.read_csv(StringIO(data))
```
Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```
In [152]: data = "a,b,c\n1,2,3\n4,5,6,7\n8,9,10"

In [153]: pd.read_csv(StringIO(data))
```

```
ParserError
Input In [153], in <module>
----> 1 pd.read_csv(StringIO(data))

```

(continues on next page)
You can elect to skip bad lines:

```
In [29]: pd.read_csv(StringIO(data), on_bad_lines="warn")
Skipping line 3: expected 3 fields, saw 4
```

```
Out[29]:
    a  b  c
0  1  2  3
1  8  9 10
```

Or pass a callable function to handle the bad line if engine="python". The bad line will be a list of strings that was split by the sep:

```
In [29]: external_list = []
```

```
In [30]: def bad_lines_func(line):
   ....:     external_list.append(line)
   ....:     return line[-3:]
```
In [31]: pd.read_csv(StringIO(data), on_bad_lines=bad_lines_func, engine="python")
Out[31]:
   a  b  c
0  1  2  3
1  5  6  7
2  8  9 10

In [32]: external_list
Out[32]: [4, 5, 6, 7]

.. versionadded:: 1.4.0

You can also use the usecols parameter to eliminate extraneous column data that appear in some lines but not others:

In [33]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])

Out[33]:
   a  b  c
0  1  2  3
1  4  5  6
2  8  9 10

In case you want to keep all data including the lines with too many fields, you can specify a sufficient number of names. This ensures that lines with not enough fields are filled with NaN.

In [34]: pd.read_csv(StringIO(data), names=['a', 'b', 'c', 'd'])

Out[34]:
   a  b  c  d
0  1  2  3  NaN
1  4  5  6  7
2  8  9 10  NaN

Dialect

The dialect keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a csv.Dialect instance.

Suppose you had data with unenclosed quotes:

In [154]: import csv

By default, read_csv uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using dialect:
All of the dialect options can be specified separately by keyword arguments:

```
In [159]: data = "a,b,c~1,2,3~4,5,6"
In [160]: pd.read_csv(StringIO(data), lineterminator="~")
Out[160]:
    a  b  c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:

```
In [161]: data = "a, b, c
        1, 2, 3
        4, 5, 6"
In [162]: print(data)
a, b, c
1, 2, 3
4, 5, 6
In [163]: pd.read_csv(StringIO(data), skipinitialspace=True)
Out[163]:
    a  b  c
0  1  2  3
1  4  5  6
```

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

**Quoting and Escape Characters**

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```
In [164]: data = 'a,b\n"hello, \"Bob\", nice to see you",5'
In [165]: print(data)
a,b
"hello, "Bob\", nice to see you",5
In [166]: pd.read_csv(StringIO(data), escapechar="\\")
Out[166]:
```
Files with fixed width columns

While \texttt{read_csv()} reads delimited data, the \texttt{read_fwf()} function works with data files that have known and fixed column widths. The function parameters to \texttt{read_fwf} are largely the same as \texttt{read_csv} with two extra parameters, and a different usage of the \texttt{delimiter} parameter:

- \texttt{colspecs}: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., \([\text{from}, \text{to}]\)). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.

- \texttt{widths}: A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

- \texttt{delimiter}: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

\begin{verbatim}
In [167]: print(open("bar.csv").read())
id8141 360.242940 149.910199 11950.7
id1594 444.953632 166.985655 11788.4
id1849 364.136849 183.628767 11806.2
id1230 413.836124 184.375703 11916.8
id1948 502.953953 173.237159 12468.3
\end{verbatim}

In order to parse this file into a \texttt{DataFrame}, we simply need to supply the column specifications to the \texttt{read_fwf} function along with the file name:

\begin{verbatim}
In [168]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]
In [169]: df = pd.read_fwf("bar.csv", colspecs=colspecs, header=None, index_col=0)
In [170]: df
Out[170]:
  1    2    3
0  id8141  360.242940  149.910199  11950.7
id1594  444.953632  166.985655  11788.4
id1849  364.136849  183.628767  11806.2
id1230  413.836124  184.375703  11916.8
id1948  502.953953  173.237159  12468.3
\end{verbatim}

Note how the parser automatically picks column names X.<column number> when \texttt{header=None} argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

\begin{verbatim}
In [171]: widths = [6, 14, 13, 10]
In [172]: df = pd.read_fwf("bar.csv", widths=widths, header=None)
\end{verbatim}
The parser will take care of extra white spaces around the columns so it’s ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file’s `colspecs` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided `delimiter` (default delimiter is whitespace).

```
In [174]: df = pd.read_fwf("bar.csv", header=None, index_col=0)

In [175]: df
Out[175]:
   1  2  3
0 id8141 360.242940 149.910199 11950.7
1 id1594 444.953632 166.985655 11788.4
2 id1849 364.136849 183.628767 11806.2
3 id1230 413.836124 184.375703 11916.8
4 id1948 502.953953 173.237159 12468.3
```

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.

```
In [176]: pd.read_fwf("bar.csv", header=None, index_col=0).dtypes
Out[176]:
 1  float64
 2  float64
 3  float64
dtype: object

In [177]: pd.read_fwf("bar.csv", header=None, dtype={2: "object"}).dtypes
Out[177]:
0  object
1  float64
2  object
3  float64
dtype: object
```
Indexes

Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```
In [178]: print(open("foo.csv").read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, `read_csv` assumes that the first column is to be used as the index of the DataFrame:

```
In [179]: pd.read_csv("foo.csv")
Out[179]:
   A  B  C
0  20090101 a 1  2
1  20090102 b 3  4
2  20090103 c 4  5
```

Note that the dates weren’t automatically parsed. In that case you would need to do as before:

```
In [180]: df = pd.read_csv("foo.csv", parse_dates=True)
In [181]: df.index
Out[181]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'],
       dtype='datetime64[ns]', freq=None)
```

Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```
In [182]: print(open("data/mindex_ex.csv").read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a MultiIndex for the index of the returned object:
pandas: powerful Python data analysis toolkit, Release 1.4.1

In [183]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0, 1])

In [184]: df
Out[184]:

<table>

Reading columns with a MultiIndex

By specifying list of row locations for the header argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

In [186]: from pandas._testing import makeCustomDataframe as mkdf

In [187]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [188]: df.to_csv("mi.csv")

In [189]: print(open("mi.csv").read())

(continues on next page)

read_csv is also able to interpret a more common format of multi-columns indices.

In [191]: print(open("mi2.csv").read())
, a, a, b, c, c
, q, r, s, t, u, v
one, 1, 2, 3, 4, 5, 6
two, 7, 8, 9, 10, 11, 12

In [192]: pd.read_csv("mi2.csv", header=[0, 1], index_col=0)
Out[192]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>q</td>
<td>r</td>
<td>s</td>
<td>t</td>
</tr>
<tr>
<td>one</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>two</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
</tbody>
</table>

Note: If an index_col is not specified (e.g. you don’t have an index, or wrote it with df.to_csv(..., index=False), then any names on the columns index will be lost.

Automatically “sniffing” the delimiter

read_csv is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the csv.Sniffer class of the csv module. For this, you have to specify sep=None.

In [193]: print(open("tmp2.csv").read())

Reading multiple files to create a single DataFrame

It's best to use `concat()` to combine multiple files. See the cookbook for an example.

Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

In [195]: print(open("tmp.sv").read())

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.469112</td>
<td>0.282863</td>
<td>1.509059</td>
<td>1.135632</td>
</tr>
<tr>
<td>1.212112</td>
<td>0.173215</td>
<td>0.119209</td>
<td>1.044236</td>
</tr>
<tr>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>1.071804</td>
</tr>
<tr>
<td>0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>0.271860</td>
</tr>
<tr>
<td>-0.424972</td>
<td>0.567020</td>
<td>0.276232</td>
<td>-1.087401</td>
</tr>
<tr>
<td>0.673690</td>
<td>0.113648</td>
<td>-1.478427</td>
<td>0.524988</td>
</tr>
<tr>
<td>0.404765</td>
<td>0.577046</td>
<td>-1.715002</td>
<td>-1.039268</td>

</tbody>
</table>
By specifying a chunksize to read_csv, the return value will be an iterable object of type TextFileReader:

```
In [198]: with pd.read_csv("tmp.sv", sep="|", chunksize=4) as reader:
      ...:     reader
      ...:     for chunk in reader:
      ...:         print(chunk)
      ...:
```

```
        Unnamed: 0    0          1     2     3
      0 0 0.469112 -0.282863 -1.509059 -1.135632
      1 1 1.212112 -0.173215  0.119209 -1.044236
      2 2 -0.861849 -2.104569 -0.494929  1.071804
      3 3 0.721555 -0.706771 -1.039575  0.271860
        Unnamed: 0    0          1     2     3
      4 4 -0.424972  0.567020  0.276232 -1.087401
      5 5 -0.673690  0.113648 -1.478427  0.524988
      6 6 0.404705  0.577046 -1.715002 -1.039268
      7 7 -0.370647 -1.157892 -1.344312  0.844885
        Unnamed: 0    0          1     2     3
      8 8 1.075770 -0.109050  1.643563 -1.469388
      9 9 0.357021 -0.674600 -1.776904 -0.968914
```

Changed in version 1.2: read_csv/json/sas return a context-manager when iterating through a file.

Specifying iterator=True will also return the TextFileReader object:

```
In [199]: with pd.read_csv("tmp.sv", sep="|", iterator=True) as reader:
      ...:     reader.get_chunk(5)
      ...:
```

**Specifying the parser engine**

Pandas currently supports three engines, the C engine, the python engine, and an experimental pyarrow engine (requires the pyarrow package). In general, the pyarrow engine is fastest on larger workloads and is equivalent in speed to the C engine on most other workloads. The python engine tends to be slower than the pyarrow and C engines on most workloads. However, the pyarrow engine is much less robust than the C engine, which lacks a few features compared to the Python engine.

Where possible, pandas uses the C parser (specified as engine='c'), but it may fall back to Python if C-unsupported options are specified.

Currently, options unsupported by the C and pyarrow engines include:

- sep other than a single character (e.g. regex separators)
- skipfooter
- sep=None with delim_whitespace=False
Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

Options that are unsupported by the pyarrow engine which are not covered by the list above include:

- `float_precision`
- `chunksize`
- `comment`
- `nrows`
- `thousands`
- `memory_map`
- `dialect`
- `warn_bad_lines`
- `error_bad_lines`
- `on_bad_lines`
- `delim_whitespace`
- `quoting`
- `lineterminator`
- `converters`
- `decimal`
- `iterator`
- `dayfirst`
- `infer_datetime_format`
- `verbose`
- `skipinitialspace`
- `low_memory`

Specifying these options with `engine='pyarrow'` will raise a `ValueError`.

**Reading/writing remote files**

You can pass in a URL to read or write remote files to many of pandas’ IO functions - the following example shows reading a CSV file:

```python
import pandas as pd
df = pd.read_csv("https://download.bls.gov/pub/time.series/cu/cu.item", sep="\t")
```

New in version 1.3.0.

A custom header can be sent alongside HTTP(s) requests by passing a dictionary of header key value mappings to the `storage_options` keyword argument as shown below:

```python
headers = {"User-Agent": "pandas"}
df = pd.read_csv("https://download.bls.gov/pub/time.series/cu/cu.item",
    sep="\t",
    storage_options=headers)
```
All URLs which are not local files or HTTP(s) are handled by fsspec, if installed, and its various filesystem implementations (including Amazon S3, Google Cloud, SSH, FTP, webHDFS…). Some of these implementations will require additional packages to be installed, for example S3 URLs require the s3fs library:

```python
storage_options=headers
)
```

When dealing with remote storage systems, you might need extra configuration with environment variables or config files in special locations. For example, to access data in your S3 bucket, you will need to define credentials in one of the several ways listed in the S3Fs documentation. The same is true for several of the storage backends, and you should follow the links at fsimpl1 for implementations built into fsspec and fsimpl2 for those not included in the main fsspec distribution.

You can also pass parameters directly to the backend driver. For example, if you do not have S3 credentials, you can still access public data by specifying an anonymous connection, such as

```
New in version 1.2.0.

```python
def = pd.read_json("s3://pandas-test/adatafile.json")
```

fsspec also allows complex URLs, for accessing data in compressed archives, local caching of files, and more. To locally cache the above example, you would modify the call to

```python
pd.read_csv("simplecache::s3://ncei-wcsd-archive/data/processed/SH1305/18kHz/SaKe2013-D20130523-T080854_to_SaKe2013-D20130523-T085643.csv",
storage_options={"s3": {"anon": True}},
)
```

where we specify that the “anon” parameter is meant for the “s3” part of the implementation, not to the caching implementation. Note that this caches to a temporary directory for the duration of the session only, but you can also specify a permanent store.

**Writing out data**

**Writing to CSV format**

The Series and DataFrame objects have an instance method to_csv which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- **path_or_buf**: A string path to the file to write or a file object. If a file object it must be opened with `newline=''`
- **sep**: Field delimiter for the output file (default ‘,’)
- **na_rep**: A string representation of a missing value (default ‘’)
- **float_format**: Format string for floating point numbers
- **columns**: Columns to write (default None)
• header: Whether to write out the column names (default True)
• index: whether to write row (index) names (default True)
• index_label: Column label(s) for index column(s) if desired. If None (default), and header and index are True, then the index names are used. (A sequence should be given if the DataFrame uses MultiIndex).
• mode : Python write mode, default ’w’
• encoding: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
• line_terminator: Character sequence denoting line end (default os.linesep)
• quoting: Set quoting rules as in csv module (default csv.QUOTE_MINIMAL). Note that if you have set a float_format then floats are converted to strings and csv.QUOTE_NONNUMERIC will treat them as non-numeric
• quotechar: Character used to quote fields (default ‘”’)
• doublequote: Control quoting of quotechar in fields (default True)
• escapechar: Character used to escape sep and quotechar when appropriate (default None)
• chunksize: Number of rows to write at a time
• date_format: Format string for datetime objects

Writing a formatted string

The DataFrame object has an instance method to_string which allows control over the string representation of the object. All arguments are optional:
• buf default None, for example a StringIO object
• columns default None, which columns to write
• col_space default None, minimum width of each column.
• na_rep default NaN, representation of NA value
• formatters default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
• float_format default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the DataFrame.
• sparsify default True, set to False for a DataFrame with a hierarchical index to print every MultiIndex key at each row.
• index_names default True, will print the names of the indices
• index default True, will print the index (ie, row labels)
• header default True, will print the column labels
• justify default left, will print column headers left- or right-justified

The Series object also has a to_string method, but with only the buf, na_rep, float_format arguments. There is also a length argument which, if set to True, will additionally output the length of the Series.
2.4.2 JSON

Read and write JSON format files and strings.

Writing JSON

A Series or DataFrame can be converted to a valid JSON string. Use to_json with optional parameters:

- path_or_buf: the pathname or buffer to write the output. This can be None in which case a JSON string is returned.
- orient:
  - Series:
    - default is index
    - allowed values are {split, records, index}
  - DataFrame:
    - default is columns
    - allowed values are {split, records, index, columns, values, table}

The format of the JSON string

<table>
<thead>
<tr>
<th>Split</th>
<th>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Records</td>
<td>list like [[column -&gt; value],...,[column -&gt; value]]</td>
</tr>
<tr>
<td>Index</td>
<td>dict like {index -&gt; [column -&gt; value]}</td>
</tr>
<tr>
<td>Columns</td>
<td>dict like {column -&gt; [index -&gt; value]}</td>
</tr>
<tr>
<td>Values</td>
<td>just the values array</td>
</tr>
<tr>
<td>Table</td>
<td>adhering to the JSON Table Schema</td>
</tr>
</tbody>
</table>

- date_format: string, type of date conversion, ‘epoch’ for timestamp, ‘iso’ for ISO8601.
- double_precision: The number of decimal places to use when encoding floating point values, default 10.
- force_ascii: force encoded string to be ASCII, default True.
- date_unit: The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’ or ‘ns’ for seconds, milliseconds, microseconds and nanoseconds respectively. Default ‘ms’.
- default_handler: The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- lines: If records orient, then will write each record per line as json.

Note NaN’s, NaT’s and None will be converted to null and datetime objects will be converted based on the date_format and date_unit parameters.

```python
In [200]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))
In [201]: json = dfj.to_json()
In [202]: json
Out[202]: '{"A":{"0":-1.2945235903,"1":0.2766617129,"2":-0.0139597524,"3":-0.0061535699,
    ..."4":0.8957173022},"B":{"0":0.4137381054,"1":-0.472034511,"2":-0.923060654,"3":0.8052440254}}'
```
Orient options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```
In [203]: dfjo = pd.DataFrame(
    .....:     dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
    .....:     columns=list("ABC"),
    .....:     index=list("xyz"),
    .....: )
```

```
In [204]: dfjo
Out[204]:
        A  B  C
x  1  4  7
y  2  5  8
z  3  6  9
```

```
In [205]: sjo = pd.Series(dict(x=15, y=16, z=17), name="D")
```

```
In [206]: sjo
Out[206]:
      x  y  z
Name: D, dtype: int64
```

Column oriented (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

```
In [207]: dfjo.to_json(orient="columns")
Out[207]:
'{"A":{"x":1,"y":4,"z":7},"B":{"x":4,"y":5,"z":6},"C":{"x":7,"y":8,"z":9}}'
```

# Not available for Series

Index oriented (the default for Series) similar to column oriented but the index labels are now primary:

```
In [208]: dfjo.to_json(orient="index")
Out[208]:
'{"x":{"A":1,"B":4,"C":7},"y":{"A":2,"B":5,"C":8},"z":{"A":3,"B":6,"C":9}}'
```

```
In [209]: sjo.to_json(orient="index")
Out[209]:
'{"x":15,"y":16,"z":17}''
```

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

```
In [210]: dfjo.to_json(orient="records")
Out[210]:
```

```
In [211]: sjo.to_json(orient="records")
Out[211]: ['15,16,17']
```

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:
In [212]: dfjo.to_json(orient="values")
Out[212]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series

**Split oriented** serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

In [213]: dfjo.to_json(orient="split")
Out[213]: '{"columns":["A","B","C"],"index":["x","y","z"],"data":[[1,4,7],[2,5,8],[3,6,9]]}'

In [214]: sjo.to_json(orient="split")
Out[214]: '{"name":"D","index":["x","y","z"],"data":[15,16,17]}'

**Table oriented** serializes to the JSON Table Schema, allowing for the preservation of metadata including but not limited to dtypes and index names.

**Note:** Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the split option as it uses ordered containers.

---

**Date handling**

Writing in ISO date format:

In [215]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))
In [216]: dfd['date'] = pd.Timestamp("20130101")
In [217]: dfd = dfd.sort_index(axis=1, ascending=False)
In [218]: json = dfd.to_json(date_format="iso")
In [219]: json
Out[219]: '{"date":{"0":"2013-01-01T00:00:00.000Z","1":"2013-01-01T00:00:00.000Z","2": ...2013-01-01T00:00:00.000Z","3":"2013-01-01T00:00:00.000Z","4":"2013-01-01T00:00:00.000Z ..."},"B":{"0":2.5656459463,"1":1.340308498,"2":-0.226192849,"3":0.8138502857,"4":-0. ...8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112, ..."4":0.132031703}}'

Writing in ISO date format, with microseconds:

In [220]: json = dfd.to_json(date_format="iso", date_unit="us")
In [221]: json
Out[221]: '{"date":{"0":"2013-01-01T00:00:00.000000Z","1":"2013-01-01T00:00:00.000000Z","2": ...2013-01-01T00:00:00.000000Z","3":"2013-01-01T00:00:00.000000Z","4":"2013-01-01T00:00:00.000000Z ..."},"B":{"0":2.5656459463,"1":1.340308498,"2":-0.226192849,"3":0.8138502857,"4":-0. ...8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112, ..."4":0.132031703}}'

Epoch timestamps, in seconds:

In [222]: json = dfd.to_json(date_format="iso", date_unit="us")
In [223]: json
Out[223]: '{"date":{"0":1357384800,"1":1357384800,"2":1357384800,"3":1357384800,"4":1357384800}}'
In [222]: json = dfd.to_json(date_format="epoch", date_unit="s")

In [223]: json
Out[223]: 
    \{
        "date":{"0":1356998400,"1":1356998400,"2":1356998400,"3":1356998400,"4":1356998400},
        "B":{"0":2.5656459463,"1":1.340388498,"2":-0.2261692849,"3":0.8138502857,"4":-0.8273169356},
        "A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112,"4":0.1320031703}
    \}

Writing to a file, with a date index and a date column:

In [224]: dfj2 = dfj.copy()
In [225]: dfj2["date"] = pd.Timestamp("20130101")
In [226]: dfj2["ints"] = list(range(5))
In [227]: dfj2["bools"] = True
In [228]: dfj2.index = pd.date_range("20130101", periods=5)
In [229]: dfj2.to_json("test.json")
In [230]: with open("test.json") as fh:
    ....:     print(fh.read())
    ....:
        {"A":{"1356998400000":-1.2945235903,"1357084800000":0.2766617129,"1357171200000":-0.3636139597524,"1357257600000":-0.0081535699,"1357344000000":0.8957173022},
         "B":{"1356998400000":0.4137381054,"1357084800000":-0.472034511,"1357171200000":-0.3636139597524,"1357257600000":-0.923060654,"1357344000000":0.8052440254},
         "date":{"1356998400000":1356998400000,"1357084800000":1357084800000,"1357171200000":1357171200000,"1357257600000":1357257600000,"1357344000000":1357344000000},
         "ints":{"1356998400000":0,"1357084800000":1,"1357171200000":2,"1357257600000":3,"1357344000000":4},
         "bools":{"1356998400000":true,"1357084800000":true,"1357171200000":true,"1357257600000":true, "1357344000000":true}}

**Fallback behavior**

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. np.complex_) then the `default_handler`, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
  - check if the object has defined a `toDict` method and call it. A `toDict` method should return a dict which will then be JSON serialized.
  - invoke the `default_handler` if one was provided.
  - convert the object to a dict by traversing its contents. However this will often fail with an `OverflowError` or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a `default_handler`. For example:
can be dealt with by specifying a simple default_handler:

```python
In [231]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out[231]: '{"0":"(1+0j)","1":"(2+0j)","2":"(1+2j)"}''
```

### Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a DataFrame if typ is not supplied or is None. To explicitly force Series parsing, pass typ=series

- **filepath_or_buffer**: a VALID JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file ://localhost/path/to/table.json

- **typ**: type of object to recover (series or frame), default ‘frame’

- **orient**: Series:
  - default is index
  - allowed values are {split, records, index}

Dataframe
  - default is columns
  - allowed values are {split, records, index, columns, values, table}

The format of the JSON string

<table>
<thead>
<tr>
<th>split</th>
<th>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td>list like [{column -&gt; value}, ..., {column -&gt; value}]</td>
</tr>
<tr>
<td>index</td>
<td>dict like {index -&gt; {column -&gt; value}}</td>
</tr>
<tr>
<td>columns</td>
<td>dict like {column -&gt; {index -&gt; value}}</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
<tr>
<td>table</td>
<td>adhering to the JSON Table Schema</td>
</tr>
</tbody>
</table>

- **dtype**: if True, infer dtypes, if a dict of column to dtype, then use those, if False, then don’t infer dtypes at all, default is True, apply only to the data.

- **convert_axes**: boolean, try to convert the axes to the proper dtypes, default is True

- **convert_dates**: a list of columns to parse for dates; If True, then try to parse date-like columns, default is True.

- **keep_default_dates**: boolean, default True. If parsing dates, then parse the default date-like columns.

- **numpy**: direct decoding to NumPy arrays. default is False; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering MUST be the same for each term if numpy=True.

- **precise_float**: boolean, default False. Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise built-in functionality.
• **date_unit**: string, the timestamp unit to detect if converting dates. Default None. By default the timestamp precision will be detected, if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.

• **lines**: reads file as one json object per line.

• **encoding**: The encoding to use to decode py3 bytes.

• **chunksize**: when used in combination with **lines=True**, return a JsonReader which reads in chunksize lines per iteration.

The parser will raise one of **ValueError/TypeError/AssertionError** if the JSON is not parseable.

If a non-default **orient** was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see **Orient Options** for an overview.

### Data conversion

The default of **convert_axes=True**, **dtype=True**, and **convert_dates=True** will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to **dtype**. **convert_axes** should only be set to **False** if you need to preserve string-like numbers (e.g. ‘1’, ‘2’) in an axes.

**Note**: Large integer values may be converted to dates if **convert_dates=True** and the data and / or column labels appear ‘date-like’. The exact threshold depends on the **date_unit** specified. ‘date-like’ means that the column label meets one of the following criteria:

- it ends with '_at'
- it ends with '_time'
- it begins with 'timestamp'
- it is 'modified'
- it is 'date'

### Warning: When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was **float** data will be converted to **integer** if it can be done safely, e.g. a column of 1.
- bool columns will be converted to **integer** on reconstruction

Thus there are times where you may want to specify specific dtypes via the **dtype** keyword argument.

**Reading from a JSON string:**

```
In [232]: pd.read_json(json)
Out[232]:
          date     B     A
0 2013-01-01  2.565646 -1.206412
1 2013-01-01  1.340309  1.431256
2 2013-01-01  -0.226169 -1.170299
3 2013-01-01  -0.827317  0.132003
4 2013-01-01  -0.827317  0.132003
```
Reading from a file:

```
In [233]: pd.read_json("test.json")
Out[233]:
          A     B   date     ints  bools
2013-01-01 -1.294524  0.413738  2013-01-01  0   True
2013-01-02  0.276662 -0.472035  2013-01-01  1   True
2013-01-03 -0.013960 -0.362543  2013-01-01  2   True
2013-01-04 -0.923061  0.006154  2013-01-01  3   True
2013-01-05  0.895717  0.805244  2013-01-01  4   True
```

Don’t convert any data (but still convert axes and dates):

```
In [234]: pd.read_json("test.json", dtype=object).dtypes
Out[234]:
A    object
B    object
date object
ints object
bools object
dtype: object
```

Specify dtypes for conversion:

```
In [235]: pd.read_json("test.json", dtype={"A": "float32", "bools": "int8"}).dtypes
Out[235]:
A    float32
B    float64
date     datetime64[ns]
ints     int64
bools    int8
dtype: object
```

Preserve string indices:

```
In [236]: si = pd.DataFrame(
        .....: np.zeros((4, 4)), columns=list(range(4)), index=[str(i) for i in range(4)]
        .....: )
          0   1   2   3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0

In [237]: si
Out[237]:
```

In [238]: si.index
Out[238]: Index(["0", "1", "2", "3"], dtype='object')

In [239]: si.columns
Out[239]: Int64Index([0, 1, 2, 3], dtype='int64')
```
In [240]: json = si.to_json()

In [241]: sij = pd.read_json(json, convert_axes=False)

In [242]: sij
Out[242]:
          0   1   2   3
0       0   0   0   0
1       0   0   0   0
2       0   0   0   0
3       0   0   0   0

In [243]: sij.index
Out[243]: Index(['0', '1', '2', '3'], dtype='object')

In [244]: sij.columns
Out[244]: Index(['0', '1', '2', '3'], dtype='object')

Dates written in nanoseconds need to be read back in nanoseconds:

In [245]: json = dfj2.to_json(date_unit="ns")

# Try to parse timestamps as milliseconds -> Won't Work
In [246]: dfju = pd.read_json(json, date_unit="ms")

In [247]: dfju
Out[247]:
   A      B    date  ints  bools
0 -1.294524 0.413738 2013-01-01 0   True
1 0.276662 -0.472035 2013-01-01 1   True
2 -0.013960 -0.362543 2013-01-01 2   True
3 -0.006154 -0.923061 2013-01-01 3   True
4 0.895717 0.805244 2013-01-01 4   True

# Let pandas detect the correct precision
In [248]: dfju = pd.read_json(json)

In [249]: dfju
Out[249]:
   A      B    date  ints  bools
0 2013-01-01 -1.294524 2013-01-01 0   True
1 2013-01-02 0.276662 2013-01-01 1   True
2 2013-01-03 -0.013960 2013-01-01 2   True
3 2013-01-04 -0.006154 2013-01-01 3   True
4 2013-01-05 0.895717 2013-01-01 4   True

# Or specify that all timestamps are in nanoseconds
In [250]: dfju = pd.read_json(json, date_unit="ns")

In [251]: dfju
Out[251]:
   A      B    date  ints  bools
0 2013-01-01 -1.294524 2013-01-01 0   True
1 2013-01-02 0.276662 2013-01-01 1   True
2 2013-01-03 -0.013960 2013-01-01 2   True
3 2013-01-04 -0.006154 2013-01-01 3   True
4 2013-01-05 0.895717 2013-01-01 4   True
The Numpy parameter

Note: This param has been deprecated as of version 1.0.0 and will raise a `FutureWarning`.

This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.

This can provide speedups if you are deserialising a large amount of numeric data:

```
In [252]: randfloats = np.random.uniform(-100, 1000, 10000)

In [253]: randfloats.shape = (1000, 10)

In [254]: dffloats = pd.DataFrame(randfloats, columns=list("ABCDEFGHIJ"))

In [255]: jsonfloats = dffloats.to_json()

In [256]: %timeit pd.read_json(jsonfloats)
   10.5 ms +- 848 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [257]: %timeit pd.read_json(jsonfloats, numpy=True)
   6.9 ms +- 216 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```
In [258]: jsonfloats = dffloats.head(100).to_json()

In [259]: %timeit pd.read_json(jsonfloats)
   5.51 ms +- 488 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [260]: %timeit pd.read_json(jsonfloats, numpy=True)
   4.82 ms +- 569 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Warning: Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
• labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using to_json but may not be the case if the JSON is from another source.

Normalization

pandas provides a utility function to take a dict or list of dicts and normalize this semi-structured data into a flat table.

```
In [261]: data = [
    ....:   {"id": 1, "name": {"first": "Coleen", "last": "Volk"}},
    ....:   {"name": {"given": "Mark", "family": "Regner"}},
    ....:   {"id": 2, "name": "Faye Raker"},
    ....: ]

In [262]: pd.json_normalize(data)
Out[262]:
     id name.first name.last name.given name.family
0  1.0     Coleen          Volk  NaN      NaN  NaN
1  NaN     NaN            NaN  Mark     Regner  NaN
2  2.0     NaN            NaN  NaN       NaN  Faye Raker
```

```
In [263]: data = [
    ....:   {
    ....:     "state": "Florida",
    ....:     "shortname": "FL",
    ....:     "info": {"governor": "Rick Scott"},
    ....:     "county": [
    ....:         {"name": "Dade", "population": 12345},
    ....:         {"name": "Broward", "population": 40000},
    ....:         {"name": "Palm Beach", "population": 60000},
    ....:     ],
    ....:   },
    ....:   {
    ....:     "state": "Ohio",
    ....:     "shortname": "OH",
    ....:     "info": {"governor": "John Kasich"},
    ....:     "county": [
    ....:         {"name": "Summit", "population": 1234},
    ....:         {"name": "Cuyahoga", "population": 1337},
    ....:     ],
    ....:   },
    ....: ]

In [264]: pd.json_normalize(data, "county", ["state", "shortname", ["info", "governor"]])
Out[264]:
     name population state shortname info.governor
0   Dade      12345 Florida     FL   Rick Scott
1 Broward          40000 Florida     FL   Rick Scott
2 Palm Beach       60000 Florida     FL   Rick Scott
```
The `max_level` parameter provides more control over which level to end normalization. With `max_level=1` the following snippet normalizes until 1st nesting level of the provided dict.

```python
In [265]: data = [
    .....:     {  
    .....:         "CreatedBy": {"Name": "User001"},  
    .....:         "Lookup": {  
    .....:             "TextField": "Some text",  
    .....:             "UserField": {"Id": "ID001", "Name": "Name001"},  
    .....:         },  
    .....:         "Image": {"a": "b"},  
    .....:     }  
    .....: ]

In [266]: pd.json_normalize(data, max_level=1)
```

```
Out[266]:
CreatedBy.Name Lookup.TextField Lookup.UserField Image.a
0 User001 Some text {"Id": 'ID001', 'Name': 'Name001'} b
```

### Line delimited json

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

For line-delimited json files, pandas can also return an iterator which reads in `chunksize` lines at a time. This can be useful for large files or to read from a stream.

```python
In [267]: jsonl = """
    .....:     {"a": 1, "b": 2}
    .....:     {"a": 3, "b": 4}
    .....: """

In [268]: df = pd.read_json(jsonl, lines=True)

In [269]: df
Out[269]:
da b
0 1 2
1 3 4

In [270]: df.to_json(orient="records", lines=True)
```

```
"{"a":1, "b":2}n{"a":3, "b":4}n'
```

```
# reader is an iterator that returns `\'chunksize\'` lines each iteration
```

```python
In [271]: with pd.read_json(StringIO(jsonl), lines=True, chunksize=1) as reader:
    .....:     reader
    .....:     for chunk in reader:
```

(continues on next page)
Table schema

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the orient table to build a JSON string with two fields, schema and data.

```
In [272]: df = pd.DataFrame(
    ......:     {
    ......:         "A": [1, 2, 3],
    ......:         "B": ["a", "b", "c"],
    ......:         "C": pd.date_range("2016-01-01", freq="d", periods=3),
    ......:     },
    ......:     index=pd.Index(range(3), name="idx"),
    ......: )
In [273]: df
Out[273]:
  A   B       C
idx
0 1 a 2016-01-01
1 2 b 2016-01-02
2 3 c 2016-01-03
```

```
In [274]: df.to_json(orient="table", date_format="iso")
Out[274]:  '{"schema":{"fields": [{"name":"idx","type":"integer"}],"name":"A","type":"integer"},"name":"B","type":"string"},"name":"C","type":"datetime"},"primaryKey": ["idx"],"pandas_version":"1.4.0"},"data": [{"idx":0,"A":1,"B":"a","C":"2016-01-01T00:00:00.000Z"},{"idx":1,"A":2,"B":"b","C":"2016-01-02T00:00:00.000Z"},{"idx":2,"A":3,"B":"c","C":"2016-01-03T00:00:00.000Z"}]'}
```

The schema field contains the fields key, which itself contains a list of column name to type pairs, including the Index or MultiIndex (see below for a list of types). The schema field also contains a primaryKey field if the (Multi)index is unique.

The second field, data, contains the serialized data with the records orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:
A few notes on the generated table schema:

- The schema object contains a pandas_version field. This contains the version of pandas' dialect of the schema, and will be incremented with each revision.

- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

  ```
  In [275]: from pandas.io.json import build_table_schema
  In [276]: s = pd.Series(pd.date_range("2016", periods=4))
  In [277]: build_table_schema(s)
  Out[277]:
  {'fields': [{'name': 'index', 'type': 'integer'},
              {'name': 'values', 'type': 'datetime'},
              'primaryKey': ['index'],
              'pandas_version': '1.4.0'}
  ```

- Datetimes with a timezone (before serializing), include an additional field tz with the time zone name (e.g. 'US/Central').

  ```
  In [278]: s_tz = pd.Series(pd.date_range("2016", periods=12, tz="US/Central")
  In [279]: build_table_schema(s_tz)
  Out[279]:
  {'fields': [{'name': 'index', 'type': 'integer'},
              {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'},
              'primaryKey': ['index'],
              'pandas_version': '1.4.0'}
  ```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain an additional field freq with the period's frequency, e.g. 'A-DEC'.

  ```
  In [280]: s_per = pd.Series(1, index=pd.period_range("2016", freq="A-DEC", periods=4))
  In [281]: build_table_schema(s_per)
  Out[281]:
  {'fields': [{'name': 'index', 'type': 'datetime'},
              {'name': 'values', 'type': 'integer'},
              'primaryKey': ['index'],
              'pandas_version': '1.4.0'}
  ```

- Categoricals use the any type and an enum constraint listing the set of possible values. Additionally, an ordered field is included:
In [282]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))

In [283]: build_table_schema(s_cat)
Out[283]:
{
'fields': [{'name': 'index', 'type': 'integer'},
{'name': 'values', 'type': 'any'},
'constraints': {'enum': ['a', 'b']},
'ordered': False],
'primaryKey': ['index'],
'pandas_version': '1.4.0'}

• A primaryKey field, containing an array of labels, is included if the index is unique:

In [284]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [285]: build_table_schema(s_dupe)
Out[285]:
{
'fields': [{'name': 'index', 'type': 'integer'},
{'name': 'values', 'type': 'integer'}],
'pandas_version': '1.4.0'}

• The primaryKey behavior is the same with MultiIndexes, but in this case the primaryKey is an array:

In [286]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'), (0, 1)]))

In [287]: build_table_schema(s_multi)
Out[287]:
{
'fields': [{'name': 'level_0', 'type': 'string'},
{'name': 'level_1', 'type': 'integer'},
{'name': 'values', 'type': 'integer'}],
'primaryKey': FrozenList(['level_0', 'level_1']),
'pandas_version': '1.4.0'}

• The default naming roughly follows these rules:
  – For series, the object.name is used. If that’s none, then the name is values
  – For DataFrames, the stringified version of the column name is used
  – For Index (not MultiIndex), index.name is used, with a fallback to index if that is None.
  – For MultiIndex, mi.names is used. If any level has no name, then level_<i> is used.

read_json also accepts orient='table' as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner:

In [288]: df = pd.DataFrame(
        {
            "foo": [1, 2, 3, 4],
            "bar": ['a', 'b', 'c', 'd'],
            "baz": pd.date_range("2018-01-01", freq="d", periods=4),
            "qux": pd.Categorical(['a', 'b', 'c', 'c']),
        },
        index=pd.Index(range(4), name="idx"),
    )
In [289]: df
Out[289]:
    foo  bar  baz  qux
idx
0  a  2018-01-01  a
1  b  2018-01-02  b
2  c  2018-01-03  c
3  d  2018-01-04  c

In [290]: df.dtypes
Out[290]:
    foo   int64
    bar   object
    baz  datetime64[ns]
    qux  category
dtype: object

In [291]: df.to_json("test.json", orient="table")

In [292]: new_df = pd.read_json("test.json", orient="table")

In [293]: new_df
Out[293]:
    foo  bar  baz  qux
idx
0  a  2018-01-01  a
1  b  2018-01-02  b
2  c  2018-01-03  c
3  d  2018-01-04  c

In [294]: new_df.dtypes
Out[294]:
    foo   int64
    bar   object
    baz  datetime64[ns]
    qux  category
dtype: object

Please note that the literal string ‘index’ as the name of an Index is not round-trippable, nor are any names beginning with 'level_' within a MultiIndex. These are used by default in DataFrame.to_json() to indicate missing values and the subsequent read cannot distinguish the intent.

In [295]: df.index.name = "index"

In [296]: df.to_json("test.json", orient="table")

In [297]: new_df = pd.read_json("test.json", orient="table")

In [298]: print(new_df.index.name)
When using `orient='table'` along with user-defined `ExtensionArray`, the generated schema will contain an additional `extDtype` key in the respective `fields` element. This extra key is not standard but does enable JSON roundtrips for extension types (e.g. `read_json(df.to_json(orient="table"), orient="table")`).

The `extDtype` key carries the name of the extension, if you have properly registered the `ExtensionDtype`, pandas will use said name to perform a lookup into the registry and re-convert the serialized data into your custom `dtype`.

### 2.4.3 HTML

#### Reading HTML content

**Warning:** We highly encourage you to read the *HTML Table Parsing gotchas* below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas DataFrames. Let's look at a few examples.

**Note:** `read_html` returns a list of `DataFrame` objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [299]: url = "https://www.fdic.gov/resources/resolutions/bank-failures/failed-bank-list"

In [300]: dfs = pd.read_html(url)

In [301]: dfs
```

```
Out[301]:
[ Bank NameBank CityCity StateSt ... ␣  
  Acquiring InstitutionAI Closing DateClosing FundFund  
  0 Almena State Bank Almena KS ...  
  1 First City Bank of Florida Fort Walton Beach FL ...  
  2 United Fidelity Bank, fsb October 16, 2020 10537  
  3 The First State Bank Barboursville WV ...  
  4 MVB Bank, Inc. April 3, 2020 10536  
  5 Ericson State Bank Ericson NE ...  
  6 Farmers and Merchants Bank February 14, 2020 10535  
  7 City National Bank of New Jersey Newark NJ ...  
  8 Industrial Bank November 1, 2019 10534  
  ... ... ... ... ...  
  558 Superior Bank, FSB Hinsdale IL ...  
  559 Superior Federal, FSB July 27, 2001 6004  
  560 Malta National Bank Malta OH ...  
  561 North Valley Bank May 3, 2001 4648
```

(continues on next page)
Note: The data from the above URL changes every Monday so the resulting data above and the data below may be slightly different.

Read in the content of the file from the above URL and pass it to `read_html` as a string:

```python
In [302]: with open(file_path, "r") as f:
......:   dfs = pd.read_html(f.read())
......:
In [303]: dfs
Out[303]:
[ Bank Name City ... Closing Date
 0 Banks of Wisconsin d/b/a Bank of Kenosha Kenosha ... May 31, 2013
 1 Central Arizona Bank Scottsdale ... May 14, 2013
 2 Sunrise Bank Valdosta ... May 10, 2013
 3 Pisgah Community Bank Asheville ... May 10, 2013
 4 Douglas County Bank Douglasville ... April 26, 2013
 5 ... ... ... ... ... ...
501 Superior Bank, FSB Hinsdale ... July 27, 2001
502 Malta National Bank Malta ... May 3, 2001
503 First Alliance Bank & Trust Co. Manchester ... February 2, 2001
504 National State Bank of Metropolis Metropolis ... December 14, 2000
505 Bank of Honolulu Honolulu ... October 13, 2000
[506 rows x 7 columns]]
```

You can even pass in an instance of `StringIO` if you so desire:

```python
In [304]: with open(file_path, "r") as f:
......:   sio = StringIO(f.read())
......:   dfs = pd.read_html(sio)
```

2.4. IO tools (text, CSV, HDF5, ...)
In [305]: dfs = pd.read_html(sio)

In [306]: dfs
Out[306]:
[ Bank Name City ... Closing Date \\
0 Banks of Wisconsin d/b/a Bank of Kenosha Kenosha ... May 31, 2013 \\
1 Central Arizona Bank Scottsdale ... May 14, 2013 \\
2 Sunrise Bank Valdosta ... May 10, 2013 \\
3 Pisgah Community Bank Asheville ... May 10, 2013 \\
4 Douglas County Bank Douglasville ... April 26, 2013 \\
... ... ... ... \\
501 Superior Bank, FSB Hinsdale ... July 27, 2001 \\
502 Malta National Bank Malta ... May 3, 2001 \\
503 First Alliance Bank & Trust Co. Manchester ... February 2, 2001 \\
504 National State Bank of Metropolis Metropolis ... December 14, 2000 \\
505 Bank of Honolulu Honolulu ... October 13, 2000 \\
[506 rows x 7 columns]]

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn’t run, please do not hesitate to report it over on pandas GitHub issues page.

Read a URL and match a table that contains specific text:

```python
match = "Metcalf Bank"
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a MultiIndex is created); if specified, the header row is taken from the data minus the parsed header elements (<th> elements).

```python
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```python
dfs = pd.read_html(url, index_col=0)
```
Specify a number of rows to skip:

```python
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (range works as well):

```python
dfs = pd.read_html(url, skiprows=range(2))
```

Specify an HTML attribute:

```python
dfs1 = pd.read_html(url, attrs={"id": "table"})
dfs2 = pd.read_html(url, attrs={"class": "sortable"})
print(np.array_equal(dfs1[0], dfs2[0]))  # Should be True
```

Specify values that should be converted to NaN:

```python
dfs = pd.read_html(url, na_values="No Acquirer")
```

Specify whether to keep the default set of NaN values:

```python
dfs = pd.read_html(url, keep_default_na=False)
```

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```python
url_mcc = "https://en.wikipedia.org/wiki/Mobile_country_code"
dfs = pd.read_html(
    url_mcc,
    match="Telekom Albania",
    header=0,
    converters={"MNC": str},
)
```

Use some combination of the above:

```python
dfs = pd.read_html(url, match="Metcalf Bank", index_col=0)
```

Read in pandas to_html output (with some loss of floating point precision):

```python
df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format="{0:.40g}".format)
dfin = pd.read_html(s, index_col=0)
```

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor="lxml")
```

Or you could pass flavor='lxml' without a list:

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor="lxml")
```

However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that as soon as a parse succeeds, the function will return.
Writing to HTML files

DataFrame objects have an instance method `to_html` which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method `to_string` described above.

**Note:** Not all of the possible options for `DataFrame.to_html` are shown here for brevity’s sake. See `to_html()` for the full set of options.

```
In [307]: df = pd.DataFrame(np.random.randn(2, 2))
```
```
In [308]: df
Out[308]:
   0   1
0 -0.184744  0.496971
1 -0.856240  1.857977
```
```
In [309]: print(df.to_html())  # raw html
<table border="1" class="dataframe">
   <thead>
   <tr style="text-align: right;">  
   <th></th>  
   <th>0</th>  
   <th>1</th>  
   </tr>
   </thead>
   <tbody>
   <tr>
   <th>0</th>  
   <td>-0.184744</td>  
   <td>0.496971</td>  
   </tr>
   <tr>
   <th>1</th>  
   <td>-0.856240</td>  
   <td>1.857977</td>  
   </tr>
   </tbody>
</table>
```

**HTML:**

The `columns` argument will limit the columns shown:

```
In [310]: print(df.to_html(columns=[0]))
<table border="1" class="dataframe">
   <thead>
   <tr style="text-align: right;">  
   <th></th>  
   <th>0</th>  
   </tr>
   </thead>
   <tbody>
   <tr>
   <th>0</th>  
   <td>-0.184744</td>  
   </tr>
   <tr>
   <th>1</th>  
   <td>-0.856240</td>  
   </tr>
   </tbody>
</table>
```

(continues on next page)
**HTML:**

float\_format takes a Python callable to control the precision of floating point values:

```python
In [311]: print(df.to_html(float_format="{0:.10f}".format))
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>0</th>  
<th>1</th> 
</tr>
</thead>
<tbody>
<tr>  
<th>0</th>  
<td>-0.1847438576</td>  
<td>0.4969711327</td>
</tr>  
<tr>  
<th>1</th>  
<td>-0.8562396763</td>  
<td>1.8579766508</td>
</tr>
</tbody>
</table>
```

**HTML:**

bold\_rows will make the row labels bold by default, but you can turn that off:

```python
In [312]: print(df.to_html(bold_rows=False))
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>0</th>  
<th>1</th> 
</tr>
</thead>
<tbody>
<tr>  
<th>0</th>  
<td>-0.1847438576</td>  
<td>0.4969711327</td>
</tr>  
<tr>  
<th>1</th>  
<td>-0.8562396763</td>  
<td>1.8579766508</td>
</tr>
</tbody>
</table>
```
The classes argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are appended to the existing 'dataframe' class.

```python
In [313]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class']))
```

```
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
<thead>
<tr style="text-align: right;">
 <th></th>
 <th>0</th>
 <th>1</th>
</tr>
</thead>
<tbody>
<tr>
 <th>0</th>
 <td>-0.184744</td>
 <td>0.496971</td>
 </tr>
<tr>
 <th>1</th>
 <td>-0.856240</td>
 <td>1.857977</td>
 </tr>
</tbody>
</table>
```

The render_links argument provides the ability to add hyperlinks to cells that contain URLs.

```python
In [314]: url_df = pd.DataFrame(
......:     {......:         "name": ["Python", "pandas"],......:         "url": ["https://www.python.org/", "https://pandas.pydata.org"],......:     }
......: )
......:

In [315]: print(url_df.to_html(render_links=True))
```

(continues on next page)
Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters are escaped in the resulting HTML (by default it is `True`). So to get the HTML without escaped characters pass `escape=False`.

```
In [316]: df = pd.DataFrame({'a': list('&<>'), 'b': np.random.randn(3)})
```

Escaped:

```
In [317]: print(df.to_html())
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>&amp;</td>
<td>-0.474063</td>
</tr>
<tr>
<th>1</th>
<td>&lt;</td>
<td>-0.230305</td>
</tr>
</tbody>
</table>
```
<tr>
  <th>2</th>
  <td>&gt;</td>
  <td>-0.400654</td>
</tr>
</tbody>
</table>

Not escaped:

In [318]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>&</td>
<td>-0.474063</td>
</tr>
<tr>
<th>1</th>
<td><</td>
<td>-0.230305</td>
</tr>
<tr>
<th>2</th>
<td>></td>
<td>-0.400654</td>
</tr>
</tbody>
</table>

Note: Some browsers may not show a difference in the rendering of the previous two HTML tables.

### HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas `io` function `read_html`.

**Issues with lxml**

- **Benefits**
  - lxml is very fast.
  - lxml requires Cython to install correctly.
• Drawbacks
  – lxml does not make any guarantees about the results of its parse unless it is given strictly valid markup.
  – In light of the above, we have chosen to allow you, the user, to use the lxml backend, but this backend will use html5lib if lxml fails to parse
  – It is therefore highly recommended that you install both BeautifulSoup4 and html5lib, so that you will still get a valid result (provided everything else is valid) even if lxml fails.

Issues with BeautifulSoup4 using lxml as a backend
• The above issues hold here as well since BeautifulSoup4 is essentially just a wrapper around a parser backend.

Issues with BeautifulSoup4 using html5lib as a backend
• Benefits
  – html5lib is far more lenient than lxml and consequently deals with real-life markup in a much saner way rather than just, e.g., dropping an element without notifying you.
  – html5lib generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  – html5lib is pure Python and requires no additional build steps beyond its own installation.
• Drawbacks
  – The biggest drawback to using html5lib is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

2.4.4 LaTeX

New in version 1.3.0.

Currently there are no methods to read from LaTeX, only output methods.

Writing to LaTeX files

Note: DataFrame and Styler objects currently have a to_latex method. We recommend using the Styler.to_latex() method over DataFrame.to_latex() due to the former’s greater flexibility with conditional styling, and the latter’s possible future deprecation.

Review the documentation for Styler.to_latex, which gives examples of conditional styling and explains the operation of its keyword arguments.

For simple application the following pattern is sufficient.

In [319]: df = pd.DataFrame([[1, 2], [3, 4]], index=["a", "b"], columns=["c", "d"])
In [320]: print(df.style.to_latex())
\begin{tabular}{lrr}
& c & d \\
\hline
a & 1 & 2 \\
\end{tabular}

(continues on next page)
To format values before output, chain the `Styler.format` method.

```
\begin{tabular}{lrr}
& c & d \\

## 2.4.5 XML

### Reading XML

New in version 1.3.0.

The top-level `read_xml()` function can accept an XML string/file/URL and will parse nodes and attributes into a pandas DataFrame.

**Note:** Since there is no standard XML structure where design types can vary in many ways, `read_xml` works best with flatter, shallow versions. If an XML document is deeply nested, use the `stylesheet` feature to transform XML into a flatter version.

Let's look at a few examples.

Read an XML string:

```
In [322]: xml = """"<?xml version="1.0" encoding="UTF-8"?>
.....: <bookstore>
.....:   <book category="cooking">
.....:     <title lang="en">Everyday Italian</title>
.....:     <author>Giada De Laurentiis</author>
.....:     <year>2005</year>
.....:     <price>30.00</price>
.....:   </book>
.....: <book category="children">
.....:   <title lang="en">Harry Potter</title>
.....:   <author>J K. Rowling</author>
.....:   <year>2005</year>
.....:   <price>29.99</price>
.....: </book>
.....: <book category="web">
.....:   <title lang="en">Learning XML</title>
.....:   <author>Erik T. Ray</author>
.....:   <year>2003</year>
.....:   <price>39.95</price>
.....: </book>
.....: </bookstore>"
```

(continues on next page)
In [323]: df = pd.read_xml(xml)

In [324]: df
Out[324]:
   category      title           author          year     price
0   cooking  Everyday Italian  Giada De Laurentiis 2005  30.00
2    web       Learning XML            Erik T. Ray 2003  39.95

Read a URL with no options:

In [325]: df = pd.read_xml("https://www.w3schools.com/xml/books.xml")

In [326]: df
Out[326]:
   category      title           author          year     price     cover
0   cooking  Everyday Italian  Giada De Laurentiis 2005  30.00    None
1   children    Harry Potter          J K. Rowling 2005  29.99    None
2    web       XQuery Kick Start    Vaidyanathan Nagarajan 2003  49.99    None
3    web       Learning XML            Erik T. Ray 2003  39.95    paperback

Read in the content of the “books.xml” file and pass it to read_xml as a string:

In [327]: with open(file_path, "r") as f:
   ....:     df = pd.read_xml(f.read())
   ....:

In [328]: df
Out[328]:
   category      title           author          year     price
0   cooking  Everyday Italian  Giada De Laurentiis 2005  30.00
2    web       Learning XML            Erik T. Ray 2003  39.95

Read in the content of the “books.xml” as instance of StringIO or BytesIO and pass it to read_xml:

In [329]: with open(file_path, "r") as f:
   ....:     sio = StringIO(f.read())
   ....:

In [330]: df = pd.read_xml(sio)

In [331]: df
Out[331]:
   category      title           author          year     price
0   cooking  Everyday Italian  Giada De Laurentiis 2005  30.00
2    web       Learning XML            Erik T. Ray 2003  39.95

In [332]: with open(file_path, "rb") as f:
   ....:     bio = BytesIO(f.read())
   ....:

Even read XML from AWS S3 buckets such as Python Software Foundation’s IRS 990 Form:

```python
In [335]: df = pd.read_xml(
    ..........:   "s3://irs-form-990/201923199349319487_public.xml",
    ..........:   xpath="//irs:Form990PartVIISectionAGrp",
    ..........:   namespaces={"irs": "http://www.irs.gov/efile"}
    ..........: )

In [336]: df
```

With `lxml` as default parser, you access the full-featured XML library that extends Python’s `ElementTree` API. One powerful tool is ability to query nodes selectively or conditionally with more expressive XPath:
pandas: powerful Python data analysis toolkit, Release 1.4.1

In [337]: df = pd.read_xml(file_path, xpath="//book[year=2005]")
In [338]: df
Out[338]:
category
title
0
cooking Everyday Italian
1 children
Harry Potter

author
Giada De Laurentiis
J K. Rowling

year
2005
2005

price
30.00
29.99

Specify only elements or only attributes to parse:
In [339]: df = pd.read_xml(file_path, elems_only=True)
In [340]: df
Out[340]:
0
1
2

title
Everyday Italian
Harry Potter
Learning XML

author
Giada De Laurentiis
J K. Rowling
Erik T. Ray

year
2005
2005
2003

price
30.00
29.99
39.95

In [341]: df = pd.read_xml(file_path, attrs_only=True)
In [342]: df
Out[342]:
category
0
cooking
1 children
2
web
XML documents can have namespaces with prefixes and default namespaces without prefixes both of which are denoted
with a special attribute xmlns. In order to parse by node under a namespace context, xpath must reference a prefix.
For example, below XML contains a namespace with prefix, doc, and URI at https://example.com. In order to
parse doc:row nodes, namespaces must be used.
In [343]: xml = """<?xml version='1.0' encoding='utf-8'?>
.....: <doc:data xmlns:doc="https://example.com">
.....:
<doc:row>
.....:
<doc:shape>square</doc:shape>
.....:
<doc:degrees>360</doc:degrees>
.....:
<doc:sides>4.0</doc:sides>
.....:
</doc:row>
.....:
<doc:row>
.....:
<doc:shape>circle</doc:shape>
.....:
<doc:degrees>360</doc:degrees>
.....:
<doc:sides/>
.....:
</doc:row>
.....:
<doc:row>
.....:
<doc:shape>triangle</doc:shape>
.....:
<doc:degrees>180</doc:degrees>
.....:
<doc:sides>3.0</doc:sides>
.....:
</doc:row>
.....: </doc:data>"""
.....:
(continues on next page)

2.4. IO tools (text, CSV, HDF5, . . . )

341


Similarly, an XML document can have a default namespace without prefix. Failing to assign a temporary prefix will return no nodes and raise a `ValueError`. But assigning any temporary name to correct URI allows parsing by nodes.

```python
In [346]: xml = """<?xml version='1.0' encoding='utf-8'?>
......: <data xmlns="https://example.com">
......: <row>
......:   <shape>square</shape>
......:   <degrees>360</degrees>
......:   <sides>4.0</sides>
......: </row>
......: <row>
......:   <shape>circle</shape>
......:   <degrees>360</degrees>
......: </row>
......: <row>
......:   <shape>triangle</shape>
......:   <degrees>180</degrees>
......: </row>
......: </data>""

In [347]: df = pd.read_xml(xml,
......: xpath="//pandas:row",
......: namespaces={"pandas": "https://example.com"})
```

```
In [348]: df
def
Out[348]:
shape  degrees  sides
   0  square   360   4.0
   1    circle 360  NaN
   2  triangle 180   3.0
```

However, if XPath does not reference node names such as default, `/*`, then `namespaces` is not required.

With `lxml` as parser, you can flatten nested XML documents with an XSLT script which also can be string/file/URL types. As background, XSLT is a special-purpose language written in a special XML file that can transform original XML documents into other XML, HTML, even text (CSV, JSON, etc.) using an XSLT processor.
For example, consider this somewhat nested structure of Chicago “L” Rides where station and rides elements encapsulate data in their own sections. With below XSLT, lxml can transform original nested document into a flatter output (as shown below for demonstration) for easier parse into DataFrame:

```python
In [349]: xml = """<?xml version='1.0' encoding='utf-8'?>
.....: <response>
.....:   <row>
.....:     <station id="40850" name="Library"/>
.....:     <month>2020-09-01T00:00:00</month>
.....:     <rides>
.....:       <avg_weekday_rides>864.2</avg_weekday_rides>
.....:       <avg_saturday_rides>534</avg_saturday_rides>
.....:       <avg_sunday_holiday_rides>417.2</avg_sunday_holiday_rides>
.....:     </rides>
.....:   </row>
.....:   <row>
.....:     <station id="41700" name="Washington/Wabash"/>
.....:     <month>2020-09-01T00:00:00</month>
.....:     <rides>
.....:       <avg_weekday_rides>2707.4</avg_weekday_rides>
.....:       <avg_saturday_rides>1909.8</avg_saturday_rides>
.....:       <avg_sunday_holiday_rides>1438.6</avg_sunday_holiday_rides>
.....:     </rides>
.....:   </row>
.....:   <row>
.....:     <station id="40380" name="Clark/Lake"/>
.....:     <month>2020-09-01T00:00:00</month>
.....:     <rides>
.....:       <avg_weekday_rides>2949.6</avg_weekday_rides>
.....:       <avg_saturday_rides>1657</avg_saturday_rides>
.....:       <avg_sunday_holiday_rides>1453.8</avg_sunday_holiday_rides>
.....:     </rides>
.....:   </row>
.....: </response>"

In [350]: xsl = """<xsl:stylesheet version='1.0' xmlns:xsl='http://www.w3.org/1999/XSL/Transform'>
.....:   <xsl:output method="xml" omit-xml-declaration="no" indent="yes"/>
.....:   <xsl:strip-space elements="*"/>
.....:   <xsl:template match="/response">
.....:     <xsl:copy>
.....:       <xsl:apply-templates select="row"/>
.....:     </xsl:copy>
.....:   </xsl:template>
.....:   <xsl:template match="row">
.....:     <xsl:copy>
.....:       <station_id><xsl:value-of select="station/@id"/></station_id>
.....:       <station_name><xsl:value-of select="station/@name"/></station_name>
.....:       <xsl:copy-of select="month|rides/*"/>
.....:     </xsl:copy>
.....:   </xsl:template>
.....: </xsl:stylesheet>"
```

(continues on next page)
In [351]: output = """<?xml version='1.0' encoding='utf-8'>
.....:
.....: <response>
.....:
.....:   <row>
.....:
.....:     <station_id>40850</station_id>

</table>
Writing XML

New in version 1.3.0.

DataFrame objects have an instance method to_xml which renders the contents of the DataFrame as an XML document.

Note: This method does not support special properties of XML including DTD, CDATA, XSD schemas, processing instructions, comments, and others. Only namespaces at the root level is supported. However, stylesheet allows design changes after initial output.

Let's look at a few examples.

**Write an XML without options:**

```python
In [354]: geom_df = pd.DataFrame(
    ...:     {  
    ...:       "shape": ["square", "circle", "triangle"],  
    ...:       "degrees": [360, 360, 180],  
    ...:       "sides": [4, np.nan, 3],  
    ...:     }  
    ...: )
```

```python
In [355]: print(geom_df.to_xml())
<?xml version='1.0' encoding='utf-8'?>
<data>
    <row>
        <index>0</index>
        <shape>square</shape>
        <degrees>360</degrees>
        <sides>4.0</sides>
    </row>
    <row>
        <index>1</index>
        <shape>circle</shape>
        <degrees>360</degrees>
        <sides/>
    </row>
    <row>
        <index>2</index>
        <shape>triangle</shape>
        <degrees>180</degrees>
        <sides>3.0</sides>
    </row>
</data>
```

**Write an XML with new root and row name:**

```python
In [356]: print(geom_df.to_xml(root_name="geometry", row_name="objects"))
<?xml version='1.0' encoding='utf-8'?>
<geometry>
    <objects>
```

(continues on next page)
Write an attribute-centric XML:

```python
In [357]: print(geom_df.to_xml(attr_cols=geom_df.columns.tolist()))
<?xml version='1.0' encoding='utf-8'?>
<data>
    <row index="0" shape="square" degrees="360" sides="4.0"/>
    <row index="1" shape="circle" degrees="360"/>
    <row index="2" shape="triangle" degrees="180" sides="3.0"/>
</data>
```

Write a mix of elements and attributes:

```python
In [358]: print(geom_df.to_xml(index=False,
         attr_cols=['shape'],
         elem_cols=['degrees', 'sides']))
<?xml version='1.0' encoding='utf-8'?>
<data>
    <row shape="square">
        <degrees>360</degrees>
        <sides>4.0</sides>
    </row>
    <row shape="circle">
        <degrees>360</degrees>
        <sides/>
    </row>
    <row shape="triangle">
        <degrees>180</degrees>
        <sides>3.0</sides>
    </row>
</data>
```
Any DataFrames with hierarchical columns will be flattened for XML element names with levels delimited by underscores:

```python
In [359]: ext_geom_df = pd.DataFrame(
    ....:     {
    ....:         "type": ["polygon", "other", "polygon"],
    ....:         "shape": ["square", "circle", "triangle"],
    ....:         "degrees": [360, 360, 180],
    ....:         "sides": [4, np.nan, 3],
    ....:     })

In [360]: pvt_df = ext_geom_df.pivot_table(index='shape',
    ....:     columns='type',
    ....:     values=['degrees', 'sides'],
    ....:     aggfunc='sum')

In [361]: pvt_df
Out[361]:

<table>
<thead>
<tr>
<th>shape</th>
<th>degrees</th>
<th>sides</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>360.0</td>
<td>NaN</td>
</tr>
<tr>
<td>square</td>
<td>NaN</td>
<td>360.0</td>
</tr>
<tr>
<td>triangle</td>
<td>180.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

In [362]: print(pvt_df.to_xml())
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row>
    <shape>circle</shape>
    <degrees_other>360.0</degrees_other>
    <degrees_polygon/>
    <sides_other>0.0</sides_other>
    <sides_polygon/>
  </row>
  <row>
    <shape>square</shape>
    <degrees_other/>
    <degrees_polygon>360.0</degrees_polygon>
    <sides_other/>
    <sides_polygon>4.0</sides_polygon>
  </row>
  <row>
    <shape>triangle</shape>
    <degrees_other/>
    <degrees_polygon>180.0</degrees_polygon>
    <sides_other/>
    <sides_polygon>3.0</sides_polygon>
  </row>
</data>
```
Write an XML with default namespace:

```python
In [363]: print(geom_df.to_xml(namespaces={"": "https://example.com"}))
<?xml version='1.0' encoding='utf-8'?>
<data xmlns="https://example.com">
  <row>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
  </row>
  <row>
    <index>2</index>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
  </row>
</data>
```

Write an XML with namespace prefix:

```python
In [364]: print(
       .....: geom_df.to_xml(namespaces={"doc": "https://example.com"},
       .....: prefix="doc")
       .....: )
       .....:
       .....:
       .....:
<?xml version='1.0' encoding='utf-8'?>
<doc:data xmlns:doc="https://example.com">
  <doc:row>
    <doc:index>0</doc:index>
    <doc:shape>square</doc:shape>
    <doc:degrees>360</doc:degrees>
    <doc:sides>4.0</doc:sides>
  </doc:row>
  <doc:row>
    <doc:index>1</doc:index>
    <doc:shape>circle</doc:shape>
    <doc:degrees>360</doc:degrees>
    <doc:sides/>
  </doc:row>
  <doc:row>
    <doc:index>2</doc:index>
    <doc:shape>triangle</doc:shape>
    <doc:degrees>180</doc:degrees>
    <doc:sides>3.0</doc:sides>
  </doc:row>
</doc:data>
```
Write an XML without declaration or pretty print:

```python
In [365]: print(geom_df.to_xml(xml_declaration=False, pretty_print=False))
<data>
  <row>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
  </row>
  <row>
    <index>2</index>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
  </row>
</data>
```

Write an XML and transform with stylesheet:

```python
In [366]: xsl = """<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
    <xsl:output method="xml" omit-xml-declaration="no" indent="yes"/>
    <xsl:strip-space elements="*"/>
    <xsl:template match="/data">
      <geometry>
        <xsl:apply-templates select="row"/>
      </geometry>
    </xsl:template>
    <xsl:template match="row">
      <object index="{index}">
        <xsl:if test="shape!='circle'">
          <xsl:attribute name="type">polygon</xsl:attribute>
        </xsl:if>
        <xsl:copy-of select="shape"/>
        <property>
          <xsl:copy-of select="degrees|sides"/>
        </property>
      </object>
    </xsl:template>
  </xsl:stylesheet>"

In [367]: print(geom_df.to_xml(stylesheet=xsl))
<?xml version="1.0"?>
<geometry>
  <object index="0" type="polygon">
    <shape>square</shape>
    <property>
      <degrees>360</degrees>
      <sides>4.0</sides>
    </property>
  </object>
  <object index="1">
    <shape>circle</shape>
    <property>
      <degrees>360</degrees>
      <sides/>
    </property>
  </object>
  <object index="2">
    <shape>triangle</shape>
    <property>
      <degrees>180</degrees>
      <sides>3.0</sides>
    </property>
  </object>
</geometry>
```

(continues on next page)
XML Final Notes

- All XML documents adhere to W3C specifications. Both etree and lxml parsers will fail to parse any markup document that is not well-formed or follows XML syntax rules. Do be aware HTML is not an XML document unless it follows XHTML specs. However, other popular markup types including KML, XAML, RSS, MusicML, MathML are compliant XML schemas.

- For above reason, if your application builds XML prior to pandas operations, use appropriate DOM libraries like etree and lxml to build the necessary document and not by string concatenation or regex adjustments. Always remember XML is a special text file with markup rules.

- With very large XML files (several hundred MBs to GBs), XPath and XSLT can become memory-intensive operations. Be sure to have enough available RAM for reading and writing to large XML files (roughly about 5 times the size of text).

- Because XSLT is a programming language, use it with caution since such scripts can pose a security risk in your environment and can run large or infinite recursive operations. Always test scripts on small fragments before full run.

- The etree parser supports all functionality of both read_xml and to_xml except for complex XPath and any XSLT. Though limited in features, etree is still a reliable and capable parser and tree builder. Its performance may trail lxml to a certain degree for larger files but relatively unnoticeable on small to medium size files.

2.4.6 Excel files

The read_excel() method can read Excel 2007+ (.xlsx) files using the openpyxl Python module. Excel 2003 (.xls) files can be read using xlrd. Binary Excel (.xlsb) files can be read using pyxlsb. The to_excel() instance method is used for saving a DataFrame to Excel. Generally the semantics are similar to working with csv data. See the cookbook for some advanced strategies.

Warning: The xlwt package for writing old-style .xls excel files is no longer maintained. The xlrd package is now only for reading old-style .xls files.

Before pandas 1.3.0, the default argument engine=None to read_excel() would result in using the xlrd engine in many cases, including new Excel 2007+ (.xlsx) files. pandas will now default to using the openpyxl engine.

It is strongly encouraged to install openpyxl to read Excel 2007+ (.xlsx) files. Please do not report issues when using "xlrd" to read "xlsx" files. This is no longer supported, switch to using openpyxl instead.

Attempting to use the xlwt engine will raise a FutureWarning unless the option io.excel.xls.writer is set to "xlwt". While this option is now deprecated and will also raise a FutureWarning, it can be globally set and the warning suppressed. Users are recommended to write .xlsx files using the openpyxl engine instead.
**Reading Excel files**

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xls", sheet_name="Sheet1")
```

**ExcelFile class**

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel`. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```python
xlsx = pd.ExcelFile("path_to_file.xls")
df = pd.read_excel(xlsx, "Sheet1")
```

The `ExcelFile` class can also be used as a context manager.

```python
with pd.ExcelFile("path_to_file.xls") as xls:
    df1 = pd.read_excel(xls, "Sheet1")
    df2 = pd.read_excel(xls, "Sheet2")
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```python
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values="NA")
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```python
# using the ExcelFile class
data = {}
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values="NA")
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=None, na_values="NA")

# equivalent using the read_excel function
data = pd.read_excel(
    "path_to_file.xls", ["Sheet1", "Sheet2"], index_col=None, na_values="NA")
```

ExcelFile can also be called with a `xlrd.book.Book` object as a parameter. This allows the user to control how the excel file is read. For example, sheets can be loaded on demand by calling `xlrd.open_workbook()` with `on_demand=True`.

```python
import xlrd
```

(continues on next page)
Specifying sheets

**Note:** The second argument is `sheet_name`, not to be confused with `ExcelFile.sheet_names`.

**Note:** An ExcelFile’s attribute `sheet_names` provides access to a list of sheets.

- The arguments `sheet_name` allows specifying the sheet or sheets to read.
- The default value for `sheet_name` is 0, indicating to read the first sheet.
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a `None` to return a dictionary of all available sheets.

```
# Returns a DataFrame
pd.read_excel("path_to_file.xls", "Sheet1", index_col=None, na_values=["NA"])
```

Using the sheet index:
```
# Returns a DataFrame
pd.read_excel("path_to_file.xls", 0, index_col=None, na_values=["NA"])
```

Using all default values:
```
# Returns a DataFrame
pd.read_excel("path_to_file.xls")
```

Using None to get all sheets:
```
# Returns a dictionary of DataFrames
pd.read_excel("path_to_file.xls", sheet_name=None)
```

Using a list to get multiple sheets:
```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel("path_to_file.xls", sheet_name=["Sheet1", 3])
```

`read_excel` can read more than one sheet, by setting `sheet_name` to either a list of sheet names, a list of sheet positions, or `None` to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.
Reading a MultiIndex

read Excel can read a MultiIndex index, by passing a list of columns to index_col and a MultiIndex column by passing a list of rows to header. If either the index or columns have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a MultiIndex index without names:

```python
In [368]: df = pd.DataFrame(
   ...:   {"a": [1, 2, 3, 4], "b": [5, 6, 7, 8]},
   ...:   index=pd.MultiIndex.from_product(["a", "b"], ["c", "d"]),
   ...: )
   ...

In [369]: df.to_excel("path_to_file.xlsx")

In [370]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])

In [371]: df
Out[371]:
   a b
  a c 1 5
d 2 6
b c 3 7
d 4 8
```

If the index has level names, they will parsed as well, using the same parameters.

```python
In [372]: df.index = df.index.set_names(["lvl1", "lvl2"])

In [373]: df.to_excel("path_to_file.xlsx")

In [374]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])

In [375]: df
Out[375]:
   a b
  lvl1 lvl2
  a c 1 5
d 2 6
b c 3 7
d 4 8
```

If the source file has both MultiIndex index and columns, lists specifying each should be passed to index_col and header:

```python
In [376]: df.columns = pd.MultiIndex.from_product(["a", ["b", "d"], names=["c1", "c2", "]")

In [377]: df.to_excel("path_to_file.xlsx")

In [378]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1], header=[0, 1])

In [379]: df
```
(continues on next page)
Parsing specific columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Changed in version 1.0.0.

Passing in an integer for `usecols` will no longer work. Please pass in a list of ints from 0 to `usecols` inclusive instead.

You can specify a comma-delimited set of Excel columns and ranges as a string:

```python
pd.read_excel("path_to_file.xls", "Sheet1", usecols="A,C:E")
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```python
pd.read_excel("path_to_file.xls", "Sheet1", usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in `names` or inferred from the document header row(s). Those strings define which columns will be parsed:

```python
pd.read_excel("path_to_file.xls", "Sheet1", usecols=["foo", "bar"])
```

Element order is ignored, so `usecols=['baz', 'joe']` is the same as `['joe', 'baz']`.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`.

```python
pd.read_excel("path_to_file.xls", "Sheet1", usecols=lambda x: x.isalpha())
```

Parsing dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that look like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```python
pd.read_excel("path_to_file.xls", "Sheet1", parse_dates=["date_strings"])
```
Cell converters

It is possible to transform the contents of Excel cells via the converters option. For instance, to convert a column to boolean:

```python
df.read_excel("path_to_file.xls", "Sheet1", converters={"MyBools": bool})
```

This option handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```python
def cfun(x):
    return int(x) if x else -1

df.read_excel("path_to_file.xls", "Sheet1", converters={"MyInts": cfun})
```

Dtype specifications

As an alternative to converters, the type for an entire column can be specified using the dtype keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type str or object.

```python
df.read_excel("path_to_file.xls", dtype={"MyInts": "int64", "MyText": str})
```

Writing Excel files

Writing Excel files to disk

To write a DataFrame object to a sheet of an Excel file, you can use the to_excel instance method. The arguments are largely the same as to_csv described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the DataFrame should be written. For example:

```python
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")
```

Files with a .xls extension will be written using xlwt and those with a .xlsx extension will be written using xlsxwriter (if available) or openpyxl.

The DataFrame will be written in a way that tries to mimic the REPL output. The index_label will be placed in the second row instead of the first. You can place it in the first row by setting the merge_cells option in to_excel() to False:

```python
df.to_excel("path_to_file.xlsx", index_label="label", merge_cells=False)
```

In order to write separate DataFrames to separate sheets in a single Excel file, one can pass an ExcelWriter.

```python
with pd.ExcelWriter("path_to_file.xlsx") as writer:
    df1.to_excel(writer, sheet_name="Sheet1")
    df2.to_excel(writer, sheet_name="Sheet2")
```
Writing Excel files to memory

pandas supports writing Excel files to buffer-like objects such as StringIO or BytesIO using ExcelWriter.

```python
from io import BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine="xlsxwriter")
df.to_excel(writer, sheet_name="Sheet1")

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

**Note:** engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (.xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (.xlsx). If omitted, an Excel 2007-formatted workbook is produced.

### Excel writer engines

Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed from a future version of pandas. This is the only engine in pandas that supports writing to .xls files.

pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the XlsxWriter for .xlsx, openpyxl for .xlsm, and xlwt for .xls files. If you have multiple engines installed, you can set the default engine through setting the config options io.excel.xlsx.writer and io.excel.xls.writer. pandas will fall back on openpyxl for .xlsx files if Xlsxwriter is not available.

To specify which writer you want to use, you can pass an engine keyword argument to `to_excel` and to `ExcelWriter`. The built-in engines are:

- openpyxl: version 2.4 or higher is required
- xlsxwriter
- xlwt

```python
# By setting the 'engine' in the DataFrame 'to_excel()' methods.
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1", engine="xlsxwriter")

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter("path_to_file.xlsx", engine="xlsxwriter")

# Or via pandas configuration.
```
from pandas import options  # noqa: E402

options.io.excel.xlsx.writer = "xlsxwriter"

df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")

Style and formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame’s to_excel method.

- float_format: Format string for floating point numbers (default None).
- freeze_panes: A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so (1, 1) will freeze the first row and first column (default None).

Using the Xlsxwriter engine provides many options for controlling the format of an Excel worksheet created with the to_excel method. Excellent examples can be found in the Xlsxwriter documentation here: https://xlsxwriter.readthedocs.io/working_with_pandas.html

2.4.7 OpenDocument Spreadsheets

New in version 0.25.

The read_excel() method can also read OpenDocument spreadsheets using the odfpy module. The semantics and features for reading OpenDocument spreadsheets match what can be done for Excel files using engine='odf'.

# Returns a DataFrame
pd.read_excel("path_to_file.ods", engine="odf")

Note: Currently pandas only supports reading OpenDocument spreadsheets. Writing is not implemented.

2.4.8 Binary Excel (.xlsb) files

New in version 1.0.0.

The read_excel() method can also read binary Excel files using the pyxlsb module. The semantics and features for reading binary Excel files mostly match what can be done for Excel files using engine='pyxlsb'. pyxlsb does not recognize datetime types in files and will return floats instead.

# Returns a DataFrame
pd.read_excel("path_to_file.xlsb", engine="pyxlsb")

Note: Currently pandas only supports reading binary Excel files. Writing is not implemented.
2.4.9 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A  B  C
x 1  4  p
y 2  5  q
z 3  6  r
```

And then import the data directly to a DataFrame by calling:

```
>>> clipdf = pd.read_clipboard()
>>> clipdf
    A  B  C
  x 1  4  p
  y 2  5  q
  z 3  6  r
```

The `to_clipboard` method can be used to write the contents of a DataFrame to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a DataFrame into clipboard and reading it back.

```
>>> df = pd.DataFrame(
...     {
...         "A": [1, 2, 3],
...         "B": [4, 5, 6],
...         "C": ["p", "q", "r"],
...         "index": ["x", "y", "z"]
...     })

>>> df
    A  B  C
  x 1  4  p
  y 2  5  q
  z 3  6  r

>>> df.to_clipboard()

>>> pd.read_clipboard()
    A  B  C
  x 1  4  p
  y 2  5  q
  z 3  6  r
```

We can see that we got the same content back, which we had earlier written to the clipboard.

**Note:** You may need to install xclip or xsel (with PyQt5, PyQt4 or qtpy) on Linux to use these methods.
2.4.10 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python’s cPickle module to save data structures to disk using the pickle format.

```python
In [380]: df
Out[380]:
c1  a
  c2  b  d
lvl1  lvl2
  a  c  1  5
      d  2  6
  b  c  3  7
      d  4  8
In [381]: df.to_pickle("foo.pkl")
```

The `read_pickle` function in the pandas namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```python
In [382]: pd.read_pickle("foo.pkl")
Out[382]:
c1  a
  c2  b  d
lvl1  lvl2
  a  c  1  5
      d  2  6
  b  c  3  7
      d  4  8
```

**Warning:** Loading pickled data received from untrusted sources can be unsafe.

See: [https://docs.python.org/3/library/pickle.html](https://docs.python.org/3/library/pickle.html)

**Warning:** `read_pickle()` is only guaranteed backwards compatible back to pandas version 0.20.3

### Compressed pickle files

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of `gzip`, `bz2`, `xz`, `zstd` are supported for reading and writing. The zip file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If ‘infer’, then use `gzip`, `bz2`, `zip`, `xz`, `zstd` if filename ends in `.gz`, `.bz2`, `.zip`, `.xz`, or `.zst`, respectively.

The compression parameter can also be a `dict` in order to pass options to the compression protocol. It must have a 'method' key set to the name of the compression protocol, which must be one of ['zip', 'gzip', 'bz2', 'xz', 'zstd']. All other key-value pairs are passed to the underlying compression library.

```python
In [383]: df = pd.DataFrame(
   ....:   {
(continues on next page)
```
Using an explicit compression type:

```
In [385]: df.to_pickle("data.pkl.compress", compression="gzip")
```

```
In [386]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
```

```
In [387]: rt
```

```
Out[387]:
     A       B       C
0 -0.288267  foo 2013-01-01 00:00:00
1 -0.084905  foo 2013-01-01 00:00:01
2  0.004772  foo 2013-01-01 00:00:02
3  1.382989  foo 2013-01-01 00:00:03
4  0.343635  foo 2013-01-01 00:00:04
..       ...     ...         ...
995 -0.220893  foo 2013-01-01 00:16:35
996  0.492996  foo 2013-01-01 00:16:36
997 -0.461625  foo 2013-01-01 00:16:37
998  1.361779  foo 2013-01-01 00:16:38
999 -1.197988  foo 2013-01-01 00:16:39
[1000 rows x 3 columns]
```

Inferring compression type from the extension:

```
In [388]: df.to_pickle("data.pkl.xz", compression="infer")
```

```
In [389]: rt = pd.read_pickle("data.pkl.xz", compression="infer")
```
In [390]: rt
Out[390]:
   A     B   C
0  0.288267  foo 2013-01-01 00:00:00
1 -0.084905  foo 2013-01-01 00:00:01
2  0.004772  foo 2013-01-01 00:00:02
3  1.382989  foo 2013-01-01 00:00:03
4  0.343635  foo 2013-01-01 00:00:04
   ...   ...   ...
995 -0.220893  foo 2013-01-01 00:16:35
996  0.492996  foo 2013-01-01 00:16:36
997 -0.461625  foo 2013-01-01 00:16:37
998  1.361779  foo 2013-01-01 00:16:38
999 -1.197988  foo 2013-01-01 00:16:39

[1000 rows x 3 columns]

The default is to ‘infer’:

In [391]: df.to_pickle("data.pkl.gz")
In [392]: rt = pd.read_pickle("data.pkl.gz")

In [393]: rt
Out[393]:
   A     B   C
0  0.288267  foo 2013-01-01 00:00:00
1 -0.084905  foo 2013-01-01 00:00:01
2  0.004772  foo 2013-01-01 00:00:02
3  1.382989  foo 2013-01-01 00:00:03
4  0.343635  foo 2013-01-01 00:00:04
   ...   ...   ...
995 -0.220893  foo 2013-01-01 00:16:35
996  0.492996  foo 2013-01-01 00:16:36
997 -0.461625  foo 2013-01-01 00:16:37
998  1.361779  foo 2013-01-01 00:16:38
999 -1.197988  foo 2013-01-01 00:16:39

[1000 rows x 3 columns]

In [394]: df["A"].to_pickle("s1.pkl.bz2")

In [395]: rt = pd.read_pickle("s1.pkl.bz2")

In [396]: rt
Out[396]:
   0  -0.288267
   1  -0.084905
   2   0.004772
   3   1.382989
   4   0.343635

(continues on next page)
...  
995  -0.220893  
996   0.492996  
997  -0.461625  
998   1.361779  
999  -1.197988  
Name: A, Length: 1000, dtype: float64

Passing options to the compression protocol in order to speed up compression:

```
In [397]: df.to_pickle("data.pkl.gz", compression={"method": "gzip", "compresslevel": 1})
```

### 2.4.11 msgpack

pandas support for msgpack has been removed in version 1.0.0. It is recommended to use pickle instead.

Alternatively, you can also the Arrow IPC serialization format for on-the-wire transmission of pandas objects. For documentation on pyarrow, see here.

### 2.4.12 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent PyTables library. See the cookbook for some advanced strategies

**Warning:** pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle. Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html for more.

```
In [398]: store = pd.HDFStore("store.h5")

In [399]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Objects can be written to the file just like adding key-value pairs to a dict:

```
In [400]: index = pd.date_range("1/1/2000", periods=8)

In [401]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [402]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=['A', 'B', 'C'])
# store.put('s', s) is an equivalent method
In [403]: store['s'] = s

In [404]: store['df'] = df

In [405]: store
```
Out[405]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In a current or later Python session, you can retrieve stored objects:

```python
# store.get('df') is an equivalent method
In [406]: store['df']
Out[406]:
   A      B      C

Deletion of the object specified by the key:

```python
# store.remove('df') is an equivalent method
In [408]: del store['df']
In [409]: store
Out[409]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Closing a Store and using a context manager:

```python
In [410]: store.close()
In [411]: store
Out[411]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
Out[412]: store.is_open
Out[412]: False
```

(continues on next page)
Read/write API

HDFStore supports a top-level API using read_hdf for reading and to_hdf for writing, similar to how read_csv and to_csv work.

In [414]: df_tl = pd.DataFrame({'A': list(range(5)), 'B': list(range(5))})

In [415]: df_tl.to_hdf('store_tl.h5', 'table', append=True)

In [416]: pd.read_hdf('store_tl.h5', 'table', where=['index>2'])
Out[416]:
   A  B
0  0  0
1  1  1
2  2  2

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting dropna=True.

In [417]: df_with_missing = pd.DataFrame(
           '      
   col1: [0, np.nan, 2],
   col2: [1, np.nan, np.nan],
   col3: [2, np.nan, 3],
   col4: [3, np.nan, 4],
   col5: [4, np.nan, 5],
           '      
)

In [418]: df_with_missing
Out[418]:
   col1  col2
0  0.0   1.0
1  NaN  NaN
2  2.0  NaN

In [419]: df_with_missing.to_hdf('file.h5', 'df_with_missing', format='table', mode='w')

In [420]: pd.read_hdf('file.h5', 'df_with_missing')
Out[420]:
   col1  col2
0  0.0   1.0
1  NaN  NaN
2  2.0  NaN

In [421]: df_with_missing.to_hdf('file.h5', 'df_with_missing', format='table', mode='w', dropna=True)

(continues on next page)
In [422]: pd.read_hdf("file.h5", "df_with_missing")
Out[422]:
   col1  col2
0   0.0   1.0
2   2.0   NaN

Fixed format

The examples above show storing using put, which write the HDF5 to PyTables in a fixed array format, called the fixed format. These types of stores are not appendable once written (though you can simply remove them and rewrite). Nor are they queryable; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The fixed format stores offer very fast writing and slightly faster reading than table stores. This format is specified by default when using put or to_hdf or by format='fixed' or format='f'.

Warning: A fixed format will raise a TypeError if you try to retrieve using a where:

```python
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf("test_fixed.h5", "df")
>>> pd.read_hdf("test_fixed.h5", "df", where="index>5")
TypeError: cannot pass a where specification when reading a fixed format.
    this store must be selected in its entirety
```

Table format

HDFStore supports another PyTables format on disk, the table format. Conceptually a table is shaped very much like a DataFrame, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by format='table' or format='t' to append or put or to_hdf.

This format can be set as an option as well pd.set_option('io.hdf.default_format','table') to enable put/append/to_hdf to by default store in the table format.

In [423]: store = pd.HDFStore("store.h5")
In [424]: df1 = df[0:4]
In [425]: df2 = df[4:]
# append data (creates a table automatically)
In [426]: store.append("df", df1)
In [427]: store.append("df", df2)
In [428]: store
Out[428]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
# select the entire object
In [429]: store.select("df")
Out[429]:

# the type of stored data
In [430]: store.root.df._v_attrs.pandas_type
Out[430]: 'frame_table'

Note: You can also create a table by passing format='table' or format='t' to a put operation.

Hierarchical keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. foo/bar/bah), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading '/' and are always absolute (e.g. ‘foo’ refers to ‘/foo’). Removal operations can remove everything in the sub-store and below, so be careful.

In [431]: store.put("foo/bar/bah", df)
In [432]: store.append("food/orange", df)
In [433]: store.append("food/apple", df)

In [434]: store
Out[434]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# a list of keys are returned
In [435]: store.keys()
Out[435]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']

# remove all nodes under this level
In [436]: store.remove("food")

In [437]: store
Out[437]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

You can walk through the group hierarchy using the walk method which will yield a tuple for each group key along with the relative keys of its contents.
```python
In [438]: for (path, subgroups, subkeys) in store.walk():
    for subgroup in subgroups:
        print("GROUP: {}\n".format(path, subgroup))
    for subkey in subkeys:
        key = "/".join([path, subkey])
        print("KEY: {}\n".format(key))
        print(store.get(key))

GROUP: /foo
KEY: /df
A  B  C
2000-01-01 1.334065 0.521036 0.930384
2000-01-02 -1.613932 1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04 0.632369 -1.249657 0.975593
2000-01-05 1.060617 -0.143682 0.218423
2000-01-06 3.050329 1.317933 -0.963725
2000-01-07 -0.539452 -0.771133 0.023751
2000-01-08 0.649464 -1.736427 0.197288
GROUP: /foo/bar
KEY: /foo/bar/bah
A  B  C
2000-01-01 1.334065 0.521036 0.930384
2000-01-02 -1.613932 1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04 0.632369 -1.249657 0.975593
2000-01-05 1.060617 -0.143682 0.218423
2000-01-06 3.050329 1.317933 -0.963725
2000-01-07 -0.539452 -0.771133 0.023751
2000-01-08 0.649464 -1.736427 0.197288
```

**Warning:** Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```python
In [8]: store.foo.bar.bah
AttributeError: 'HDFStore' object has no attribute 'foo'
```

# you can directly access the actual PyTables node but using the root node

```python
In [9]: store.root.foo.bar.bah
Out[9]:
/foo/bar/bah (Group) ''
    children := [ 'block0_items' (Array), 'block0_values' (Array), 'axis0' (Array),
                  'axis1' (Array)]
```

Instead, use explicit string based keys:

```python
In [439]: store["foo/bar/bah"]
Out[439]:
A  B  C
2000-01-01 1.334065 0.521036 0.930384
2000-01-02 -1.613932 1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04 0.632369 -1.249657 0.975593
2000-01-05 1.060617 -0.143682 0.218423
2000-01-06 3.050329 1.317933 -0.963725
2000-01-07 -0.539452 -0.771133 0.023751
2000-01-08 0.649464 -1.736427 0.197288
```
Storing types

Storing mixed types in a table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={`values`: size}` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
in [440]: df_mixed = pd.DataFrame(
    ...:     {
    ...:         "A": np.random.randn(8),
    ...:         "B": np.random.randn(8),
    ...:         "C": np.array(np.random.randn(8), dtype="float32"),
    ...:         "string": "string",
    ...:         "int": 1,
    ...:         "bool": True,
    ...:         "datetime64": pd.Timestamp("20010102"),
    ...:     },
    ...:     index=list(range(8)),
    ...: )
```

```
in [441]: df_mixed.loc[df_mixed.index[3:5], ["A", "B", "string", "datetime64"]] = np.nan
```

```
in [442]: store.append("df_mixed", df_mixed, min_itemsize={"values": 50})
```

```
in [443]: df_mixed1 = store.select("df_mixed")
```

```
in [444]: df_mixed1
Out[444]:
   A         B       C  string  int    bool  datetime64
0 -0.116008  0.743946 -0.398501  string   1   True  2001-01-02

object        1
int64         1
```

(continues on next page)
Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```
In [447]: index = pd.MultiIndex(
    ....:     levels=["foo", "bar", "baz", "qux"], ["one", "two", "three"],
    ....:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
    ....:     names=["foo", "bar"],
    ....: )
    ....:

In [448]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B", "C "])

In [449]: df_mi
Out[449]:
       A    B    C
foo  bar
foo one  0.667450 0.169405 -1.358046
    two -0.105563 0.492195  0.076693
    three 0.213685 -0.285283 -1.210529
bar one -1.408386 0.941577 -0.342447
    two  0.222031 0.052607  2.093214
baz two 1.064908 1.778161 -0.913867
    three -0.030004 -0.399846 -1.234765
qux one  0.081323 -0.268494  0.168016
    two -0.898283 -0.218499  1.408028
    three -1.267828 -0.689263  0.520995
```

(continues on next page)
In [450]: store.append("df_mi", df_mi)

In [451]: store.select("df_mi")

Out[451]:
   A    B      C
foo bar  
foo one  0.667450 0.169405 -1.358046
   two -0.105563 0.492195  0.076693
   three 0.213685 -0.285283 -1.210529
bar one  -1.408386 0.941577 -0.342447
two 0.222031 0.052607  2.093214
baz two  1.064908 1.778161 -0.913867
two -0.030004 -0.399846 -1.234765
   three 0.081323 -0.268494  0.168016
qux one  -0.898283 -0.218499  1.408028
two -1.267828 -0.689263  0.520995
   three -0.030004 -0.399846 -1.234765

# the levels are automatically included as data columns
In [452]: store.select("df_mi", "foo=bar")

Out[452]:
   A    B      C
foo bar  
bar one  -1.408386 0.941577 -0.342447
two 0.222031 0.052607  2.093214

Note: The index keyword is reserved and cannot be use as a level name.

Querying

Querying a table

select and delete operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the Term class under the hood, as a boolean expression.

• index and columns are supported indexers of DataFrames.
  
• if data_columns are specified, these can be used as additional indexers.
  
• level name in a MultiIndex, with default name level_0, level_1,... if not provided.

Valid comparison operators are:

• =, ==, !=, >, >=, <, <=

Valid boolean expressions are combined with:

• |: or
• &: and
• ( and ): for grouping
These rules are similar to how boolean expressions are used in pandas for indexing.

Note:
- `=` will be automatically expanded to the comparison operator `==`
- `~` is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via `&`

The following are valid expressions:

- `'index >= date'`
- `"columns = ['A', 'D']"`
- `"columns in ['A', 'D']"`
- `'columns = A'`
- `'columns == A'`
- `"~(columns = ['A', 'B'])"`
- `'index > df.index[3] & string = "bar"'`
- `'(index > df.index[3] & index <= df.index[6]) | string = "bar"'`
- `"ts >= Timestamp('2012-02-01')"`
- "major_axis>=20130101"

The indexers are on the left-hand side of the sub-expression:

```python
columns, major_axis, ts
```

The right-hand side of the sub-expression (after a comparison operator) can be:

- functions that will be evaluated, e.g. `Timestamp('2012-02-01')`
- strings, e.g. "bar"
- date-like, e.g. `20130101`, or "20130101"
- lists, e.g. "['A', 'B']"
- variables that are defined in the local names space, e.g. `date`

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this:

```python
string = "HolyMoly"
store.select("df", "index == string")
```

instead of this:

```python
string = "HolyMoly"
store.select('df', f'index == {string}')
```

The latter will not work and will raise a `SyntaxError`. Note that there's a single quote followed by a double quote in the `string` variable.

If you must interpolate, use the `%r` format specifier.
store.select("df", "index == %r" % string)

which will quote string.

Here are some examples:

```python
In [453]: dfq = pd.DataFrame(
    .....:    np.random.randn(10, 4),
    .....:    columns=list("ABCD"),
    .....:    index=pd.date_range("20130101", periods=10),
    .....:    )
    .....:

In [454]: store.append("dfq", dfq, format="table", data_columns=True)

Use boolean expressions, with in-line function evaluation.

```python
In [455]: store.select("dfq", "index>pd.Timestamp('20130104') & columns=['A', 'B']")
```

Out[455]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>

The columns keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a 'columns=list_of_columns_to_filter':

```python
In [457]: store.select("df", "columns=['A', 'B']")
```

Out[457]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>

</tbody>
</table>
start and stop parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

Note: select will raise a ValueError if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is not a data_column.

select will raise a SyntaxError if the query expression is not valid.

### Query timedelta64[ns]

You can store and query using the timedelta64[ns] type. Terms can be specified in the format: <float>(<unit>), where float may be signed (and fractional), and unit can be D, s, ms, us, ns for the timedelta. Here’s an example:

```
In [458]: from datetime import timedelta

In [459]: dftd = pd.DataFrame(
   ....:     {
   ....:         "A": pd.Timestamp("20130101"),
   ....:         "B": [pd.Timestamp("20130101") + timedelta(days=i, seconds=10) for i in range(10)],
   ....:     }
   ....: )

In [460]: dftd["C"] = dftd["A"] - dftd["B"]

In [461]: dftd

Out[461]:
        A          B             C
   0 2013-01-01  00:00:10 -1 days +23:59:50
   1 2013-01-01  00:00:10 -2 days +23:59:50
   2 2013-01-01  00:00:10 -3 days +23:59:50
   3 2013-01-01  00:00:10 -4 days +23:59:50
   4 2013-01-01  00:00:10 -5 days +23:59:50
   5 2013-01-01  00:00:10 -6 days +23:59:50
   6 2013-01-01  00:00:10 -7 days +23:59:50
   7 2013-01-01  00:00:10 -8 days +23:59:50
   8 2013-01-01  00:00:10 -9 days +23:59:50
   9 2013-01-01  00:00:10 -10 days +23:59:50

In [462]: store.append("dftd", dftd, data_columns=True)

In [463]: store.select("dftd", "C<\'-3.5D'")

Out[463]:
      A          B             C
   0 2013-01-01  00:00:10 -1 days +23:59:50
   1 2013-01-01  00:00:10 -2 days +23:59:50
   2 2013-01-01  00:00:10 -3 days +23:59:50
   3 2013-01-01  00:00:10 -4 days +23:59:50
   4 2013-01-01  00:00:10 -5 days +23:59:50
   5 2013-01-01  00:00:10 -6 days +23:59:50
   6 2013-01-01  00:00:10 -7 days +23:59:50
   7 2013-01-01  00:00:10 -8 days +23:59:50
   8 2013-01-01  00:00:10 -9 days +23:59:50
   9 2013-01-01  00:00:10 -10 days +23:59:50
```
Query MultiIndex

Selecting from a MultiIndex can be achieved by using the name of the level.

```python
In [464]: df_mi.index.names
Out[464]: FrozenList(['foo', 'bar'])

In [465]: store.select("df_mi", "foo=baz and bar=two")
Out[465]:
   A    B    C
foo  bar
baz  two 1.064908 1.778161 -0.913867
```

If the MultiIndex levels names are `None`, the levels are automatically made available via the `level_n` keyword with `n` the level of the MultiIndex you want to select from.

```python
In [466]: index = pd.MultiIndex(...:
   ......:     levels=["foo", "bar", "baz", "qux"], ["one", "two", "three"],
   ......:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
   ......:)
   ......:

In [467]: df_mi_2 = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B", ...
   .....
     "C")

In [468]: df_mi_2
Out[468]:
   A    B    C
foo one 0.856838 1.491776 0.001283
two 0.701816 -1.097917 0.102588
three 0.661740 0.443531 0.559313
bar one -0.459055 -1.222598 -0.455304
two -0.781163 0.826204 -0.530057
baz two 0.296135 1.366810 1.073372
three -0.994957 0.755314 2.119746
qux one -2.628174 -0.089460 -0.133636
two 0.337920 -0.634027 0.421107
three 0.604303 1.053434 1.109090

In [469]: store.append("df_mi_2", df_mi_2)

# the levels are automatically included as data columns with keyword level_n
In [470]: store.select("df_mi_2", "level_0=foo and level_1=two")
Out[470]:
```
Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and `append/put` operation). Creating a table index is highly encouraged. This will speed your queries a great deal when you use a `select` with the indexed dimension as the `where`.  

**Note:** Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.  

```python
# we have automagically already created an index (in the first section)
In [471]: i = store.root.df.table.cols.index.index

In [472]: i.optlevel, i.kind
Out[472]: (6, 'medium')

# change an index by passing new parameters
In [473]: store.create_table_index("df", optlevel=9, kind="full")

In [474]: i = store.root.df.table.cols.index.index

In [475]: i.optlevel, i.kind
Out[475]: (9, 'full')
```

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

```python
In [476]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [477]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [478]: st = pd.HDFStore("appends.h5", mode="w")

In [479]: st.append("df", df_1, data_columns=["B"], index=False)

In [480]: st.append("df", df_2, data_columns=["B"], index=False)

In [481]: st.get_storer("df").table
Out[481]:
```

```
'/df/table (Table(20,)) '
    description := {
        "index": Int64Col(shape=(), dflt=0, pos=0),
        "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
        "B": Float64Col(shape=(), dflt=0.0, pos=2)}
    byteorder := 'little'
    chunkshape := (2730,)
```

Then create the index when finished appending.
See here for how to create a completely-sorted-index (CSI) on an existing store.

**Query via data columns**

You can designate (and index) certain columns that you want to be able to perform queries (other than the indexable columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be data_columns.

```python
In [485]: df_dc = df.copy()

In [486]: df_dc['string'] = "foo"

In [487]: df_dc.loc[df_dc.index[4:6], "string"] = np.nan

In [488]: df_dc.loc[df_dc.index[7:9], "string"] = "bar"

In [489]: df_dc['string2'] = "cool"

In [490]: df_dc.loc[df_dc.index[1:3], ["B", "C"] = 1.0

In [491]: df_dc
```

    "autoindex": True
}
colindexes := {
    "index": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "B": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "C": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "string": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "string2": Index(6, mediumshuffle, zlib(1)).is_csi=False
}

There is some performance degradation by making lots of columns into data columns, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

2.4. IO tools (text, CSV, HDF5, …)
You can pass `iterator=True` or `chunksize=number_in_a_chunk` to `select` and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```
In [497]: for df in store.select("df", chunksize=3):
    .....:    print(df)
    .....:
   A     B     C
2000-01-01 1.334065 0.521036 0.930384
2000-01-02 -1.613932 1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
   A     B     C
2000-01-04 0.632369 -1.249657 0.975593
2000-01-05 1.060617 -0.143682 0.218423
2000-01-06 3.050329 1.317933 -0.963725
   A     B     C
2000-01-07 -0.539452 -0.771133 0.023751
2000-01-08 0.649464 -1.736427 0.197288
```

Note: You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```
for df in pd.read_hdf("store.h5", "df", chunksize=3):
    print(df)
```

Note, that the chunksize keyword applies to the source rows. So if you are doing a query, then the chunksize will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```
In [498]: dfeq = pd.DataFrame({"number": np.arange(1, 11)})

In [499]: dfeq
Out[499]:
   number
0      1
1      2
2      3
3      4
4      5
5      6
6      7
7      8
8      9
9     10

In [500]: store.append("dfeq", dfeq, data_columns=["number"])

In [501]: def chunks(l, n):
    .....:    return [l[i: i + n] for i in range(0, len(l), n)]
    .....:
(continues on next page)
Advanced queries

Select a single column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```
In [505]: store.select_column("df_dc", "index")
Out[505]:
0   2000-01-01
1   2000-01-02
2   2000-01-03
3   2000-01-04
4   2000-01-05
5   2000-01-06
6   2000-01-07
7   2000-01-08
Name: index, dtype: datetime64[ns]
```

```
In [506]: store.select_column("df_dc", "string")
Out[506]:
0    foo
1    foo
2    foo
3    foo
4   NaN
5   NaN
6    foo
7    bar
Name: string, dtype: object
```
Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an `Int64Index` of the resulting locations. These coordinates can also be passed to subsequent `where` operations.

```
In [507]: df_coord = pd.DataFrame(  
      ......:     np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)  
      ......: )  
      ......:

In [508]: store.append("df_coord", df_coord)

In [509]: c = store.select_as_coordinates("df_coord", "index > 20020101")

In [510]: c
Out[510]: Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,  
                  ...  
                  990, 991, 992, 993, 994, 995, 996, 997, 998, 999],  
                  dtype='int64', length=268)

In [511]: store.select("df_coord", where=c)
Out[511]:  
      0       1  
2002-01-02 -0.165548  0.646989  
2002-01-03  0.782753 -0.123409  
2002-01-04 -0.391932 -0.740915

Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting `index` from an indexing operation. This example selects the months of a `datetimeindex` which are 5.

```
In [512]: df_mask = pd.DataFrame(  
      ......:     np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)  
      ......: )  
      ......:

In [513]: store.append("df_mask", df_mask)

In [514]: c = store.select_column("df_mask", "index")
```
In [515]: where = c[pd.DatetimeIndex(c).month == 5].index

In [516]: store.select("df_mask", where=where)

Out[516]:

Storer object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programmatically to say get the number of rows in an object.

In [517]: store.get_storer("df_dc").nrows

Out[517]: 8

Multiple table queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table’s index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single DataFrame into multiple tables according to `d`, a dictionary that maps the table names to a list of ‘columns’ you want in that table. If `None` is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument `selector` defines which table is the selector table (which you can make queries from). The argument `dropna` will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.Nan`, that row will be dropped from all tables.

If `dropna` is False, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES**. Remember that entirely `np.Nan` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

Delete from a table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then moving the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. To get optimal performance, it’s worthwhile to have the dimension you are deleting be the first of the indexables.

Data is ordered (on the disk) in terms of the indexables. Here’s a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- `date_1
  - id_1
  - id_2
  - 
  - id_n
- `date_2
  - id_1
  - 
  - id_n

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

**Warning:** Please note that HDF5 **DOES NOT RECLAIM SPACE** in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, **WILL TEND TO INCREASE THE FILE SIZE**.

To repack and clean the file, use `ptrepack`.

Notes & caveats

Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

- `complevel` specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0<complevel<10` enables compression.
- `complib` specifies which compression library to use. If nothing is specified the default library `zlib` is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:
  - `zlib`: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
pandas: powerful Python data analysis toolkit, Release 1.4.1

- lzo: Fast compression and decompression.
- bzip2: Good compression rates.
- blosc: Fast compression and decompression.

Support for alternative blosc compressors:

* blosc:blosclz This is the default compressor for blosc
* blosc:lz4: A compact, very popular and fast compressor.
* blosc:lz4hc: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
* blosc:snappy: A popular compressor used in many places.
* blosc:zlib: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
* blosc:zstd: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

**Note:** If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```python
store_compressed = pd.HDFStore(  
    "store_compressed.h5", complevel=9, complib="blosc:blosclz"
)
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```python
store.append("df", df, complib="zlib", complevel=5)
```

**ptrepack**

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility ptrepack. In addition, ptrepack can change compression levels after the fact.

```
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will repack the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.
Caveats

**Warning:** **HDFStore is not-threadsafe for writing.** The underlying PyTables only supports concurrent reads (via threading or processes). If you need reading and writing at the same time, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the (GH2397) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsync=True)` to do this for you.
- Once a table is created columns (DataFrame) are fixed; only exactly the same columns can be appended
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

**Warning:** PyTables will show a NaturalNameWarning if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

**DataTypes**

HDFStore will map an object dtype to the PyTables underlying dtype. This means the following types are known to work:

<table>
<thead>
<tr>
<th>Type</th>
<th>Represents missing values</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating</td>
<td>np.nan</td>
</tr>
<tr>
<td>integer</td>
<td></td>
</tr>
<tr>
<td>boolean</td>
<td>NaT</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>timedelta64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>categorical</td>
<td>see the section below</td>
</tr>
<tr>
<td>object</td>
<td>np.nan</td>
</tr>
</tbody>
</table>

unicode columns are not supported, and **WILL FAIL.**

**Categorical data**

You can write data that contains category dtypes to a HDFStore. Queries work the same as if it was an object array. However, the category dtyped data is stored in a more efficient manner.

```python
In [526]: dcat = pd.DataFrame(
    ...:       {"A": pd.Series(list("aabbcdba")).astype("category"), "B": np.random.randn(8)})
    ...:       )
    ...:
```

(continues on next page)
In [527]: dfcat
Out[527]:
   A  B
0  a  0.477849
1  a  0.283128
2  b -2.045700
3  b -0.338206
4  c -0.423113
5  d  2.314361
6  b -0.033100
7  a -0.965461

In [528]: dfcat.dtypes
Out[528]:
        A    B
dtype: object

In [529]: cstore = pd.HDFStore("cats.h5", mode="w")
In [530]: cstore.append("dfcat", dfcat, format="table", data_columns=["A"])
In [531]: result = cstore.select("dfcat", where="A in ['b', 'c']")
In [532]: result
Out[532]:
   A  B
2  b -2.045700
3  b -0.338206
4  c -0.423113
6  b -0.033100

In [533]: result.dtypes
Out[533]:
        A    B
dtype: object

String columns

min_itemsize

The underlying implementation of HDFStore uses a fixed column width (itemsize) for string columns. A string column itemsize is calculated as the maximum of the length of data (for that column) that is passed to the HDFStore, in the first append. Subsequent appends, may introduce a string for a column larger than the column can hold, an Exception will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass min_itemsize on the first table creation to a-priori specify the minimum length of a particular string column. min_itemsize can be an integer, or a dict mapping a column name to an integer. You can pass values as a key to allow all indexables or data_columns to have this min_itemsize.

Passing a min_itemsize dict will cause all passed columns to be created as data_columns automatically.
Note: If you are not passing any data_columns, then the min_itemsize will be the maximum of the length of any string passed

In [534]: dfs = pd.DataFrame({'A': 'foo', 'B': 'bar'}, index=list(range(5)))

In [535]: dfs
Out[535]:
   A   B
0  foo bar
1  foo bar
2  foo bar
3  foo bar
4  foo bar

# A and B have a size of 30
In [536]: store.append("dfs", dfs, min_itemsize=30)

In [537]: store.get_storer("dfs").table
Out[537]:
/dfs/table (Table(5,))
    description := {
        "index": Int64Col(shape=(), dflt=0, pos=0),
        "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)}
    byteorder := 'little'
    chunkshape := (963,)
    autoindex := True
    colindexes := {
        "index": Index(6, mediumshuffle, zlib(1)).is_csi=False}

# A is created as a data_column with a size of 30
# B is size is calculated
In [538]: store.append("dfs2", dfs, min_itemsize={'A': 30})

In [539]: store.get_storer("dfs2").table
Out[539]:
/dfs2/table (Table(5,))
    description := {
        "index": Int64Col(shape=(), dflt=0, pos=0),
        "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
        "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)}
    byteorder := 'little'
    chunkshape := (1598,)
    autoindex := True
    colindexes := {
        "index": Index(6, mediumshuffle, zlib(1)).is_csi=False,
        "A": Index(6, mediumshuffle, zlib(1)).is_csi=False}

nan_rep

String columns will serialize a np.nan (a missing value) with the nan_rep string representation. This defaults to the string value nan. You could inadvertently turn an actual nan value into a missing value.
In [540]: dfss = pd.DataFrame({"A": ["foo", "bar", "nan"]})

In [541]: dfss
Out[541]:
   A
0  foo
1  bar
2  nan

In [542]: store.append("dfss", dfss)

In [543]: store.select("dfss")
Out[543]:
   A
0  foo
1  bar
2  NaN

# here you need to specify a different nan rep
In [544]: store.append("dfss2", dfss, nan_rep="_nan_")

In [545]: store.select("dfss2")
Out[545]:
   A
0  foo
1  bar
2  nan

**External compatibility**

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the rhdf5 library (Package website). Create a table format store like this:

```python
In [546]: df_for_r = pd.DataFrame(
........:   {
........:     "first": np.random.rand(100),
........:     "second": np.random.rand(100),
........:     "class": np.random.randint(0, 2, (100,)),
........:   },
........:   index=range(100),
........: )

In [547]: df_for_r.head()
```

(continues on next page)
In [548]: store_export = pd.HDFStore("export.h5")

In [549]: store_export.append("df_for_r", df_for_r, data_columns=df_dc.columns)

In [550]: store_export
Out[550]:
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5

In this file can be read into a data.frame object using the rhdf5 library. The following example function reads the corresponding column names and data values from the values and assembles them into a data.frame:

```r
# Load values and column names for all datasets from corresponding nodes and 
# insert them into one data.frame object.

library(rhdf5)

loadhdf5data <- function(h5File) {

  listing <- h5ls(h5File)
  # Find all data nodes, values are stored in *_values and corresponding column
  # titles in *_items
  data_nodes <- grep("_values", listing$name)
  name_nodes <- grep("_items", listing$name)
  data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
  name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
  columns = list()
  for (idx in seq(data_paths)) {
    # NOTE: matrices returned by h5read have to be transposed to obtain
    # required Fortran order!
    data <- data.frame(t(h5read(h5File, data_paths[idx])))
    names <- t(h5read(h5File, name_paths[idx]))
    entry <- data.frame(data)
    colnames(entry) <- names
    columns <- append(columns, entry)
  }
  data <- data.frame(columns)
  return(data)
}
```

Now you can import the DataFrame into R:

```r
> data = loadhdf5data("transfer.hdf5")
> head(data)
   first  second class
1 0.4170220047 0.3266449 0
2 0.7203244934 0.5270581 0
```

2.4. IO tools (text, CSV, HDF5, ...)
The R function lists the entire HDF5 file’s contents and assembles the data.frame object from all matching nodes, so use this only as a starting point if you have stored multiple DataFrame objects to a single HDF5 file.

### Performance

- **tables** format come with a writing performance penalty as compared to **fixed** stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of rows that PyTables will expect. This will optimize read/write performance.
- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)
- A **PerformanceWarning** will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See Here for more information and some solutions.

### 2.4.13 Feather

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize DataFrames, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats:

- The format will NOT write an Index, or MultiIndex for the DataFrame and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.
- Duplicate column names and non-string columns names are not supported
- Actual Python objects in object dtype columns are not supported. These will raise a helpful error message on an attempt at serialization.

See the Full Documentation.

```python
In [551]: df = pd.DataFrame(
.....:
.....:   {  
.....:     "a": list("abc"),  
.....:     "b": list(range(1, 4)),  
.....:     "c": np.arange(3, 6).astype("u1"),  
.....:     "d": np.arange(4.0, 7.0, dtype="float64"),  
.....:     "e": [True, False, True],  
)```

(continues on next page)
```python
.....:
    "f": pd.Categorical(list("abc")),
.....:
    "g": pd.date_range("20130101", periods=3),
.....:
    "h": pd.date_range("20130101", periods=3, tz="US/Eastern"),
.....:
    "i": pd.date_range("20130101", periods=3, freq="ns"),
.....:
}
.....:
)

In [552]: df
Out[552]:
    a   b   c   d   e   f  g  h
0  a  1   3   4.0 True a 2013-01-01 2013-01-01 00:00:00-05:00
1  b  2   4   5.0 False b 2013-01-02 2013-01-02 00:00:00-05:00
2  c  3   5   6.0 True  c 2013-01-03 2013-01-03 00:00:00-05:00

In [553]: df.dtypes
Out[553]:
a          object
b          int64
c          uint8
d          float64
e          bool
f         category
g  datetime64[ns]
h  datetime64[ns, US/Eastern]
i  datetime64[ns]
```

Write to a feather file.

```python
In [554]: df.to_feather("example.feather")
```

Read from a feather file.

```python
In [555]: result = pd.read_feather("example.feather")
```

```python
In [556]: result
Out[556]:
    a   b   c   d   e   f  g  h
0  a  1   3   4.0 True a 2013-01-01 2013-01-01 00:00:00-05:00
1  b  2   4   5.0 False b 2013-01-02 2013-01-02 00:00:00-05:00
2  c  3   5   6.0 True  c 2013-01-03 2013-01-03 00:00:00-05:00
```

# we preserve dtypes

(continues on next page)
2.4.14 Parquet

Apache Parquet provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize DataFrame s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string columns names are not supported.
- The pyarrow engine always writes the index to the output, but fastparquet only writes non-default indexes. This extra column can cause problems for non-pandas consumers that are not expecting it. You can force including or omitting indexes with the index argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- In the pyarrow engine, categorical dtypes for non-string types can be serialized to parquet, but will de-serialize as their primitive dtype.
- The pyarrow engine preserves the ordered flag of categorical dtypes with string types. fastparquet does not preserve the ordered flag.
- Non supported types include Interval and actual Python object types. These will raise a helpful error message on an attempt at serialization. Period type is supported with pyarrow >= 0.16.0.
- The pyarrow engine preserves extension data types such as the nullable integer and string data type (requiring pyarrow >= 0.16.0, and requiring the extension type to implement the needed protocols, see the extension types documentation).

You can specify an engine to direct the serialization. This can be one of pyarrow, or fastparquet, or auto. If the engine is NOT specified, then the pd.options.io.parquet.engine option is checked; if this is also auto, then pyarrow is tried, and falling back to fastparquet.

See the documentation for pyarrow and fastparquet.

Note: These engines are very similar and should read/write nearly identical parquet format files. Currently pyarrow does not support timedelta data, fastparquet>=0.1.4 supports timezone aware datetimes. These libraries differ by having different underlying dependencies (fastparquet by using numba, while pyarrow uses a c-library).
In [558]: df = pd.DataFrame(
......:     {
......:         "a": list("abc"),
......:         "b": list(range(1, 4)),
......:         "c": np.arange(3, 6).astype("u1"),
......:         "d": np.arange(4.0, 7.0, dtype="float64"),
......:         "e": [True, False, True],
......:         "f": pd.date_range("20130101", periods=3),
......:         "g": pd.date_range("20130101", periods=3, tz="US/Eastern"),
......:         "h": pd.Categorical(list("abc")),
......:         "i": pd.Categorical(list("abc"), ordered=True),
......:     }
......: )

In [559]: df
Out[559]:
   a    b    c    d       e      f                 g               h               i
0  a    1    3  4.0  True 2013-01-01 2013-01-01 00:00:00-05:00 a    a
1  b    2    4  5.0  False 2013-01-02 2013-01-02 00:00:00-05:00 b    b
2  c    3    5  6.0  True 2013-01-03 2013-01-03 00:00:00-05:00 c    c

In [560]: df.dtypes
Out[560]:
   a    object
   b      int64
   c     uint8
   d     float64
   e       bool
   f  datetime64[ns]
   g  datetime64[ns, US/Eastern]
   h     category
   i     category
dtype: object

Write to a parquet file.

In [561]: df.to_parquet("example_pa.parquet", engine="pyarrow")

In [562]: df.to_parquet("example_fp.parquet", engine="fastparquet")

Read from a parquet file.

In [563]: result = pd.read_parquet("example_fp.parquet", engine="fastparquet")

In [564]: result = pd.read_parquet("example_pa.parquet", engine="pyarrow")

In [565]: result.dtypes
Out[565]:
   a    object
   b      int64
   c     uint8
   d     float64

(continues on next page)
Read only certain columns of a parquet file.

```
In [566]: result = pd.read_parquet(
......:   "example_fp.parquet",
......:   engine="fastparquet",
......:   columns=["a", "b"],
......: )
......:

In [567]: result = pd.read_parquet(
......:   "example_pa.parquet",
......:   engine="pyarrow",
......:   columns=["a", "b"],
......: )
......:

In [568]: result.dtypes
Out[568]:
a  object
b  int64
dtype: object
```

### Handling indexes

Serializing a DataFrame to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```
In [569]: df = pd.DataFrame({"a": [1, 2], "b": [3, 4]})
In [570]: df.to_parquet("test.parquet", engine="pyarrow")
```

creates a parquet file with *three* columns if you use `pyarrow` for serialization: `a`, `b`, and `__index_level_0__`. If you’re using `fastparquet`, the index *may* or *may not* be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn’t exist in the target table.

If you want to omit a dataframe’s indexes when writing, pass `index=False` to `to_parquet()`:

```
In [571]: df.to_parquet("test.parquet", index=False)
```

This creates a parquet file with just the two expected columns, `a` and `b`. If your DataFrame has a custom index, you won’t get it back when you load this file into a DataFrame.

Passing `index=True` will *always* write the index, even if that’s not the underlying engine’s default behavior.
Partitioning Parquet files

Parquet supports partitioning of data based on the values of one or more columns.

```python
In [572]: df = pd.DataFrame({"a": [0, 0, 1, 1], "b": [0, 1, 0, 1]})

In [573]: df.to_parquet(path="test", engine="pyarrow", partition_cols=["a"],
                  compression=None)
```

The path specifies the parent directory to which data will be saved. The `partition_cols` are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
| a  | 0bac803e32dc42ae83fddfd029cbdebc.parquet | ... |
| a=0| 0bac803e32dc42ae83fddfd029cbdebc.parquet | ... |
| a=1| e6ab24a4f45147b49b54a662f0c412a3.parquet | ... |
```

2.4.15 ORC

New in version 1.0.0.

Similar to the parquet format, the ORC Format is a binary columnar serialization for data frames. It is designed to make reading data frames efficient. pandas provides only a reader for the ORC format, `read_orc()`. This requires the pyarrow library.

Warning:
- It is highly recommended to install pyarrow using conda due to some issues occurred by pyarrow.
- `read_orc()` is not supported on Windows yet, you can find valid environments on install optional dependencies.

2.4.16 SQL queries

The pandas.io.sql module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are psycopg2 for PostgreSQL or pymysql for MySQL. For SQLite this is included in Python’s standard library by default. You can find an overview of supported drivers for each SQL dialect in the SQLAlchemy docs.

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the Python DB-API.

See also some cookbook examples for some advanced strategies.

The key functions are:
**Note:** The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the SQLite SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the SQLAlchemy documentation.

```python
In [574]: from sqlalchemy import create_engine

# Create your engine.
In [575]: engine = create_engine("sqlite:///::memory:"
```

If you want to manage your own connections you can pass one of those instead. The example below opens a connection to the database using a Python context manager that automatically closes the connection after the block has completed. See the SQLAlchemy docs for an explanation of how the database connection is handled.

```python
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table("data", conn)
```

**Warning:** When you open a connection to a database you are also responsible for closing it. Side effects of leaving a connection open may include locking the database or other breaking behaviour.

### Writing DataFrames

Assuming the following data is in a DataFrame `data`, we can insert it into the database using `to_sql()`.

<table>
<thead>
<tr>
<th>id</th>
<th>Date</th>
<th>Col_1</th>
<th>Col_2</th>
<th>Col_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>2012-10-18</td>
<td>X</td>
<td>25.7</td>
<td>True</td>
</tr>
<tr>
<td>42</td>
<td>2012-10-19</td>
<td>Y</td>
<td>-12.4</td>
<td>False</td>
</tr>
<tr>
<td>63</td>
<td>2012-10-20</td>
<td>Z</td>
<td>5.73</td>
<td>True</td>
</tr>
</tbody>
</table>

```python
In [576]: data
Out[576]:
<table>
<thead>
<tr>
<th>id</th>
<th>Date</th>
<th>Col_1</th>
<th>Col_2</th>
<th>Col_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2010-10-18</td>
<td>X</td>
<td>27.50</td>
<td>True</td>
</tr>
<tr>
<td>1</td>
<td>2010-10-19</td>
<td>Y</td>
<td>-12.50</td>
<td>False</td>
</tr>
<tr>
<td>2</td>
<td>2010-10-20</td>
<td>Z</td>
<td>5.73</td>
<td>True</td>
</tr>
</tbody>
</table>

In [577]: data.to_sql("data", engine)
Out[577]: 3
```
With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the chunksize parameter when calling to_sql. For example, the following writes data to the database in batches of 1000 rows at a time:

```python
In [578]: data.to_sql("data_chunked", engine, chunksize=1000)
Out[578]: 3
```

**SQL data types**

to_sql() will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype object, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the dtype argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchemys String type instead of the default Text type for string columns:

```python
In [579]: from sqlalchemy.types import String
In [580]: data.to_sql("data_dtype", engine, dtype={"Col_1": String})
Out[580]: 3
```

**Note:** Due to the limited support for timedelta’s in the different database flavors, columns with type timedelta64 will be written as integer values as nanoseconds to the database and a warning will be raised.

**Note:** Columns of category dtype will be converted to the dense representation as you would get with np.asarray(categorical) (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does not generate a categorical.

**Datetime data types**

Using SQLAlchemy, to_sql() is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

<table>
<thead>
<tr>
<th>Database</th>
<th>SQL Datetime Types</th>
<th>Timezone Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLite</td>
<td>TEXT</td>
<td>No</td>
</tr>
<tr>
<td>MySQL</td>
<td>TIMESTAMP or DATETIME</td>
<td>No</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>TIMESTAMP or TIMESTAMP WITH TIME ZONE</td>
<td>Yes</td>
</tr>
</tbody>
</table>

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

read_sql_table() is also capable of reading datetime data that is timezone aware or naive. When reading TIMESTAMP WITH TIME ZONE types, pandas will convert the data to UTC.
Insertion method

The parameter `method` controls the SQL insertion clause used. Possible values are:

- **None**: Uses standard SQL `INSERT` clause (one per row).
- `'multi'`: Pass multiple values in a single `INSERT` clause. It uses a special SQL syntax not supported by all backends. This usually provides better performance for analytic databases like **Presto** and **Redshift**, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy documentation.
- callable with signature `(pd_table, conn, keys, data_iter)`: This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL COPY clause:

```python
# Alternative to to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO
def psql_insert_copy(table, conn, keys, data_iter):
    """
    Execute SQL statement inserting data
    Parameters
    -----------
    table : pandas.io.sql.SQLTable
    conn : sqlalchemy.engine.Engine or sqlalchemy.engine.Connection
    keys : list of str
        Column names
    data_iter : Iterable that iterates the values to be inserted
    """
    # gets a DBAPI connection that can provide a cursor
dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        s_buf = StringIO()
        writer = csv.writer(s_buf)
        writer.writerows(data_iter)
        s_buf.seek(0)
        columns = ','.join([''{}'''.format(k) for k in keys])
        if table.schema:
            table_name = '{}.{}'.format(table.schema, table.name)
        else:
            table_name = table.name
        sql = 'COPY {} ({}) FROM STDIN WITH CSV'.format( table_name, columns)
cur.copy_expert(sql=sql, file=s_buf)
```
Reading tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

**Note:** In order to use `read_sql_table()`, you must have the SQLAlchemy optional dependency installed.

```
In [581]: pd.read_sql_table("data", engine)
Out[581]:
   index  id   Date  Col_1  Col_2  Col_3
0      0   26  2010-10-18    X    27.50  True
1      1   42  2010-10-19    Y   -12.50 False
2      2   63  2010-10-20    Z     5.73  True

Note:  Note that pandas infers column dtypes from query outputs, and not by looking up data types in the physical database schema. For example, assume `userid` is an integer column in a table. Then, intuitively, `select userid ..` will return integer-valued series, while `select cast(userid as text) ..` will return object-valued (str) series. Accordingly, if the query output is empty, then all resulting columns will be returned as object-valued (since they are most general). If you foresee that your query will sometimes generate an empty result, you may want to explicitly typecast afterwards to ensure dtype integrity.

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.

```
In [582]: pd.read_sql_table("data", engine, index_col="id")
Out[582]:
   Date  Col_1  Col_2  Col_3
id
26  2010-10-18    X    27.50  True
42  2010-10-19    Y   -12.50 False
63  2010-10-20    Z     5.73  True

In [583]: pd.read_sql_table("data", engine, columns=["Col_1", "Col_2"])
Out[583]:
   Col_1  Col_2
0    X    27.50
1    Y   -12.50
2    Z     5.73

And you can explicitly force columns to be parsed as dates:

```
In [584]: pd.read_sql_table("data", engine, parse_dates=["Date"])
Out[584]:
   index  id   Date  Col_1  Col_2  Col_3
0      0   26  2010-10-18    X    27.50  True
1      1   42  2010-10-19    Y   -12.50 False
2      2   63  2010-10-20    Z     5.73  True

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```
pd.read_sql_table("data", engine, parse_dates=["Date"])
pd.read_sql_table("data", engine, parse_dates=
    "%Y-%m-%d")
```

(continues on next page)
You can check if a table exists using `has_table()`

### Schema support

Reading from and writing to different schema’s is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema’s). For example:

```python
df.to_sql("table", engine, schema="other_schema")
pd.read_sql_table("table", engine, schema="other_schema")
```

### Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```python
In [585]: pd.read_sql_query("SELECT * FROM data", engine)
Out[585]:
  index  id  Date               Col_1  Col_2  Col_3
0      0  26 2010-10-18 00:00:00.000000  X     27.5   1
1      1  42 2010-10-19 00:00:00.000000  Y   -12.5   0
2      2  63 2010-10-20 00:00:00.000000  Z      5.7   1
```

Of course, you can specify a more “complex” query.

```python
In [586]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;", engine)
Out[586]:
  id  Col_1  Col_2
0  42   Y   -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```python
In [587]: df = pd.DataFrame(np.random.randn(20, 3), columns=list("abc"))
In [588]: df.to_sql("data_chunks", engine, index=False)
Out[588]: 20
```

```python
In [589]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks", engine, chunksize=5):
    ...:     print(chunk)
    ...:     print(a, b, c)
      a   b   c
0  0.092961 -0.674003 1.104153
1  0.092732 -0.156246 -0.585167
```

(continues on next page)
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-1.627786</td>
<td>-0.692062</td>
<td>1.039548</td>
</tr>
<tr>
<td>1</td>
<td>-1.802313</td>
<td>-0.890905</td>
<td>-0.881794</td>
</tr>
<tr>
<td>2</td>
<td>0.630492</td>
<td>0.016739</td>
<td>0.014500</td>
</tr>
<tr>
<td>3</td>
<td>-0.438358</td>
<td>0.647275</td>
<td>-0.052075</td>
</tr>
<tr>
<td>4</td>
<td>0.673137</td>
<td>1.227539</td>
<td>0.203534</td>
</tr>
</tbody>
</table>

You can also run a plain query without creating a DataFrame with `execute()`. This is useful for queries that don’t return values, such as INSERT. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

```python
from pandas.io import sql

sql.execute("SELECT * FROM table_name", engine)
sql.execute(
    "INSERT INTO table_name VALUES(?, ?, ?)", engine, params=[("id", 1, 12.2, True)]
)
```

**Engine connection examples**

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```python
from sqlalchemy import create_engine

engine = create_engine("postgresql://scott:tiger@localhost:5432/mydatabase")

engine = create_engine("mysql+mysqldb://scott:tiger@localhost/foo")

engine = create_engine("oracle://scott:tiger@127.0.0.1:1521/sidname")

engine = create_engine("mssql+pyodbc://mydsn")

# sqlite://<nohostname>/<path>
# where <path> is relative:
engine = create_engine("sqlite:///foo.db")
```
# or absolute, starting with a slash:
engine = create_engine("sqlite:///absolute/path/to/foo.db")

For more information see the examples the SQLAlchemy documentation

**Advanced SQLAlchemy queries**

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```
In [590]: import sqlalchemy as sa

In [591]: pd.read_sql(sa.text("SELECT * FROM data where Col_1=:col1"), engine, params={"col1": "X"})
```

```
Out[591]:
 index id Date Col_1 Col_2 Col_3
0 0 26 2010-10-18 00:00:00.000000 X 27.5 1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```
In [592]: metadata = sa.MetaData()

In [593]: data_table = sa.Table("data",
      metadata,  
      sa.Column("index", sa.Integer),
      sa.Column("Date", sa.DateTime),
      sa.Column("Col_1", sa.String),
      sa.Column("Col_2", sa.Float),
      sa.Column("Col_3", sa.Boolean),
      )

In [594]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 is True), engine)
Out[594]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [595]: import datetime as dt

In [596]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam("date"))
```
In [597]: pd.read_sql(expr, engine, params={"date": dt.datetime(2010, 10, 18))
Out[597]:
        index Date Col_1 Col_2 Col_3
0          1 2010-10-19 Y  -12.50  False
1          2 2010-10-20 Z   5.73   True

Sqlite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the Python DB-API.

You can create connections like so:

```python
import sqlite3
con = sqlite3.connect(":memory:"
```

And then issue the following queries:

```python
data.to_sql("data", con)
pd.read_sql_query("SELECT * FROM data", con)
```

### 2.4.17 Google BigQuery

**Warning:** Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package pandas-gbq. You can `pip install pandas-gbq` to get it.

The pandas-gbq package provides functionality to read/write from Google BigQuery.

pandas integrates with this external package. if pandas-gbq is installed, you can use the pandas methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from pandas-gbq.

Full documentation can be found [here](#).

### 2.4.18 Stata format

#### Writing to stata format

The method `to_stata()` will write a DataFrame into a .dta file. The format version of this file is always 115 (Stata 12).

```python
In [598]: df = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))
In [599]: df.to_stata("stata.dta")
```

Stata data files have limited data type support; only strings with 244 or fewer characters, `int8`, `int16`, `int32`, `float32` and `float64` can be stored in .dta files. Additionally, Stata reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in Stata for a particular data type will retype the variable to the next larger size. For example, `int8` values are restricted to lie between -127 and 100 in Stata, and so variables
with values above 100 will trigger a conversion to int16. nan values in floating points data types are stored as the basic missing data type (.` in Stata).

**Note:** It is not possible to export missing data values for integer data types.

The Stata writer gracefully handles other data types including int64, bool, uint8, uint16, uint32 by casting to the smallest supported type that can represent the data. For example, data with a type of uint8 will be cast to int8 if all values are less than 100 (the upper bound for non-missing int8 data in Stata), or, if values are outside of this range, the variable is cast to int16.

**Warning:** Conversion from int64 to float64 may result in a loss of precision if int64 values are larger than \(2^{**53}\).

**Warning:** StataWriter and to_stata() only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write Stata dta files with strings longer than 244 characters raises a ValueError.

### Reading from Stata format

The top-level function `read_stata` will read a dta file and return either a DataFrame or a StataReader that can be used to read the file incrementally.

```
In [600]: pd.read_stata("stata.dta")
Out[600]:
   index  A          B
   0     0 0.608228 1.064810
   1     1 -0.780506 -2.736887
   2     2 0.143539 1.170191
   3     3 -1.573076 0.075792
   4     4 -1.722223 -0.774650
   5     5 0.803627 0.221665
   6     6 0.584637 0.147264
   7     7 1.057825 -0.284136
   8     8 0.912395 1.552808
   9     9 0.189376 -0.109830
```

Specifying a chunksize yields a StataReader instance that can be used to read chunksize lines from the file at a time. The StataReader object can be used as an iterator.

```
In [601]: with pd.read_stata("stata.dta", chunksize=3) as reader:
   ....:     for df in reader:
   ....:         print(df.shape)
   ....:
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify chunksize with each call to `read()`.
Currently the index is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have `object` data type.

**Note:** `read_stata()` and `StataReader` support `.dta` formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

**Note:** Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

### Categorical data

Categorical data can be exported to `Stata` data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. `Stata` does not have an explicit equivalent to a `Categorical` and information about whether the variable is ordered is lost when exporting.

**Warning:** `Stata` only supports string value labels, and so `str` is called on the categories when exporting data. Exporting `Categorical` variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from `Stata` data files as `Categorical` variables using the keyword argument `convert_categoricals` (true by default). The keyword argument `order_categoricals` (true by default) determines whether imported `Categorical` variables are ordered.

**Note:** When importing categorical data, the values of the variables in the `Stata` data file are not preserved since `Categorical` variables always use integer data types between -1 and n-1 where n is the number of categories. If the original values in the `Stata` data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original `Stata` data values and the category codes of imported `Categorical` variables: missing values are assigned code -1, and the smallest original value is assigned 0, the second smallest is assigned 1 and so on until the largest original value is assigned the code n-1.

**Note:** `Stata` supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and numeric categories for values with no label.
2.4.19 SAS formats

The top-level function `read_sas()` can read (but not write) SAS XPORT (.xpt) and (since v0.18.0) SAS7BDAT (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For xport files, there is no automatic type conversion to integers, dates, or categoricals. For SAS7BDAT files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a DataFrame.

Specify a chunksize or use iterator=True to obtain reader objects (XportReader or SAS7BDATReader) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```python
df = pd.read_sas("sas_data.sas7bdat")
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```python
def do_something(chunk):
    pass

with pd.read_sas("sas_xport.xpt", chunk=100000) as rdr:
    for chunk in rdr:
        do_something(chunk)
```

The specification for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

2.4.20 SPSS formats

New in version 0.25.0.

The top-level function `read_spss()` can read (but not write) SPSS SAV (.sav) and ZSAV (.zsav) format files.

SPSS files contain column names. By default the whole file is read, categorical columns are converted into pd.Categorical, and a DataFrame with all columns is returned.

Specify the usecols parameter to obtain a subset of columns. Specify convert_categoricals=False to avoid converting categorical columns into pd.Categorical.

Read an SPSS file:

```python
df = pd.read_spss("spss_data.sav")
```

Extract a subset of columns contained in usecols from an SPSS file and avoid converting categorical columns into pd.Categorical:

```python
df = pd.read_spss(  "spss_data.sav",  usecols=["foo", "bar"],  convert_categoricals=False,  )
```

More information about the SAV and ZSAV file formats is available here.
2.4.21 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

netCDF

xarray provides data structures inspired by the pandas DataFrame for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

2.4.22 Performance considerations

This is an informal comparison of various IO methods, using pandas 0.24.2. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000

In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
   A  1000000 non-null float64
   B  1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

The following test functions will be used below to compare the performance of several IO methods:

```
import numpy as np
import os

sz = 1000000

sz = 1000000
np.random.seed(42)

def test_sql_write(df):
    if os.path.exists("test.sql"):
        os.remove("test.sql")
    sql_db = sqlite3.connect("test.sql")
    df.to_sql(name="test_table", con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect("test.sql")
    pd.read_sql_query("select * from test_table", sql_db)
```

(continues on next page)
sql_db.close()

```python
def test_hdf_fixed_write(df):
    df.to_hdf("test_fixed.hdf", "test", mode="w")

def test_hdf_fixed_read():
    pd.read_hdf("test_fixed.hdf", "test")

def test_hdf_fixed_write_compress(df):
    df.to_hdf("test_fixed_compress.hdf", "test", mode="w", complib="blosc")

def test_hdf_fixed_read_compress():
    pd.read_hdf("test_fixed_compress.hdf", "test")

def test_hdf_table_write(df):
    df.to_hdf("test_table.hdf", "test", mode="w", format="table")

def test_hdf_table_read():
    pd.read_hdf("test_table.hdf", "test")

def test_hdf_table_write_compress(df):
    df.to_hdf(
        "test_table_compress.hdf", "test", mode="w", complib="blosc", format="table"
    )

def test_hdf_table_read_compress():
    pd.read_hdf("test_table_compress.hdf", "test")

def test_csv_write(df):
    df.to_csv("test.csv", mode="w")

def test_csv_read():
    pd.read_csv("test.csv", index_col=0)

def test_feather_write(df):
    df.to_feather("test.feather")

def test_feather_read():
    pd.read_feather("test.feather")
```
def test_pickle_write(df):
    df.to_pickle("test.pkl")

def test_pickle_read():
    pd.read_pickle("test.pkl")

def test_pickle_write_compress(df):
    df.to_pickle("test.pkl.compress", compression="xz")

def test_pickle_read_compress():
    pd.read_pickle("test.pkl.compress", compression="xz")

def test_parquet_write(df):
    df.to_parquet("test.parquet")

def test_parquet_read():
    pd.read_parquet("test.parquet")

When writing, the top three functions in terms of speed are test_feather_write, test_hdf_fixed_write and test_hdf_fixed_write_compress.
4.29 s ± 15.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [13]: %timeit test_parquet_write(df)
67.6 ms ± 706 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

When reading, the top three functions in terms of speed are test_feather_read, test_pickle_read and test_hdf_fixed_read.

In [14]: %timeit test_sql_read()
1.77 s ± 17.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [15]: %timeit test_hdf_fixed_read()
19.4 ms ± 436 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [16]: %timeit test_hdf_fixed_read_compress()
19.5 ms ± 222 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [17]: %timeit test_hdf_table_read()
38.6 ms ± 857 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [18]: %timeit test_hdf_table_read_compress()
38.8 ms ± 1.49 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [19]: %timeit test_csv_read()
452 ms ± 9.04 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [20]: %timeit test_feather_read()
12.4 ms ± 99.7 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [21]: %timeit test_pickle_read()
18.4 ms ± 191 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [22]: %timeit test_pickle_read_compress()
915 ms ± 7.48 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [23]: %timeit test_parquet_read()
24.4 ms ± 146 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

The files test.pkl.compress, test.parquet and test.feather took the least space on disk (in bytes).

29519500 Oct 10 06:45 test.csv
16000248 Oct 10 06:45 test.feather

24458940 Oct 10 06:44 test_table_compress.hdf
2.5 Indexing and selecting data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides metadata) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

**Note:** The Python and NumPy indexing operators [] and attribute operator . provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there’s little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn’t known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

See the MultiIndex / Advanced Indexing for MultiIndex and more advanced indexing documentation. See the cookbook for some advanced strategies.

2.5.1 Different choices for indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise KeyError when the items are not found. Allowed inputs are:
  - A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index.).
  - A list or array of labels ['a', 'b', 'c'].
  - A slice object with labels 'a':'f' (Note that contrary to usual Python slices, both the start and the stop are included, when present in the index! See Slicing with labels and Endpoints are inclusive.)
  - A boolean array (any NA values will be treated as False).
  - A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at Selection by Label.

- `.iloc` is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array. `.iloc` will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy slice semantics). Allowed inputs are:
  - An integer e.g. 5.
— A list or array of integers [4, 3, 0].
— A slice object with ints 1:7.
— A boolean array (any NA values will be treated as False).
— A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at Selection by Position, Advanced Indexing and Advanced Hierarchical.

• .loc, .iloc, and also [] indexing can accept a callable as indexer. See more at Selection By Callable.

Getting values from an object with multi-axes selection uses the following notation (using .loc as an example, but the following applies to .iloc as well). Any of the axes accessors may be the null slice :. Axes left out of the specification are assumed to be :, e.g. p.loc['a'] is equivalent to p.loc['a', :, :].

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Indexers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>s.loc[indexer]</td>
</tr>
<tr>
<td>DataFrame</td>
<td>df.loc[row_indexer,column_indexer]</td>
</tr>
</tbody>
</table>

### 2.5.2 Basics

As mentioned when introducing the data structures in the last section, the primary function of indexing with [] (a.k.a. \_getitem\_ for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Selection</th>
<th>Return Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>series[label]</td>
<td>scalar value</td>
</tr>
<tr>
<td>DataFrame</td>
<td>frame[colname]</td>
<td>Series corresponding to colname</td>
</tr>
</tbody>
</table>

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```python
In [1]: dates = pd.date_range('1/1/2000', periods=8)
In [2]: df = pd.DataFrame(np.random.randn(8, 4),
                      index=dates, columns=['A', 'B', 'C', 'D'])
In [3]: df
```

```
Out[3]:
          A         B         C         D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705 -1.157892 -1.344312  0.844885
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
```

Note: None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:
In [4]: s = df['A']
In [5]: s[dates[5]]
Out[5]: -0.67369070883706

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

In [6]: df
Out[6]:
   A     B     C     D
0 2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
1 2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2 2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
3 2000-01-04  0.721555 -0.706771 -1.039575  0.271860
4 2000-01-05 -0.424972  0.567020  0.276232 -1.087401
5 2000-01-06 -0.673690  0.113648 -1.478427  0.524988
6 2000-01-07  0.404705  0.577046 -1.715002 -1.039268
7 2000-01-08 -0.370647 -1.157892 -1.344312  0.844885

In [7]: df[['B', 'A']] = df[['A', 'B']]
In [8]: df
Out[8]:
   A     B     C     D
0 2000-01-01 -0.282863  0.469112 -1.509059 -1.135632
1 2000-01-02 -0.173215  1.212112  0.119209 -1.044236
2 2000-01-03 -2.104569 -0.861849 -0.494929  1.071804
3 2000-01-04 -0.706771 -0.706771 -1.039575  0.271860
4 2000-01-05  0.567020 -0.424972  0.276232 -1.087401
5 2000-01-06  0.113648 -0.673690 -1.478427  0.524988
6 2000-01-07  0.577046  0.404705 -1.715002 -1.039268
7 2000-01-08 -1.157892 -0.370647 -1.344312  0.844885

You may find this useful for applying a transform (in-place) to a subset of the columns.

Warning: pandas aligns all AXES when setting Series and DataFrame from .loc, and .iloc.
This will not modify df because the column alignment is before value assignment.
In [9]: df[['A', 'B']]  
Out[9]:
   A     B
0 2000-01-01 -0.282863  0.469112
1 2000-01-02 -0.173215  1.212112
2 2000-01-03 -2.104569 -0.861849
3 2000-01-04 -0.706771 -0.706771
4 2000-01-05  0.567020 -0.424972
5 2000-01-06  0.113648 -0.673690
6 2000-01-07  0.577046  0.404705
7 2000-01-08 -1.157892 -0.370647

In [10]: df.loc[:, ['B', 'A']] = df[['A', 'B']]
The correct way to swap column values is by using raw values:

```
In [12]: df.loc[:, ["B", "A"] ] = df[["A", "B"]].to_numpy()
```

```
In [13]: df[["A", "B"]]
```

![Image of DataFrame output]

```
Out[13]:
    A   B
2000-01-01  0.469112 -0.282863
2000-01-02  1.212112 -0.173215
2000-01-03 -0.861849 -2.104569
2000-01-04  0.721555 -0.706771
2000-01-05  0.567020 -0.424972
2000-01-06 -0.673690  0.113648
2000-01-07  0.404705  0.577046
2000-01-08 -1.157892 -0.370647
```

### 2.5.3 Attribute access

You may access an index on a `Series` or column on a `DataFrame` directly as an attribute:

```
In [14]: sa = pd.Series([1, 2, 3], index=list('abc'))
```

```
In [15]: dfa = df.copy()
```

```
In [16]: sa.b
Out[16]: 2
```

```
In [17]: dfa.A
Out[17]:
Freq: D, Name: A, dtype: float64
```

```
  2000-01-01  0.469112
  2000-01-02  1.212112
  2000-01-03 -0.861849
  2000-01-04  0.721555
  2000-01-05 -0.424972
  2000-01-06 -0.673690
  2000-01-07  0.404705
  2000-01-08 -0.370647
```

```
Freq: D, Name: A, dtype: float64
```
In [18]: sa.a = 5

In [19]: sa
Out[19]
  a  5
  b  2
  c  3
dtype: int64

In [20]: dfa.A = list(range(len(dfa.index)))  # ok if A already exists

In [21]: dfa
Out[21]
  A  B   C    D
2000-01-01  0 -0.282863 -1.509059 -1.135632

2000-01-06  5  0.113648 -1.478427  0.524988
2000-01-07  6  0.577046 -1.715002 -1.039268
2000-01-08  7 -1.157892 -1.344312  0.844885

Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See here for an explanation of valid identifiers.
- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed, but `s['min']` is possible.
- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.
- In any of these cases, standard indexing will still work, e.g. `s[1]`, `s['min']`, and `s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes. You can also assign a dict to a row of a DataFrame:

2.5. Indexing and selecting data
pandas: powerful Python data analysis toolkit, Release 1.4.1

In [24]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})

In [25]: x.iloc[1] = {'x': 9, 'y': 99}

In [26]: x
Out[26]:
   x  y
0  1  3
1  9 99
2  3  5

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a UserWarning:

In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns - see...
   https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In [3]: df
Out[3]:
   one
0   1.0
1   2.0
2   3.0

2.5.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the Selection by Position section detailing the .iloc method. For now, we explain the semantics of slicing using the [] operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

In [27]: s[:5]
Out[27]:
2000-01-01  0.469112
2000-01-02  1.212112
2000-01-03 -0.861849
2000-01-04  0.721555
2000-01-05 -0.424972
Freq: D, Name: A, dtype: float64

In [28]: s[::2]
Out[28]:
2000-01-01  0.469112
2000-01-03 -0.861849
2000-01-05 -0.424972
2000-01-07  0.404705
Freq: 2D, Name: A, dtype: float64

In [29]: s[::-1]
Out[29]:
(continues on next page)
2000-01-08  -0.370647
2000-01-07   0.404705
2000-01-06   -0.673690
2000-01-05   -0.424972
2000-01-04    0.721555
2000-01-03   -0.861849
2000-01-02    1.212112
2000-01-01    0.469112
Freq: -1D, Name: A, dtype: float64

Note that setting works as well:

In [30]: s2 = s.copy()

In [31]: s2[:5] = 0

In [32]: s2

Out[32]:
2000-01-01  0.000000
2000-01-02  0.000000
2000-01-03  0.000000
2000-01-04  0.000000
2000-01-05  0.000000
2000-01-06  -0.673690
2000-01-07   0.404705
2000-01-08  -0.370647
Freq: D, Name: A, dtype: float64

With DataFrame, slicing inside of [] slices the rows. This is provided largely as a convenience since it is such a common operation.

In [33]: df[:3]

Out[33]:
     A   B   C   D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804

In [34]: df[::-1]

Out[34]:
     A   B   C   D
2000-01-08 -0.370647 -1.157892  1.509059  1.135632
2000-01-07  0.404705  0.577046 -1.715002  1.044236
2000-01-06  0.673690  0.113648  1.478427  0.524988
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-03 -0.861849  2.104569  0.494929  1.071804
2000-01-02  1.212112  0.173215  0.119209 -1.044236
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632

2.5. Indexing and selecting data
2.5.5 Selection by label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy.*

```
In [35]: df1 = pd.DataFrame(np.random.randn(5, 4),
                  columns=list('ABCD'),
                  index=pd.date_range('20130101', periods=5))

In [36]: df1.loc[2:3]
```

```
TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with these indexers [2] of <type 'int'>
```

String likes in slicing *can* be convertible to the type of the index and lead to natural slicing.

```
In [37]: df1.loc['20130102':'20130104']
```

```
Warning: Changed in version 1.0.0.
pandas will raise a KeyError if indexing with a list with missing labels. See *list-like Using loc with missing keys in a list is Deprecated.*
```

pandas provides a suite of methods in order to have purely label based indexing. This is a strict inclusion based protocol. Every label asked for must be in the index, or a KeyError will be raised. When slicing, both the start bound AND the stop bound are *included*, if present in the index. Integers are valid labels, but they refer to the label and not the position.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is not an integer position along the index.).
• A list or array of labels ['a', 'b', 'c'].

• A slice object with labels 'a':'f' (Note that contrary to usual Python slices, both the start and the stop are included, when present in the index! See Slicing with labels.

• A boolean array.

• A callable, see Selection By Callable.

```python
In [38]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
In [39]: s1
Out[39]:
    a   1.431256
    b   1.340309
    c  -1.170299
    d  -0.226169
    e   0.410835
    f   0.813850
Name: 0, dtype: float64

In [40]: s1.loc['c':]
Out[40]:
    c  -1.170299
    d  -0.226169
    e   0.410835
    f   0.813850
Name: 2, dtype: float64

In [41]: s1.loc['b']
Out[41]: 1.340309

Note that setting works as well:

In [42]: s1.loc['c'] = 0
In [43]: s1
Out[43]:
    a   1.431256
    b   1.340309
    c  0.000000
    d  0.000000
    e  0.000000
    f  0.000000
Name: 0, dtype: float64

With a DataFrame:

In [44]: df1 = pd.DataFrame(np.random.randn(6, 4),
                        index=list('abcdef'),
                        columns=list('ABCD'))

In [45]: df1
Out[45]:
```

(continues on next page)
In [46]: df1.loc[['a', 'b', 'd'], :]
Out[46]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.132003</td>
<td>-0.827317</td>
<td>-0.076467</td>
</tr>
<tr>
<td>b</td>
<td>1.130127</td>
<td>-1.436737</td>
<td>-1.413681</td>
</tr>
<tr>
<td>c</td>
<td>1.024180</td>
<td>0.569605</td>
<td>0.875906</td>
</tr>
<tr>
<td>d</td>
<td>0.974466</td>
<td>-2.006747</td>
<td>-0.410001</td>
</tr>
<tr>
<td>e</td>
<td>0.545952</td>
<td>-1.219217</td>
<td>-1.226825</td>
</tr>
<tr>
<td>f</td>
<td>-1.281247</td>
<td>-0.727707</td>
<td>-0.121306</td>
</tr>
</tbody>
</table>

Accessing via label slices:

In [47]: df1.loc['d':, 'A':'C']
Out[47]:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>0.974466</td>
<td>-2.006747</td>
</tr>
<tr>
<td>e</td>
<td>0.545952</td>
<td>-1.219217</td>
</tr>
<tr>
<td>f</td>
<td>-1.281247</td>
<td>-0.727707</td>
</tr>
</tbody>
</table>

For getting a cross section using a label (equivalent to df.xs('a')):

In [48]: df1.loc['a']
Out[48]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.132003</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>-0.827317</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>-0.076467</td>
<td></td>
<td></td>
</tr>
<tr>
<td>D</td>
<td>-1.187678</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Name: a, dtype: float64

For getting values with a boolean array:

In [49]: df1.loc['a'] > 0
Out[49]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>True</td>
</tr>
<tr>
<td>B</td>
<td>False</td>
</tr>
<tr>
<td>C</td>
<td>False</td>
</tr>
<tr>
<td>D</td>
<td>False</td>
</tr>
</tbody>
</table>

Name: a, dtype: bool

In [50]: df1.loc[:, df1.loc['a'] > 0]
Out[50]:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.132003</td>
<td></td>
</tr>
<tr>
<td>b</td>
<td>1.130127</td>
<td></td>
</tr>
<tr>
<td>c</td>
<td>1.024180</td>
<td></td>
</tr>
<tr>
<td>d</td>
<td>0.974466</td>
<td></td>
</tr>
<tr>
<td>e</td>
<td>0.545952</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td>-1.281247</td>
<td></td>
</tr>
</tbody>
</table>
NA values in a boolean array propagate as False:

Changed in version 1.0.2.

```
In [51]: mask = pd.array([True, False, True, False, pd.NA, False], dtype="boolean")
```

```
In [52]: mask
Out[52]:
<BooleanArray> [True, False, True, False, <NA>, False]
Length: 6, dtype: boolean
```

```
In [53]: df1[mask]
Out[53]:
    A    B    C    D
a 0.132003 -0.827317 -0.076467 -1.187678
c 1.024180  0.569605  0.875906 -2.211372
```

For getting a value explicitly:

```
# this is also equivalent to `df1.at['a','A']`
In [54]: df1.loc['a', 'A']
Out[54]:
0.13200317033032932
```

Slicing with labels

When using .loc with slices, if both the start and the stop labels are present in the index, then elements located between the two (including them) are returned:

```
In [55]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])
```

```
In [56]: s.loc[3:5]
Out[56]:
3  b
2  c
5  d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which rank between the two:

```
In [57]: s.sort_index()
Out[57]:
0  a
2  c
3  b
4  e
5  d
dtype: object
```

```
In [58]: s.sort_index().loc[1:6]
Out[58]:
2  c
```

(continues on next page)
However, if at least one of the two is absent and the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, s.loc[1:6] would raise KeyError.

For the rationale behind this behavior, see Endpoints are inclusive.

Also, if the index has duplicate labels and either the start or the stop label is duplicated, an error will be raised. For instance, in the above example, s.loc[2:5] would raise a KeyError.

For more information about duplicate labels, see Duplicate Labels.

2.5.6 Selection by position

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

pandas provides a suite of methods in order to get purely integer based indexing. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bound is included, while the upper bound is excluded. Trying to use a non-integer, even a valid label will raise an IndexError.

The .iloc attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable, see Selection By Callable.

In [61]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2)))

In [62]: s1
Out[62]:
0   0.695775
2   0.341734
4   0.959726
6   -1.110336

8  -0.619976
dtype: float64

```python
In [63]: s1.iloc[:3]
Out[63]:
0   0.695775
2   0.341734
4   0.959726
dtype: float64

In [64]: s1.iloc[3]
Out[64]:
-1.110336102891167
```

Note that setting works as well:

```python
In [65]: s1.iloc[:3] = 0

In [66]: s1
Out[66]:
0   0.000000
2   0.000000
4   0.000000
6  -1.110336
8  -0.619976
dtype: float64
```

With a DataFrame:

```python
In [67]: df1 = pd.DataFrame(np.random.randn(6, 4),
                      index=list(range(0, 12, 2)),
                      columns=list(range(0, 8, 2)))

In [68]: df1
Out[68]:
        0        2        4        6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161
6 -0.826591 -0.345352  1.314232  0.690579
8  0.995761  2.396780  0.014871  3.357427
10 -0.317441 -1.236269  0.896171 -0.487602

Select via integer slicing:

```python
In [69]: df1.iloc[:3]
Out[69]:
        0        2        4        6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161
```

(continues on next page)
Select via integer list:

```
In [71]: df1.iloc[[1, 3, 5], [1, 3]]
Out[71]:
       0  2   4   6
   0 -0.732339 0.687738  
   2 -0.154951 0.301624 -2.179861
   4 -0.954208 1.462696
   6 -0.345352 1.314232
   8  2.396780 0.014871
  10 -1.236269 0.896171
```

# this is also equivalent to `df1.iat[1,1]`

```
In [74]: df1.iloc[1, 1]
Out[74]:
       0  2   4   6
   0 -0.732339 0.687738  
   2 -0.154951 0.301624 -2.179861
   4 -0.954208 1.462696
   6 -0.345352 1.314232
   8  2.396780 0.014871
  10 -1.236269 0.896171
```

For getting a cross section using an integer position (equiv to df.xs(1)):

```
In [73]: df1.iloc[:, 1:3]
Out[73]:
      2   4
   0 -0.732339 0.687738
   2 -0.154951 0.301624
   4 -0.954208 1.462696
   6 -0.345352 1.314232
   8  2.396780 0.014871
  10 -1.236269 0.896171
```

Out of range slice indexes are handled gracefully just as in Python/NumPy.

```
# these are allowed in Python/NumPy.
In [76]: x = list('abcdef')
In [77]: x
```
Out[77]: ['a', 'b', 'c', 'd', 'e', 'f']

In [78]: x[4:10]
Out[78]: ['e', 'f']

In [79]: x[8:10]
Out[79]: []

In [80]: s = pd.Series(x)

In [81]: s
Out[81]:
0   a
1   b
2   c
3   d
4   e
5   f
dtype: object

In [82]: s.iloc[4:10]
Out[82]:
4   e
5   f
dtype: object

In [83]: s.iloc[8:10]
Out[83]: Series([], dtype: object)

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

In [84]: dfl = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))

In [85]: dfl
Out[85]:
   A         B
0 -0.082240 -2.182937
1  0.380396  0.084844
2  0.432390  1.519970
3 -0.493662  0.600178
4  0.274230  0.132885

In [86]: dfl.iloc[:, 2:3]
Out[86]:
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

In [87]: dfl.iloc[:, 1:3]
Out[87]:
   B
0 -2.182937

(continues on next page)
A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

```python
>>> dfl.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> dfl.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

### 2.5.7 Selection by callable

`.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series or DataFrame) that returns valid output for indexing.

```python
In [89]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....: index=list('abcdef'),
.....: columns=list('ABCD'))

In [90]: df1
Out[90]:
   A     B     C     D
a -0.023688 2.410179 1.450520 0.206053
b -0.251905 -2.213588 1.063327 1.266143
c  0.299368 -0.863838 0.408204 -1.048089
d -0.025747 -0.988387 0.094055 1.262731
e  1.289997  0.082423 -0.055758 0.536580
f -0.489682  0.369374 -0.034571 -2.484478

In [91]: df1.loc[lambda df: df['A'] > 0, :]
Out[91]:
   A     B     C     D
   c  0.299368 -0.863838 0.408204 -1.048089
e  1.289997  0.082423 -0.055758 0.536580

In [92]: df1.loc[:, lambda df: ['A', 'B']]
Out[92]:
   A     B
   a -0.023688 2.410179
   b -0.251905 -2.213588
c  0.299368 -0.863838
```
You can use callable indexing in Series.

In [95]: df1['A'].loc[lambda s: s > 0]
Out[95]:
  c 0.299368
  e 1.289997
Name: A, dtype: float64

Using these methods / indexers, you can chain data selection operations without using a temporary variable.

In [96]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [97]: (bb.groupby(['year', 'team']).sum()
     ....: .loc[lambda df: df['r'] > 100])
Out[97]:
   stint  g   ab  r  h  X2b  X3b  hr  rbi  sb  cs  bb  so  ibb  hbp  sh  sf  gidp
   year team
   2007  CIN   6  379  745  101  203  35  2  36  125.0  10.0  1.0  105  127.0  14.0

       9.0  16.0  6.0  17.0
       9.0  16.0  6.0  17.0
   2008  LAN  11  413 1021  153  293  61  3  36  154.0  7.0  5.0  114  141.0  8.0
       9.0  3.0  8.0  29.0
   (continues on next page)
2.5.8 Combining positional and label-based indexing

If you wish to get the 0th and the 2nd elements from the index in the 'A' column, you can do:

```
In [98]: dfd = pd.DataFrame({'A': [1, 2, 3],
                      'B': [4, 5, 6]},
                     index=list('abc'))

In [99]: dfd
Out[99]:
   A  B
a 1  4
b 2  5
c 3  6

In [100]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[100]:
a  1
b  2
c  3
Name: A, dtype: int64
```

This can also be expressed using .iloc, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```
In [101]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[101]:
a  1
b  2
c  3
Name: A, dtype: int64
```

For getting *multiple* indexers, using .get_indexer:

```
In [102]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[102]:
   A  B
a  1  4
b  2  5
c  3  6
```
2.5.9 Indexing with list with missing labels is deprecated

**Warning:** Changed in version 1.0.0.
Using `.loc` or `[]` with a list with one or more missing labels will no longer reindex, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior was changed and will now raise a `KeyError` if at least one label is missing. The recommended alternative is to use `.reindex()`.

For example.

```python
In [103]: s = pd.Series([1, 2, 3])
In [104]: s
Out[104]:
0   1
1   2
2   3
dtype: int64
```

Selection with all keys found is unchanged.

```python
In [105]: s.loc[[1, 2]]
Out[105]:
1   2
2   3
dtype: int64
```

Previous behavior

```python
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1   2.0
2   3.0
3   NaN
dtype: float64
```

Current behavior

```python
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to `.loc` with any non-matching elements will raise
KeyError in the future, you can use `.reindex()` as an alternative.
```

See the documentation here: https://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-listlike

```python
Out[4]:
1   2.0
2   3.0
3   NaN
dtype: float64
```
Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on reindexing.

```
In [106]: s.reindex([1, 2, 3])
Out[106]:
1  2.0
2  3.0
3  NaN
dtype: float64
```

Alternatively, if you want to select only valid keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```
In [107]: labels = [1, 2, 3]
In [108]: s.loc[s.index.intersection(labels)]
Out[108]:
1  2
2  3
dtype: int64
```

Having a duplicated index will raise for a `.reindex()`:

```
In [109]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
In [110]: labels = ['c', 'd']
In [17]: s.reindex(labels)
ValueError: cannot reindex on an axis with duplicate labels
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```
In [111]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[111]:
c  3.0
d  NaN
dtype: float64
```

However, this would still raise if your resulting index is duplicated.

```
In [41]: labels = ['a', 'd']
In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex on an axis with duplicate labels
```
2.5.10 Selecting random samples

A random selection of rows or columns from a Series or DataFrame with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [112]: s = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1 row.
In [113]: s.sample()
Out[113]:
4  4
dtype: int64

# One may specify either a number of rows:
In [114]: s.sample(n=3)
Out[114]:
0  0
4  4
1  1
dtype: int64

# Or a fraction of the rows:
In [115]: s.sample(frac=0.5)
Out[115]:
5  5
3  3
1  1
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [116]: s = pd.Series([0, 1, 2, 3, 4, 5])

# Without replacement (default):
In [117]: s.sample(n=6, replace=False)
Out[117]:
0  0
1  1
5  5
3  3
2  2
4  4
dtype: int64

# With replacement:
In [118]: s.sample(n=6, replace=True)
Out[118]:
0  0
4  4
3  3
2  2
4  4
4  4
```

(continues on next page)
By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```python
In [119]: s = pd.Series([0, 1, 2, 3, 4, 5])
In [120]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]
In [121]: s.sample(n=3, weights=example_weights)
Out[121]:
   5
   4
   3
dtype: int64
```

# Weights will be re-normalized automatically

```python
In [122]: example_weights2 = [0.5, 0, 0, 0, 0, 0]
In [123]: s.sample(n=1, weights=example_weights2)
Out[123]:
   0
dtype: int64
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```python
In [124]: df2 = pd.DataFrame({'col1': [9, 8, 7, 6],
                       'weight_column': [0.5, 0.4, 0.1, 0]})
In [125]: df2.sample(n=3, weights='weight_column')
Out[125]:
          col1  weight_column
     0     8         0.4
     1     9         0.5
     2     7         0.1
```

`sampling` also allows users to sample columns instead of rows using the `axis` argument.

```python
In [126]: df3 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
In [127]: df3.sample(n=1, axis=1)
Out[127]:
          col1
     0     1
     1     2
     2     3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will
accept either an integer (as a seed) or a NumPy RandomState object.

```python
In [128]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})

# With a given seed, the sample will always draw the same rows.
In [129]: df4.sample(n=2, random_state=2)
Out[129]:
   col1 col2
0    2    3
1    1    2

In [130]: df4.sample(n=2, random_state=2)
Out[130]:
   col1 col2
0    2    3
1    1    2
```

### 2.5.11 Setting with enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis. In the Series case this is effectively an appending operation.

```python
In [131]: se = pd.Series([1, 2, 3])

In [132]: se
Out[132]:
0   1
1   2
2   3
dtype: int64

In [133]: se[5] = 5.

In [134]: se
Out[134]:
0   1.0
1   2.0
2   3.0
5   5.0
dtype: float64
```

A DataFrame can be enlarged on either axis via `.loc`.

```python
In [135]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
columns=['A', 'B'])

In [136]: dfi
Out[136]:
   A  B
0  0  1
1  2  3
```

(continues on next page)
In [137]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [138]: dfi
Out[138]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4

This is like an `append` operation on the DataFrame.

In [139]: dfi.loc[3] = 5

In [140]: dfi
Out[140]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5

### 2.5.12 Fast scalar value getting and setting

Since indexing with [] must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you’re asking for. If you only want to access a scalar value, the fastest way is to use the `at` and `iat` methods, which are implemented on all of the data structures. Similarly to `loc`, `at` provides **label** based scalar lookups, while, `iat` provides **integer** based lookups analogously to `iloc`

In [141]: s.iat[5]
Out[141]: 5

In [142]: df.at[dates[5], 'A']
Out[142]: -0.6736897080883706

In [143]: df.iat[3, 0]
Out[143]: 0.7215551622443669

You can also set using these same indexers.

In [144]: df.at[dates[5], 'E'] = 7

In [145]: df.iat[3, 0] = 7

at may enlarge the object in-place as above if the indexer is missing.

In [146]: df.at[dates[-1] + pd.Timedelta('1 day'), 0] = 7

In [147]: df
2.5.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: | for or, & for and, and ~ for not. These must be grouped by using parentheses, since by default Python will evaluate an expression such as \( \text{df}[\text{A}] > 2 \) \& \( \text{df}[\text{B}] < 3 \) as \( \text{df}[\text{A}] > (2 \& \text{df}[\text{B}]) < 3 \), while the desired evaluation order is \( (\text{df}[\text{A}] > 2) \& (\text{df}[\text{B}] < 3) \).

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```
In [148]: s = pd.Series(range(-3, 4))
```

```
In [149]: s
Out[149]:
   0    -3
   1    -2
   2    -1
   3     0
   4     1
   5     2
   6     3
dtype: int64
```

```
In [150]: s[s > 0]
Out[150]:
   4
   5
   6
dtype: int64
```

```
In [151]: (s < -1) | (s > 0.5))
Out[151]:
   0    -3
   1    -2
   4
   5
   6
   7
dtype: int64
```

```
In [152]: s[~(s < 0)]
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame’s index (for example, something derived from one of the columns of the DataFrame):

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame’s index (for example, something derived from one of the columns of the DataFrame):

<table>
<thead>
<tr>
<th>In [153]:</th>
<th>df[df['A'] &gt; 0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[153]:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>A</td>
</tr>
<tr>
<td>2000-01-01</td>
<td>0.469112</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>1.212112</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>7.000000</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.404705</td>
</tr>
</tbody>
</table>

List comprehensions and the map method of Series can also be used to produce more complex criteria:

In [154]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six'],
                      ....:
                      'b': ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
                      ....:
                      'c': np.random.randn(7))

# only want 'two' or 'three'
In [155]: criterion = df2['a'].map(lambda x: x.startswith('t'))

In [156]: df2[criterion]
Out[156]:
   a  b  c
2  two  y  0.041290
3  three  x  0.361719
4  two  y  -0.238075

# equivalent but slower
In [157]: df2[[x.startswith('t') for x in df2['a']]]
Out[157]:
   a  b  c
2  two  y  0.041290
3  three  x  0.361719
4  two  y  -0.238075

# Multiple criteria
In [158]: df2[criterion & (df2['b'] == 'x')]
Out[158]:
   a  b  c
3  three  x  0.361719

With the choice methods Selection by Label, Selection by Position, and Advanced Indexing you may select along more than one axis using boolean vectors combined with other indexing expressions.
### 2.5.14 Indexing with `isin`

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```python
In [165]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')

In [166]: s
Out[166]:
                   4
            0       1
            1       2
            2       3
            3       4
        dtype: int64
```

(continues on next page)
The same method is available for Index objects and is useful for the cases when you don’t know which of the sought labels are in fact present:

```
In [169]: s[s.index.isin([2, 4, 6])]
Out[169]:
4   0
2   2
0   4
dtype: int64
```

# compare it to the following
```
In [170]: s.reindex([2, 4, 6])
Out[170]:
2   2.0
4   0.0
6   NaN
dtype: float64
```

In addition to that, MultiIndex allows selecting a separate level to use in the membership check:

```
In [171]: s_mi = pd.Series(np.arange(6),
       index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']]))
In [172]: s_mi
Out[172]:
0  a  0
   b  1
   c  2
1  a  3
   b  4
   c  5
dtype: int64
In [173]: s_miiloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c')])]
Out[173]:
0  c  2
(continues on next page)```
DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```python
In [175]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
                      'ids2': ['a', 'n', 'c', 'n']})

In [176]: values = ['a', 'b', 1, 3]

In [177]: df.isin(values)
```

```
vals     ids     ids2
0  True    True    True
1  False   True    False
2  True    False   False
3  False   False   False
```

Oftentimes you’ll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```python
In [178]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [179]: df.isin(values)
```

```
vals     ids     ids2
0  True    True    False
1  False   True    False
2  True    False   False
3  False   False   False
```

To return the DataFrame of booleans where the values are **not** in the original DataFrame, use the ~ operator:

```python
In [180]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [181]: ~df.isin(values)
```

```
vals     ids     ids2
0  False   False   True
1  True    False   True
2  False   True    True
3  True    True    True
```
Combine DataFrame's `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```python
In [182]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}
In [183]: row_mask = df.isin(values).all(1)
In [184]: df[row_mask]
Out[184]:
   vals ids  ids2
0    1    a    a
```

### 2.5.15 The `where()` Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in `Series` and `DataFrame`.

To return only the selected rows:

```python
In [185]: s[s > 0]
Out[185]:
3    1
2    2
1    3
0    4
```

To return a Series of the same shape as the original:

```python
In [186]: s.where(s > 0)
Out[186]:
4    NaN
3    1.0
2    2.0
1    3.0
0    4.0
```

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df.where(df < 0)`.

```python
In [187]: df[df < 0]
Out[187]:
          A         B          C         D
2000-01-01 -2.104139 -1.309525 NaN        NaN
2000-01-02 -0.352480 NaN        -1.192319 NaN
2000-01-03 -0.864883 NaN        -0.227870 NaN
2000-01-04 NaN        -1.222082 NaN        NaN
2000-01-05 NaN        -0.605656 -1.169184 NaN
2000-01-06 NaN        -0.948458 NaN        -0.684718
2000-01-07 -2.670153 -0.114722 NaN        -0.808838
2000-01-08 NaN        NaN        -0.048788 -0.808838
```
In addition, `where` takes an optional `other` argument for replacement of values where the condition is False, in the returned copy.

```python
In [188]: df.where(df < 0, -df)
```

```
Out[188]:
    A         B         C         D
2000-01-01 -2.104139 -1.309525 -0.485855 -0.245166
2000-01-02 -0.352480 -0.390389 -1.192319 -1.655824
2000-01-03 -0.864883 -0.299674 -0.227870 -0.281059
2000-01-04 -0.846958 -1.222082 -0.600705 -1.233203
2000-01-05 -0.669692 -0.605656 -1.169184 -0.342416
2000-01-06 -0.868584 -0.948458 -2.297780 -0.684718
2000-01-07 -2.670153 -0.114722 -0.168904 -0.048048
2000-01-08 -0.801196 -1.392071 -0.048788 -0.808838
```

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```python
In [189]: s2 = s.copy()
In [190]: s2[s2 < 0] = 0
In [191]: s2
```

```
Out[191]:
  0   1   2   3
4  0  1  2  3
0  0  0  0  0
```

```python
Out[191]:
 0  4
dtype: int64
```

```python
In [192]: df2 = df.copy()
In [193]: df2[df2 < 0] = 0
In [194]: df2
```

```
Out[194]:
      A         B         C         D
2000-01-01  0.000000  0.000000  0.485855  0.245166
2000-01-02  0.000000  0.390389  0.000000  1.655824
2000-01-03  0.000000  0.299674  0.000000  0.281059
2000-01-04  0.846958  0.000000  0.600705  0.000000
2000-01-05  0.669692  0.000000  0.000000  0.342416
2000-01-06  0.868584  0.000000  2.297780  0.000000
2000-01-07  0.000000  0.000000  0.168904  0.000000
2000-01-08  0.801196  1.392071  0.000000  0.000000
```

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```python
In [195]: df_orig = df.copy()
In [196]: df_orig.where(df > 0, -df, inplace=True)
In [197]: df_orig
```

(continues on next page)
Note: The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

In [198]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
    
Out[198]:

<table>

Alignment

Furthermore, where aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via .loc (but on the contents rather than the axis labels).

In [199]: df2 = df.copy()

In [200]: df2[df2[1:4] > 0] = 3

In [201]: df2

Out[201]:

<table>

</tr>
</tbody>
</table>

where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

In [206]: df3 = pd.DataFrame({'A': [1, 2, 3],
                       'B': [4, 5, 6],
                       'C': [7, 8, 9]})

In [207]: df3.where(lambda x: x > 4, lambda x: x + 10)

Out[207]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>11</td>
<td>14</td>
<td>7</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>2</td>
<td>13</td>
<td>6</td>
<td>9</td>
</tr>
</tbody>
</table>
Mask

`mask()` is the inverse boolean operation of `where`.  

```python
In [208]: s.mask(s >= 0)
Out[208]:
  4    NaN
  3    NaN
  2    NaN
  1    NaN
  0    NaN
dtype: float64

In [209]: df.mask(df >= 0)
Out[209]:
     A    B    C    D
2000-01-01 -2.104139 -1.309525 NaN   NaN
2000-01-02 -0.352480   NaN -1.192319   NaN
2000-01-03 -0.864883   NaN  -0.227870   NaN
2000-01-04   NaN  -1.222082   NaN  -1.233203
2000-01-05   NaN -0.605656 -1.169184   NaN
2000-01-06   NaN -0.948458   NaN -0.684718
2000-01-07 -2.670153   NaN   NaN -0.048788
2000-01-08   NaN   NaN  -0.048788 -0.808838
```

2.5.16 Setting with enlargement conditionally using `numpy()`

An alternative to `where()` is to use `numpy.where()`. Combined with setting a new column, you can use it to enlarge a DataFrame where the values are determined conditionally.

Consider you have two choices to choose from in the following DataFrame. And you want to set a new column color to ‘green’ when the second column has ‘Z’. You can do the following:

```python
In [210]: df = pd.DataFrame({'col1': list('ABBC'), 'col2': list('ZZXY'))

In [211]: df['color'] = np.where(df['col2'] == 'Z', 'green', 'red')

In [212]: df
Out[212]:
     col1 col2   color
    0     A    Z green
    1     B    Z green
    2     B    X  red
    3     C    Y  red
```

If you have multiple conditions, you can use `numpy.select()` to achieve that. Say corresponding to three conditions there are three choice of colors, with a fourth color as a fallback, you can do the following.

```python
In [213]: conditions = [
       ......: (df['col2'] == 'Z') & (df['col1'] == 'A'),
       ......: (df['col2'] == 'Z') & (df['col1'] == 'B'),
       ......: (df['col1'] == 'B')
       ......: ]
```
In [214]: choices = ['yellow', 'blue', 'purple']

In [215]: df['color'] = np.select(conditions, choices, default='black')

In [216]: df

Out[216]:
   col1  col2  color
0     A   Z    yellow
1     B   Z      blue
2     B   X    purple
3     C   Y     black

2.5.17 The query() Method

DataFrame objects have a query() method that allows selection using an expression.

You can get the value of the frame where column b has values between the values of columns a and c. For example:

In [217]: n = 10

In [218]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [219]: df

Out[219]:
     a      b      c
0  0.438921  0.118680  0.863670
1  0.138138  0.577363  0.686602
2  0.595307  0.564592  0.520630
3  0.913052  0.926075  0.616184
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
6  0.792342  0.216974  0.564056
7  0.397890  0.454131  0.915716
8  0.074315  0.437913  0.019794
9  0.559209  0.502065  0.026437

# pure python
In [220]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]

Out[220]:
     a      b      c
1  0.138138  0.577363  0.686602
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716

# query
In [221]: df.query('(a < b) & (b < c)')

Out[221]:
     a      b      c
Do the same thing but fall back on a named index if there is no column with the name `a`.

```
In [222]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
In [223]: df.index.name = 'a'
In [224]: df
Out[224]:
   b  c
a  
0  0  4
1  0  1
2  3  4
3  4  3
4  1  4
5  0  3
6  0  1
7  3  4
8  2  3
9  1  1
```

```
In [225]: df.query('a < b and b < c')
Out[225]:
   b  c
a  
2  3  4
```

If instead you don’t want to or cannot name your index, you can use the name `index` in your query expression:

```
In [226]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
In [227]: df
Out[227]:
   b  c
  
0  3  1
1  3  0
2  5  6
3  5  2
4  7  4
5  0  1
6  2  5
7  0  1
8  6  0
9  7  9
```

```
In [228]: df.query('index < b < c')
Out[228]:
   b  c
2  3  4
```
Note: If the name of your index overlaps with a column name, the column name is given precedence. For example,

```
In [229]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
In [230]: df.index.name = 'a'
In [231]: df.query('a > 2')  # uses the column 'a', not the index
Out[231]:
   a
0  3
1  3
2  3
```

You can still use the index in a query expression by using the special identifier ‘index’:

```
In [232]: df.query('index > 2')
Out[232]:
   a
0  3
1  3
2  4
```

If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

**MultiIndex query() Syntax**

You can also use the levels of a DataFrame with a *MultiIndex* as if they were columns in the frame:

```
In [233]: n = 10
In [234]: colors = np.random.choice(['red', 'green'], size=n)
In [235]: foods = np.random.choice(['eggs', 'ham'], size=n)
In [236]: colors
Out[236]:
array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green', 'green', 'green'], dtype='<U5')
In [237]: foods
Out[237]:
array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs', 'eggs'], dtype='<U4')
In [238]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])
```
In [239]: df = pd.DataFrame(np.random.randn(n, 2), index=index)

In [240]: df

Out[240]:
          0       1
color  food
red   ham  0.194889 -0.381994
       ham  0.318587  2.089075
       eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
       eggs -2.029766  0.792652
       ham  0.461007 -0.542749
       ham -0.305384 -0.479195
       eggs  0.095031 -0.270099
       eggs -0.707140 -0.773882
       eggs  0.229453  0.304418

In [241]: df.query('color == "red"')

Out[241]:
          0       1
color  food
red   ham  0.194889 -0.381994
       ham  0.318587  2.089075
       eggs -0.728293 -0.090255

If the levels of the MultiIndex are unnamed, you can refer to them using special names:

In [242]: df.index.names = [None, None]

In [243]: df

Out[243]:
          0       1
       red   ham  0.194889 -0.381994
       ham  0.318587  2.089075
       eggs -0.728293 -0.090255
       green eggs -0.748199  1.318931
             eggs -2.029766  0.792652
             ham  0.461007 -0.542749
             ham -0.305384 -0.479195
             eggs  0.095031 -0.270099
             eggs -0.707140 -0.773882
             eggs  0.229453  0.304418

In [244]: df.query('ilevel_0 == "red"')

Out[244]:
          0       1
       red   ham  0.194889 -0.381994
       ham  0.318587  2.089075
       eggs -0.728293 -0.090255

The convention is ilevel_0, which means “index level 0” for the 0th level of the index.
query() Use Cases

A use case for query() is when you have a collection of DataFrame objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames without having to specify which frame you're interested in querying.

```python
In [245]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [246]: df
Out[246]:
   a    b    c
0 0.224283 0.736107 0.139168
1 0.302827 0.657803 0.713897
2 0.611185 0.136624 0.984960
3 0.195246 0.123436 0.627712
4 0.618673 0.371660 0.047902
5 0.480088 0.062993 0.185760
6 0.568018 0.483467 0.445289
7 0.309040 0.274580 0.587101
8 0.258993 0.477769 0.370255
9 0.550459 0.840870 0.304611

In [247]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)

In [248]: df2
Out[248]:
   a    b    c
0 0.357579 0.229800 0.596001
1 0.309059 0.957923 0.965663
2 0.123102 0.336914 0.318616
3 0.526506 0.323321 0.860813
4 0.518736 0.486514 0.384724
5 0.190804 0.505723 0.614533
6 0.891939 0.623977 0.676639
7 0.480559 0.378528 0.460858
8 0.420223 0.136404 0.141295
9 0.732206 0.419540 0.604675
10 0.604466 0.848974 0.896165
11 0.589168 0.920046 0.732716

In [249]: expr = '0.0 <= a <= c <= 0.5'

In [250]: map(lambda frame: frame.query(expr), [df, df2])
Out[250]: <map at 0x7f54a647bdf0>
```
query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

```python
In [251]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))
In [252]: df
Out[252]:
   a  b  c
0   7  8  9
1   1  0  7
2   2  7  2
3   6  2  2
4   4  6  3
5   3  8  2
6   1  7  2
7   5  1  5
8   9  8  0
9   1  5  0
```

```python
In [253]: df.query('(a < b) & (b < c)')
Out[253]:
   a  b  c
0   7  8  9
```

Slightly nicer by removing the parentheses (comparison operators bind tighter than & and |):

```python
In [255]: df.query('a < b & b < c')
Out[255]:
   a  b  c
0   7  8  9
```

Use English instead of symbols:

```python
In [256]: df.query('a < b and b < c')
Out[256]:
   a  b  c
0   7  8  9
```

Pretty close to how you might write it on paper:

```python
In [257]: df.query('a < b < c')
Out[257]:
   a  b  c
0   7  8  9
```
The \texttt{in} and \texttt{not in} operators

\textit{query()} also supports special use of Python’s \texttt{in} and \texttt{not in} comparison operators, providing a succinct syntax for calling the \texttt{isin} method of a \texttt{Series} or \texttt{DataFrame}.

\begin{verbatim}
# get all rows where columns "a" and "b" have overlapping values
In [258]: df = pd.DataFrame({'a': list('aabbcdddeeff'), 'b': list('aaaabbbcccc'),
                        'c': np.random.randint(5, size=12),
                        'd': np.random.randint(9, size=12))

In [259]: df
Out[259]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2

In [260]: df.query('a in b')
Out[260]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2

# How you'd do it in pure Python
In [261]: df[df['a'].isin(df['b'])]
Out[261]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2

In [262]: df.query('a not in b')
Out[262]:
   a  b  c  d
6  d  b  3  3
7  d  b  2  1

(continues on next page)
\end{verbatim}
You can combine this with other expressions for very succinct queries:

```python
# rows where cols a and b have overlapping values
# and col c's values are less than col d's
In [264]: df.query('a in b and c < d')
Out[264]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  c  b  3  6
4  c  b  0  2

# pure Python
In [265]: df[df['b'].isin(df['a']) & (df['c'] < df['d'])]
Out[265]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  c  b  3  6
5  c  b  0  2
10 f  c  0  6
11 f  c  1  2
```

**Note:** Note that **in** and **not in** are evaluated in Python, since `numexpr` has no equivalent of this operation. However, only the **in**/**not in** expression itself is evaluated in vanilla Python. For example, in the expression

```python
df.query('a in b + c + d')
```

(b + c + d) is evaluated by `numexpr` and then the **in** operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.
Special use of the $==$ operator with list objects

Comparing a list of values to a column using $==$/$!=$ works similarly to in/not in.

```
In [266]: df.query('b == ["a", "b", "c"]')
Out[266]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

# pure Python
```
In [267]: df[df['b'].isin(["a", "b", "c")])
Out[267]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

```
In [268]: df.query('c == [1, 2]')
Out[268]:
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

In [269]: df.query('c != [1, 2]')
Out[269]:
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
```

(continues on next page)
# using in/not in
In [270]: df.query('[1, 2] in c')
Out[270]:
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

In [271]: df.query('[1, 2] not in c')
Out[271]:
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

# pure Python
In [272]: df[df['c'].isin([1, 2])]  
Out[272]:
   a  b  c  bools
2  0.697753  0.212799  0.329209 False
7  0.275396  0.691034  0.826619 False
8  0.190649  0.558748  0.262467 False

Boolean operators

You can negate boolean expressions with the word `not` or the `~` operator.
Of course, expressions can be arbitrarily complex too:

```python
In [278]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [279]: longer = df[(df['a'] < df['b']) & (df['b'] < df['c']) & (~df['bools']) | (df['bools'] > 2)]

In [280]: shorter
Out[280]:
   a    b    c  bools
 0  0.275396 0.691034 0.826619  False

In [281]: longer
Out[281]:
   a    b    c  bools
 0  0.275396 0.691034 0.826619  False

In [282]: shorter == longer
Out[282]:
   a    b    c  bools
 0  True  True  True  True
```

2.5. Indexing and selecting data
Performance of `query()`

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

![Graph showing performance comparison between `python` and `numexpr` for `DataFrame.query()`](image)

**Note:** You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`. 
2.5.18 Duplicate data

If you want to identify and remove duplicate rows in a DataFrame, there are two methods that will help: duplicated and drop_duplicates. Each takes as an argument the columns to use to identify duplicated rows.

- duplicated returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- drop_duplicates removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a keep parameter to specify targets to be kept.

- keep='first' (default): mark / drop duplicates except for the first occurrence.
- keep='last': mark / drop duplicates except for the last occurrence.
- keep=False: mark / drop all duplicates.

```python
In [283]: df2 = pd.DataFrame({
    'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four'],
    'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
    'c': np.random.randn(7)},

In [284]: df2
Out[284]:
   a    b         c
0  one  x  -1.067137
1  one  y   0.309500
2  two  x  -0.211056
3  two  y  -1.842023
4  two  x  -0.390820
5  three  x  -1.964475
6   four  x   1.298329

In [285]: df2.duplicated('a')
Out[285]:
0   False
1    True
2   False
3    True
4    True
5   False
6   False
dtype: bool

In [286]: df2.duplicated('a', keep='last')
Out[286]:
0    True
1   False
2    True
3    True
4   False
5   False
6   False
dtype: bool
```

(continues on next page)
In [287]: df2.duplicated('a', keep=False)
Out[287]:
0    True
1    True
2    True
3    True
4    True
5   False
6   False
dtype: bool

In [288]: df2.drop_duplicates('a')
Out[288]:
   a    b    c
0  one  x -1.067137
1  one  y  0.309500
2  two  x -0.211056
3  three x -1.964475
4  four  x  1.298329

In [289]: df2.drop_duplicates('a', keep='last')
Out[289]:
   a    b    c
0  one  y  0.309500
1  two x -0.390820
2  three x -1.964475
3  four  x  1.298329

In [290]: df2.drop_duplicates('a', keep=False)
Out[290]:
   a    b    c
5  three x -1.964475
6  four  x  1.298329

Also, you can pass a list of columns to identify duplications.

In [291]: df2.duplicated(['a', 'b'])
Out[291]:
0   False
1   False
2   False
3   False
4    True
5   False
6   False
dtype: bool

In [292]: df2.drop_duplicates(['a', 'b'])
Out[292]:
   a    b    c
0  one  x -1.067137
1  one  y  0.309500

(continues on next page)
To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the keep parameter.

```
In [293]: df3 = pd.DataFrame({'a': np.arange(6),
                           'b': np.random.randn(6),
                           index=['a', 'a', 'b', 'c', 'b', 'a'])

In [294]: df3
Out[294]:
   a   b
0  0  1.440455
1  1  2.456086
2  2  1.038402
3  3 -0.894409
4  4  0.683536
5  5  3.082764

In [295]: df3.index.duplicated()
Out[295]: array([False, True, False, False, True, True])

In [296]: df3[~df3.index.duplicated()]
Out[296]:
   a   b
0  0  1.440455
2  2  1.038402
3  3 -0.894409

In [297]: df3[~df3.index.duplicated(keep='last')]
Out[297]:
   a   b
3  3 -0.894409
4  4  0.683536
5  5  3.082764

In [298]: df3[~df3.index.duplicated(keep=False)]
Out[298]:
   a   b
3  3 -0.894409
```
2.5.19 Dictionary-like get() method

Each of Series or DataFrame have a get method which can return a default value.

```python
In [299]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [300]: s.get('a')  # equivalent to s['a']
Out[300]: 1
In [301]: s.get('x', default=-1)
Out[301]: -1
```

2.5.20 Looking up values by index/column labels

Sometimes you want to extract a set of values given a sequence of row labels and column labels, this can be achieved by pandas.factorize and NumPy indexing. For instance:

```python
In [302]: df = pd.DataFrame({'col': ['A', 'A', 'B', 'B'],
                      'A': [80, 23, np.nan, 22],
                      'B': [80, 55, 76, 67]})

In [303]: df
Out[303]:
   col  A    B
0    A  80.0  80
1    A  23.0  55
2    B   NaN  76
3    B  22.0  67

In [304]: idx, cols = pd.factorize(df['col'])
In [305]: df.reindex(cols, axis=1).to_numpy()[np.arange(len(df)), idx]
Out[305]: array([80., 23., 76., 67.])
```

Formerly this could be achieved with the dedicated DataFrame.lookup method which was deprecated in version 1.2.0.

2.5.21 Index objects

The pandas Index class and its subclasses can be viewed as implementing an ordered multiset. Duplicates are allowed. However, if you try to convert an Index object with duplicate entries into a set, an exception will be raised.

Index also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an Index directly is to pass a list or other sequence to Index:

```python
In [306]: index = pd.Index(['e', 'd', 'a', 'b'])
In [307]: index
Out[307]: Index(['e', 'd', 'a', 'b'], dtype='object')
In [308]: 'd' in index
Out[308]: True
```
You can also pass a name to be stored in the index:

```
In [309]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')
```

```
In [310]: index.name
Out[310]: 'something'
```

The name, if set, will be shown in the console display:

```
In [311]: index = pd.Index(list(range(5)), name='rows')
In [312]: columns = pd.Index(['A', 'B', 'C'], name='cols')
In [313]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)
In [314]: df
Out[314]:
   col1  col2  col3
rows
  0    1.295989 -1.051694  1.340429
  1   -2.366110  0.428241  0.387275
  2    0.433306  0.929548  0.278094
  3    2.154730 -0.315628  0.264223
  4    1.126818  1.132290 -0.353310
```

```
In [315]: df['A']
Out[315]:
   rows
0    1.295989
1   -2.366110
2    0.433306
3    2.154730
4    1.126818
Name: A, dtype: float64
```

### Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their `name` attribute. You can use the `rename`, `set_names` to set these attributes directly, and they default to returning a copy.

See Advanced Indexing for usage of MultiIndexes.

```
In [316]: ind = pd.Index([1, 2, 3])
In [317]: ind.rename("apple")
Out[317]: Int64Index([1, 2, 3], dtype='int64', name='apple')
In [318]: ind
Out[318]: Int64Index([1, 2, 3], dtype='int64')
In [319]: ind.set_names(['apple'], inplace=True)
In [320]: ind.name = "bob"
(continues on next page)"
set_names, set_levels, and set_codes also take an optional level argument

```python
In [322]: index = pd.MultiIndex.from_product([[range(3), ['one', 'two']], names=['first', 'second'])
```

```python
In [323]: index
Out[323]: MultiIndex([(0, 'one'), (0, 'two'), (1, 'one'), (1, 'two'), (2, 'one'), (2, 'two')], names=['first', 'second'])
```

```python
In [324]: index.levels[1]
Out[324]: Index(['one', 'two'], dtype='object', name='second')
```

```python
In [325]: index.set_levels(['a', 'b'], level=1)
Out[325]: MultiIndex([(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b'), (2, 'a'), (2, 'b')], names=['first', 'second'])
```

### Set operations on Index objects

The two main operations are union and intersection. Difference is provided via the `.difference()` method.

```python
In [326]: a = pd.Index(['c', 'b', 'a'])
```

```python
In [327]: b = pd.Index(['c', 'e', 'd'])
```

```python
In [328]: a.difference(b)
Out[328]: Index(['a', 'b'], dtype='object')
```

Also available is the `symmetric_difference` operation, which returns elements that appear in either idx1 or idx2, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```python
In [329]: idx1 = pd.Index([1, 2, 3, 4])
```

```python
In [330]: idx2 = pd.Index([2, 3, 4, 5])
```
In [331]: idx1.symmetric_difference(idx2)
Out[331]: Int64Index([1, 5], dtype='int64')

Note: The resulting index from a set operation will be sorted in ascending order.

When performing `Index.union()` between indexes with different dtypes, the indexes must be cast to a common dtype. Typically, though not always, this is object dtype. The exception is when performing a union between integer and float data. In this case, the integer values are converted to float.

In [332]: idx1 = pd.Index([0, 1, 2])
In [333]: idx2 = pd.Index([0.5, 1.5])
In [334]: idx1.union(idx2)
Out[334]: Float64Index([0.0, 0.5, 1.0, 1.5, 2.0], dtype='float64')

### Missing values

**Important**: Even though `Index` can hold missing values (NaN), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

In [335]: idx1 = pd.Index([1, np.nan, 3, 4])
In [336]: idx1
Out[336]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')

In [337]: idx1.fillna(2)
Out[337]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')

In [338]: idx2 = pd.DatetimeIndex([pd.Timestamp('2011-01-01'),
                        pd.NaT,
                        pd.Timestamp('2011-01-03')])

In [339]: idx2
Out[339]: DatetimeIndex(['2011-01-01', 'NaT', '2011-01-03'], dtype='datetime64[ns]', freq=None)

In [340]: idx2.fillna(pd.Timestamp('2011-01-02'))
Out[340]: DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], dtype='datetime64[ns]', freq=None)
2.5.22 Set / reset index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you’ve already done so. There are a couple of different ways.

Set an index

DataFrame has a set_index() method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

```python
In [341]: data
Out[341]:
   a  b  c  d
0  bar one  z  1.0
1  bar  two  y  2.0
2  foo one  x  3.0
3  foo  two  w  4.0

In [342]: indexed1 = data.set_index('c')

In [343]: indexed1
Out[343]:
   a  b  d
   c
   z  bar one  1.0
   y  bar  two  2.0
   x  foo one  3.0
   w  foo  two  4.0

In [344]: indexed2 = data.set_index([ 'a',  'b'], append=False)

In [345]: indexed2
Out[345]:
   c  d
   a  b
   bar one  z  1.0
     two  y  2.0
   foo one  x  3.0
     two  w  4.0
```

The append keyword option allow you to keep the existing index and append the given columns to a MultiIndex:

```python
In [346]: frame = data.set_index('c', drop=False)
In [347]: frame = frame.set_index([ 'a',  'b'], append=True)

In [348]: frame
Out[348]:
   c  d
   a  b
   bar one  z  1.0
     two  y  2.0
   foo one  x  3.0
     two  w  4.0
```

(continues on next page)
Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

```
In [349]: data.set_index('c', drop=False)
Out[349]:
   a   b  c  d
   c
   z  bar one z 1.0
   y  bar two y 2.0
   x  foo one x 3.0
   w  foo two w 4.0
```

```
In [350]: data.set_index(['a', 'b'], inplace=True)

In [351]: data
Out[351]:
   c  d
   a  b
   bar one z 1.0
       two y 2.0
   foo one x 3.0
       two w 4.0
```

**Reset the index**

As a convenience, there is a new function on DataFrame called `reset_index()` which transfers the index values into the DataFrame’s columns and sets a simple integer index. This is the inverse operation of `set_index()`.

```
In [352]: data
Out[352]:
   c  d
   a  b
   bar one z 1.0
       two y 2.0
   foo one x 3.0
       two w 4.0
```

```
In [353]: data.reset_index()
Out[353]:
   a  b  c  d
   0 bar one z 1.0
   1 bar two y 2.0
   2 foo one x 3.0
   3 foo two w 4.0
```

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [354]:
```

```
In [355]:
```
In [354]: frame
Out[354]:
    c  d
    c  a  b
    z  bar  one  z  1.0
    y  bar  two  y  2.0
    x  foo  one  x  3.0
    w  foo  two  w  4.0

In [355]: frame.reset_index(level=1)
Out[355]:
       a  c  d
       c  b
    z  one  bar  z  1.0
    y  two  bar  y  2.0
    x  one  foo  x  3.0
    w  two  foo  w  4.0

reset_index takes an optional parameter drop which if true simply discards the index, instead of putting index values in the DataFrame's columns.

Adding an ad hoc index

If you create an index yourself, you can just assign it to the index field:

data.index = index

2.5.23 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called chained indexing. Here is an example.

In [356]: dfmi = pd.DataFrame([list('abcd'),
                        ........:       list('efgh'),
                        ........:       list('ijkl'),
                        ........:       list('mnop'),
                        ........:       columns=pd.MultiIndex.from_product([[  
                         .........:       'one', 'two'],
                                    .........:       ['first', 'second']])
                        .........:       ])

In [357]: dfmi
Out[357]:
          one  two
       first  second  first  second
0       a   b   c   d
1       e   f   g   h
2       i   j   k   l
3       m   n   o   p

Compare these two access methods:
In [358]: dfmi['one']['second']
Out[358]:
0  b
1  f
2  j
3  n
Name: second, dtype: object

In [359]: dfmi.loc[:, ('one', 'second')]
Out[359]:
0  b
1  f
2  j
3  n
Name: (one, second), dtype: object

These both yield the same results, so which should you use? It is instructive to understand the order of operations on
these and why method 2 (.loc) is much preferred over method 1 (chained []).

dfmi['one'] selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python
operation dfmi_with_one['second'] selects the series indexed by 'second'. This is indicated by the variable
dfmi_with_one because pandas sees these operations as separate events. e.g. separate calls to __getitem__, so it
has to treat them as linear operations, they happen one after another.

Contrast this to df.loc[:, ('one', 'second')] which passes a nested tuple of (slice(None), ('one',
'second')) to a single call to __getitem__. This allows pandas to deal with this as a single entity. Furthermore this
order of operations can be significantly faster, and allows one to index both axes if so desired.

**Why does assignment fail when using chained indexing?**

The problem in the previous section is just a performance issue. What’s up with the SettingWithCopy warning? We
don’t usually throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think
about how the Python interpreter executes this code:

defi.loc[:, ('one', 'second')] = value
# becomes
defi.loc._setitem__((slice(None), ('one', 'second')), value)

But this code is handled differently:

defi['one']['second'] = value
# becomes
defi.__getitem__('one').__setitem__('second', value)

See that __getitem__ in there? Outside of simple cases, it’s very hard to predict whether it will return a view or a
copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether
the __setitem__ will modify dfmi or a temporary object that gets thrown out immediately afterward. That’s what
SettingWithCopy is warning you about!

**Note:** You may be wondering whether we should be concerned about the loc property in the first example. But
dfmi.loc is guaranteed to be dfmi itself with modified indexing behavior, so dfmi.loc.__getitem__/dfmi.loc.__setitem__ operate on dfmi directly. Of course, dfmi.loc.__getitem__(idx) may be a view or a copy of dfmi.

Sometimes a SettingWithCopy warning will arise at times when there’s no obvious chained indexing going on. These are the bugs that SettingWithCopy is designed to catch! pandas is probably trying to warn you that you’ve done this:

```python
def do_something(df):
    foo = df[['bar', 'baz']]  # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    # We don't know whether this will modify df or not!
    foo['quux'] = value
    return foo
```

Yikes!

**Evaluation order matters**

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

pandas has the SettingWithCopyWarning because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the option `mode.chained_assignment` to one of these values:

- 'warn', the default, means a SettingWithCopyWarning is printed.
- 'raise' means pandas will raise a SettingWithCopyException you have to deal with.
- None will suppress the warnings entirely.

```text
In [360]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
               ......: 'three', 'two', 'one', 'six'],
               ......: 'c': np.arange(7))
               ......:
# This will show the SettingWithCopyWarning
# but the frame values will be set
In [361]: dfb['c'][dfb['a'].str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```text
>>> pd.set_option('mode.chained_assignment','warn')
>>> dfb[dfb['a'].str.startswith('o')]['c'] = 42
Traceback (most recent call last)
... SettingWithCopyWarning:
    A value is trying to be set on a copy of a slice from a DataFrame.
    Try using .loc[row_index,col_indexer] = value instead
```

A chained assignment can also crop up in setting in a mixed dtype frame.

**Note:** These setting rules apply to all of `.loc/.iloc`.  

The following is the recommended access method using .loc for multiple items (using mask) and a single item using a fixed index:

```
In [362]: dfc = pd.DataFrame({'a': ['one', 'one', 'two',
                           'three', 'two', 'one', 'six'],
                          'c': np.arange(7))

In [363]: dfd = dfc.copy()

# Setting multiple items using a mask
In [364]: mask = dfd['a'].str.startswith('o')
In [365]: dfd.loc[mask, 'c'] = 42
```

```
In [366]: dfd
Out[366]:
          a  c
    0    one  42
    1    one  42
    2    two  2
    3  three  3
    4    two  4
    5    one  42
    6    six  6

# Setting a single item
In [367]: dfd = dfc.copy()
In [368]: dfd.loc[2, 'a'] = 11
```

```
In [369]: dfd
Out[369]:
          a  c
    0    one  0
    1    one  1
    2    11  2
    3  three  3
    4    two  4
    5    one  5
    6    six  6
```

The following can work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [370]: dfd = dfc.copy()
In [371]: dfd['a'][2] = 111
```

```
In [372]: dfd
Out[372]:
          a  c
    0    one  0
    1    one  1
    2    111  2
```

(continues on next page)
Last, the subsequent example will **not** work at all, and so should be avoided:

```python
>>> pd.set_option('mode.chained_assignment', 'raise')
>>> dfd.loc[0]['a'] = 1111
Traceback (most recent call last)
... SettingWithCopyException:
    A value is trying to be set on a copy of a slice from a DataFrame.
    Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

## 2.6 MultIndex / advanced indexing

This section covers *indexing with a MultiIndex and other advanced indexing features*.

See the **Indexing and Selecting Data** for general indexing documentation.

**Warning:** Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called **chained assignment** and should be avoided. See **Returning a View versus Copy**.

See the **cookbook** for some advanced strategies.

### 2.6.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like Series (1d) and DataFrame (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing **group by** and **pivoting and reshaping data**, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the **cookbook** for some advanced strategies.
Creating a MultiIndex (hierarchical index) object

The MultiIndex object is the hierarchical analogue of the standard Index object which typically stores the axis labels in pandas objects. You can think of MultiIndex as an array of tuples where each tuple is unique. A MultiIndex can be created from a list of arrays (using MultiIndex.from_arrays()), an array of tuples (using MultiIndex.from_tuples()), a crossed set of iterables (using MultiIndex.from_product()), or a DataFrame (using MultiIndex.from_frame()). The Index constructor will attempt to return a MultiIndex when it is passed a list of tuples. The following examples demonstrate different ways to initialize MultiIndexes.

```
In [1]: arrays = [
    ...:     ['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
    ...:     ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'],
    ...:     ]
    ...

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]: [('bar', 'one'), ('bar', 'two'), ('baz', 'one'), ('baz', 'two'),
           ('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]: MultiIndex([(‘bar’, ‘one’), (‘bar’, ‘two’), (‘baz’, ‘one’), (‘baz’, ‘two’),
                        (‘foo’, ‘one’), (‘foo’, ‘two’), (‘qux’, ‘one’), (‘qux’, ‘two’)],
                        names=[‘first’, ‘second’])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first  second
bar  one    0.469112
      two  -0.282863
baz  one  -1.509059
      two  -1.135632
foo  one   1.212112
      two  -0.173215
```

(continues on next page)

2.6. MultiIndex / advanced indexing
When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product()` method:

```python
In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]
In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('baz', 'one'),
            ('baz', 'two'),
            ('foo', 'one'),
            ('foo', 'two'),
            ('qux', 'one'),
            ('qux', 'two')],
           names=['first', 'second'])
```

You can also construct a `MultiIndex` from a `DataFrame` directly, using the method `MultiIndex.from_frame()`. This is a complementary method to `MultiIndex.to_frame()`.

```python
In [10]: df = pd.DataFrame(
    ....:     [['bar', 'one'], ['bar', 'two'], ['foo', 'one'], ['foo', 'two']],
    ....:     columns=['first', 'second'],
    ....: )
In [11]: pd.MultiIndex.from_frame(df)
Out[11]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('foo', 'one'),
            ('foo', 'two')],
           names=['first', 'second'])
```

As a convenience, you can pass a list of arrays directly into `Series` or `DataFrame` to construct a `MultiIndex` automatically:

```python
In [12]: arrays = [
    ....:     np.array(['bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
    ....:     np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']),
    ....: ]
In [13]: s = pd.Series(np.random.randn(8), index=arrays)
In [14]: s
Out[14]:
bar  one   -0.861849
    two   -2.104569
```

(continues on next page)
All of the `MultiIndex` constructors accept a `names` argument which stores string names for the levels themselves. If no names are provided, `None` will be assigned:

```python
In [17]: df.index.names
Out[17]: FrozenList([None, None])
```

This index can back any axis of a pandas object, and the number of `levels` of the index is up to you:

```python
In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=["A", "B", "C"], columns=index)
In [19]: df
Out[19]:
   first  bar  baz  foo  qux
A 0.895717 0.805244 -1.206412 2.565646
   0.410835 0.813850 0.132003 -0.827317
   -1.413681 1.607920 1.024180 0.569605
B 0.407265 -0.081836 -0.429272 1.164561
   -0.121393 0.276314 -0.094664 0.736643
   0.176444 0.403310 -0.154951
C -1.340028 -1.166084 -0.700487 -0.471352
   -0.079933 0.083352 -0.612441
   -0.176444 0.403310 -0.154951
```

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how
the index is displayed can be controlled using the `multi_sparse` option in `pandas.set_options()`:

```
In [21]: with pd.option_context("display.multi_sparse", False):
       ....: df
       ....:
```

It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

```
In [22]: pd.Series(np.random.randn(8), index=tuples)
Out[22]:
           (bar, one) -1.236269
           (bar, two)  0.896171
           (baz, one) -0.487602
           (baz, two) -0.082240
           (foo, one) -2.182937
           (foo, two)  0.380396
           (qux, one)  0.084844
           (qux, two)  0.432390
dtype: float64
```

The reason that the `MultiIndex` matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a `MultiIndex` explicitly yourself. However, when loading data from a file, you may wish to generate your own `MultiIndex` when preparing the data set.

**Reconstructing the level labels**

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```
In [23]: index.get_level_values(0)
Out[23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object',
       name='first')
```

```
In [24]: index.get_level_values("second")
Out[24]: Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object',
       name='second')
```

**Basic indexing on axis with MultiIndex**

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. Partial selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular DataFrame:

```
In [25]: df["bar"]
Out[25]:
           second  one   two
         A   0.895717  0.805244
         B   0.410835  0.813850
         C  -1.413681  1.607920
```

```
In [26]: df["bar", "one"]
Out[26]:
```

(continues on next page)
A 0.895717
B 0.410835
C -1.413681
Name: (bar, one), dtype: float64

In [27]: df["bar"]["one"]
Out[27]:
A 0.895717
B 0.410835
C -1.413681
Name: one, dtype: float64

In [28]: s["qux"]
Out[28]:
one -1.039575
two 0.271860
dtype: float64

See *Cross-section with hierarchical index* for how to select on a deeper level.

### Defined levels

The *MultiIndex* keeps all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

```
In [29]: df.columns.levels  # original MultiIndex
Out[29]: FrozenList([('bar', 'baz', 'foo', 'qux'), ['one', 'two'])

In [30]: df["foo","qux"].columns.levels  # sliced
Out[30]: FrozenList([('bar', 'baz', 'foo', 'qux'), ['one', 'two'])
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the *get_level_values()* method.

```
In [31]: df["foo","qux"].columns.to_numpy()
Out[31]:
array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],
dtype=object)

# for a specific level
In [32]: df["foo","qux"].columns.get_level_values(0)
Out[32]: Index(['foo', 'foo', 'qux', 'qux'], dtype=object, name='first')
```

To reconstruct the *MultiIndex* with only the used levels, the *remove_unused_levels()* method may be used.

```
In [33]: new_mi = df["foo","qux"].columns.remove_unused_levels()

In [34]: new_mi.levels
Out[34]: FrozenList([('foo', 'qux'), ['one', 'two'])
```
### Data alignment and using reindex

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```python
In [35]: s + s[:-2]
Out[35]:
bar  one   -1.723698
    two   -4.209138
baz  one   -0.989859
    two    2.143608
foo  one    1.443110
    two   -1.413542
qux  one     NaN
    two    NaN
dtype: float64
```

```python
In [36]: s + s[::2]
Out[36]:
bar  one   -1.723698
    two     NaN
baz  one   -0.989859
    two     NaN
foo  one    1.443110
    two     NaN
qux  one   -2.079150
    two     NaN
dtype: float64
```

The `reindex()` method of `Series/DataFrames` can be called with another `MultiIndex`, or even a list or array of tuples:

```python
In [37]: s.reindex(index[:3])
Out[37]:
first  second
bar  one    -0.861849
    two   -2.104569
baz  one   -0.494929
dtype: float64
```

```python
In [38]: s.reindex([("foo", "two"), ("bar", "one"), ("qux", "one"), ("baz", "one")])
Out[38]:
foo  two    -0.706771
bar  one    -0.861849
qux  one   -1.039575
baz  one   -0.494929
dtype: float64
```
2.6.2 Advanced indexing with hierarchical index

Syntactically integrating MultiIndex in advanced indexing with .loc is a bit challenging, but we’ve made every effort to do so. In general, MultiIndex keys take the form of tuples. For example, the following works as you would expect:

```
In [39]: df = df.T

In [40]: df
Out[40]:
      A     B     C
first second
bar  one  0.895717  0.410835 -1.413681
two  0.805244  0.813850  1.607920
baz  one -1.206412  0.132003  1.024180
two  2.565646 -0.827317  0.569605
foo  one  1.431256 -0.764670  0.875906
two  1.340309 -1.187678 -2.211372
qux  one -1.170299  1.130127  0.974466
two  -0.226169 -1.436737  2.006747
```

```
In [41]: df.loc[('bar', 'two')]
Out[41]:
      A
bar  one  0.805244
      B
bar  two  0.813850
Name: (bar, two), dtype: float64
```

Note that df.loc['bar', 'two'] would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with .loc, you must use a tuple like this:

```
In [42]: df.loc[('bar', 'two'), 'A']
Out[42]: 0.8052440253863785
```

You don’t have to specify all levels of the MultiIndex by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with bar in the first level as follows:

```
In [43]: df.loc["bar"]
Out[43]:
      A     B     C
second
one  0.895717  0.410835 -1.413681
two  0.805244  0.813850  1.607920
```

This is a shortcut for the slightly more verbose notation df.loc[('bar', ),] (equivalent to df.loc['bar',] in this example).

“Partial” slicing also works quite nicely.

```
In [44]: df.loc["baz":"foo"]
Out[44]:
      A     B     C
first second
baz  one -1.206412  0.132003  1.024180
```

(continues on next page)
You can slice with a ‘range’ of values, by providing a slice of tuples.

```
In [45]: df.loc[('baz', 'two'):('qux', 'one')]
Out[45]:
     A    B    C
first second
baz  two  2.565646 -0.827317  0.569605
foo  one  1.431256 -0.076467  0.875906
two  1.340309 -1.187678 -2.211372
qux  one  -1.170299  1.130127  0.974466
```

```
In [46]: df.loc[('baz', 'two'):'foo']
Out[46]:
     A    B    C
first second
baz  two  2.565646 -0.827317  0.569605
foo  one  1.431256 -0.076467  0.875906
two  1.340309 -1.187678 -2.211372
```

Passing a list of labels or tuples works similar to reindexing:

```
In [47]: df.loc[['bar', 'two'], ['qux', 'one']]
Out[47]:
     A    B    C
first second
bar  two  0.805244  0.813850  1.607920
qux  one  -1.170299  1.130127  0.974466
```

**Note:** It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete `MultiIndex` keys, whereas a tuple of lists refer to several values within a level:

```
In [48]: s = pd.Series(  ....: [1, 2, 3, 4, 5, 6],  ....: index=pd.MultiIndex.from_product([['A', 'B'], ['c', 'd', 'e']]),  ....: )
    ....:

In [49]: s.loc[['A', 'c'], ['B', 'd']]  # list of tuples
Out[49]:
     A c  1
B d  5
dtype: int64
```
Using slicers

You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see Selection by Label, including slices, lists of labels, labels, and boolean indexers.

You can use \texttt{slice(\text{None})} to select all the contents of that level. You do not need to specify all the deeper levels, they will be implied as \texttt{slice(\text{None})}.

As usual, \textbf{both sides} of the slicers are included as this is label indexing.

\begin{footnotesize}
\begin{Verbatim}
\begin{Verbatim}
\textbf{Warning:} You should specify all axes in the \texttt{.loc} specifier, meaning the indexer for the \texttt{index} and for the \texttt{columns}. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the \texttt{MultiIndex} for the rows.

You should do this:
\texttt{df.loc[(\texttt{slice("A1", "A3")}, ...), :]} \# \texttt{noqa: E999}
\end{Verbatim}
\end{Verbatim}
\end{footnotesize}

\begin{footnotesize}
\begin{Verbatim}
\begin{Verbatim}
You should \textbf{not} do this:
\texttt{df.loc[(\texttt{slice("A1", "A3")}, ...)]} \# \texttt{noqa: E999}
\end{Verbatim}
\end{Verbatim}
\end{footnotesize}

\begin{footnotesize}
\begin{Verbatim}
\begin{Verbatim}
In [50]: s.loc(["A", "B"], ["c", "d"]) \# tuple of lists
Out[50]:
   A  c  1
   d  2
   B  c  4
   d  5
dtype: int64
\end{Verbatim}
\end{Verbatim}
\end{footnotesize}
### Basic MultiIndex slicing using slices, lists, and labels.

```python
In [56]: dfmi.loc[(slice("A1", "A3"), slice(None), ["C1", "C3"]), :]
Out[56]:
   a  b
  lvl0  
  lvl1 bar foo bah foo
A0 B0 C0 D0  1  0  3  2
D1  5  4  7  6
C1 D0  9  8 11 10
D1  13 12 15 14
C2 D0  17 16 19 18
... ... ... ... ...
A3 B1 C1 D1 237 236 239 238
C2 D0 241 240 243 242
D1 245 244 247 246
C3 D0 249 248 251 250
D1 253 252 255 254
[24 rows x 4 columns]
```

You can use `pandas.IndexSlice` to facilitate a more natural syntax using `:` rather than using `slice(None)`.

```python
In [57]: idx = pd.IndexSlice
In [58]: dfmi.loc[idx[:, :, ["C1", "C3"]], idx[:, "foo"]]
Out[58]:
  a  b
  lvl0  
  lvl1 bar foo bah foo
A0 B0 C0 D0  1  0  3  2
D1  5  4  7  6
C1 D0  9  8 11 10
D1  13 12 15 14
C2 D0  17 16 19 18
... ... ... ... ...
A3 B1 C1 D1 237 236 239 238
C2 D0 241 240 243 242
D1 245 244 247 246
C3 D0 249 248 251 250
D1 253 252 255 254
[64 rows x 4 columns]
```
It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [59]: dfmi.loc["A1", (slice(None), "foo")]
Out[59]:
lvl0  a  b
lvl1 foo foo
B0  C0 D0  64  66
   D1  68  70
   C1 D0  72  74
   D1  76  78
   C2 D0  80  82
...
B1  C1 D1 108 110
C2  D0 112 114
   D1 116 118
   C3 D0 120 122
   D1 124 126
[16 rows x 2 columns]
```

```
In [60]: dfmi.loc[idx[:, :, ["C1", "C3"]], idx[:, "foo"]]
Out[60]:
lvl0  a  b
lvl1 foo foo
A0  B0 C1 D0  8  10
   D1  12  14
   C3 D0  24  26
   D1  28  30
   B1 C1 D0  40  42
...
A3  B0 C3 D1 220 222
B1  C1 D0 232 234
   D1 236 238
   C3 D0 248 250
   D1 252 254
```

Using a boolean indexer you can provide selection related to the values.

```python
In [61]: mask = dfmi["a", "foo"] > 200

In [62]: dfmi.loc[idx[mask, :, ["C1", "C3"]], idx[:, "foo"]]
```

```
Out[62]:
        lvl0 a   b
        lvl1 foo foo
      A3  B0  C1  D1  204  206
          C3  D0  216  218
          D1  220  222
      B1  C1  D0  232  234
          D1  236  238
          C3  D0  248  250
          D1  252  254
```

You can also specify the axis argument to .loc to interpret the passed slicers on a single axis.

```python
In [63]: dfmi.loc(axis=0)[(:, :, ["C1", "C3"])]
```

```
Out[63]:
        lvl0 a   b
        lvl1   foo foo
      A0  B0  C1  D0   9   8
          D1  13  12  15  14
      C3  D0  25  24  27  26
          D1  29  28  31  30
      B1  C1  D0  41  40  43  42
      ... ... ... ... ...
      A3  B0  C3  D1  221  220  223  222
      B1  C1  D0  233  232  235  234
          D1  237  236  239  238
      C3  D0  249  248  251  250
          D1  253  252  255  254
```

[32 rows x 4 columns]

Furthermore, you can set the values using the following methods.

```python
In [64]: df2 = dfmi.copy()

In [65]: df2.loc(axis=0)[(:, :, ["C1", "C3"])] = -10

In [66]: df2
```

```
Out[66]:
        lvl0 a   b
        lvl1   foo foo
      A0  B0  C0  D0   1   0
          D1   5   4   7
      C1  D0 -10 -10 -10 -10
          D1 -10 -10 -10 -10
      C2  D0  17  16  19  18
```

(continues on next page)
You can use a right-hand-side of an alignable object as well.

In [67]: df2 = dfmi.copy()

In [68]: df2.loc[idx[:, :,  ['C1', 'C3']], :] = df2 * 1000

In [69]: df2

Out[69]:
lvl0    a    b
lvl1    bar  foo  bah  foo
A0      B0  C0  D0         1   0   3   2
      D1     5    4    7    6
  C1     D0     9000  8000 11000 10000
  D1    13000 12000 15000 14000
  C2     D0     17    16    19    18
...  ...  ...  ...  ...  ...
A3  B1  C1  D1     237000 236000 239000 238000
  C2  D0     241    240    243    242
  D1     245    244    247    246
  C3  D0     249000 248000 251000 250000
  D1    253000 252000 255000 254000

[64 rows x 4 columns]

Cross-section

The xs() method of DataFrame additionally takes a level argument to make selecting data at a particular level of a MultiIndex easier.

In [70]: df

Out[70]:
   A    B    C
first second
bar  one  -0.895717  0.410835 -1.413681
     two  -0.805244  0.813850  1.607920
baz  one  -1.206412  0.132003  1.024180
     two   2.565646 -0.827317  0.569605
foo  one   1.431256 -0.076467  0.875906
     two   1.340309 -1.187678 -2.211372
qux  one  -1.170299  1.130127  0.974466
     two  -0.226169 -1.436737 -2.006747

(continues on next page)
In [71]: df.xs("one", level="second")
Out[71]:
first  A      B      C
bar   0.895717 0.410835 -1.413681
baz  -1.206412 0.132003  1.024180
foo   1.431256 -0.076467  0.875906
qux  -1.170299 1.130127  0.974466

# using the slicers
In [72]: df.loc[(slice(None), "one"), :]
Out[72]:
first second  A      B      C
bar    one   0.895717 0.410835 -1.413681
baz    one  -1.206412 0.132003  1.024180
foo    one   1.431256 -0.076467  0.875906
qux    one  -1.170299 1.130127  0.974466

You can also select on the columns with xs, by providing the axis argument.

In [73]: df = df.T
In [74]: df.xs("one", level="second", axis=1)
Out[74]:
first  bar  baz  foo  qux
A     0.895717 -1.206412  1.431256 -1.170299
B     0.410835  0.132003 -0.076467  1.130127
C    -1.413681  1.024180  0.875906  0.974466

# using the slicers
In [75]: df.loc[:, (slice(None), "one")]
Out[75]:
first second one one one one
A     0.895717 -1.206412  1.431256 -1.170299
B     0.410835  0.132003 -0.076467  1.130127
C    -1.413681  1.024180  0.875906  0.974466

xs also allows selection with multiple keys.

In [76]: df.xs(("one", "bar"), level=("second", "first"), axis=1)
Out[76]:
first   bar
A  0.895717
B  0.410835
C -1.413681

# using the slicers
In [77]: df.loc[:, ("bar", "one")]
Out[77]:
You can pass `drop_level=False` to `xs` to retain the level that was selected.

```
In [78]: df.xs("one", level="second", axis=1, drop_level=False)
Out[78]:
first  bar  baz  foo  qux
   second  one  one  one  one
     A  0.895717 -1.206412 1.431256 -1.170299
     B  0.410835  0.132003 -0.076467  1.130127
     C -1.413681  1.024180  0.875906  0.974466
```

Compare the above with the result using `drop_level=True` (the default value).

```
In [79]: df.xs("one", level="second", axis=1, drop_level=True)
Out[79]:
first  bar  baz  foo  qux
   A  0.895717 -1.206412 1.431256 -1.170299
   B  0.410835  0.132003 -0.076467  1.130127
   C -1.413681  1.024180  0.875906  0.974466
```

### Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```
In [80]: midx = pd.MultiIndex(
                           .....:     levels=["zero", "one"], ["x", "y"],
                           .....:     codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
                           .....: )
In [81]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)
In [82]: df
Out[82]:
   0    1
one  y  1.519970 -0.493662
   x  0.600178  0.274230
zero y  0.132885 -0.023688
   x  2.410179  1.450520
In [83]: df2 = df.groupby(level=0).mean()
In [84]: df2
Out[84]:
   0    1
one  y  1.060074 -0.109716
   x  0.600074 -0.109716
zero y  1.271532  0.713416
```

(continues on next page)
In [85]: df2.reindex(df.index, level=0)
Out[85]:
     0  1
one y 1.060074 -0.109716
     x 1.060074 -0.109716
zero y 1.271532  0.713416
     x 1.271532  0.713416

# aligning
In [86]: df_aligned, df2_aligned = df.align(df2, level=0)

In [87]: df_aligned
Out[87]:
     0  1
one y 1.519970 -0.493662
     x 0.600178  0.274230
zero y 0.132885 -0.023688
     x 2.410179  1.450520

In [88]: df2_aligned
Out[88]:
     0  1
one y 1.060074 -0.109716
     x 1.060074 -0.109716
zero y 1.271532  0.713416
     x 1.271532  0.713416

Swapping levels with swaplevel

The `swaplevel()` method can switch the order of two levels:

In [89]: df[:5]
Out[89]:
     0  1
one y 1.519970 -0.493662
     x 0.600178  0.274230
zero y 0.132885 -0.023688
     x 2.410179  1.450520

In [90]: df[:5].swaplevel(0, 1, axis=0)
Out[90]:
      0  1
y one 1.519970 -0.493662
     x 0.600178  0.274230
y zero 0.132885 -0.023688
     x 2.410179  1.450520
Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```python
In [91]: df[:5].reorder_levels([1, 0], axis=0)
Out[91]:
   0    1
y one 1.519970 -0.493662
  x one 0.600178 0.274230
y zero 0.132885 -0.023688
  x zero 2.410179 1.450520
```

Renaming names of an Index or MultiIndex

The `rename()` method is used to rename the labels of a `MultiIndex`, and is typically used to rename the columns of a `DataFrame`. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```python
In [92]: df.rename(columns={0: "col0", 1: "col1"})
Out[92]:
   col0  col1
  one y  1.519970 -0.493662
     x  0.600178  0.274230
  zero y  0.132885 -0.023688
     x  2.410179  1.450520
```

This method can also be used to rename specific labels of the main index of the `DataFrame`.

```python
In [93]: df.rename(index={"one": "two", "y": "z"})
Out[93]:
   0    1
two z  1.519970 -0.493662
     x  0.600178  0.274230
zero z  0.132885 -0.023688
     x  2.410179  1.450520
```

The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a `MultiIndex` can be specified, which is useful if `reset_index()` is later used to move the values from the `MultiIndex` to a column.

```python
In [94]: df.rename_axis(index=["abc", "def"])
Out[94]:
   0    1
abc   def
one y  1.519970 -0.493662
     x  0.600178  0.274230
zero y  0.132885 -0.023688
     x  2.410179  1.450520
```

Note that the columns of a `DataFrame` are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.
Both `rename` and `rename_axis` support specifying a dictionary, Series or a mapping function to map labels/names to new values.

When working with an `Index` object directly, rather than via a `DataFrame`, `Index.set_names()` can be used to change the names.

```python
In [96]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])

In [97]: mi.names
Out[97]: FrozenList(['x', 'y'])

In [98]: mi2 = mi.rename("new name", level=0)

In [99]: mi2
Out[99]: MultiIndex([(1, 'a'),
          (1, 'b'),
          (2, 'a'),
          (2, 'b')],
          names=['new name', 'y'])
```

You cannot set the names of the `MultiIndex` via a level.

```python
In [100]: mi.levels[0].name = "name via level"
```

```
File /pandas/pandas/core/indexes/base.py:1661, in Index.name(self, value)
    1657             @name.setter
    1658         def name(self, value: Hashable):
    1659             if self._no_setting_name:
    1660                 # Used in MultiIndex.levels to avoid silently ignoring name updates.
    1661                 raise RuntimeError(
    1662                     "Cannot set name on a level of a MultiIndex. Use 
    1663                     'MultiIndex.set_names' instead."
    1664             )
    1665             maybe_extract_name(value, None, type(self))
    1666             self._name = value

RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names' instead.
```

Use `Index.set_names()` instead.
2.6.3 Sorting a MultiIndex

For MultiIndex-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```python
In [101]: import random

In [102]: random.shuffle(tuples)

In [103]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))

In [104]: s
Out[104]:
baz two   0.206053
qux two  -0.251905
foo one  -2.213588
bar one   1.063327
qux one  1.266143
baz one   0.299368
bar two  -0.863838
foo two   0.408204
dtype: float64

In [105]: s.sort_index()
Out[105]:
bar one   1.063327
baz one   0.299368
foo one  -2.213588
qux one  1.266143
bar two  -0.863838
baz two   0.206053
foo two   0.408204
qux two  -0.251905
dtype: float64

In [106]: s.sort_index(level=0)
Out[106]:
bar one   1.063327
two -0.863838
baz one   0.299368
two 0.206053
foo one  -2.213588
two 0.408204
qux one  1.266143
two -0.251905
dtype: float64

In [107]: s.sort_index(level=1)
Out[107]:
bar one   1.063327
baz one   0.299368
foo one  -2.213588
qux one  1.266143
```

(continues on next page)
You may also pass a level name to `sort_index` if the MultiIndex levels are named.

```python
In [108]: s.index.set_names(["L1", "L2"], inplace=True)

In [109]: s.sort_index(level="L1")
Out[109]:
L1  L2
bar one  1.063327
        two -0.863838
baz one  0.299368
        two  0.206053
foo one  -2.213588
        two  0.408204
qux one  1.266143
        two -0.251905
dtype: float64

In [110]: s.sort_index(level="L2")
Out[110]:
L1  L2
bar one  1.063327
baz one  0.299368
foo one  -2.213588
qux one  1.266143
bar two -0.863838
baz two  0.206053
foo two  0.408204
qux two -0.251905
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a MultiIndex:

```python
In [111]: df.T.sort_index(level=1, axis=1)
Out[111]:
    one  zero  one  zero
     x     y     x     y
0   1.519970  0.132885  2.410179  0.600178
1  -0.493662 -0.023688  -0.023688  1.450520
```

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```python
In [112]: dfm = pd.DataFrame(
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:

    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
    .....:     .....:
In [113]: dfm = dfm.set_index(['jim', 'joe'])

In [114]: dfm
Out[114]:

<table>
<thead>
<tr>
<th></th>
<th>jim</th>
<th>joe</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>0.490671</td>
<td></td>
</tr>
<tr>
<td>y</td>
<td>0.120248</td>
<td>0.110968</td>
</tr>
<tr>
<td>z</td>
<td>0.537020</td>
<td></td>
</tr>
</tbody>
</table>

Furthermore, if you try to index something that is not fully lexsord, this can raise:

In [4]: dfm.loc[(0, 'y'):(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.

Out[4]:

<table>
<thead>
<tr>
<th></th>
<th>jim</th>
<th>joe</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>0.490671</td>
<td></td>
<td>0.120248</td>
</tr>
<tr>
<td>y</td>
<td>0.110968</td>
<td>0.537020</td>
<td></td>
</tr>
</tbody>
</table>

The is_monotonic_increasing() method on a MultiIndex shows if the index is sorted:

In [115]: dfm.index.is_monotonic_increasing
Out[115]: False

In [116]: dfm = dfm.sort_index()

In [117]: dfm
Out[117]:

<table>
<thead>
<tr>
<th></th>
<th>jim</th>
<th>joe</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>0.490671</td>
<td></td>
</tr>
<tr>
<td>y</td>
<td>0.110968</td>
<td>0.537020</td>
</tr>
<tr>
<td>z</td>
<td>0.120248</td>
<td></td>
</tr>
</tbody>
</table>

In [118]: dfm.index.is_monotonic_increasing
Out[118]: True

And now selection works as expected.

In [119]: dfm.loc[(0, 'y'):(1, 'z')]
Out[119]:

<table>
<thead>
<tr>
<th></th>
<th>jim</th>
<th>joe</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>0.490671</td>
<td></td>
<td>0.120248</td>
</tr>
<tr>
<td>y</td>
<td>0.110968</td>
<td>0.537020</td>
<td></td>
</tr>
</tbody>
</table>

2.6. MultiIndex / advanced indexing
2.6.4 Take methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [120]: index = pd.Index(np.random.randint(0, 1000, 10))
In [121]: index
Out[121]: Int64Index([214, 502, 712, 567, 786, 175, 993, 133, 758, 329], dtype='int64')
In [122]: positions = [0, 9, 3]
In [123]: index[positions]
Out[123]: Int64Index([214, 329, 567], dtype='int64')
In [124]: index.take(positions)
Out[124]: Int64Index([214, 329, 567], dtype='int64')
```

```
In [125]: ser = pd.Series(np.random.randn(10))
In [126]: ser.iloc[positions]
Out[126]:
0  -0.179666
9   1.824375
3   0.392149
dtype: float64
In [127]: ser.take(positions)
Out[127]:
0  -0.179666
9   1.824375
3   0.392149
dtype: float64
```

```
In [128]: frm = pd.DataFrame(np.random.randn(5, 3))
In [129]: frm.take([1, 4, 3])
Out[129]:
    0   1   2
0 -1.237881 0.106854 -1.276829
1  0.629675 -1.425966  1.857704
3  0.979542 -1.633678  0.615855
In [130]: frm.take([0, 2], axis=1)
Out[130]:
    0  2
0  0.595974 0.601544
1 -1.237881 -1.276829
2 -0.767101  1.499591
3  0.979542  0.615855
4  0.629675  1.857704
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [128]: frm = pd.DataFrame(np.random.randn(5, 3))
In [129]: frm.take([1, 4, 3])
Out[129]:
    0   1   2
0 -1.237881 0.106854 -1.276829
1  0.629675 -1.425966  1.857704
3  0.979542 -1.633678  0.615855
In [130]: frm.take([0, 2], axis=1)
Out[130]:
    0  2
0  0.595974 0.601544
1 -1.237881 -1.276829
2 -0.767101  1.499591
3  0.979542  0.615855
4  0.629675  1.857704
```
It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```
In [131]: arr = np.random.randn(10)

In [132]: arr.take([False, False, True, True])
Out[132]: array([-1.1935, -1.1935,  0.6775,  0.6775])

In [133]: arr[[0, 1]]
Out[133]: array([-1.1935,  0.6775])

In [134]: ser = pd.Series(np.random.randn(10))

In [135]: ser.take([False, False, True, True])
Out[135]:
   0   0.233141
   1  -0.223540
   dtype: float64

In [136]: ser.iloc[[0, 1]]
Out[136]:
   0   0.233141
   1  -0.223540
   dtype: float64
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

```
In [137]: arr = np.random.randn(10000, 5)

In [138]: indexer = np.arange(10000)

In [139]: random.shuffle(indexer)

In [140]: %timeit arr[indexer]
   ....: %timeit arr.take(indexer, axis=0)
   ....:
210 us +- 12.5 us per loop (mean +- std. dev. of 7 runs, 1,000 loops each)
63.6 us +- 6.41 us per loop (mean +- std. dev. of 7 runs, 10,000 loops each)

In [141]: ser = pd.Series(arr[:, 0])

In [142]: %timeit ser.iloc[indexer]
   ....: %timeit ser.take(indexer)
   ....:
99.2 us +- 9.69 us per loop (mean +- std. dev. of 7 runs, 10,000 loops each)
92.6 us +- 6.58 us per loop (mean +- std. dev. of 7 runs, 10,000 loops each)
```
2.6.5 Index types

We have discussed MultiIndex in the previous sections pretty extensively. Documentation about DatetimeIndex and PeriodIndex are shown here, and documentation about TimedeltaIndex is found here.

In the following sub-sections we will highlight some other index types.

CategoricalIndex

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [143]: from pandas.api.types import CategoricalDtype

In [144]: df = pd.DataFrame({'A': np.arange(6), 'B': list('aabbc')})

In [145]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))  

In [146]: df
Out[146]:  
   A  B
  -----
   0 0 a
   1 1 a
   2 2 b
   3 3 b
   4 4 c
   5 5 a

In [147]: df.dtypes
Out[147]:  
   A     int64
   B   category
dtype: object

In [148]: df['B'].cat.categories
Out[148]: Index(['c', 'a', 'b'], dtype='object')
```

Setting the index will create a CategoricalIndex.

```
In [149]: df2 = df.set_index('B')

In [150]: df2.index
Out[150]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'b'], categories=['c', 'a', 'b'],  
ordered=False, dtype='category', name='B')
```

Indexing with __getitem__/.iloc/.loc works similarly to an Index with duplicates. The indexers must be in the category or the operation will raise a KeyError.

```
In [151]: df2.loc['a']
Out[151]:  
   A  
   B  
   a  0
```

The `CategoricalIndex` is **preserved** after indexing:

```python
In [152]: df2.loc["a"].index
Out[152]: CategoricalIndex(["a", "a", "a"], categories=["c", "a", "b"], ordered=False,
                      dtype='category', name='B')
```

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(['cab'])`, so the sorted order is `cab`).

```python
In [153]: df2.sort_index()
```

Groupby operations on the index will preserve the index nature as well.

```python
In [154]: df2.groupby(level=0).sum()
Out[154]:
   A  B
   c 4
   a 0
   a 1
   a 5
   b 2
   b 3
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old `Index`; indexing with a `Categorical` will return a `CategoricalIndex`, indexed according to the categories of the passed `Categorical` dtype. This allows one to arbitrarily index these even with values **not** in the categories, similarly to how you can reindex any pandas index.

```python
In [156]: df3 = pd.DataFrame(
      .....:     {"A": np.arange(3), "B": pd.Series(list("abc")).astype("category")}
      .....: )
      .....:
In [157]: df3 = df3.set_index("B")

In [158]: df3
Out[158]:
   A  B
   0 1
   1 2
   2 3
```

 switched to category index.
In [159]: df3.reindex(["a", "e"])
Out[159]:
   A  B
a 0.0
e NaN

In [160]: df3.reindex(["a", "e"]).index
Out[160]: Index(["a", "e"], dtype='object', name='B')

In [161]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe")))
Out[161]:
   A  B
a 0.0
e NaN

In [162]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe"))).index
Out[162]: CategoricalIndex(["a", "e"], categories=["a", "b", "e"], ordered=False, dtype='category', name='B')

Warning: Reshaping and Comparison operations on a CategoricalIndex must have the same categories or a TypeError will be raised.

In [163]: df4 = pd.DataFrame({"A": np.arange(2), "B": list("ba")})

In [164]: df4["B"] = df4["B"].astype(CategoricalDtype(list("ab")))

In [165]: df4 = df4.set_index("B")

In [166]: df4.index
Out[166]: CategoricalIndex(["b", "a"], categories=["a", "b"], ordered=False, dtype='category', name='B')

In [167]: df5 = pd.DataFrame({"A": np.arange(2), "B": list("bc")})

In [168]: df5["B"] = df5["B"].astype(CategoricalDtype(list("bc")))

In [169]: df5 = df5.set_index("B")

In [170]: df5.index
Out[170]: CategoricalIndex(["b", "c"], categories=["b", "c"], ordered=False, dtype='category', name='B')

In [1]: pd.concat([df4, df5])
TypeError: categories must match existing categories when appending
Int64Index and RangeIndex

 Deprecated since version 1.4.0: In pandas 2.0, `Index` will become the default index type for numeric types instead of `Int64Index`, `Float64Index` and `UInt64Index` and those index types are therefore deprecated and will be removed in a future version. `RangeIndex` will not be removed, as it represents an optimized version of an integer index.

`Int64Index` is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set.

`RangeIndex` is a sub-class of `Int64Index` that provides the default index for all `NDFrame` objects. `RangeIndex` is an optimized version of `Int64Index` that can represent a monotonic ordered set. These are analogous to Python `range` types.

Float64Index

 Deprecated since version 1.4.0: `Index` will become the default index type for numeric types in the future instead of `Int64Index`, `Float64Index` and `UInt64Index` and those index types are therefore deprecated and will be removed in a future version of Pandas. `RangeIndex` will not be removed as it represents an optimized version of an integer index.

 By default a `Float64Index` will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes [], `ix`, `loc` for scalar indexing and slicing work exactly the same.

```
In [171]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])

In [172]: indexf
Out[172]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [173]: sf = pd.Series(range(5), index=indexf)

In [174]: sf
Out[174]:
1.5  0
2.0  1
3.0  2
4.5  3
5.0  4
dtype: int64
```

Scalar selection for [], `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```
In [175]: sf[3]
Out[175]: 2

In [176]: sf[3.0]
Out[176]: 2

In [177]: sf.loc[3]
Out[177]: 2

In [178]: sf.loc[3.0]
Out[178]: 2
```

2.6. MultiIndex / advanced indexing
The only positional indexing is via \texttt{iloc}.

\begin{verbatim}
In [179]: sf.iloc[3]
Out[179]: 3
\end{verbatim}

A scalar index that is not found will raise a \texttt{KeyError}. Slicing is primarily on the values of the index when using \texttt{[],ix,loc}, and \texttt{always} positional when using \texttt{iloc}. The exception is when the slice is boolean, in which case it will always be positional.

\begin{verbatim}
In [180]: sf[2:4]
Out[180]:
   2.0  1
   3.0  2
   dtype: int64

In [181]: sf.loc[2:4]
Out[181]:
   2.0  1
   3.0  2
   dtype: int64

In [182]: sf.iloc[2:4]
Out[182]:
   3.0  2
   4.5  3
   dtype: int64
\end{verbatim}

In float indexes, slicing using floats is allowed.

\begin{verbatim}
In [183]: sf[2.1:4.6]
Out[183]:
   3.0  2
   4.5  3
   dtype: int64

In [184]: sf.loc[2.1:4.6]
Out[184]:
   3.0  2
   4.5  3
   dtype: int64
\end{verbatim}

In non-float indexes, slicing using floats will raise a \texttt{TypeError}.

\begin{verbatim}
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type (Int64Index)
\end{verbatim}

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

\begin{verbatim}
In [185]: dfir = pd.concat([...
   .....:   [...
\end{verbatim}
Selection operations then will always work on a value basis, for all selection operators.

In [187]: dfir[0:1000.4]
Out[187]:

<table>

</tr>
</tbody>
</table>

Name: A, dtype: float64

In [189]: dfir.loc[1000.4]
Out[189]:

(continues on next page)
You could retrieve the first 1 second (1000 ms) of data as such:

```
In [190]: dfir[0:1000]
Out[190]:
   A       B
0  0.0 -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243407  0.514704
1000.0  1.162969 -0.287725
```

If you need integer based selection, you should use `iloc`:

```
In [191]: dfir.iloc[0:5]
Out[191]:
   A       B
0  0.0 -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243487  0.514704
1000.0  1.162969 -0.287725
```

**IntervalIndex**

`IntervalIndex` together with its own dtype, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

**Indexing with an IntervalIndex**

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```
In [192]: df = pd.DataFrame(      ....:     {"A": [1, 2, 3, 4]}, index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4])
      ....: )
      ....:

In [193]: df
Out[193]:
   A
(0, 1] 1
(1, 2] 2
(2, 3] 3
(3, 4] 4
```
Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [194]: df.loc[2]
Out[194]:
   A  2
Name: (1, 2], dtype: int64

In [195]: df.loc[[2, 3]]
Out[195]:
   A
(1, 2]  2
(2, 3]  3
```

If you select a label contained within an interval, this will also select the interval.

```
In [196]: df.loc[2.5]
Out[196]:
   A  3
Name: (2, 3], dtype: int64

In [197]: df.loc[[2.5, 3.5]]
Out[197]:
   A
(2, 3]  3
(3, 4]  4
```

Selecting using an `Interval` will only return exact matches (starting from pandas 0.25.0).

```
In [198]: df.loc[pd.Interval(1, 2)]
Out[198]:
   A  2
Name: (1, 2], dtype: int64

In [7]: df.loc[pd.Interval(0.5, 2.5)]
---------------------------------------------------------------------------
KeyError: Interval(0.5, 2.5, closed='right')
```

Selecting all `Intervals` that overlap a given `Interval` can be performed using the `overlaps()` method to create a boolean indexer.

```
In [199]: idxr = df.index.overlaps(pd.Interval(0.5, 2.5))
In [200]: idxr
Out[200]: array([ True, True, True, False])

In [201]: df[idxr]
Out[201]:
   A
(0, 1]  1
(1, 2]  2
(2, 3]  3
```

---

### 2.6. Multiindex / advanced indexing

501
Binning data with cut and qcut

cut() and qcut() both return a Categorical object, and the bins they create are stored as an IntervalIndex in its .categories attribute.

```python
In [202]: c = pd.cut(range(4), bins=2)

In [203]: c
Out[203]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64, right]): [(-0.003, 1.5] < (1.5, 3.0]]

In [204]: c.categories
Out[204]: IntervalIndex([-0.003, 1.5], (1.5, 3.0]], dtype='interval[float64, right]')
```

cut() also accepts an IntervalIndex for its bins argument, which enables a useful pandas idiom. First, We call cut() with some data and bins set to a fixed number, to generate the bins. Then, we pass the values of .categories as the bins argument in subsequent calls to cut(), supplying new data which will be binned into the same bins.

```python
In [205]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[205]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64, right]): [(-0.003, 1.5] < (1.5, 3.0]]
```

Any value which falls outside all bins will be assigned a NaN value.

Generating ranges of intervals

If we need intervals on a regular frequency, we can use the interval_range() function to create an IntervalIndex using various combinations of start, end, and periods. The default frequency for interval_range is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```python
In [206]: pd.interval_range(start=0, end=5)
Out[206]: IntervalIndex([0, 1, 2, 3, 4, 5], dtype='interval[int64, right]')

In [207]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4)
Out[207]: IntervalIndex(["2017-01-01", "2017-01-02", "2017-01-03", "2017-01-04"], dtype='interval[datetime64[ns], right]')

In [208]: pd.interval_range(end=pd.Timedelta("3 days"), periods=3)
Out[208]: IntervalIndex([0 days 00:00:00, 1 days 00:00:00, 2 days 00:00:00], dtype='interval[timedelta64[ns], right]')
```

The freq parameter can used to specify non-default frequencies, and can utilize a variety of frequency aliases with datetime-like intervals:

```python
In [209]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[209]: IntervalIndex([0.0, 1.5], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]], dtype='interval[float64, right]')

In [210]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4, freq="W")
Out[210]: IntervalIndex(["2017-01-08", "2017-01-15", "2017-01-22", "2017-01-29"], dtype='interval[datetime64[ns], right]')
```
In [211]: pd.interval_range(start=pd.Timedelta("0 days"), periods=3, freq="9H")
Out[211]: IntervalIndex([(0 days 00:00:00, 0 days 09:00:00], (0 days 09:00:00, 0 days 18:...
          (0 days 18:00:00, 1 days 03:00:00]], dtype='interval[timedelta64[ns], right]')

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

In [212]: pd.interval_range(start=0, end=4, closed="both")
Out[212]: IntervalIndex([(0, 1], [1, 2], [2, 3], [3, 4]], dtype='interval[int64, both]')

In [213]: pd.interval_range(start=0, end=4, closed="neither")
Out[213]: IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4]], dtype='interval[int64, neither]

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

In [214]: pd.interval_range(start=0, end=6, periods=4)
Out[214]: IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]], dtype='interval[float64, right]')

In [215]: pd.interval_range(pd.Timestamp("2018-01-01"), pd.Timestamp("2018-02-28"),
   ...: periods=3)
Out[215]: IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-
   ...: 02-08 16:00:00], (2018-02-08 16:00:00, 2018-02-28]], dtype='interval[datetime64[ns],
   ...: right]')

2.6.5.6 Miscellaneous indexing FAQ

**Integer indexing**

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index only label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

In [216]: s = pd.Series(range(5))
In [217]: s[-1]
---------------------------------------------------------------------------
ValueError Traceback (most recent call last)
File /pandas/pandas/core/indexes/range.py:385, in RangeIndex.get_loc(self, key, method,
   ...: tolerance)
    384 try:
    385     return self._range.index(new_key)
-> 386 except ValueError as err:
    387     if self._closed:
    388         raise ValueError(err) from err
ValueError: -1 is not in range

The above exception was the direct cause of the following exception:

(continues on next page)
KeyError Traceback (most recent call last)

   389     raise KeyError(key)

KeyError: -1

In [218]: df = pd.DataFrame(np.random.randn(5, 4))

In [219]: df
Out[219]:
    0   1   2   3
0 -0.130121 -0.476046 0.759104 0.213379
1 -0.082641 0.448008 0.656420 -1.051443
2  0.594956 -0.151360 -0.069303 1.221431
3 -0.182832 0.791235 0.042745 2.069775
4  1.446552 0.019814 -1.389212 -0.702312

In [220]: df.loc[-2:]
Out[220]:
    0   1   2   3
0 -0.130121 -0.476046 0.759104 0.213379
1 -0.082641 0.448008 0.656420 -1.051443
2  0.594956 -0.151360 -0.069303 1.221431
3 -0.182832 0.791235 0.042745 2.069775
4  1.446552 0.019814 -1.389212 -0.702312

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).
Non-monotonic indexes require exact matches

If the index of a Series or DataFrame is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

```python
In [221]: df = pd.DataFrame(index=[2, 3, 4, 5], columns=["data"], data=list(range(5)))
In [222]: df.index.is_monotonic_increasing
Out[222]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [223]: df.loc[0:4, :]
Out[223]:
   data
2   0
3   1
3   2
4   3

# slice is are outside the index, so empty DataFrame is returned
In [224]: df.loc[13:15, :]
Out[224]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```python
In [225]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5], columns=["data"],
   ...: data=list(range(6)))
   ...
In [226]: df.index.is_monotonic_increasing
Out[226]: False

# OK because 2 and 4 are in the index
In [227]: df.loc[2:4, :]
Out[227]:
   data
2   0
3   1
1   2
4   3

# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing` and `Index.is_monotonic_decreasing` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with the `is_unique()` attribute.
In [228]: weakly_monotonic = pd.Index(['a', 'b', 'c', 'c'])

In [229]: weakly_monotonic
Out[229]: Index(['a', 'b', 'c', 'c'], dtype='O')

In [230]: weakly_monotonic.is_monotonic_increasing
Out[230]: True

In [231]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique
Out[231]: False

Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas is inclusive. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

In [232]: s = pd.Series(np.random.randn(6), index=list('abcdef'))

In [233]: s
Out[233]:
     a    0.301379
     b    1.240445
     c   -0.846068
     d   -0.043312
     e   -1.658747
     f   -0.819549
dtype: float64

Suppose we wished to slice from c to e, using integers this would be accomplished as such:

In [234]: s[2:5]
Out[234]:
     c   -0.846068
     d   -0.043312
     e   -1.658747

dtype: float64

However, if you only had c and e, determining the next element in the index can be somewhat complicated. For example, the following does not work:

s.loc['c':'e' + 1]

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design choice to make label-based slicing include both endpoints:

In [235]: s.loc['c':'e']
Out[235]:
     c   -0.846068
     d   -0.043312
     e   -1.658747
dtype: float64
This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

## Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [236]: series1 = pd.Series([1, 2, 3])

In [237]: series1.dtype
Out[237]: dtype('int64')

In [238]: res = series1.reindex([0, 4])

In [239]: res.dtype
Out[239]: dtype('float64')

In [240]: res
Out[240]:
0  1.0
4  NaN
```

```
In [241]: series2 = pd.Series([True])

In [242]: series2.dtype
Out[242]: dtype('bool')

In [243]: res = series2.reindex_like(series1)

In [244]: res.dtype
Out[244]: dtype('O')

In [245]: res
Out[245]:
0  True
1  NaN
2  NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as numpy.logical_and.

See the GH2388 for a more detailed discussion.
2.7 Merge, join, concatenate and compare

pandas provides various facilities for easily combining together Series or DataFrame with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

In addition, pandas also provides utilities to compare two Series or DataFrame and summarize their differences.

2.7.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```python
In [1]: df1 = pd.DataFrame(
    ...:     {
    ...:         "B": ["B0", "B1", "B2", "B3"],
    ...:         "C": ["C0", "C1", "C2", "C3"],
    ...:         "D": ["D0", "D1", "D2", "D3"],
    ...:     },
    ...:     index=[0, 1, 2, 3],
    ...: )
...

In [2]: df2 = pd.DataFrame(
    ...:     {
    ...:         "A": ["A4", "A5", "A6", "A7"],
    ...:         "B": ["B4", "B5", "B6", "B7"],
    ...:         "C": ["C4", "C5", "C6", "C7"],
    ...:         "D": ["D4", "D5", "D6", "D7"],
    ...:     },
    ...:     index=[4, 5, 6, 7],
    ...: )
...

In [3]: df3 = pd.DataFrame(
    ...:     {
    ...:         "B": ["B8", "B9", "B10", "B11"],
    ...:         "C": ["C8", "C9", "C10", "C11"],
    ...:         "D": ["D8", "D9", "D10", "D11"],
    ...:     },
    ...:     index=[8, 9, 10, 11],
    ...: )
...

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```
Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```python
pd.concat(
    objs,
    axis=0,
    join="outer",
    ignore_index=False,
    keys=None,
    levels=None,
    names=None,
    verify_integrity=False,
    copy=True,
)
```

- **objs**: a sequence or mapping of Series or DataFrame objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.
- **axis**: {0, 1, ...}, default 0. The axis to concatenate along.
- **join**: {'inner', 'outer'}, default ‘outer’. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- **ignore_index**: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.
• **keys**: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.

• **levels**: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise, they will be inferred from the keys.

• **names**: list, default None. Names for the levels in the resulting hierarchical index.

• **verify_integrity**: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

• **copy**: boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context, many of these arguments don’t make much sense. Let’s revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the **keys** argument:

```python
In [6]: result = pd.concat(frames, keys=["x", "y", "z"])
```

As you can see (if you’ve read the rest of the documentation), the resulting object’s index has a hierarchical index. This means that we can now select out each chunk by key:

```python
In [7]: result.loc["y"]
Out[7]:
A  B  C  D
4  A4 B4 C4 D4
5  A5 B5 C5 D5
6  A6 B6 C6 D6
7  A7 B7 C7 D7
```

As you can see (if you’ve read the rest of the documentation), the resulting object’s index has a hierarchical index. This means that we can now select out each chunk by key:
It's not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```python
frames = [process_your_file(f) for f in files]
result = pd.concat(frames)
```

**Note:** When concatenating DataFrames with named axes, pandas will attempt to preserve these index/column names whenever possible. In the case where all inputs share a common name, this name will be assigned to the result. When the input names do not all agree, the result will be unnamed. The same is true for `MultiIndex`, but the logic is applied separately on a level-by-level basis.

### Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following two ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```python
In [8]: df4 = pd.DataFrame(
   ...:     {
   ...:         "B": ["B2", "B3", "B6", "B7"],
   ...:         "D": ["D2", "D3", "D6", "D7"],
   ...:         "F": ["F2", "F3", "F6", "F7"],
   ...:     },
   ...:     index=[2, 3, 6, 7],
   ...: )
```

```python
In [9]: result = pd.concat([df1, df4], axis=1)
```

Here is the same thing with `join='inner'`:

<table>
<thead>
<tr>
<th>df1</th>
<th>df4</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>A</td>
</tr>
<tr>
<td>0</td>
<td>A0</td>
<td>0 A0 B0 C0 D0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>1 A1 B1 C1 D1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>2 A2 B2 C2 D2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>3 A3 B3 C3 D3</td>
</tr>
<tr>
<td>B</td>
<td>D</td>
<td>B</td>
</tr>
<tr>
<td>0</td>
<td>B</td>
<td>0 A0 B0 C0 D0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>1 A1 B1 C1 D1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>2 A2 B2 C2 D2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>3 A3 B3 C3 D3</td>
</tr>
<tr>
<td>C</td>
<td>D</td>
<td>C</td>
</tr>
<tr>
<td>0</td>
<td>C0</td>
<td>0 A0 B0 C0 D0</td>
</tr>
<tr>
<td>1</td>
<td>C1</td>
<td>1 A1 B1 C1 D1</td>
</tr>
<tr>
<td>2</td>
<td>C2</td>
<td>2 A2 B2 C2 D2</td>
</tr>
<tr>
<td>3</td>
<td>C3</td>
<td>3 A3 B3 C3 D3</td>
</tr>
<tr>
<td>D</td>
<td>F</td>
<td>D</td>
</tr>
<tr>
<td>0</td>
<td>B</td>
<td>0 A0 B0 C0 D0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>1 A1 B1 C1 D1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>2 A2 B2 C2 D2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>3 A3 B3 C3 D3</td>
</tr>
<tr>
<td>2.7. Merge, join, concatenate and compare</td>
<td></td>
<td>511</td>
</tr>
</tbody>
</table>
In [10]: result = pd.concat([df1, df4], axis=1, join="inner")

Lastly, suppose we just wanted to reuse the exact index from the original DataFrame:

In [11]: result = pd.concat([df1, df4], axis=1).reindex(df1.index)

Similarly, we could index before the concatenation:

In [12]: pd.concat([df1, df4.reindex(df1.index)], axis=1)

Out[12]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>B</th>
<th>D</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
<td>C0</td>
<td>D0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
<td>C1</td>
<td>D1</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
<td>C2</td>
<td>D2</td>
<td>B2</td>
<td>D2</td>
<td>F2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
<td>C3</td>
<td>D3</td>
<td>B3</td>
<td>D3</td>
<td>F3</td>
</tr>
</tbody>
</table>

Ignoring indexes on the concatenation axis

For DataFrame objects which don’t have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the ignore_index argument:

In [13]: result = pd.concat([df1, df4], ignore_index=True, sort=False)
Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame objects. The Series will be transformed to DataFrame with the column name as the name of the Series.

\[
\text{In [14]: } s1 = \text{pd.Series(["X0", "X1", "X2", "X3"], name="X")}
\]

\[
\text{In [15]: result = pd.concat([df1, s1], axis=1)}
\]

Note: Since we’re concatenating a Series to a DataFrame, we could have achieved the same result with DataFrame. \text{assign().} To concatenate an arbitrary number of pandas objects (DataFrame or Series), use \text{concat.}

If unnamed Series are passed they will be numbered consecutively.

\[
\text{In [16]: } s2 = \text{pd.Series(["_0", "_1", "_2", "_3"])}
\]

\[
\text{In [17]: result = pd.concat([df1, s2, s2, s2], axis=1)}
\]
Passing `ignore_index=True` will drop all name references.

```
In [18]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new DataFrame based on existing Series. Notice how the default behaviour consists on letting the resulting DataFrame inherit the parent Series’ name, when these existed.

```
In [19]: s3 = pd.Series([0, 1, 2, 3], name="foo")

In [20]: s4 = pd.Series([0, 1, 2, 3])

In [21]: s5 = pd.Series([0, 1, 4, 5])

In [22]: pd.concat([s3, s4, s5], axis=1)
Out[22]:
     0  1  2
0  0  0  0
1  1  1  1
2  2  2  4
3  3  3  5
```

Through the `keys` argument we can override the existing column names.

```
In [23]: pd.concat([s3, s4, s5], axis=1, keys=["red", "blue", "yellow")
Out[23]:
     red  blue  yellow
0     0     0     0
1     1     1     1
2     2     2     4
3     3     3     5
```
Let's consider a variation of the very first example presented:

```
In [24]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [25]: pieces = {'x': df1, 'y': df2, 'z': df3}

In [26]: result = pd.concat(pieces)
```
In [27]: result = pd.concat(pieces, keys=['z', 'y'])

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:
In [28]: result.index.levels
Out[28]: FrozenList([[‘z’, ‘y’], [4, 5, 6, 7, 8, 9, 10, 11]])

If you wish to specify other levels (as will occasionally be the case), you can do so using the levels argument:

In [29]: result = pd.concat(
       ....:     pieces, keys=[“x”, “y”, “z”], levels=[[“z”, “y”, “x”, “w”]], names=[“group_ →key”]
       ....: )
       ....:

2.7. Merge, join, concatenate and compare

This is fairly esoteric, but it is actually necessary for implementing things like GroupBy where the order of a categorical variable is meaningful.
Appending rows to a DataFrame

If you have a series that you want to append as a single row to a DataFrame, you can convert the row into a DataFrame and use concat:

```
In [31]: s2 = pd.Series(["X0", "X1", "X2", "X3"], index=["A", "B", "C", "D"])
In [32]: result = pd.concat([df1, s2.to_frame().T], ignore_index=True)
```

You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

2.7.2 Database-style DataFrame or named Series joining/merging

pandas has full-featured, high performance in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the cookbook for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a comparison with SQL.

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between DataFrame or named Series objects:

```
pd.merge(
    left,
    right,
    how="inner",
    on=None,
    left_on=None,
    right_on=None,
    left_index=False,
    right_index=False,
    sort=True,
    (continues on next page)
```
suffixes="("_x", "_y")",
copy=True,
indicator=False,
validate=None,
)

- **left**: A DataFrame or named Series object.
- **right**: Another DataFrame or named Series object.
- **on**: Column or index level names to join on. Must be found in both the left and right DataFrame and/or Series objects. If not passed and left_index and right_index are False, the intersection of the columns in the DataFrames and/or Series will be inferred to be the join keys.
- **left_on**: Columns or index levels from the left DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **right_on**: Columns or index levels from the right DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **left_index**: If True, use the index (row labels) from the left DataFrame or Series as its join key(s). In the case of a DataFrame or Series with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame or Series.
- **right_index**: Same usage as left_index for the right DataFrame or Series
- **how**: One of 'left', 'right', 'outer', 'inner', 'cross'. Defaults to inner. See below for more detailed description of each method.
- **sort**: Sort the result DataFrame by the join keys in lexicographical order. Defaults to True, setting to False will improve performance substantially in many cases.
- **suffixes**: A tuple of string suffixes to apply to overlapping columns. Defaults to ('_x', '_y').
- **copy**: Always copy data (default True) from the passed DataFrame or named Series objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- **indicator**: Add a column to the output DataFrame called _merge with information on the source of each row. _merge is Categorical-type and takes on a value of left_only for observations whose merge key only appears in 'left' DataFrame or Series, right_only for observations whose merge key only appears in 'right' DataFrame or Series, and both if the observation's merge key is found in both.
- **validate**: string, default None. If specified, checks if merge is of specified type.
  - “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
  - “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
  - “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
  - “many_to_many” or “m:m”: allowed, but does not result in checks.

**Note**: Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0. Support for merging named Series objects was added in version 0.24.0.

The return type will be the same as left. If left is a DataFrame or named Series and right is a subclass of DataFrame, the return type will still be DataFrame.
merge is a function in the pandas namespace, and it is also available as a DataFrame instance method `merge()`, with the calling DataFrame being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use DataFrame.join to save yourself some typing.

**Brief primer on merge methods (relational algebra)**

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (DataFrame objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two DataFrame objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different DataFrame.
- **many-to-many** joins: joining columns on columns.

**Note:** When joining columns on columns (potentially a many-to-many join), any indexes on the passed DataFrame objects will be discarded.

It is worth spending some time understanding the result of the many-to-many join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the Cartesian product of the associated data. Here is a very basic example with one unique key combination:

```python
In [33]: left = pd.DataFrame(
    ....:     
    ....:         
    ....:

    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
    ....:         
```
Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```python
In [36]: left = pd.DataFrame(
    ...:     {
    ...:         "key1": ["K0", "K0", "K1", "K2"],
    ...:         "key2": ["K0", "K1", "K0", "K1"],
    ...:         "B": ["B0", "B1", "B2", "B3"],
    ...:     }
    ...: )
```

```python
In [37]: right = pd.DataFrame(
    ...:     {
    ...:         "key1": ["K0", "K1", "K1", "K2"],
    ...:         "key2": ["K0", "K0", "K0", "K0"],
    ...:         "C": ["C0", "C1", "C2", "C3"],
    ...:         "D": ["D0", "D1", "D2", "D3"],
    ...:     }
    ...: )
```

```python
In [38]: result = pd.merge(left, right, on="["key1", "key2"]")
```

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination does not appear in either the left or right tables, the values in the joined table will be `NA`. Here is a summary of the `how` options and their SQL equivalent names:
Merge method | SQL Join Name         | Description                                    |
-------------|----------------------|------------------------------------------------|
left         | LEFT OUTER JOIN      | Use keys from left frame only                  |
right        | RIGHT OUTER JOIN     | Use keys from right frame only                 |
outer        | FULL OUTER JOIN      | Use union of keys from both frames             |
inner        | INNER JOIN           | Use intersection of keys from both frames      |
cross        | CROSS JOIN           | Create the cartesian product of rows of both frames |

In [39]: result = pd.merge(left, right, how="left", on=["key1", "key2"])

In [42]: result = pd.merge(left, right, how="inner", on=['key1', 'key2'])

In [43]: result = pd.merge(left, right, how="cross")

You can merge a multi-indexed Series and a DataFrame, if the names of the MultiIndex correspond to the columns from the DataFrame. Transform the Series to a DataFrame using `Series.reset_index()` before merging, as shown in the following example.

In [44]: df = pd.DataFrame({'Let': ['A', 'B', 'C'], 'Num': [1, 2, 3]})

In [45]: df
Out[45]:
   Let  Num
0    A   1
1    B   2

(continues on next page)
In [46]: ser = pd.Series(
    ....:     ['a', 'b', 'c', 'd', 'e', 'f'],
    ....:     index=pd.MultiIndex.from_arrays(
    ....:         [['A', 'B', 'C'] * 2, [1, 2, 3, 4, 5, 6]], names=['Let', 'Num']
    ....:     ),
    ....: )

In [47]: ser
Out[47]:
Let  Num
A  1  a
B  2  b
C  3  c
A  4  d
B  5  e
C  6  f
dtype: object

In [48]: pd.merge(df, ser.reset_index(), on=['Let', 'Num'])
Out[48]:
    Let Num 0
0   A   1  a
1   B   2  b
2   C   3  c

Here is another example with duplicate join keys in DataFrames:

In [49]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
In [50]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
In [51]: result = pd.merge(left, right, on='B', how='outer')

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>0</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>2</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>
Warning: Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user’s responsibility to manage duplicate values in keys before joining large DataFrames.

Checking for duplicate keys

Users can use the validate argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of B in the right DataFrame. As this is not a one-to-one merge – as specified in the validate argument – an exception will be raised.

```
In [52]: left = pd.DataFrame({"A": [1, 2], "B": [1, 2]})
In [53]: right = pd.DataFrame({"A": [4, 5, 6], "B": [2, 2, 2]})
In [53]: result = pd.merge(left, right, on="B", how="outer", validate="one_to_one")
...: MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the validate='one_to_many' argument instead, which will not raise an exception.

```
In [54]: pd.merge(left, right, on="B", how="outer", validate="one_to_many")
Out[54]:
   A_x B   A_y
0  1  1   NaN
1  2  2   4.0
2  2  2   5.0
3  2  2   6.0
```

The merge indicator

`merge()` accepts the argument indicator. If True, a Categorical-type column called _merge will be added to the output object that takes on values:

<table>
<thead>
<tr>
<th>Observation Origin</th>
<th>_merge value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td>right_only</td>
</tr>
<tr>
<td>Merge key in both frames</td>
<td>both</td>
</tr>
</tbody>
</table>

```
In [55]: df1 = pd.DataFrame({"col1": [0, 1], "col_left": ["a", "b"]})
In [56]: df2 = pd.DataFrame({"col1": [1, 2, 2], "col_right": [2, 2, 2]})
In [57]: pd.merge(df1, df2, on="col1", how="outer", indicator=True)
Out[57]:
   col1  col_left  col_right   _merge
0     0       a         NaN     left_only
1     1       b         NaN     left_only
2     1       a         2.0     both
3     2       b         2.0     both
```

(continues on next page)
The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```python
In [58]: pd.merge(df1, df2, on="col1", how="outer", indicator="indicator_column")
Out[58]:
      col1  col_left  col_right  indicator_column
0      0      a        NaN  left_only
1      1      b         2.0  both
2      2        NaN      2.0  right_only
3      2        NaN      2.0  right_only
```

**Merge dtypes**

Merging will preserve the dtype of the join keys.

```python
In [59]: left = pd.DataFrame({"key": [1], "v1": [10]})
In [60]: left
Out[60]:
   key v1
0   1  10

In [61]: right = pd.DataFrame({"key": [1, 2], "v1": [20, 30]})
In [62]: right
Out[62]:
   key v1
0   1  20
1   2  30
```

We are able to preserve the join keys:

```python
In [63]: pd.merge(left, right, how="outer")
Out[63]:
   key  v1
0   1   10
1   1   20
2   2   30

In [64]: pd.merge(left, right, how="outer").dtypes
Out[64]:
   key  int64
   v1   int64
dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.
In [65]: `pd.merge(left, right, how="outer", on="key")`  
Out[65]:  
<table>
<thead>
<tr>
<th>key</th>
<th>v1_x</th>
<th>v1_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>10.0</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>NaN</td>
</tr>
</tbody>
</table>

In [66]: `pd.merge(left, right, how="outer", on="key").dtypes`  
Out[66]:  
| key   | int64 |
| v1_x  | float64 |
| v1_y  | int64 |
| dtype | object |

Merging will preserve category dtypes of the mergands. See also the section on `categoricals`.

The left frame.

In [67]: `from pandas.api.types import CategoricalDtype`  
In [68]: `X = pd.Series(np.random.choice(\["foo", "bar\], size=(10,)))`  
In [69]: `X = X.astype(CategoricalDtype(categories=["foo", "bar\]))`  
In [70]: `left = pd.DataFrame(`  
   `.....:  {"X": X, "Y": np.random.choice(["one", "two", "three\], size=(10,))})`  
   `.....:  )`  
   `.....:  )`

</tr>
</tbody>
</table>

In [72]: `left.dtypes`  
Out[72]:  
| X     | category |
| Y     | object   |
| dtype | object   |

The right frame.

In [73]: `right = pd.DataFrame(`  
   `.....:  {`  
   `.....:  "X": pd.Series(["foo", "bar\], dtype=CategoricalDtype(["foo", "bar\]))`, `.....:  "Z": [1, 2],`  
   `.....:  )`  
   `.....:  )`  
   `.....:  )`  

(continues on next page)
In [74]: right
Out[74]:
   X  Z
0  foo  1
1  bar  2

In [75]: right.dtypes
Out[75]:
X   category
Z     int64
dtype: object

The merged result:

In [76]: result = pd.merge(left, right, how="outer")

In [77]: result
Out[77]:
   X  Y  Z
0  bar  one  2
1  bar  three  2
2  bar  one  2
3  bar  three  2
4  bar  three  2
5  bar  three  2
6  foo  one  1
7  foo  three  1
8  foo  one  1
9  foo  three  1

In [78]: result.dtypes
Out[78]:
X   category
Y    object
Z     int64
dtype: object

Note: The category dtypes must be exactly the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to the categories’ dtype.

Note: Merging on category dtypes that are the same can be quite performant compared to object dtype merging.
Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```python
In [79]: left = pd.DataFrame(
       ....:     }
       ....: )

In [80]: right = pd.DataFrame(
       ....:     {"C": ["C0", "C2", "C3"], "D": ["D0", "D2", "D3"], index=["K0", "K2", "K3"]
       ....:     }
       ....: )

In [81]: result = left.join(right)
```

```plaintext
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>K0</td>
<td>A0</td>
<td>B0</td>
<td>K0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>K1</td>
<td>A1</td>
<td>B1</td>
<td>K2</td>
<td>C2</td>
<td>D2</td>
</tr>
<tr>
<td>K2</td>
<td>A2</td>
<td>B2</td>
<td>K3</td>
<td>C3</td>
<td>D3</td>
</tr>
</tbody>
</table>
```

```python
In [82]: result = left.join(right, how="outer")
```

```plaintext
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>K0</td>
<td>A0</td>
<td>B0</td>
<td>K0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>K1</td>
<td>A1</td>
<td>B1</td>
<td>K1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>K3</td>
<td>NaN</td>
<td>NaN</td>
<td>K3</td>
<td>C3</td>
<td>D3</td>
</tr>
</tbody>
</table>
```

The same as above, but with `how='inner'`.

```python
In [83]: result = left.join(right, how="inner")
```

```plaintext
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>K0</td>
<td>A0</td>
<td>B0</td>
<td>K0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>K1</td>
<td>A1</td>
<td>B1</td>
<td>K2</td>
<td>C2</td>
<td>D2</td>
</tr>
<tr>
<td>K2</td>
<td>A2</td>
<td>B2</td>
<td>K3</td>
<td>C3</td>
<td>D3</td>
</tr>
</tbody>
</table>
```

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

2.7. Merge, join, concatenate and compare
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how="outer")

```
<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>K0</td>
<td>A0</td>
<td>K0</td>
</tr>
<tr>
<td>K1</td>
<td>A1</td>
<td>K1</td>
</tr>
<tr>
<td>K2</td>
<td>A2</td>
<td>K2</td>
</tr>
</tbody>
</table>
```

In [85]: result = pd.merge(left, right, left_index=True, right_index=True, how="inner")

```
<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>K0</td>
<td>A0</td>
<td>K0</td>
</tr>
<tr>
<td>K1</td>
<td>A1</td>
<td>K1</td>
</tr>
<tr>
<td>K2</td>
<td>A2</td>
<td>K2</td>
</tr>
</tbody>
</table>
```

Joining key columns on an index

join() takes an optional on argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(
    left, right, left_on=key_or_keys, right_index=True, how="left", sort=False
)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame's is already indexed by the join key), using join may be more convenient. Here is a simple example:

In [86]: left = pd.DataFrame(
    ....:     {      
    ....:         "B": ["B0", "B1", "B2", "B3"],  
    ....:         "key": ["K0", "K1", "K0", "K1"],  
    ....:     }    
    ....: )    

In [87]: right = pd.DataFrame({"C": ["C0", "C1"], "D": ["D0", "D1"], index=["K0", "K1"]})

In [88]: result = left.join(right, on="key")
In [89]: result = pd.merge(
    ....:     left, right, left_on="key", right_index=True, how="left", sort=False
    ....: )
    ....:

To join on multiple keys, the passed DataFrame must have a MultiIndex:

In [90]: left = pd.DataFrame(
    ....:     
    ....:     "B": ["B0", "B1", "B2", "B3"],
    ....:     "key1": ["K0", "K0", "K1", "K2"],
    ....:     "key2": ["K0", "K1", "K0", "K1"],
    ....: )
    ....:

In [91]: index = pd.MultiIndex.from_tuples(
    ....:     [("K0", "K0"), ("K1", "K0"), ("K2", "K0"), ("K2", "K1")]
    ....: )
    ....:

In [92]: right = pd.DataFrame(
    ....:     
    ....:     "C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"], index=index
    ....: )
    ....:

Now this can be joined by passing the two key column names:

In [93]: result = left.join(right, on=["key1", "key2"])
The default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

In [94]: result = left.join(right, on="key1", "key2", how="inner")

As you can see, this drops any rows where there was no match.

## Joining a single Index to a MultiIndex

You can join a singly-indexed DataFrame with a level of a MultiIndexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

In [95]: left = pd.DataFrame(
    .....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"],
    .....:     index=pd.Index(["K0", "K1", "K2"], name="key"),
    .....:     )
    .....:

In [96]: index = pd.MultiIndex.from_tuples(
    .....:     [("K0", "Y0"), ("K1", "Y1"), ("K2", "Y2"), ("K2", "Y3")],
    .....:     names=["key", "Y"],
    .....:     )
    .....:

In [97]: right = pd.DataFrame(
    .....:     {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"],
    .....:     index=index,
    .....:     )
    .....:

In [98]: result = left.join(right, how="inner")
This is equivalent but less verbose and more memory efficient / faster than this.

```
In [99]: result = pd.merge(
    ....:     left.reset_index(), right.reset_index(), on="key", how="inner"
    ....: ).set_index(["key","Y"])
```

### Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```
In [100]: leftindex = pd.MultiIndex.from_product(
    ....:     [list("abc"), list("xy"), [1, 2]], names=['abc', 'xy', 'num'])
    ....: )
    ....:

In [101]: left = pd.DataFrame({"v1": range(12)}, index=leftindex)
In [102]: left
```

<table>
<thead>
<tr>
<th>abc</th>
<th>xy</th>
<th>num</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>a</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>y</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>b</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>y</td>
<td>1</td>
<td>6</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>7</td>
</tr>
</tbody>
</table>

(continues on next page)
In [103]: rightindex = pd.MultiIndex.from_product(  .....:     [list("abc"), list("xy")], names=["abc", "xy"]  .....:     )  .....:

In [104]: right = pd.DataFrame({"v2": [100 * i for i in range(1, 7)]}, index=rightindex)

In [105]: right
Out[105]:
   v2
  abc  xy
  a    100
       200
  b    300
       400
  c    500
       600

In [106]: left.join(right, on=["abc", "xy"], how="inner")
Out[106]:
   v1  v2
  abc  xy num
  a    x  1  0  100
       2  1  100
       y  1  2  200
       2  3  200
  b    x  1  4  300
       2  5  300
       y  1  6  400
       2  7  400
  c    x  1  8  500
       2  9  500
       y  1 10  600
       2 11  600

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

In [107]: leftindex = pd.MultiIndex.from_tuples(  .....:     [("K0", "X0"), ("K0", "X1"), ("K1", "X2")], names=["key", "X"]  .....:     )  .....:

In [108]: left = pd.DataFrame(  .....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"]}, index=leftindex  .....:     )  .....:

(continues on next page)
In [109]: rightindex = pd.MultiIndex.from_tuples(  ....:     [("K0", "Y0"), ("K1", "Y1"), ("K2", "Y2"), ("K2", "Y3")], names=["key", "Y"]  ....: )  ....:  

In [110]: right = pd.DataFrame(  ....:     {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"]}, index=rightindex  ....: )  ....:  

In [111]: result = pd.merge(  ....:     left.reset_index(), right.reset_index(), on="key", how="inner"  ....: ).set_index(["key", "X", "Y"])  ....:  

Merging on a combination of columns and index levels

Strings passed as the on, left_on, and right_on parameters may refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes.

In [112]: left_index = pd.Index(["K0", "K0", "K1", "K2"], name="key1")  

In [113]: left = pd.DataFrame(  ....:     {  ....:         "A": ["A0", "A1", "A2", "A3"],  ....:         "B": ["B0", "B1", "B2", "B3"],  ....:         "key2": ["K0", "K1", "K0", "K1"],  ....:     },  ....:     index=left_index,  ....: )  ....:  

In [114]: right_index = pd.Index(["K0", "K1", "K2", "K2"], name="key1")  

In [115]: right = pd.DataFrame(  ....:     {  ....:         "C": ["C0", "C1", "C2", "C3"],  ....:         "D": ["D0", "D1", "D2", "D3"],  ....:     },  ....:     index=right_index,  ....: )  

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.1

In [116]: result = left.merge(right, on=["key1", "key2"])

Note: When DataFrames are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting DataFrame.

Note: When DataFrames are merged using only some of the levels of a MultiIndex, the extra levels will be dropped from the resulting merge. In order to preserve those levels, use \texttt{reset\_index} on those level names to move those levels to columns prior to doing the merge.

Note: If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

Overlapping value columns

The merge \texttt{suffixes} argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

In [117]: left = pd.DataFrame({"k": ["K0", "K1", "K2"], "v": [1, 2, 3]})

In [118]: right = pd.DataFrame({"k": ["K0", "K0", "K3"], "v": [4, 5, 6]})

In [119]: result = pd.merge(left, right, on="k")
In [120]: result = pd.merge(left, right, on="k", suffixes=("_l", "_r"))

DataFrame.join() has lsuffix and rsuffix arguments which behave similarly.

In [121]: left = left.set_index("k")
In [122]: right = right.set_index("k")
In [123]: result = left.join(right, lsuffix="_l", rsuffix="_r")

Joining multiple DataFrames

A list or tuple of DataFrames can also be passed to join() to join them together on their indexes.

In [124]: right2 = pd.DataFrame({"v": [7, 8, 9]}, index=["K1", "K1", "K2"])
In [125]: result = left.join([right, right2])

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>k</td>
<td>v</td>
<td>k</td>
</tr>
<tr>
<td>0</td>
<td>K0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>K1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>K2</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>

2.7. Merge, join, concatenate and compare
Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```python
In [126]: df1 = pd.DataFrame(
    ....:     [[np.nan, 3.0, 5.0], [-4.6, np.nan, np.nan], [np.nan, 7.0, np.nan]],
    ....:     index=[1, 2, 3])

In [127]: df2 = pd.DataFrame([[np.nan, -42.6, np.nan], [-5.0, 1.6, 4]], index=[1, 2])
```

For this, use the `combine_first()` method:

```python
In [128]: result = df1.combine_first(df2)
```

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values in place:

```python
In [129]: df1.update(df2)
```
2.7.3 Timeseries friendly merging

Merging ordered data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```python
In [130]: left = pd.DataFrame(
       ......: {"k": ["K0", "K1", "K1", "K2"], "lv": [1, 2, 3, 4], "s": ["a", "b", "c", "d"]}
       ......: )
       ......:

In [131]: right = pd.DataFrame({"k": ["K1", "K2", "K4"], "rv": [1, 2, 3]})

In [132]: pd.merge_ordered(left, right, fill_method="ffill", left_by="s")
Out[132]:
       k  lv  s  rv
0   K0  1.0  a  NaN
1   K1  1.0  a  1.0
2   K2  1.0  a  2.0
3   K4  1.0  a  3.0
4   K1  2.0  b  1.0
5   K2  2.0  b  2.0
6   K4  2.0  b  3.0
7   K1  3.0  c  1.0
8   K2  3.0  c  2.0
9   K4  3.0  c  3.0
10  K1  NaN  d  1.0
11  K2  4.0  d  2.0
12  K4  4.0  d  3.0
```

Merging asof

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `left DataFrame`, we select the last row in the `right DataFrame` whose `on key` is less than the `left`'s key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the by key equally, in addition to the nearest match on the on key.

For example, we might have `trades` and `quotes` and we want to `asof` merge them.

```python
In [133]: trades = pd.DataFrame(
       ......: {
       ......:     "time": pd.to_datetime(
       ......:         ["20160525 13:30:00.023",
       ......:           "20160525 13:30:00.038",
       ......:           "20160525 13:30:00.048",
       ......:           "20160525 13:30:00.048",
       ......:           "20160525 13:30:00.048",
       ......:           "20160525 13:30:00.048",
       ......:         ]
       ......: )
       ......:
```
In [134]: quotes = pd.DataFrame(
        
            
            
            },
            
            
            ),
            
            
            },
            
            
            },
            
            
            },
            
            
            columns=["time", "ticker", "price", "quantity"],
        
        
        
        )

In [135]: trades

Out[135]:

<table>

```

### 2.7.4 Comparing objects

The `compare()` and `compare()` methods allow you to compare two `DataFrame` or `Series`, respectively, and summarize their differences.

This feature was added in `V1.1.0`.

For example, you might want to compare two `DataFrame` and stack their differences side by side.

```
In [140]: df = pd.DataFrame(
       .....:   {}
       (continues on next page)
```

# 2.7. Merge, join, concatenate and compare
"col1": ["a", "a", "b", "b", "a"],
"col2": [1.0, 2.0, 3.0, np.nan, 5.0],
"col3": [1.0, 2.0, 3.0, 4.0, 5.0],

),
columns=["col1", "col2", "col3"],
)

\[
\begin{array}{ccc}
\text{col1} & \text{col2} & \text{col3} \\
0 & a & 1.0 & 1.0 \\
1 & a & 2.0 & 2.0 \\
2 & b & 3.0 & 3.0 \\
3 & b & \text{NaN} & 4.0 \\
4 & a & 5.0 & 5.0 \\
\end{array}
\]

\[
\begin{array}{ccc}
\text{col1} & \text{col2} & \text{col3} \\
0 & c & 1.0 & 1.0 \\
1 & a & 2.0 & 2.0 \\
2 & b & 3.0 & 4.0 \\
3 & b & \text{NaN} & 4.0 \\
4 & a & 5.0 & 5.0 \\
\end{array}
\]

By default, if two corresponding values are equal, they will be shown as NaN. Furthermore, if all values in an entire row / column, the row / column will be omitted from the result. The remaining differences will be aligned on columns.

If you wish, you may choose to stack the differences on rows.

\[
\begin{array}{ccc}
\text{col1} & \text{col3} \\
0 & a & \text{NaN} \\
2 & \text{NaN} & 3.0 & 4.0 \\
\end{array}
\]

If you wish to keep all original rows and columns, set keep_shape argument to True.
In[148]: df.compare(df2, keep_shape=True)
Out[148]:
<table>
<thead>
<tr>
<th></th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>self</td>
<td>other</td>
<td>self</td>
</tr>
<tr>
<td>0</td>
<td>a</td>
<td>c</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>NaN</td>
<td>3.0</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

You may also keep all the original values even if they are equal.

In [149]: df.compare(df2, keep_shape=True, keep_equal=True)
Out[149]:
<table>
<thead>
<tr>
<th></th>
<th>col1</th>

</tbody>
</table>

2.8 Reshaping and pivot tables

2.8.1 Reshaping by pivoting DataFrame objects

Pivot

\[
\text{df.pivot(index='foo', columns='bar', values='baz')}
\]

Data is often stored in so-called “stacked” or “record” format:
In [1]: import pandas._testing as tm

In [2]: def unpivot(frame):
   ...:     N, K = frame.shape
   ...:     data = {
   ...:         "value": frame.to_numpy().ravel("F"),
   ...:         "variable": np.asarray(frame.columns).repeat(N),
   ...:         "date": np.tile(np.asarray(frame.index), K),
   ...:     }
   ...:     return pd.DataFrame(data, columns=["date", "variable", "value"])
   ...

In [3]: df = unpivot(tm.makeTimeDataFrame(3))

In [4]: df
Out[4]:
   date variable  value
0 2000-01-03    A  0.469112
1 2000-01-04    A -0.282863
2 2000-01-05    A -1.509059
3 2000-01-03    B -1.135632
4 2000-01-04    B  1.212112
5 2000-01-05    B -0.173215
6 2000-01-03    C  0.119209
7 2000-01-04    C -1.044236
8 2000-01-05    C -0.861849
9 2000-01-03    D -2.104569
10 2000-01-04   D -0.494929
11 2000-01-05   D  1.071804

To select out everything for variable A we could do:

In [5]: filtered = df[df["variable"] == "A"]

In [6]: filtered
Out[6]:
   date variable  value
0 2000-01-03    A  0.469112
1 2000-01-04    A -0.282863
2 2000-01-05    A -1.509059

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the DataFrame.pivot() method (also implemented as a top level function pivot()):

In [7]: pivoted = df.pivot(index="date", columns="variable", values="value")

In [8]: pivoted
Out[8]:
   variable  A  B  C  D
   date
2000-01-03  0.469112 -1.135632  0.119209 -2.104569
2000-01-04 -0.282863  1.212112 -1.044236 -0.494929

(continues on next page)
If the `values` argument is omitted, and the input `DataFrame` has more than one column of values which are not used as column or index inputs to `pivot()`, then the resulting “pivoted” `DataFrame` will have hierarchical columns whose topmost level indicates the respective value column:

```
In [9]: df["value2"] = df["value"] * 2
In [10]: pivoted = df.pivot(index="date", columns="variable")
In [11]: pivoted
```

```
Out[11]:

<table>
<thead>
<tr>
<th></th>
<th>value</th>
<th>value2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>date</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.469112</td>
<td>-1.135632</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.282863</td>
<td>1.212112</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-1.509059</td>
<td>-0.173215</td>
</tr>
</tbody>
</table>
```

You can then select subsets from the pivoted `DataFrame`:

```
In [12]: pivoted["value2"]
```

```
Out[12]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.938225</td>
<td>-2.271265</td>
<td>0.238417</td>
<td>-4.209138</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.565727</td>
<td>2.424224</td>
<td>-2.088472</td>
<td>-0.989859</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-3.018117</td>
<td>-0.346429</td>
<td>-1.723698</td>
<td>2.143608</td>
</tr>
</tbody>
</table>
```

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

**Note:** `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape` if the index/column pair is not unique. In this case, consider using `pivot_table()` which is a generalization of pivot that can handle duplicate values for one index/column pair.
2.8.2 Reshaping by stacking and unstacking

Stack

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on hierarchical indexing). Here are essentially what these methods do:

- **stack()**: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.

- **unstack()**: (inverse operation of `stack()”) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.
The clearest way to explain is by example. Let’s take a prior example data set from the hierarchical indexing section:

```python
In [13]: tuples = list(zip(*
          
    ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
    ["one", "two", "one", "two", "one", "two", "one", "two"],
    )

In [14]: index = pd.MultiIndex.from_tuples(tuples, names=["first", "second"])

In [15]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=["A", "B"])

In [16]: df2 = df[:4]

In [17]: df2
Out[17]:

+----------+----------+
<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
</tr>
<tr>
<td></td>
<td>A</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>B</td>
</tr>
<tr>
<td></td>
<td>2</td>
</tr>
<tr>
<td>two</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>B</td>
</tr>
<tr>
<td></td>
<td>4</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
</tr>
<tr>
<td></td>
<td>A</td>
</tr>
<tr>
<td></td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>B</td>
</tr>
<tr>
<td></td>
<td>6</td>
</tr>
<tr>
<td>two</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>B</td>
</tr>
<tr>
<td></td>
<td>8</td>
</tr>
<tr>
<td>-----------</td>
<td>----------</td>
</tr>
</tbody>
</table>
```

The `stack()` function “compresses” a level in the `DataFrame` columns to produce either:
- A `Series`, in the case of a simple column Index.

The `stack()` function “compresses” a level in the `DataFrame` columns to produce either:
- A `Series`, in the case of a simple column Index.
A *DataFrame*, in the case of a *MultiIndex* in the columns.

If the columns have a *MultiIndex*, you can choose which level to stack. The stacked level becomes the new lowest level in a *MultiIndex* on the columns:

```python
In [18]: stacked = df2.stack()

In [19]: stacked
Out[19]:
first  second
bar    one  A 0.721555
       B -0.706771
       two A -1.039575
         B  0.271860
baz    one A -0.424972
       B  0.567020
       two A  0.276232
         B -1.087401
dtype: float64
```

With a “stacked” *DataFrame* or *Series* (having a *MultiIndex* as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the last level:

```python
In [20]: stacked.unstack()
Out[20]:
first  second
bar    one  A 0.721555 -0.706771
         B -1.039575  0.271860
baz    one A -0.424972  0.567020
         B  0.276232 -1.087401

In [21]: stacked.unstack(1)
Out[21]:
second  one  two
first
bar    A 0.721555 -1.039575
       B -0.706771  0.271860
baz    A -0.424972  0.276232
       B  0.567020 -1.087401

In [22]: stacked.unstack(0)
Out[22]:
first  bar  baz
second
one  A 0.721555 -0.424972
    B -0.706771  0.567020
two A -1.039575  0.276232
    B  0.271860 -1.087401
```
If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [23]: stacked.unstack("second")
Out[23]:
   second  one  two
first
bar   A  0.721555 -1.039575
      B -0.706771  0.271860
baz   A -0.424972  0.276232
      B  0.567020 -1.087401
```

```
In [24]: stacked.unstack('second')
```

2.8. Reshaping and pivot tables
Unstack(0)

Notice that the `stack()` and `unstack()` methods implicitly sort the index levels involved. Hence a call to `stack()` and then `unstack()`, or vice versa, will result in a sorted copy of the original `DataFrame` or `Series`:

```
In [24]: index = pd.MultiIndex.from_product([[2, 1], ["a", "b"]])
In [25]: df = pd.DataFrame(np.random.randn(4), index=index, columns=["A"])
In [26]: df
Out[26]:
          A
2  a    -0.370647
    b    -1.157892
1  a    -1.344312
    b     0.844885
```

```
In [27]: all(df.unstack().stack() == df.sort_index())
Out[27]: True
```

The above code will raise a `TypeError` if the call to `sort_index()` is removed.

**Multiple levels**

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [28]: columns = pd.MultiIndex.from_tuples(
             .....:     [  
             .....:         ("A", "cat", "long"),
             .....:         ("B", "cat", "long"),
             .....:         ("A", "dog", "short"),
             .....:         ("B", "dog", "short"),
             (continues on next page)
```
In [29]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)

In [30]: df
Out[30]:
exp  A  B  A  B
animal  cat  cat  dog  dog
hair_length  long  long  short  short
0  1.075770 -0.109050  1.643563 -1.469388
1   0.357021  -0.674600 -1.776904   -0.968914
2  -1.294524   0.413738   0.276662 -0.472035
3  -0.013960  -0.362543  -0.006154 -0.923061

In [31]: df.stack(level=["animal", "hair_length"])
Out[31]:
exp  A  B
animal hair_length
0  cat  long  1.075770 -0.109050
  dog  short  1.643563 -1.469388
1  cat  long   0.357021  -0.674600
  dog  short  -1.776904  -0.968914
2  cat  long  -1.294524   0.413738
  dog  short   0.276662  -0.472035
3  cat  long  -0.013960  -0.362543
  dog  short  -0.006154  -0.923061

The list of levels can contain either level names or level numbers (but not a mixture of the two).

# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
In [32]: df.stack(level=[1, 2])
Out[32]:
exp  A  B
animal hair_length
0  cat  long  1.075770 -0.109050
  dog  short  1.643563 -1.469388
1  cat  long   0.357021  -0.674600
  dog  short  -1.776904  -0.968914
2  cat  long  -1.294524   0.413738
  dog  short   0.276662  -0.472035
3  cat  long  -0.013960  -0.362543
  dog  short  -0.006154  -0.923061

2.8. Reshaping and pivot tables 551
Missing data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index()`, of course). Here is a more complex example:

```python
In [33]: columns = pd.MultiIndex.from_tuples(
    ....:     ["A", "cat"),
    ....:             ("B", "dog"),
    ....:             ("C", "cat"),
    ....:             ("D", "dog"),
    ....:     ],
    ....:     names=["exp", "animal"],
    ....: )

In [34]: index = pd.MultiIndex.from_product(
    ....:     [("bar", "baz", "foo", "qux"), ("one", "two")],
    ....:     names=["first", "second"])

In [35]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [36]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [37]: df2
Out[37]:
exp   A    B    A
animal cat  dog  cat  dog
first second
bar   one -0.895717 0.805244 -1.206412 2.565646
      two 1.431256 1.340309 -1.170299 -0.226169
baz   one 0.410835 0.813850 0.132003 -0.827317
      two -1.413681 1.607920 1.024180 0.569605
foo   one -0.875906 -2.211372 0.974466 -2.006747
      two -1.226825 0.769804 -1.281247 -0.727707
qux   one -1.226825 0.769804 -1.281247 -0.727707
      two 1.431256 1.340309 -1.170299 -0.226169

As mentioned above, `stack()` can be called with a `level` argument to select which level in the columns to stack:

```python
In [38]: df2.stack("exp")
Out[38]:
animal   A   B
first second
bar   one  0.895717 0.805244 -1.206412 2.565646
      two 1.431256 1.340309 -1.170299 -0.226169
baz   one 0.410835 0.813850 0.132003 -0.827317
      two -1.413681 1.607920 1.024180 0.569605

      two 1.431256 1.340309 -1.170299 -0.226169
```

(continues on next page)
```
qux  two  A  -1.226825  -0.727707
     B  -1.281247  0.769804

In [39]: df2.stack("animal")
Out[39]:
     exp  A      B
first  second animal
bar   one   cat  0.895717  -1.206412
dog   two   cat  1.431256  -1.170299
dog   one   cat  2.565646   0.805244
dog   two   cat -0.226169   1.340309
baz   one   cat  0.410835   0.132003
dog   one   cat  0.827317   0.813850
dog   two   cat -1.413681  1.024180
dog   two   cat  0.569605  1.607920
foo   one   cat -1.413681  1.024180
dog   two   cat  0.875906   0.974466
dog   two   cat -2.006747  0.211372
qux   two   cat -1.226825  -1.281247
dog   two   cat  0.769804   0.769804

Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types, by default data will converted to float and missing values will be set to NaN.

In [40]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]
In [41]: df3
Out[41]:
     exp  B
animal  dog  cat
first  second
bar   one  0.805244  -1.206412
dog   two  1.340309  -1.170299
foo   one  1.607920  1.024180
qux   two  0.769804  -1.281247

In [42]: df3.unstack()
Out[42]:
     exp  B
animal  dog  cat
second  one  two  one  two
first  bar  0.805244  1.340309  -1.206412  -1.170299
foo   1.607920  NaN  1.024180  NaN
qux   NaN  0.769804  NaN  -1.281247

Alternatively, unstack takes an optional fill_value argument, for specifying the value of missing data.

In [43]: df3.unstack(fill_value=-1e9)
Out[43]:
     exp  B
animal  dog  cat
second  one  two  one  two
first  bar  0.805244  1.340309  -1.206412  -1.170299
foo   1.607920  NaN  1.024180  NaN
qux   NaN  0.769804  NaN  -1.281247
```

2.8. Reshaping and pivot tables
second  | one   | two   | one   | two
---    | ---   | ---   | ---   | ---
first  |       |       |       |       
bar    | 8.052440e-01 | 1.340309e+00 | -1.206412e+00 | -1.170299e+00
foo    | 1.607920e+00 | -1.000000e+09 | 1.024180e+00 | -1.000000e+09
qux    | -1.000000e+09 | 7.698036e-01 | -1.000000e+09 | -1.281247e+00

With a MultiIndex

Unstacking when the columns are a MultiIndex is also careful about doing the right thing:

```
In [44]: df[:3].unstack(0)
Out[44]:
exp  | A          | B          | C          | D          | E          | F          | G          | H          | I          |
     | animal     | cat        | dog        | cat        | dog        | cat        | dog        | cat        | dog        |
     | first      | bar        | baz        | bar        | baz        | bar        | baz        | bar        | baz        |
     | second     | one        | two        | one        | two        | one        | two        | one        | two        |
one  | 0.895717   | 0.410835   | 0.805244   | 0.813850   | -1.206412  | 0.132003   | 2.565646   | -0.827317  |
two  | 1.431256   | NaN        | 1.340309   | NaN        | -1.170299  | NaN        | -0.226169  | NaN        |
In [45]: df2.unstack(1)
Out[45]:
exp  | A          | B          | C          | D          | E          | F          | G          | H          | I          |
     | animal     | cat        | dog        | cat        | dog        | cat        | dog        | cat        | dog        |
     | first      | one        | two        | one        | two        | one        | two        | one        | two        |
     | second     |           |            |            |            |            |            |            |            |
bar  | 0.895717   | 1.431256   | 0.805244   | 1.340309   | -1.206412  | -1.170299  | 2.565646   | -0.226169  |
baz  | 0.410835   | NaN        | 0.813850   | NaN        | 0.132003   | NaN        | -0.827317  | NaN        |
foo  | -1.413681  | 0.875906   | 1.607920   | -2.211372  | 1.024180   | 0.974466   | 0.569605   | -2.006747  |
qux  | NaN        | -1.226825  | NaN        | 0.769804   | NaN        | -1.281247  | NaN        | -0.727707  |
```
2.8.3 Reshaping by melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a `DataFrame` into a format where one or more columns are identifier variables, while all other columns, considered measured variables, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```python
In [46]: cheese = pd.DataFrame(
    ....:     {  
    ....:         "first": ["John", "Mary"],  
    ....:         "last": ["Doe", "Bo"],  
    ....:         "height": [5.5, 6.0],  
    ....:         "weight": [130, 150],  
    ....:     }
    ....: )
    ....:

In [47]: cheese
Out[47]:
first  last  height  weight
0     John  Doe     5.5      130
1     Mary  Bo      6.0      150

In [48]: cheese.melt(id_vars=["first", "last"],
Out[48]:
first  last  variable  value
0     John  Doe  height    5.5
1     Mary  Bo  height    6.0
2     John  Doe  weight   130.0
3     Mary  Bo  weight   150.0
```

(continues on next page)
When transforming a DataFrame using `melt()`, the index will be ignored. The original index values can be kept around by setting the `ignore_index` parameter to `False` (default is `True`). This will however duplicate them.

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.
In [55]: dft = pd.DataFrame(
        ...:
        ...:     {
        ...:         "A1970": {0: "a", 1: "b", 2: "c"},
        ...:         "A1980": {0: "d", 1: "e", 2: "f"},
        ...:         "B1970": {0: 2.5, 1: 1.2, 2: 0.7},
        ...:         "B1980": {0: 3.2, 1: 1.3, 2: 0.1},
        ...:         "X": dict(zip(range(3), np.random.randn(3)))},
        ...:     }
        ...:
    )

In [56]: dft["id"] = dft.index

In [57]: dft
Out[57]:
0     a     d     2.5    3.2 -0.121306   0
1     b     e     1.2    1.3 -0.097883   1
2     c     f     0.7    0.1  0.695775   2

In [58]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
Out[58]:
       X  A  B
id year
0 1970 -0.121306 a 2.5
1 1970 -0.097883 b 1.2
2 1970  0.695775 c 0.7
0 1980 -0.121306 d 3.2
1 1980 -0.097883 e 1.3
2 1980  0.695775 f 0.1

2.8.4 Combining with stats and GroupBy

It should be no shock that combining \texttt{pivot()} / \texttt{stack()} / \texttt{unstack()} with GroupBy and the basic Series and DataFrame statistical functions can produce some very expressive and fast data manipulations.

In [59]: df
Out[59]:
     exp  A  B  A
animal first second  cat  dog  cat  dog

2.8.5 Pivot tables

While pivot() provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides pivot_table() for pivoting with aggregation of numeric data.

The function pivot_table() can be used to create spreadsheet-style pivot tables. See the cookbook for some advanced strategies.

It takes a number of arguments:

- data: a DataFrame object.
- values: a column or a list of columns to aggregate.
• **index**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

• **columns**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

• **aggfunc**: function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```python
In [64]: import datetime
In [65]:
df = pd.DataFrame(
    ...
    {
        ...
        "A": ["one", "one", "two", "three"] * 6,
        ...
        "B": ["A", "B", "C"] * 8,
        ...
        "C": ["foo", "foo", "foo", "bar", "bar"] * 4,
        ...
        "D": np.random.randn(24),
        ...
        "E": np.random.randn(24),
        ...
        "F": [datetime.datetime(2013, i, 1) for i in range(1, 13)]
        ...
    + [datetime.datetime(2013, i, 15) for i in range(1, 13)],
    ...
    }
    ...
)
In [66]:
df
Out[66]:
   A  B  C    D     E     F
0  one A  foo  0.341734 -0.317441 2013-01-01
1  one B  foo  0.959726 -1.236269 2013-02-01
2  two C  foo -1.110336  0.896171 2013-03-01
3  three A  bar -0.619976 -0.487602 2013-04-01
4  one B  bar  0.149748 -0.082240 2013-05-01
..   ..   ..     ...     ...     ...
19 three B  foo  0.690579 -2.213588 2013-08-15
20 one C  foo  0.995761  1.063327 2013-09-15
21 one A  bar  2.396780  1.266143 2013-10-15
22 two B  bar  0.014871  0.299368 2013-11-15
23 three C  bar  3.357427 -0.863838 2013-12-15
[24 rows x 6 columns]
```

We can produce pivot tables from this data very easily:

```python
In [67]: pd.pivot_table(df, values="D", index=["A", "B"], columns=["C"])
Out[67]:
   C     bar     foo
   A  B
one  A  1.120915 -0.514058
     B -0.338421  0.002759
     C -0.538846  0.699535
three A -1.181568 NaN
         B NaN  0.433512
         C 0.588783 NaN
two  A  NaN  1.000985
```

(continues on next page)
B 0.158248 NaN  
C NaN 0.176180

**In [68]:** pd.pivot_table(df, values="D", index=["B"], columns=["A", "C"], aggfunc=np.sum)

**Out[68]:**

<table>
<thead>
<tr>
<th></th>
<th>A one</th>
<th>three</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>C bar</td>
<td>foo</td>
<td>bar</td>
<td>foo</td>
</tr>
<tr>
<td>B A 2.241830</td>
<td>-1.028115</td>
<td>-2.363137</td>
<td>NaN</td>
</tr>
<tr>
<td>B -0.676843</td>
<td>0.005518</td>
<td>NaN</td>
<td>0.867024</td>
</tr>
<tr>
<td>C -1.077692</td>
<td>1.399070</td>
<td>1.177566</td>
<td>NaN</td>
</tr>
</tbody>
</table>

**In [69]:**

```
...:
...: pd.pivot_table(
...:     ...
...:     df, values=["D", "E"],
...:     ...
...:     index=["B"],
...:     ...
...:     columns=["A", "C"],
...:     ...
...:     aggfunc=np.sum,
...:     ...
...: )
```

**Out[69]:**

```
D               E
| --- |
A one three two one |      |
| three two         |      |
C bar foo bar foo bar foo bar foo |      |
| bar foo bar foo   |      |
| foo               |      |
| foo               |      |
| foo               |      |
| B A 2.241830 | -1.028115 | -2.363137 | NaN | NaN | 2.001971 | 2.786113 | -0.043211 | 1.922577 | NaN | 0.128491 |
| B -0.676843 | 0.005518 | NaN | 0.867024 | 0.316495 | NaN | 1.368280 | -1.103384 | NaN | 1.368280 | -1.103384 | NaN | 1.368280 | -1.03384 |
| C -1.077692 | 1.399070 | 1.177566 | NaN | NaN | 0.352360 | -1.976883 | 1.495717 | -0.263660 | NaN | 0.872482 |
```

The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [70]: pd.pivot_table(df, index=["A", "B"], columns=["C"])
```

**Out[70]:**

```
D               E
| --- |
A one B
| three two
| C bar foo bar foo
| bar foo bar foo
| foo
| foo
| foo
| B A 1.120915 | -0.514058 | 1.393057 | -0.021605 |
| B -0.338421 | 0.002759 | 0.684140 | -0.551692 |
| C -0.538846 | 0.699535 | -0.988442 | 0.747859 |
| three A -1.181568 | NaN | 0.961289 | NaN |
| B NaN | 0.433512 | NaN | -1.064372 |
| C 0.588783 | NaN | -0.131830 | NaN |
| two A NaN | 1.000985 | NaN | 0.064245 |
| B 0.158248 | NaN | -0.097147 | NaN |
```
Also, you can use `Grouper` for index and columns keywords. For detail of `Grouper`, see `Grouping with a Grouper specification`.

```
In [71]: pd.pivot_table(df, values="D", index=pd.Grouper(freq="M", key="F"), columns="C")
Out[71]:
   F
C      bar   foo
2013-01-31  NaN -0.514058
2013-02-28  NaN  0.002759
2013-03-31  NaN  0.176180
2013-04-30 -1.181568  NaN
2013-05-31 -0.338421  NaN
2013-06-30 -0.538846  NaN
2013-07-31  NaN  1.000985
2013-08-31  NaN  0.433512
2013-09-30  NaN  0.699535
2013-10-31  NaN  1.120915
2013-11-30  NaN  0.158248
2013-12-31  NaN  0.588783
```

You can render a nice output of the table omitting the missing values by calling `to_string()` if you wish:

```
In [72]: table = pd.pivot_table(df, index=["A", "B"], columns=["C"])
```

```
In [73]: print(table.to_string(na_rep=""))
```

```
     D       E
C      bar   foo   bar   foo
A  B
one A  1.120915 -0.514058  1.393057 -0.021605
  B  0.338421  0.002759  0.84140  -0.551692
  C -0.538846  0.699535  0.984842  0.747859
three A -1.181568  0.961289
  B  0.433512  1.064372
  C  0.588783  0.131830
two A  1.000985  0.064245
  B  0.158248  0.097147
  C  0.176180  0.436241
```

Note that `pivot_table()` is also available as an instance method on DataFrame, i.e. `DataFrame.pivot_table()`.

2.8. Reshaping and pivot tables
Adding margins

If you pass `margins=True` to `pivot_table()`, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```python
In [74]: table = df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)

In [75]: table
```

```
Out[75]:
D     E

```

[24 rows x 2 columns]
2.8.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab()` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- **index**: array-like, values to group by in the rows.
- **columns**: array-like, values to group by in the columns.
- **values**: array-like, optional, array of values to aggregate according to the factors.
- **aggfunc**: function, optional, If no values array is passed, computes a frequency table.
- **rownames**: sequence, default `None`, must match number of row arrays passed.
- **colnames**: sequence, default `None`, if passed, must match number of column arrays passed.
- **margins**: boolean, default `False`, Add row/column margins (subtotals)
- **normalize**: boolean, {'all', 'index', 'columns'}, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any `Series` passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

For example:

```
In [77]: foo, bar, dull, shiny, one, two = "foo", "bar", "dull", "shiny", "one", "two"
In [78]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [79]: b = np.array([one, one, two, one, two, one], dtype=object)
In [80]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
In [81]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
```

```
Out[81]:
   b  one  two
c  dull  shiny dull  shiny
   bar  1   0   0   1
   foo  2   1   1   0
```

If `crosstab()` receives only two Series, it will provide a frequency table.

```
In [82]: df = pd.DataFrame(
    ....:      {"A": [1, 2, 2, 2, 2], "B": [3, 3, 4, 4, 4], "C": [1, 1, np.nan, 1, 1]}
    ....:    )
In [83]: df
```

```
Out[83]:
   A  B  C
0 1  3  1.0
1 2  3  1.0
2 2  4  NaN
3 2  4  1.0
```

(continues on next page)
crosstab() can also be implemented to *Categorical* data.

```python
In [85]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
In [86]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
In [87]: pd.crosstab(foo, bar)
Out[87]:
     col_0  d  e  f
row_0  a  1  0  0
      b  0  1  0
      c  0  0  0
```

If you want to include all of data categories even if the actual data does not contain any instances of a particular category, you should set dropna=False.

For example:

```python
In [88]: pd.crosstab(foo, bar, dropna=False)
Out[88]:
     col_0  d  e  f
row_0  a  1  0  0
      b  0  1  0
      c  0  0  0
```

**Normalization**

Frequency tables can also be normalized to show percentages rather than counts using the normalize argument:

```python
In [89]: pd.crosstab(df['A'], df['B'], normalize=True)
Out[89]:
     B   3  4
A
0  0.2  0.0
1  0.2  0.6
```

normalize can also normalize values within each row or within each column:

```python
In [90]: pd.crosstab(df['A'], df['B'], normalize='columns')
Out[90]:
     B   3  4
A
0  0.2  0.0
1  0.2  0.6
```
crosstab() can also be passed a third Series and an aggregation function (aggfunc) that will be applied to the values of the third Series within each group defined by the first two Series:

```
In [91]: pd.crosstab(df["A"], df["B"], values=df["C"], aggfunc=np.sum)
Out[91]:
   B  3  4
  A
  1  1.0 NaN
  2  1.0  2.0
```

Adding margins

Finally, one can also add margins or normalize this output.

```
In [92]: pd.crosstab(
    .....:    df["A"], df["B"], values=df["C"], aggfunc=np.sum, normalize=True,
    .....:    margins=True
    .....: )
Out[92]:
   B  3  4  All
  A
  1 0.25 0.0 0.25
  2 0.25 0.5 0.75
 All 0.50 0.5 1.00
```

2.8.7 Tiling

The cut() function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [93]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])
In [94]: pd.cut(ages, bins=3)
Out[94]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]
Categories (3, interval[float64, right]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.0]
```

If the bins keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [95]: c = pd.cut(ages, bins=[0, 18, 35, 70])
In [96]: c
Out[96]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]
Categories (3, interval[int64, right]): [(0, 18] < (18, 35] < (35, 70]
```

2.8. Reshaping and pivot tables
If the bins keyword is an `IntervalIndex`, then these will be used to bin the passed data:

```python
pd.cut([25, 20, 50], bins=c.categories)
```

### 2.8.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” `DataFrame`, for example a column in a `DataFrame` (a `Series`) which has k distinct values, can derive a `DataFrame` containing k columns of 1s and 0s using `get_dummies()`:

```python
In [97]: df = pd.DataFrame({"key": list("bbacab"), "data1": range(6)})
In [98]: pd.get_dummies(df["key"])  
Out[98]:
   a  b  c
0  0  1  0
1  0  1  0
2  1  0  0
3  0  0  1
4  1  0  0
5  0  1  0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original `DataFrame`:

```python
In [99]: dummies = pd.get_dummies(df["key"], prefix="key")
```

```python
In [100]: dummies
Out[100]:
   key_a  key_b  key_c
0      0      1      0
1      0      1      0
2      1      0      0
3      0      0      1
4      1      0      0
5      0      1      0
```

```python
In [101]: df["data1"].join(dummies)
```

```python
Out[101]:
   data1   key_a  key_b  key_c
0       0      0      1      0
1       1      0      1      0
2       2      1      0      0
3       3      0      0      1
4       4      1      0      0
5       5      0      1      0
```

This function is often used along with discretization functions like `cut()`:

```python
In [102]: values = np.random.randn(10)
In [103]: values
Out[103]:
array([-1.0481, -0.0257, -0.9884, 0.0941, 1.2627, 1.29, 0.4082, 1.6273,
   ...: 0.1547, 0.1568])
```

(continues on next page)
0.0824, -0.0558, 0.5366]

In [104]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]

In [105]: pd.get_dummies(pd.cut(values, bins))

Out[105]:

<table>
<thead>
<tr>
<th>(0.0, 0.2]</th>
<th>(0.2, 0.4]</th>
<th>(0.4, 0.6]</th>
<th>(0.6, 0.8]</th>
<th>(0.8, 1.0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>9</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

See also `Series.str.get_dummies`.

`get_dummies()` also accepts a DataFrame. By default all categorical variables (categorical in the statistical sense, those with object or categorical dtype) are encoded as dummy variables.

In [106]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'], 'C': [1, 2, 3]})

In [107]: pd.get_dummies(df)

Out[107]:

<table>
<thead>
<tr>
<th>C</th>
<th>A_a</th>
<th>A_b</th>
<th>B_b</th>
<th>B_c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

In [108]: pd.get_dummies(df, columns=['A'])

Out[108]:

<table>
<thead>
<tr>
<th>B</th>
<th>C</th>
<th>A_a</th>
<th>A_b</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>c</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>c</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

Notice that the B column is still included in the output, it just hasn’t been encoded. You can drop B before calling `get_dummies` if you don’t want to include it in the output.

As with the `Series` version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and _ as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.
In [109]: simple = pd.get_dummies(df, prefix="new_prefix")

In [110]: simple
Out[110]:
   C  new_prefix_a  new_prefix_b  new_prefix_b  new_prefix_c
0  1              1            0            0            1
1  2              0            1            0            1
2  3              1            0            1            0

In [111]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])

In [112]: from_list
Out[112]:
   C  from_A_a  from_A_b  from_B_b  from_B_c
0  1              1            0            0            1
1  2              0            1            0            1
2  3              1            0            1            0

In [113]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})

In [114]: from_dict
Out[114]:
   C  from_A_a  from_A_b  from_B_b  from_B_c
0  1              1            0            0            1
1  2              0            1            0            1
2  3              1            0            1            0

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on drop_first.

In [115]: s = pd.Series(list("abcaa"))

In [116]: pd.get_dummies(s)
Out[116]:
   a  b  c
0  1  0  0
1  0  1  0
2  1  0  1
3  0  0  0
4  0  0  0

In [117]: pd.get_dummies(s, drop_first=True)
Out[117]:
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0

When a column contains only one level, it will be omitted in the result.
In [119]: pd.get_dummies(df)
Out[119]:
    A_a  B_a  B_b  B_c
0    1    1    0    0
1    1    0    1    0
2    1    1    0    0
3    1    0    1    0
4    1    0    0    1

In [120]: pd.get_dummies(df, drop_first=True)
Out[120]:
    B_b  B_c
0    0    0
1    1    0
2    0    0
3    1    0
4    0    1

By default new columns will have np.uint8 dtype. To choose another dtype, use the dtype argument:

In [121]: df = pd.DataFrame({"A": list("abc"), "B": [1.1, 2.2, 3.3]})

In [122]: pd.get_dummies(df, dtype=bool).dtypes
Out[122]:
     B  A_a  A_b  A_c
dtype: object

2.8.9 Factorizing values

To encode 1-d values as an enumerated type use factorize():

In [124]: x
Out[124]:
0   A
1   A
2  NaN
3   B
4  3.14
5   inf
dtype: object

In [125]: labels, uniques = pd.factorize(x)

In [126]: labels
Out[126]: array([ 0,  0, -1,  1,  2,  3])

2.8. Reshaping and pivot tables
Note that `factorize()` is similar to `numpy.unique`, but differs in its handling of NaN:

```
In [130]: np.unique(ser, return_inverse=True)[::-1]
---------------------------------------------------------------------------
TypeError                       Traceback (most recent call last)
Input In [130], in <module>----> 1 np.unique(ser, return_inverse=True)[::-1]

File /opt/conda/envs/pandas/lib/python3.8/site-packages/numpy/lib/arraysetops.py:272, in
   ...unique(*args, return_index=True)
     270 ar = np.asanyarray(ar)
     271 if axis is None:
--> 272 ret = _unique1d(ar, return_index, return_inverse, return_counts)
     273 return _unpack_tuple(ret)
     274 # axis was specified and not None

File /opt/conda/envs/pandas/lib/python3.8/site-packages/numpy/lib/arraysetops.py:330, in
   ...unique1d(ar, return_index, return_inverse, return_counts)
     327 optional_indices = return_index or return_inverse
     329 if optional_indices:
--> 330 perm = ar.argsort(kind='mergesort' if return_index else 'quicksort')
     331 aux = ar[perm]
     332 else:

TypeError: '<' not supported between instances of 'float' and 'str'
```

Note: If you just want to handle one column as a categorical variable (like R’s factor), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on `Categorical`, see the `Categorical introduction` and the `API documentation`.  

---

570 Chapter 2. User Guide
2.8.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```
In [131]: np.random.seed([3, 1415])
In [132]: n = 20
In [133]: cols = np.array(['key', 'row', 'item', 'col'])
In [134]: df = cols + pd.DataFrame(
    .....:   (np.random.randint(5, size=(n, 4)) // [2, 1, 2, 1]).astype(str)
    .....:)
In [135]: df.columns = cols
In [136]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix("val"))
In [137]: df
```

```
Out [137]:
   key  row   item  col   val0  val1
0  key0  row3  item1  col3  0.810  0.045
1  key1  row2  item1  col2  0.440  0.065
2  key1  row0  item1  col0  0.770  0.010
3  key0  row4  item0  col2  0.150  0.590
4  key1  row0  item2  col1  0.810  0.640
...   ...    ...   ...    ...    ...
15  key0  row3  item1  col1  0.310  0.230
16  key0  row0  item2  col3  0.130  0.450
17  key0  row4  item0  col3  0.640  0.210
18  key2  row2  item2  col0  0.370  0.700
19  key0  row2  item0  col4  0.370  0.700
[20 rows x 6 columns]
```

Pivoting with single aggregations

Suppose we wanted to pivot `df` such that the `col` values are columns, `row` values are the index, and the mean of `val0` are the values? In particular, the resulting DataFrame should look like:

```
col  col0   col1  col2  col3  col4
row0  0.77   0.605 NaN  0.860  0.65
row02  0.13   NaN  0.395  0.500  0.25
row03  NaN  0.310  NaN  0.545  NaN
row04  NaN  0.100  0.395  0.760  0.24
```

This solution uses `pivot_table()`. Also note that `aggfunc='mean'` is the default. It is included here to be explicit.

```
In [138]: df.pivot_table(values="val0", index="row", columns="col", aggfunc="mean")
Out [138]:
```

(continues on next page)
Note that we can also replace the missing values by using the `fill_value` parameter.

```
In [139]: df.pivot_table(
       ...:     values="val0",
       ...:     index="row",
       ...:     columns="col",
       ...:     aggfunc="mean",
       ...:     fill_value=0,
       ...:     )
```

```
Out[139]:
row col col0 col1 col2 col3 col4
row0 0.77 0.605 NaN 0.86 0.65
row2 0.13 NaN 0.395 0.50 0.25
row3 NaN 0.310 NaN 0.545 NaN
row4 NaN 0.100 0.395 0.76 0.24
```

Also note that we can pass in other aggregation functions as well. For example, we can also pass in `sum`.

```
In [140]: df.pivot_table(
       ...:     values="val0",
       ...:     index="row",
       ...:     columns="col",
       ...:     aggfunc="sum",
       ...:     fill_value=0,
       ...:     )
```

```
Out[140]:
row col col0 col1 col2 col3 col4
row0 0.77 1.21 0.00 0.86 0.65
row2 0.13 0.00 0.79 0.50 0.50
row3 0.00 0.31 0.00 1.09 0.00
row4 0.00 0.10 0.79 1.52 0.24
```

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass `size` to the `aggfunc` parameter.

```
In [141]: df.pivot_table(index="row", columns="col", fill_value=0, aggfunc="size")
```

```
Out[141]:
row col col0 col1 col2 col3 col4
row0 1 2 0 1 1
row2 1 0 2 1 2
```
Pivoting with multiple aggregations

We can also perform multiple aggregations. For example, to perform both a sum and mean, we can pass in a list to the aggfunc argument.

```
In [142]: df.pivot_table(
       .....: values="val0",
       .....: index="row",
       .....: columns="col",
       .....: aggfunc=["mean", "sum"],
       .....: )
```

```
Out[142]:
```
```
<table>
<thead>
<tr>
<th>mean</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>col</td>
<td>col0</td>
</tr>
<tr>
<td>row</td>
<td></td>
</tr>
<tr>
<td>row0</td>
<td>0.77</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
</tr>
<tr>
<td>row3</td>
<td>NaN</td>
</tr>
<tr>
<td>row4</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```

Note to aggregate over multiple value columns, we can pass in a list to the values parameter.

```
In [143]: df.pivot_table(
       .....: values=["val0", "val1"],
       .....: index="row",
       .....: columns="col",
       .....: aggfunc=["mean"],
       .....: )
```

```
Out[143]:
```
```
<table>
<thead>
<tr>
<th>mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>val0</td>
</tr>
<tr>
<td>val1</td>
</tr>
<tr>
<td>col</td>
</tr>
<tr>
<td>row</td>
</tr>
<tr>
<td>row0</td>
</tr>
<tr>
<td>row2</td>
</tr>
<tr>
<td>row3</td>
</tr>
<tr>
<td>row4</td>
</tr>
</tbody>
</table>
```

Note to subdivide over multiple columns we can pass in a list to the columns parameter.

```
In [144]: df.pivot_table(
       .....: values=["val0"],
       .....: index="row",
       .....: columns=["item", "col"],
       .....: aggfunc=["mean"],
       .....: )
```

(continues on next page)

2.8. Reshaping and pivot tables
2.8.11 Exploding a list-like column

New in version 0.25.0.

Sometimes the values in a column are list-like.

```python
In [145]: keys = ["panda1", "panda2", "panda3"]

In [146]: values = [["eats", "shoots"], ["shoots", "leaves"], ["eats", "leaves"]]

In [147]: df = pd.DataFrame({"keys": keys, "values": values})

In [148]: df
Out[148]:
   keys values
0  panda1   [eats, shoots]
1  panda2   [shoots, leaves]
2  panda3   [eats, leaves]
```

We can ‘explode’ the values column, transforming each list-like to a separate row, by using `explode()`. This will replicate the index values from the original row:

```python
In [149]: df["values"].explode()
Out[149]:
   eats   shoots  leaves
0  eats         shoots  leaves
1  shoots         shoots
2  eats         leaves
```

You can also explode the column in the `DataFrame`.

```python
In [150]: df.explode("values")
Out[150]:
   keys values
0  panda1  eats
0  panda1  shoots
1  panda2  shoots
```
Series.explode() will replace empty lists with np.nan and preserve scalar entries. The dtype of the resulting Series is always object.

```
In [151]: s = pd.Series([[1, 2, 3], "foo", [], ["a", "b"]])

In [152]: s
Out[152]:
0    [1, 2, 3]
1      foo
2        []
3    [a, b]
dtype: object

In [153]: s.explode()
Out[153]:
0    1
0    2
0    3
1      foo
2    NaN
3      a
3      b
dtype: object
```

Here is a typical use case. You have comma separated strings in a column and want to expand this.

```
In [154]: df = pd.DataFrame([{"var1": "a,b,c", "var2": 1}, {"var1": "d,e,f", "var2": 2}]])

In [155]: df
Out[155]:
  var1  var2
0  a,b,c     1
1  d,e,f     2

Creating a long form DataFrame is now straightforward using explode and chained operations.

```
In [156]: df.assign(var1=df['var1'].str.split(',')).explode('var1')
Out[156]:
  var1  var2
0     a     1
0     b     1
0     c     1
1     d     2
1     e     2
1     f     2
```
2.9 Working with text data

2.9.1 Text data types

New in version 1.0.0.

There are two ways to store text data in pandas:

1. **object**-dtype NumPy array.
2. **StringDtype** extension type.

We recommend using **StringDtype** to store text data.

Prior to pandas 1.0, **object** dtype was the only option. This was unfortunate for many reasons:

1. You can accidentally store a mixture of strings and non-strings in an **object** dtype array. It’s better to have a dedicated dtype.
2. **object** dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn’t a clear way to select just text while excluding non-text but still object-dtype columns.
3. When reading code, the contents of an **object** dtype array is less clear than 'string'.

Currently, the performance of **object** dtype arrays of strings and `arrays.StringArray` are about the same. We expect future enhancements to significantly increase the performance and lower the memory overhead of `StringArray`.

**Warning**: `StringArray` is currently considered experimental. The implementation and parts of the API may change without warning.

For backwards-compatibility, **object** dtype remains the default type we infer a list of strings to

```
In [1]: pd.Series(["a", "b", "c"])
Out[1]:
0  a
1  b
2  c
dtype: object
```

To explicitly request string dtype, specify the dtype

```
In [2]: pd.Series(["a", "b", "c"], dtype="string")
Out[2]:
0  a
1  b
2  c
dtype: string
```

```
In [3]: pd.Series(["a", "b", "c"], dtype=pd.StringDtype())
Out[3]:
0  a
1  b
2  c
dtype: string
```

Or astype after the Series or DataFrame is created
In [4]: s = pd.Series(['a', 'b', 'c'])

In [5]: s
Out[5]:
0   a
1   b
2   c
dtype: object

In [6]: s.astype('string')
Out[6]:
0   a
1   b
2   c
dtype: string

Changed in version 1.1.0.
You can also use StringDtype/"string" as the dtype on non-string data and it will be converted to string dtype:

In [7]: s = pd.Series(['a', 2, np.nan], dtype='string')

In [8]: s
Out[8]:
0   a
1   2
2   <NA>
dtype: string

In [9]: type(s[1])
Out[9]: str

or convert from existing pandas data:

In [10]: s1 = pd.Series([1, 2, np.nan], dtype='Int64')

In [11]: s1
Out[11]:
0    1
1    2
2   <NA>
dtype: Int64

In [12]: s2 = s1.astype("string")

In [13]: s2
Out[13]:
0    1
1    2
2   <NA>
dtype: string

In [14]: type(s2[0])
Out[14]: str
Behavior differences

These are places where the behavior of `StringDtype` objects differ from `object` `dtype`:

1. For `StringDtype`, string accessor methods that return numeric output will always return a nullable integer `dtype`, rather than either int or float `dtype`, depending on the presence of NA values. Methods returning boolean output will return a nullable boolean `dtype`.

```python
In [15]: s = pd.Series(["a", None, "b"], dtype="string")

In [16]: s
Out[16]:
    0   a
    1  <NA>
    2   b
dtype: string

In [17]: s.str.count("a")
Out[17]:
    0   1
    1  <NA>
    2   0
dtype: Int64

In [18]: s.dropna().str.count("a")
Out[18]:
    0   1
    2   0
dtype: Int64
```

Both outputs are `Int64` `dtype`. Compare that with object-`dtype`:

```python
In [19]: s2 = pd.Series(["a", None, "b"], dtype="object")

In [20]: s2.str.count("a")
Out[20]:
    0   1.0
    1   NaN
    2   0.0
dtype: float64

In [21]: s2.dropna().str.count("a")
Out[21]:
    0   1
    2   0
dtype: int64
```

When NA values are present, the output `dtype` is `float64`. Similarly for methods returning boolean values.

```python
In [22]: s.str.isdigit()
Out[22]:
    0   False
    1  <NA>
    2   False
```

(continues on next page)
2. Some string methods, like `Series.str.decode()` are not available on `StringArray` because `StringArray` only holds strings, not bytes.

3. In comparison operations, `arrays.StringArray` and `Series` backed by a `StringArray` will return an object with `BooleanDtype`, rather than a `bool` dtype object. Missing values in a `StringArray` will propagate in comparison operations, rather than always comparing unequal like `numpy.nan`.

Everything else that follows in the rest of this document applies equally to `string` and `object` dtype.

### 2.9.2 String methods

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```
In [24]: s = pd.Series(
    ....:     ['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
    ....:     dtype='string'
)
   
In [25]: s.str.lower()
Out[25]:
0    a
1    b
2    c
3   aaba
4    baca
5    <NA>
6    caba
7    dog
8    cat
   dtype: string

In [26]: s.str.upper()
Out[26]:
0    A
1    B
2    C
3   AABA
4   BACA
5    <NA>
6    CABA
```
In [27]: s.str.len()
    Out[27]:
      0   1
      1   1
      2   1
      3   4
      4   4
    <NA> 0
      6   4
      7   3
      8   3
    dtype: int64

In [28]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])

In [29]: idx.str.strip()
    Out[29]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

In [30]: idx.str.lstrip()
    Out[30]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

In [31]: idx.str.rstrip()
    Out[31]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

In [32]: df = pd.DataFrame(
    ....:     np.random.randn(3, 2), columns=[' Column A ', ' Column B '], index=range(3)
    ....: )

In [33]: df
    Out[33]:
    Column A   Column B
    0  0.469112 -0.282863
    1 -1.509059 -1.135632
    2  1.212112 -0.173215

Since df.columns is an Index object, we can use the .str accessor

In [34]: df.columns.str.strip()
    Out[34]: Index([' Column A ', 'Column B'], dtype='object')

In [35]: df.columns.str.lower()
    Out[35]: Index([' column a ', ' column b '], dtype='object')

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lower casing all names, and replacing any remaining whitespaces with underscores:
In [36]: df.columns = df.columns.str.strip().str.lower().str.replace(" ", ".")

In [37]: df
Out[37]:

<table>
<thead>
<tr>
<th>column_a</th>
<th>column_b</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0.469112 0.282863</td>
<td></td>
</tr>
<tr>
<td>1 -1.509059 -1.135632</td>
<td></td>
</tr>
<tr>
<td>2 1.212112 -0.173215</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** If you have a Series where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series), it can be faster to convert the original Series to one of type category and then use .str.<method> or .dt.<property> on that. The performance difference comes from the fact that, for Series of type category, the string operations are done on the .categories and not on each element of the Series.

Please note that a Series of type category with string .categories has some limitations in comparison to Series of type string (e.g. you can’t add strings to each other: `s + " " + s` won’t work if `s` is a Series of type category). Also, .str methods which operate on elements of type list are not available on such a Series.

**Warning:** Before v.0.25.0, the .str-accessor did only the most rudimentary type checks. Starting with v.0.25.0, the type of the Series is inferred and the allowed types (i.e. strings) are enforced more rigorously.

Generally speaking, the .str accessor is intended to work only on strings. With very few exceptions, other uses are not supported, and may be disabled at a later point.

### 2.9.3 Splitting and replacing strings

Methods like split return a Series of lists:

In [38]: s2 = pd.Series(["a_b_c", "c_d_e", np.nan, "f_g_h"], dtype="string")

In [39]: s2.str.split("_")
Out[39]:

| 0 | [a, b, c] |
| 1 | [c, d, e] |
| 2 | <NA> |
| 3 | [f, g, h] |

dtype: object

Elements in the split lists can be accessed using get or [] notation:

In [40]: s2.str.split("_").str.get(1)
Out[40]:

| 0 | b |
| 1 | d |
| 2 | <NA> |
| 3 | g |

dtype: object

In [41]: s2.str.split("_").str[1]
Out[41]: (continues on next page)
It is easy to expand this to return a DataFrame using `expand`.

```
In [42]: s2.str.split("_", expand=True)
```

```
Out[42]:
0  1  2
0  a  b  c
1  c  d  e
2 <NA> <NA> <NA>
3  f  g  h
```

When original Series has `StringDtype`, the output columns will all be `StringDtype` as well.

It is also possible to limit the number of splits:

```
In [43]: s2.str.split("_", expand=True, n=1)
```

```
Out[43]:
0  1
0  a  b_c
1  c  d_e
2 <NA> <NA>
3  f  g_h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```
In [44]: s2.str.rsplit("_", expand=True, n=1)
```

```
Out[44]:
0  1
0  a_b  c
1  c_d  e
2 <NA> <NA>
3  f_g  h
```

`replace` optionally uses regular expressions:

```
In [45]: s3 = pd.Series(
        ....:     dtype="string",
        ....: )
```

```
In [46]: s3
```

```
Out[46]:
0   A
1   B
2   C
3  Aaba
```
Warning: Some caution must be taken when dealing with regular expressions! The current behavior is to treat single character patterns as literal strings, even when regex is set to True. This behavior is deprecated and will be removed in a future version so that the regex keyword is always respected.

Changed in version 1.2.0.

If you want literal replacement of a string (equivalent to str.replace()), you can set the optional regex parameter to False, rather than escaping each character. In this case both pat and repl must be strings:

```
In [48]: dollars = pd.Series(["12", "-$10", "$10,000"], dtype="string")

# These lines are equivalent
In [49]: dollars.str.replace(r"-\$", "-", regex=True)
Out[49]:
0   12
1  -10
2 $10,000
dtype: string

In [50]: dollars.str.replace("-$", "-", regex=False)
Out[50]:
0   12
1  -10
2 $10,000
dtype: string
```

The replace method can also take a callable as replacement. It is called on every pat using re.sub(). The callable should expect one positional argument (a regex object) and return a string.
# Reverse every lowercase alphabetic word
In [51]: pat = r"[a-z]+"

In [52]: def repl(m):
   .....:     return m.group(0)[::-1]
   .....:

In [53]: pd.Series(["foo 123", "bar baz", np.nan], dtype="string").str.replace(
   .....:     pat, repl, regex=True
   .....: )
   .....:
Out[53]:
0  oof 123
1  rab zab
2  <NA>
dtype: string

# Using regex groups
In [54]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [55]: def repl(m):
   .....:     return m.group("two").swapcase()
   .....:

In [56]: pd.Series(["Foo Bar Baz", np.nan], dtype="string").str.replace(
   .....:     pat, repl, regex=True
   .....: )
   .....:
Out[56]:
0  bAR
1  <NA>
dtype: string

The replace method also accepts a compiled regular expression object from re.compile() as a pattern. All flags should be included in the compiled regular expression object.

In [57]: import re

In [58]: regex_pat = re.compile(r"^[a|dog]", flags=re.IGNORECASE)

In [59]: s3.str.replace(regex_pat, "XX-XX ", regex=True)
Out[59]:
0   A
1   B
2   C
3 XX-XX ba
4 XX-XX ca
5
6  <NA>
7 XX-XX BA
8 XX-XX
9 XX-XX t
dtype: string
Including a flags argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```python
In [60]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
---------------------------------------------------------------------------
ValueError: case and flags cannot be set when pat is a compiled regex
```

`removeprefix` and `removesuffix` have the same effect as `str.removeprefix` and `str.removesuffix` added in Python 3.9 <https://docs.python.org/3/library/stdtypes.html#str.removeprefix>

New in version 1.4.0.

```python
In [61]: s = pd.Series(['str_foo', 'str_bar', 'no_prefix'])
In [62]: s.str.removeprefix("str_")
Out[62]:
0   foo
1   bar
2  no_prefix
dtype: object
In [63]: s = pd.Series(['foo_str', 'bar_str', 'no_suffix'])
In [64]: s.str.removesuffix('_str')
Out[64]:
0   foo
1   bar
2  no_suffix
dtype: object
```

### 2.9.4 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

#### Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:

```python
In [65]: s = pd.Series(['a', 'b', 'c', 'd'], dtype='string')
In [66]: s.str.cat(sep='')
Out[66]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=':'`:

```python
In [67]: s.str.cat()  
Out[67]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```python
In [68]: t = pd.Series(['a', 'b', np.nan, 'd'], dtype='string')
In [69]: t.str.cat(sep=':')
```

(continues on next page)
Out[69]: 'a,b,d'

In [70]: t.str.cat(sep='",", na_rep="-"
Out[70]: 'a,b,-,d'

Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling Series (or Index).

In [71]: s.str.cat(['A', 'B', 'C', 'D'])
Out[71]:
0  aA
1  bB
2  cC
3  dD
dtype: string

Missing values on either side will result in missing values in the result as well, unless `na_rep` is specified:

In [72]: s.str.cat(t)
Out[72]:
0  aa
1  bb
2  <NA>
3  dd
dtype: string

In [73]: s.str.cat(t, na_rep='-')
Out[73]:
0  aa
1  bb
2  c-
3  dd
dtype: string

Concatenating a Series and something array-like into a Series

The parameter `others` can also be two-dimensional. In this case, the number or rows must match the lengths of the calling Series (or Index).

In [74]: d = pd.concat([t, s], axis=1)

In [75]: s
Out[75]:
0  a
1  b
2  c
3  d
dtype: string
In [76]: d
Out[76]:
      0  1
    0  a a
    1  b b
    2 <NA> c
    3  d d

In [77]: s.str.cat(d, na_rep="-")
Out[77]:
    0  aaa
    1  bbb
    2  c-c
    3  ddd
dtype: string

Concatenating a Series and an indexed object into a Series, with alignment

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the join-keyword.

In [78]: u = pd.Series(["b", "d", "a", "c"], index=[1, 3, 0, 2], dtype="string")

In [79]: s
Out[79]:
    0  a
    1  b
    2  c
    3  d
dtype: string

In [80]: u
Out[80]:
    1  b
    3  d
    0  a
    2  c
dtype: string

In [81]: s.str.cat(u)
Out[81]:
    0  aa
    1  bb
    2  cc
    3  dd
dtype: string

In [82]: s.str.cat(u, join="left")
Out[82]:
    0  aa
Warning: If the join keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of 'left', 'outer', 'inner', 'right'). In particular, alignment also means that the different lengths do not need to coincide anymore.

```python
In [83]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4], dtype='string')
In [84]: s
Out[84]:
     0  a
    1  b
    2  c
    3  d
    dtype: string
In [85]: v
Out[85]:
   -1  z
    0  a
    1  b
    2  d
    4  e
    dtype: string
In [86]: s.str.cat(v, join='left', na_rep='-')
Out[86]:
     0  aa
    1  bb
    2  c-
    3  dd
    dtype: string
In [87]: s.str.cat(v, join='outer', na_rep='-')
Out[87]:
    -1  -z
    0   aa
    1   bb
    2  c-
    3  dd
    4   -e
    dtype: string
```

The same alignment can be used when `others` is a `DataFrame`:
### Concatenating a Series and many objects into a Series

Several array-like items (specifically: Series, Index, and 1-dimensional variants of np.ndarray) can be combined in a list-like container (including iterators, dict-views, etc.).
All elements without an index (e.g. np.ndarray) within the passed list-like must match in length to the calling Series (or Index), but Series and Index may have arbitrary length (as long as alignment is not disabled with join=None):

```
In [95]: v
Out[95]:
-1  z
 0  a
 1  b
 3  d
 4  e
dtype: string
```

```
In [96]: s.str.cat([v, u, u.to_numpy()], join="outer", na_rep="-")
Out[96]:
-1 -z--
 0 aaab
 1 bbbd
 2 c-c-
 3 dddc
 4 -e--
dtype: string
```

If using join='right' on a list-like of others that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```
In [97]: u.loc[[3]]
Out[97]:
 3  d
dtype: string
```

```
In [98]: v.loc[[-1, 0]]
Out[98]:
-1  z
 0  a
dtype: string
```

```
In [99]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join="right", na_rep="-")
Out[99]:
 3  dd-
-1  --z
 0  a-a
dtype: string
```
2.9.5 Indexing with `.str`

You can use [] notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```
In [100]: s = pd.Series(
        .....:     "string"
        .....:     )
        .....:

In [101]: s.str[0]
Out[101]:
          0  A
         1  B
         2  C
         3  A
         4  B
         5 <NA>
         6  C
         7  d
         8  c
dtype: string

In [102]: s.str[1]
Out[102]:
          0  <NA>
          1  <NA>
          2  <NA>
          3   a
          4   a
          5  <NA>
          6   A
          7   o
          8   a
dtype: string
```

2.9.6 Extracting substrings

**Extract first match in each subject (extract)**

**Warning:** Before version 0.23, argument expand of the `extract` method defaulted to False. When expand=False, `expand` returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern. When expand=True, it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user. expand=True has been the default since version 0.23.0.

The `extract` method accepts a regular expression with at least one capture group.

Extracting a regular expression with more than one group returns a DataFrame with one column per group.
In [103]: pd.Series(
    ....:     ["a1", "b2", "c3"],
    ....:     dtype="string",
    ....: ).str.extract(r"([ab])\(\d\)\", expand=False)
Out[103]:
     0  1
0   a  1
1   b  2
2  <NA> <NA>

Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating get() to access tuples or re.match objects. The dtype of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

In [104]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(
    ....:     r"(?P<letter>[ab])(?P<digit>\d)\", expand=False
    ....: )
Out[104]:
   letter  digit
0     a      1
1     b      2
2  <NA>  <NA>

and optional groups like

In [105]: pd.Series(["a1", "b2", "3"], dtype="string").str.extract(r"([ab])?\(\d\)\", expand=False)
Out[105]:
     0  1
0   a  1
1   b  2
2  <NA>  3

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if expand=True.

In [106]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(r"[ab]\(\d\)\", expand=True)
Out[106]:
       0
0    1
1    2
2 <NA>

It returns a Series if expand=False.
In [107]: pd.Series(['a1', 'b2', 'c3'], dtype='string').str.extract(r'[ab](\d)', expand=False)
Out[107]:
        0  1
   0 <NA> 1
   1  2  <NA>
dtype: string

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if expand=True.

In [108]: s = pd.Series(['a1', 'b2', 'c3'], ['A11', 'B22', 'C33'], dtype='string')

In [109]: s
Out[109]:
   A11  a1
   B22  b2
   C33  c3
dtype: string

In [110]: s.index.str.extract('(\w)', expand=True)
Out[110]:
   letter
   0 A
   1 B
   2 C

It returns an Index if expand=False.

In [111]: s.index.str.extract('(\w)', expand=False)
Out[111]: Index(['A', 'B', 'C'], dtype='object', name='letter')

Calling on an Index with a regex with more than one capture group returns a DataFrame if expand=True.

In [112]: s.index.str.extract('(?P<letter>[a-zA-Z])([0-9]+)', expand=True)
Out[112]:
   letter  1
   0 A  11
   1 B  22
   2 C  33

It raises ValueError if expand=False.

>>> s.index.str.extract('(?P<letter>[a-zA-Z])([0-9]+)', expand=False)
ValueError: only one regex group is supported with Index

The table below summarizes the behavior of extract(expand=False) (input subject in first column, number of groups in regex in first row)

<table>
<thead>
<tr>
<th></th>
<th>1 group</th>
<th>&gt;1 group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>Index</td>
<td>ValueError</td>
</tr>
<tr>
<td>Series</td>
<td>Series</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>
Extract all matches in each subject (extractall)

Unlike `extract` (which returns only the first match),

```python
In [113]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"], dtype="string")
In [114]: s
Out[114]:
A    a1a2
B     b1
C     c1
dtype: string

In [115]: two_groups = "(?P<letter>[a-z])(?P<digit>[0-9])"
In [116]: s.str.extract(two_groups, expand=True)
Out[116]:
   letter digit
A    a    1
B    b    1
C    c    1
```

the `extractall` method returns every match. The result of `extractall` is always a DataFrame with a MultiIndex on its rows. The last level of the MultiIndex is named `match` and indicates the order in the subject.

```python
In [117]: s.str.extractall(two_groups)
Out[117]:
   letter digit
match
   A    0    a    1
         1    a    2
   B    0    b    1
       C    0    c    1
```

When each subject string in the Series has exactly one match,

```python
In [118]: s = pd.Series(["a3", "b3", "c2"], dtype="string")
In [119]: s
Out[119]:
0    a3
1    b3
2    c2
dtype: string
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```python
In [120]: extract_result = s.str.extract(two_groups, expand=True)
In [121]: extract_result
Out[121]:
   letter digit
match
   0    a    3
   1    b    3
```

(continues on next page)
In [122]: extractall_result = s.str.extractall(two_groups)

In [123]: extractall_result
Out[123]:
   letter digit
0          a   3
1          b   3
2          c   2

In [124]: extractall_result.xs(0, level="match")
Out[124]:
   letter digit
0   a   3
1  b   3
2  c   2

Index also supports .str.extractall. It returns a DataFrame which has the same result as a Series.str.extractall with a default index (starts from 0).

In [125]: pd.Index(["a1a2", "b1", "c1"]).str.extractall(two_groups)
Out[125]:
   letter digit
0   a   1
1  a   2
1   b   1
2  c   1

In [126]: pd.Series(["a1a2", "b1", "c1"], dtype="string").str.extractall(two_groups)
Out[126]:
   letter digit
0   a   1
1  a   2
1   b   1
2  c   1

2.9.7 Testing for strings that match or contain a pattern

You can check whether elements contain a pattern:

In [127]: pattern = r"[^0-9][a-z]"

In [128]: pd.Series(["1", "2", "3a", "3b", "03c", "4dx"],
      ...
    dtype="string",
       ...:
    .str.contains(pattern)
       ...:

2.9. Working with text data 595
Or whether elements match a pattern:

```python
In [129]: pd.Series(
       ....:    ["1", "2", "3a", "3b", "03c", "4dx"],
       ....:    dtype="string",
       ....: ).str.match(pattern)
```

```
Out[129]:
0 False 
1 False 
2 True  
3 True 
4 True 
5 True 
dtype: boolean
```

New in version 1.1.0.

```python
In [130]: pd.Series(
       ....:    ["1", "2", "3a", "3b", "03c", "4dx"],
       ....:    dtype="string",
       ....: ).str.fullmatch(pattern)
```

```
Out[130]:
0 False 
1 False 
2 True  
3 True 
4 False 
5 False 
dtype: boolean
```

**Note:** The distinction between match, fullmatch, and contains is strictness: fullmatch tests whether the entire string matches the regular expression; match tests whether there is a match of the regular expression that begins at the first character of the string; and contains tests whether there is a match of the regular expression at any position within the string.

The corresponding functions in the re package for these three match modes are re.fullmatch, re.match, and re.search, respectively.

Methods like match, fullmatch, contains, startswith, and endswith take an extra na argument so missing values can be considered True or False:
2.9.8 Creating indicator variables

You can extract dummy variables from string columns. For example if they are separated by a ' | ':

```
In [133]: s = pd.Series(["a", "a|b", np.nan, "a|c"], dtype="string")
```

```
In [134]: s.str.get_dummies(sep="|")
Out[134]:
   a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1
```

String Index also supports `get_dummies` which returns a `MultiIndex`.

```
In [135]: idx = pd.Index(["a", "a|b", np.nan, "a|c"])
```

```
In [136]: idx.str.get_dummies(sep="|")
Out[136]:
MultiIndex([(1, 0, 0),
            (1, 1, 0),
            (0, 0, 0),
            (1, 0, 1)],
           names=['a', 'b', 'c'])
```

See also `get_dummies()`.
## 2.9.9 Method summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat()</td>
<td>Concatenate strings</td>
</tr>
<tr>
<td>split()</td>
<td>Split strings on delimiter</td>
</tr>
<tr>
<td>rsplit()</td>
<td>Split strings on delimiter working from the end of the string</td>
</tr>
<tr>
<td>get()</td>
<td>Index into each element (retrieve i-th element)</td>
</tr>
<tr>
<td>join()</td>
<td>Join strings in each element of the Series with passed separator</td>
</tr>
<tr>
<td>get_dummies()</td>
<td>Split strings on the delimiter returning DataFrame of dummy variables</td>
</tr>
<tr>
<td>contains()</td>
<td>Return boolean array if each string contains pattern/regex</td>
</tr>
<tr>
<td>replace()</td>
<td>Replace occurrences of pattern/regex/string with some other string or the return value of a callable given the occurrence</td>
</tr>
<tr>
<td>removeprefix()</td>
<td>Remove prefix from string, i.e. only remove if string starts with prefix.</td>
</tr>
<tr>
<td>removesuffix()</td>
<td>Remove suffix from string, i.e. only remove if string ends with suffix.</td>
</tr>
<tr>
<td>repeat()</td>
<td>Duplicate values (s.str.repeat(3) equivalent to x * 3)</td>

2.10 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

Note: The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. Starting from pandas 1.0, some optional data types start experimenting with a native NA scalar using a mask-based approach. See here for more.

See the cookbook for some advanced strategies.

2.10.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python None will arise and we wish to also consider that “missing” or “not available” or “NA”.

Note: If you want to consider inf and -inf to be “NA” in computations, you can set pandas.options.mode.use_inf_as_na = True.

In [1]: df = pd.DataFrame(
    ...:     np.random.randn(5, 3),
    ...:     index=["a", "c", "e", "f", "h"],
    ...:     columns=["one", "two", "three"],
    ...: )

In [2]: df["four"] = "bar"

In [3]: df["five"] = df["one"] > 0

In [4]: df
Out[4]:

   one  two  three  four  five
a  0.469112 -0.282863 -1.509059  bar  True
b -1.135632  1.212112 -0.173215  bar  False
c  0.119209 -1.044236 -0.861849  bar  True
d -2.104569 -0.494929  1.071804  bar  False

(continues on next page)
In [5]: df2 = df.reindex(["a", "b", "c", "d", "e", "f", "g", "h"])

In [6]: df2
Out[6]:
   one    two    three    four    five
a  0.469112 -0.282863 -1.509059  bar  True
b   NaN      NaN      NaN      NaN
   NaN      NaN      NaN      NaN
c -1.135632  1.212112 -0.173215  bar  False
d   NaN      NaN      NaN      NaN
e  0.119209 -1.044236 -0.861849  bar  True
f -2.104569 -0.494929  1.071804  bar  False
g   NaN      NaN      NaN      NaN
h  0.721555 -0.706771 -1.039575  bar  True

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

In [7]: df2["one"]
Out[7]:
   a  0.469112
   b  NaN
   c -1.135632
   d  NaN
   e  0.119209
   f -2.104569
   g  NaN
   h  0.721555
Name: one, dtype: float64

In [8]: pd.isna(df2["one"])
Out[8]:
   a  False
   b   True
   c  False
   d   True
   e  False
   f  False
   g   True
   h  False
Name: one, dtype: bool

In [9]: df2["four"].notna()
Out[9]:
   a   True
   b   False
   c   True
   d  False
   e   True
   f   True
   g   False

(continues on next page)
Warning: One has to be mindful that in Python (and NumPy), the NaN’s don’t compare equal, but None’s do. Note that pandas/NumPy uses the fact that np.nan != np.nan, and treats None like np.nan.

In [11]: None == None  # noqa: E711
Out[11]: True

In [12]: np.nan == np.nan
Out[12]: False

So as compared to above, a scalar equality comparison versus a None/np.nan doesn’t provide useful information.

In [13]: df2["one"] == np.nan
Out[13]:
    a  False
    b  False
    c  False
    d  False
    e  False
    f  False
    g  False
    h  False
Name: one, dtype: bool

Integer dtypes and missing data

Because NaN is a float, a column of integers with even one missing values is cast to floating-point dtype (see Support for integer NA for more). pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())
Out[14]:
0    1
1    2
2    <NA>
3    4
dtype: Int64
Alternatively, the string alias `dtype='Int64'` (note the capital "I") can be used. See `Nullable integer data type` for more.

**Datetimes**

For datetime64[ns] types, `NaT` represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (datetime64[ns]). pandas objects provide compatibility between `NaT` and `NaN`.

```
In [15]: df2 = df.copy()
In [16]: df2["timestamp"] = pd.Timestamp("20120101")
In [17]: df2
Out[17]:
   one   two  three    four   five    timestamp
  a   0.469112  -0.282863  -1.509059   bar  True  2012-01-01
  c  -1.135632   1.212112  -0.173215   bar  False  2012-01-01
  e   0.119209  -1.044236  -0.861849   bar  True  2012-01-01
  f  -2.104569  -0.494929   1.071804   bar  False  2012-01-01
  h   0.721555  -0.706771  -1.039575   bar  True  2012-01-01
In [18]: df2.loc[\["a", "c", "h"\], ["one", "timestamp"]]= np.nan
In [19]: df2
Out[19]:
   one two three four five    timestamp
  a NaN  0.469112  -0.282863  -1.509059   bar  True  2012-01-01
  c NaN  1.212112 -1.135632  -0.173215   bar  False  2012-01-01
  e NaN  0.119209  -1.044236  -0.861849   bar  True  2012-01-01
  f NaN -2.104569  -0.494929   1.071804   bar  False  2012-01-01
  h NaN  0.721555  -0.706771 -1.039575   bar  True  2012-01-01
In [20]: df2.dtypes.value_counts()
Out[20]:
float64    3
object     1
bool       1
datetime64[ns]    1
dtype: int64
```

### 2.10.2 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use `NaN` regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])
In [22]: s.loc[0] = None
```

(continues on next page)
Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```python
In [24]: s = pd.Series(["a", "b", "c"])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan

In [27]: s
Out[27]:
0   None
1   NaN
2    c
dtype: object
```

### 2.10.3 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```python
In [28]: a
Out[28]:
 one  two
a   NaN -0.282863
 c  NaN  1.212112
e  0.119209 -1.044236
f -2.104569 -0.494929
h -2.104569 -0.706771

In [29]: b
Out[29]:
 one  two  three
a   NaN -0.282863 -1.509059
 c  NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h   NaN -0.706771 -1.039575

In [30]: a + b
Out[30]:
 one  two  three
a   NaN  NaN  NaN
 c  NaN  NaN  NaN
```

(continues on next page)
The descriptive statistics and computational methods discussed in the data structure overview (and listed here and here) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```python
In [31]: df
Out[31]:
    one   two    three
   ---   ---     ---
a   NaN  -0.282863 -1.509059
c   NaN   1.212112  -0.173215
e -0.119209 -1.044236  -0.861849
f -2.104569  -0.494929   1.071804
h   NaN  -0.706771  -1.039575

In [32]: df["one"].sum()
Out[32]: -1.9853605075978744

In [33]: df.mean(1)
Out[33]:
   a   0.895961
   c  0.519449
   e -0.595625
   f -0.509232
   h -0.873173
dtype: float64

In [34]: df.cumsum()
Out[34]:
   one   two    three
   ---   ---     ---
a   NaN  -0.282863 -1.509059
c   NaN   0.929249  -1.682273
e -0.119209 -0.114987  -2.544122
f -1.985361 -0.609917  -1.472318
h   NaN -1.316688  -2.511893

In [35]: df.cumsum(skipna=False)
Out[35]:
   one   two    three
   ---   ---     ---
a   NaN  -0.282863 -1.509059
c   NaN   0.929249  -1.682273
e   NaN  -0.114987  -2.544122
f   NaN  -0.609917  -1.472318
h   NaN -1.316688  -2.511893
```
2.10.4 Sum/prod of empties/nans

**Warning:** This behavior is now standard as of v0.22.0 and is consistent with the default in numpy; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See v0.22.0 `whatsnew` for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```
In [36]: pd.Series([np.nan]).sum()
Out[36]: 0.0

In [37]: pd.Series([], dtype="float64").sum()
Out[37]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```
In [38]: pd.Series([np.nan]).prod()
Out[38]: 1.0

In [39]: pd.Series([], dtype="float64").prod()
Out[39]: 1.0
```

2.10.5 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [40]: df
Out[40]:
   one  two   three
a  NaN 0.282863 -1.509059
 c  NaN 1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
 f -2.104569 -0.494929  1.071804
 h  NaN -0.706771 -1.039575

In [41]: df.groupby("one").mean()
Out[41]:
   two    three
one
-2.104569 -0.494929  1.071804
 0.119209 -1.044236 -0.861849
```

See the groupby section `here` for more information.
Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

2.10.6 Filling missing values: fillna

fillna() can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

Replace NA with a scalar value

```
In [42]: df2
Out[42]:
   one    two    three    four    five       timestamp
0   NaN -0.28286  -1.509059  bar  True       NaT
1   NaN  1.212112 -0.173215  bar False       NaT
2  0.119209 -1.044236 -0.861849  bar  True 2012-01-01
3 -2.104569 -0.494929  1.071804  bar False 2012-01-01
4  NaN -0.706771 -1.039575  bar  True       NaT
In [43]: df2.fillna(0)
Out[43]:
   one    two    three    four    five       timestamp
0   0.000000 -0.28286  -1.509059  bar  True       0
1   0.000000  1.212112 -0.173215  bar False       0
2  0.119209 -1.044236 -0.861849  bar  True 2012-01-01 00:00:00
3 -2.104569 -0.494929  1.071804  bar False 2012-01-01 00:00:00
4  0.000000 -0.706771 -1.039575  bar  True       0
In [44]: df2["one"]["missing"
Out[44]:
   a  missing
   c  missing
   e  0.119209
   f -2.104569
   h  missing
Name: one, dtype: object
```

Fill gaps forward or backward

Using the same filling arguments as reindexing, we can propagate non-NA values forward or backward:

```
In [45]: df
Out[45]:
   one    two    three
0   NaN -0.28286  -1.509059
1   NaN  1.212112 -0.173215
2  0.119209 -1.044236 -0.861849
3 -2.104569 -0.494929  1.071804
4  NaN -0.706771 -1.039575
In [46]: df.fillna(method="pad")
Out[46]:
   one    two    three
0   NaN -0.28286  -1.509059
(continues on next page)```
Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the `limit` keyword:

```python
In [47]: df
Out[47]:
   one   two   three
a  NaN  0.282863  1.509059
b  NaN  1.212112  0.173215
c  NaN  1.212112  0.173215
d  NaN  1.212112  0.173215
e  NaN  1.212112  0.173215
f  NaN  1.212112  0.173215
h  NaN  1.212112  0.173215

In [48]: df.fillna(method="pad", limit=1)
Out[48]:
   one   two   three
a  NaN  0.282863  1.509059
b  NaN  1.212112  0.173215
c  NaN  1.212112  0.173215
d  NaN  1.212112  0.173215
e  NaN  1.212112  0.173215
f  NaN  1.212112  0.173215
h  NaN  1.212112  0.173215
```

To remind you, these are the available filling methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
</tbody>
</table>

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

### 2.10.7 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```python
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list("ABC"))
In [50]: dff.iloc[3:5, 0] = np.nan
In [51]: dff.iloc[4:6, 1] = np.nan
In [52]: dff.iloc[5:8, 2] = np.nan
In [53]: dff
```
```
Out[53]:
   A     B     C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3  NaN  0.577046 -1.715002
4  NaN  NaN     -1.157892
5 -1.344312  NaN     NaN
6 -0.109050  1.643563  NaN
7  0.357021  -0.674600  NaN
8  NaN  0.577046 -1.715002
9  NaN  NaN     -1.157892
```

```
In [54]: dff.fillna(dff.mean())
Out[54]:
   A     B     C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3 -0.140857  0.577046 -1.715002
4 -0.140857 -0.401419 -1.157892
5 -1.344312 -0.401419  -0.293543
6 -0.109050  1.643563  NaN
7  0.357021  -0.674600  NaN
8 -0.968914 -1.294524  0.413738
9  0.276662  -0.472035  -0.013960
```

```
In [55]: dff.fillna(dff.mean()[:"C"])
Out[55]:
   A     B     C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3 -0.140857  0.577046 -1.715002
4 -0.140857 -0.401419 -1.157892
5 -1.344312 -0.401419  -0.293543
6 -0.109050  1.643563  NaN
7  0.357021  -0.674600  NaN
8 -0.968914 -1.294524  0.413738
9  0.276662  -0.472035  -0.013960
```

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

```
In [56]: dff.where(pd.notna(dff), dff.mean(), axis=\"columns\")
Out[56]:
   A     B     C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3  NaN  0.577046 -1.715002
4  NaN  NaN     -1.157892
5 -1.344312  NaN     NaN
6 -0.109050  1.643563  NaN
7  0.357021  -0.674600  NaN
8 -0.968914 -1.294524  0.413738
9  0.276662  -0.472035  -0.013960
```

(continues on next page)
### 2.10.8 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```python
In [57]: df
Out[57]:
   one      two      three
a  NaN  -0.282863  -1.509059
b  NaN  1.212112   -0.173215
c  NaN     0.000000     0.000000
d  NaN     0.000000     0.000000
e  NaN  -0.706771  -1.039575

In [58]: df.dropna(axis=0)
Out[58]:
Empty DataFrame
Columns: [one, two, three]
Index: []

In [59]: df.dropna(axis=1)
Out[59]:
   two      three
a -0.282863  -1.509059
b  1.212112  -0.173215
c     0.000000     0.000000
d     0.000000     0.000000
e -0.706771  -1.039575

In [60]: df["one"].dropna()
Out[60]:
Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. `DataFrame.dropna` has considerably more options than `Series.dropna`, which can be examined in the API.

### 2.10.9 Interpolation

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.

```python
In [61]: ts
Out[61]:
2000-01-31    0.469112
2000-02-29    NaN
2000-03-31    NaN
2000-04-28    NaN
```

(continues on next page)
2000-05-31  NaN
2007-12-31  -6.950267
2008-01-31  -7.904475
2008-02-29  -6.441779
2008-03-31  -8.184940
2008-04-30  -9.011531
Freq: BM, Length: 100, dtype: float64

In [62]: ts.count()
Out[62]: 66

In [63]: ts.plot()
Out[63]: <AxesSubplot:>

In [64]: ts.interpolate()
Out[64]:
2000-01-31  0.469112
2000-02-29  0.434469
2000-03-31  0.399826
2000-04-28  0.365184
2000-05-31  0.330541

(continues on next page)
Index aware interpolation is available via the method keyword:

```
In [67]: ts2
Out[67]:
2000-01-31   0.469112
2000-02-29   NaN
2002-07-31  -5.785037
2005-01-31   NaN
```

(continues on next page)
2008-04-30  -9.011531  
dtype: float64  

**In [68]:** ts2.interpolate()  
**Out[68]:**  
2000-01-31  0.469112  
2000-02-29  -2.657962  
2002-07-31  -5.785037  
2005-01-31  -7.398284  
2008-04-30  -9.011531  
dtype: float64  

**In [69]:** ts2.interpolate(method="time")  
**Out[69]:**  
2000-01-31  0.469112  
2000-02-29  0.270241  
2002-07-31  -5.785037  
2005-01-31  -7.190866  
2008-04-30  -9.011531  
dtype: float64  

For a floating-point index, use `method='values'`:  

**In [70]:** ser  
**Out[70]:**  
0.0  0.0  
1.0  NaN  
10.0  10.0  
dtype: float64  

**In [71]:** ser.interpolate()  
**Out[71]:**  
0.0  0.0  
1.0  5.0  
10.0  10.0  
dtype: float64  

**In [72]:** ser.interpolate(method="values")  
**Out[72]:**  
0.0  0.0  
1.0  1.0  
10.0  10.0  
dtype: float64  

You can also interpolate with a DataFrame:  

**In [73]:** df = pd.DataFrame(  
       ....: {  
       ....:     "A": [1, 2.1, np.nan, 4.7, 5.6, 6.8],  
       ....:     "B": [0.25, np.nan, np.nan, 4, 12.2, 14.4],  
       ....: }  
       ....: )  
(continues on next page)
In [74]: df
Out[74]:
     A    B
0  1.0  0.25
1  2.1   NaN
2   NaN   NaN
3  4.7   4.00
4  5.6  12.20
5  6.8  14.40

In [75]: df.interpolate()
Out[75]:
     A    B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40

The method argument gives access to fancier interpolation methods. If you have scipy installed, you can pass the name of a 1-d interpolation routine to method. You'll want to consult the full scipy interpolation documentation and reference guide for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, method='quadratic' may be appropriate.
- If you have values approximating a cumulative distribution function, then method='pchip' should work well.
- To fill missing values with goal of smooth plotting, consider method='akima'.

Warning: These methods require scipy.

In [76]: df.interpolate(method="barycentric")
Out[76]:
     A    B
0  1.00  0.250
1  2.10 -7.660
2  3.53 -4.515
3  4.70  4.000
4  5.60 12.200
5  6.80 14.400

In [77]: df.interpolate(method="pchip")
Out[77]:
     A    B
0  1.00000  0.250000
1  2.10000  0.672808
2  3.43454  1.928950
3  4.70000  4.000000
When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```
In [79]: df.interpolate(method="spline", order=2)
Out[79]:
   A   B
0 1.000000 0.250000
1 2.100000 -0.428598
2 3.451351 -1.453846
3 4.700000 4.000000
4 5.600000 12.200000
5 6.800000 14.400000
```

Compare several methods:

```
In [81]: np.random.seed(2)
In [82]: ser = pd.Series(np.arange(1, 10.1, 0.25) ** 2 + np.random.randn(37))
In [83]: missing = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])
In [84]: ser[missing] = np.nan
In [85]: methods = ["linear", "quadratic", "cubic"]
In [86]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
In [87]: df.plot()
Out[87]: <AxesSubplot:>
```
Another use case is interpolation at new values. Suppose you have 100 observations from some distribution. And let’s suppose that you’re particularly interested in what’s happening around the middle. You can mix pandas’ `reindex` and `interpolate` methods to interpolate at the new values.

```python
In [88]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [89]: new_index = ser.index.union(pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75]))

In [90]: interp_s = ser.reindex(new_index).interpolate(method="pchip")

In [91]: interp_s[49:51]
Out[91]:
   49.00    0.471410
   49.25    0.476841
   49.50    0.481780
   49.75    0.485998
   50.00    0.489266
   50.25    0.491814
   50.50    0.493995
   50.75    0.495763
   51.00    0.497074
dtype: float64
```
**Interpolation limits**

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```
In [92]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])
In [93]: ser
Out[93]:
0    NaN
1    NaN
2    5.0
3    NaN
4    NaN
5    NaN
6    13.0
7    NaN
8    NaN
dtype: float64
```

# fill all consecutive values in a forward direction
```
In [94]: ser.interpolate()
Out[94]:
0    NaN
1    NaN
2    5.0
3    7.0
4    9.0
5    11.0
6    13.0
7    13.0
8    13.0
dtype: float64
```

# fill one consecutive value in a forward direction
```
In [95]: ser.interpolate(limit=1)
Out[95]:
0    NaN
1    NaN
2    5.0
3    7.0
4    NaN
5    NaN
6    13.0
7    13.0
8    NaN
dtype: float64
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

# fill one consecutive value backwards
```
In [96]: ser.interpolate(limit=1, limit_direction="backward")
Out[96]:
(continues on next page)
```
0  NaN
1   5.0
2   5.0
3   NaN
4   NaN
5  11.0
6  13.0
7  NaN
8  NaN
dtype: float64

# fill one consecutive value in both directions
In [97]: ser.interpolate(limit=1, limit_direction="both")
Out[97]:
0  NaN
1   5.0
2   5.0
3    7.0
4   NaN
5  11.0
6  13.0
7  13.0
8  NaN
dtype: float64

# fill all consecutive values in both directions
In [98]: ser.interpolate(limit_direction="both")
Out[98]:
0   5.0
1   5.0
2   5.0
3    7.0
4    9.0
5  11.0
6  13.0
7  13.0
8  13.0
dtype: float64

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. The limit_area parameter restricts filling to either inside or outside values.

# fill one consecutive inside value in both directions
In [99]: ser.interpolate(limit_direction="both", limit_area="inside", limit=1)
Out[99]:
0  NaN
1   NaN
2   5.0
3    7.0
4   NaN
5  11.0
6  13.0
7  13.0
8  13.0

(continues on next page)
# fill all consecutive outside values backward

```python
In [100]: ser.interpolate(limit_direction="backward", limit_area="outside")
```
```
Out[100]:
0   5.0
1   5.0
2   5.0
3   NaN
4   NaN
5   NaN
6  13.0
7   NaN
8   NaN
dtype: float64
```

# fill all consecutive outside values in both directions

```python
In [101]: ser.interpolate(limit_direction="both", limit_area="outside")
```
```
Out[101]:
0   5.0
1   5.0
2   5.0
3   NaN
4   NaN
5   NaN
6  13.0
7  13.0
8  13.0
dtype: float64
```

## 2.10.10 Replacing generic values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```python
In [102]: ser = pd.Series([0.0, 1.0, 2.0, 3.0, 4.0])
```
```
In [103]: ser.replace(0, 5)
```
```
Out[103]:
0   5.0
1   1.0
2   2.0
3   3.0
4   4.0
dtype: float64
```

You can replace a list of values by a list of other values:
You can also specify a mapping dict:

```python
In [105]: ser.replace({0: 10, 1: 100})
Out[105]:
0   10.0
1  100.0
2   2.0
3   3.0
4   4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```python
In [106]: df = pd.DataFrame({"a": [0, 1, 2, 3, 4], "b": [5, 6, 7, 8, 9]})

In [107]: df.replace({"a": 0, "b": 5}, 100)
Out[107]:
a  b  
0  100 100
1   1   6
2   2   7
3   3   8
4   4   9
```

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```python
In [108]: ser.replace([1, 2, 3], method="pad")
Out[108]:
0   0.0
1   0.0
2   0.0
3   0.0
4   4.0
dtype: float64
```
2.10.11 String/regular expression replacement

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\' == '\\'. You should read about them if this is unclear.

Replace the ‘.’ with NaN (str -> str):

```
In [109]: d = {"a": list(range(4)), "b": list("ab.."), "c": ["a", "b", np.nan, "d"]}
In [110]: df = pd.DataFrame(d)
In [111]: df.replace(".", np.nan)
Out[111]:
a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN d
```

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```
In [112]: df.replace(r"\s*\..\s*", np.nan, regex=True)
Out[112]:
a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN d
```

Replace a few different values (list -> list):

```
In [113]: df.replace(["a", "."], ["b", np.nan])
Out[113]:
a  b  c
0  0  b  b
1  1  b  b
2  NaN NaN
3  NaN d
```

list of regex -> list of regex:

```
In [114]: df.replace([r".", r"(a)"], ["dot", r"\1stuff"], regex=True)
Out[114]:
a  b  c
0  0  astuff astuff
1  1  b  b
2  dot NaN
3  dot d
```

Only search in column 'b' (dict -> dict):
In [115]: df.replace({"b": "."}, {"b": np.nan})
Out[115]:
   a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

In [116]: df.replace({"b": r"\s*\./\s*"}, {"b": np.nan}, regex=True)
Out[116]:
   a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d

You can pass nested dictionaries of regular expressions that use regex=True:

In [117]: df.replace({"b": {"b": r""}}, regex=True)
Out[117]:
   a  b  c
0  0  a  a
1  1  b  b
2  .  NaN
3  .  d

Alternatively, you can pass the nested dictionary like so:

In [118]: df.replace(regex={"b": {r"\s*\./\s*": np.nan}})
Out[118]:
   a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

In [119]: df.replace({"b": r"\s*(\.)\s*"}, {"b": r"\1ty"}, regex=True)
Out[119]:
   a  b  c
0  0  a  a
1  1  b  b
2  .ty NaN
3  .ty  d

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

In [120]: df.replace([r"\s*\./\s*", r"a|b"], np.nan, regex=True)
Out[120]:
(continues on next page)
All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```python
In [121]: df.replace(regex=[r"\s*\.\s*", r"a|b"], value=np.nan)
Out[121]:
     a  b  c
0  NaN NaN NaN
1  NaN NaN NaN
2  NaN NaN NaN
3  NaN  d NaN
```

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

**Note:** Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

## 2.10.12 Numeric replacement

`replace()` is similar to `fillna()`.

```python
In [122]: df = pd.DataFrame(np.random.randn(10, 2))
In [123]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
In [124]: df.replace(1.5, np.nan)
Out[124]:
     0  1
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4  NaN  NaN
5  NaN  NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9  NaN  NaN
```

Replacing more than one value is possible by passing a list.

```python
In [125]: df00 = df.iloc[0, 0]
In [126]: df.replace([1.5, df00], [np.nan, "a"])
```

(continues on next page)
Out[126]:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>a</td>
<td>-1.021415</td>
</tr>
<tr>
<td>1</td>
<td>0.432396</td>
<td>-0.323580</td>
</tr>
<tr>
<td>2</td>
<td>0.423825</td>
<td>0.799180</td>
</tr>
<tr>
<td>3</td>
<td>1.262614</td>
<td>0.751965</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>5</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>6</td>
<td>-0.498174</td>
<td>-1.060799</td>
</tr>
<tr>
<td>7</td>
<td>0.591667</td>
<td>-0.183257</td>
</tr>
<tr>
<td>8</td>
<td>1.019855</td>
<td>-1.482465</td>
</tr>
<tr>
<td>9</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

In [127]: df[1].dtype
Out[127]: dtype('float64')

You can also operate on the DataFrame in place:

In [128]: df.replace(1.5, np.nan, inplace=True)

**Missing data casting rules and indexing**

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we've established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

<table>
<thead>
<tr>
<th>data type</th>
<th>Cast to</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>float</td>
</tr>
<tr>
<td>boolean</td>
<td>object</td>
</tr>
<tr>
<td>float</td>
<td>no cast</td>
</tr>
<tr>
<td>object</td>
<td>no cast</td>
</tr>
</tbody>
</table>

For example:

In [129]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [130]: s > 0
Out[130]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>True</td>
</tr>
<tr>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>4</td>
<td>True</td>
</tr>
<tr>
<td>6</td>
<td>True</td>
</tr>
<tr>
<td>7</td>
<td>True</td>
</tr>
</tbody>
</table>

dtype: bool

In [131]: (s > 0).dtype
Out[131]: dtype('bool')

In [132]: crit = (s > 0).reindex(list(range(8)))

(continues on next page)
Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```python
In [135]: reindexed = s.reindex(list(range(8))).fillna(0)
In [136]: reindexed[crit]
---------------------------------------------------------------------------

ValueError: Cannot mask with non-boolean array containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

```python
In [137]: reindexed[crit.fillna(False)]
Out[137]:
0   0.126504
2   0.696198
4   0.697416
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.1

(continued from previous page)

<table>
<thead>
<tr>
<th></th>
<th>6</th>
<th>0.601516</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>0.003659</td>
<td></td>
</tr>
</tbody>
</table>

dtype: float64

In [138]: reindexed[crit.fillna(True)]

Out[138]:
0  0.126504
1  0.000000
2  0.696198
3  0.000000
4  0.697416
5  0.000000
6  0.601516
7  0.003659
dtype: float64

Pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the dtype="Int64".

In [139]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")

In [140]: s

Out[140]:
0  0
1  1
2 <NA>
3  3
4  4
dtype: Int64

See Nullable integer data type for more.

### 2.10.13 Experimental NA scalar to denote missing values

**Warning**: Experimental: the behaviour of pd.NA can still change without warning.

New in version 1.0.0.

Starting from pandas 1.0, an experimental pd.NA value (singleton) is available to represent scalar missing values. At this moment, it is used in the nullable integer, boolean and dedicated string data types as the missing value indicator.

The goal of pd.NA is provide a “missing” indicator that can be used consistently across data types (instead of np.nan, None or pd.NaT depending on the data type).

For example, when having missing values in a Series with the nullable integer dtype, it will use pd.NA:

In [141]: s = pd.Series([1, 2, None], dtype="Int64")

In [142]: s

Out[142]:
0  1

(continues on next page)
Currently, pandas does not yet use those data types by default (when creating a DataFrame or Series, or when reading in data), so you need to specify the dtype explicitly. An easy way to convert to those dtypes is explained here.

**Propagation in arithmetic and comparison operations**

In general, missing values propagate in operations involving pd.NA. When one of the operands is unknown, the outcome of the operation is also unknown.

For example, pd.NA propagates in arithmetic operations, similarly to np.nan:

```
In [145]: pd.NA + 1
Out[145]: <NA>
```

```
In [146]: "a" * pd.NA
Out[146]: <NA>
```

There are a few special cases when the result is known, even when one of the operands is NA.

```
In [147]: pd.NA ** 0
Out[147]: 1
```

```
In [148]: 1 ** pd.NA
Out[148]: 1
```

In equality and comparison operations, pd.NA also propagates. This deviates from the behaviour of np.nan, where comparisons with np.nan always return False.

```
In [149]: pd.NA == 1
Out[149]: <NA>
```

```
In [150]: pd.NA == pd.NA
Out[150]: <NA>
```

```
In [151]: pd.NA < 2.5
Out[151]: <NA>
```

To check if a value is equal to pd.NA, the isna() function can be used:

```
In [152]: pd.isna(pd.NA)
Out[152]: True
```

An exception on this basic propagation rule are reductions (such as the mean or the minimum), where pandas defaults to skipping missing values. See above for more.
Logical operations

For logical operations, `pd.NA` follows the rules of the three-valued logic (or Kleene logic, similarly to R, SQL and Julia). This logic means to only propagate missing values when it is logically required.

For example, for the logical “or” operation (`|`), if one of the operands is `True`, we already know the result will be `True`, regardless of the other value (so regardless the missing value would be `True` or `False`). In this case, `pd.NA` does not propagate:

```
In [153]: True  |  False
Out[153]: True

In [154]: True  |  pd.NA
Out[154]: True

In [155]: pd.NA  |  True
Out[155]: True
```

On the other hand, if one of the operands is `False`, the result depends on the value of the other operand. Therefore, in this case `pd.NA` propagates:

```
In [156]: False  |  True
Out[156]: True

In [157]: False  |  False
Out[157]: False

In [158]: False  |  pd.NA
Out[158]: <NA>
```

The behaviour of the logical “and” operation (`&`) can be derived using similar logic (where now `pd.NA` will not propagate if one of the operands is already `False`):

```
In [159]: False  &  True
Out[159]: False

In [160]: False  &  False
Out[160]: False

In [161]: False  &  pd.NA
Out[161]: False

In [162]: True  &  True
Out[162]: True

In [163]: True  &  False
Out[163]: False

In [164]: True  &  pd.NA
Out[164]: <NA>
```
**NA in a boolean context**

Since the actual value of an NA is unknown, it is ambiguous to convert NA to a boolean value. The following raises an error:

```python
In [165]: bool(pd.NA)
---------------------------------------------------------------------------
TypeError                                 Traceback (most recent call last)
Input In [165], in <module>             ----> 1 bool(pd.NA)

File /pandas/pandas/_libs/missing.py:382, in pandas._libs.missing.NAType.__bool__
    TypeError: boolean value of NA is ambiguous
```

This also means that `pd.NA` cannot be used in a context where it is evaluated to a boolean, such as `if condition:`. Where `condition` can potentially be `pd.NA`. In such cases, `isna()` can be used to check for `pd.NA` or condition being `pd.NA` can be avoided, for example by filling missing values beforehand.

A similar situation occurs when using Series or DataFrame objects in `if` statements, see *Using if/truth statements with pandas*.

**NumPy ufuncs**

`pandas.NA` implements NumPy’s `__array_ufunc__` protocol. Most ufuncs work with `NA`, and generally return `NA`:

```python
In [166]: np.log(pd.NA)
Out[166]: <NA>

In [167]: np.add(pd.NA, 1)
Out[167]: <NA>
```

**Warning:** Currently, ufuncs involving an ndarray and `NA` will return an object-dtype filled with NA values.

```python
In [168]: a = np.array([1, 2, 3])
In [169]: np.greater(a, pd.NA)
Out[169]: array([<NA>, <NA>, <NA>], dtype=object)
```

The return type here may change to return a different array type in the future.

See *DataFrame interoperability with NumPy functions* for more on ufuncs.
Conversion

If you have a DataFrame or Series using traditional types that have missing data represented using `np.nan`, there are convenience methods `convert_dtypes()` in Series and `convert_dtypes()` in DataFrame that can convert data to use the newer dtypes for integers, strings and booleans listed [here](#). This is especially helpful after reading in data sets when letting the readers such as `read_csv()` and `read_excel()` infer default dtypes.

In this example, while the dtypes of all columns are changed, we show the results for the first 10 columns.

```python
In [170]: bb = pd.read_csv("data/baseball.csv", index_col="id")

In [171]: bb[bb.columns[:10]].dtypes
Out[171]:
player       object
year          int64
stint         int64
team         object
lg            object
g             int64
ab            int64
r             int64
h             int64
X2b           int64
dtype: object
```

```python
In [172]: bbn = bb.convert_dtypes()

In [173]: bbn[bbn.columns[:10]].dtypes
Out[173]:
player       string
year          Int64
stint         Int64
team          string
lg            string
g             Int64
ab            Int64
r             Int64
h             Int64
X2b           Int64
dtype: object
```

2.11 Duplicate Labels

Index objects are not required to be unique; you can have duplicate row or column labels. This may be a bit confusing at first. If you’re familiar with SQL, you know that row labels are similar to a primary key on a table, and you would never want duplicates in a SQL table. But one of pandas’ roles is to clean messy, real-world data before it goes to some downstream system. And real-world data has duplicates, even in fields that are supposed to be unique.

This section describes how duplicate labels change the behavior of certain operations, and how prevent duplicates from arising during operations, or to detect them if they do.
In [1]: import pandas as pd
In [2]: import numpy as np

2.11.1 Consequences of Duplicate Labels

Some pandas methods (Series.reindex() for example) just don’t work with duplicates present. The output can’t be determined, and so pandas raises.

In [3]: s1 = pd.Series([0, 1, 2], index=["a", "b", "b"])
In [4]: s1.reindex(["a", "b", "c"])

---------------------------------------------------------------------------
ValueError                               Traceback (most recent call last)
Input In [4], in <module>                ----> 1 s1.reindex(["a", "b", "c"])
File /pandas/pandas/core/series.py:4672, in Series.reindex(self, *args, **kwargs)
    4668     raise TypeError(
    4669             "'index' passed as both positional and keyword argument"
    4670         )
    4671     kwargs.update("index": index))
    4672 return super().reindex(**kwargs)

File /pandas/pandas/core/generic.py:4974, in NDFrame.reindex(self, *args, **kwargs)
    4971     return self._reindex_axes(axes, level, limit, tolerance, method, fill_value, copy)
    4972 return super().reindex(**kwargs)

File /pandas/pandas/core/generic.py:4994, in NDFrame._reindex_axes(self, axes, level,
    ... limit, tolerance, method, fill_value, copy)
    4989     new_index, indexer = ax.reindex(  
    4990     labels, level=level, limit=limit, tolerance=tolerance, method=method
    4991     )
    4992     axis = self._get_axis_number(a)
    4993     obj = obj._reindex_with_indexers(  
    4994     axis= [new_index, indexer]),
    4995     fill_value=fill_value,
    4996     copy=copy,
    4997     allow_dups=False,
    4998     )
    4999     if _reindex_multi:
    5000     copy = False

File /pandas/pandas/core/generic.py:5040, in NDFrame._reindex_with_indexers(self,
    ... reindexers, fill_value, copy, allow_dups)
    5037     indexer = ensure_platform_int(indexer)
    5038     # TODO: speed up on homogeneous DataFrame objects (see _reindex_multi)
    5039     new_data = new_data.reindex_indexer(

(continues on next page)
Other methods, like indexing, can give very surprising results. Typically indexing with a scalar will reduce dimensionality. Slicing a DataFrame with a scalar will return a Series. Slicing a Series with a scalar will return a scalar. But with duplicates, this isn’t the case.

We have duplicates in the columns. If we slice 'B', we get back a Series

But slicing 'A' returns a DataFrame
This applies to row labels as well

```
In [9]: df2 = pd.DataFrame({'A': [0, 1, 2]}, index=['a', 'a', 'b'])

In [10]: df2
Out[10]:
   A
a  0
a  1
b  2

In [11]: df2.loc['b', 'A']  # a scalar
Out[11]: 2

In [12]: df2.loc['a', 'A']  # a Series
Out[12]:
   A
  a  0
  a  1
Name: A, dtype: int64
```

### 2.11.2 Duplicate Label Detection

You can check whether an Index (storing the row or column labels) is unique with `Index.is_unique`:

```
In [13]: df2
Out[13]:
   A
a  0
a  1
b  2

In [14]: df2.index.is_unique
Out[14]: False

In [15]: df2.columns.is_unique
Out[15]: True
```

**Note:** Checking whether an index is unique is somewhat expensive for large datasets. pandas does cache this result, so re-checking on the same index is very fast.

`Index.duplicated()` will return a boolean ndarray indicating whether a label is repeated.

```
In [16]: df2.index.duplicated()
Out[16]: array([False, True, False])
```

Which can be used as a boolean filter to drop duplicate rows.
If you need additional logic to handle duplicate labels, rather than just dropping the repeats, using `groupby()` on the index is a common trick. For example, we’ll resolve duplicates by taking the average of all rows with the same label.

```python
In [17]: df2.loc[~df2.index.duplicated(), :]
Out[17]:
A
a 0
b 2
```

2.11.3 Disallowing Duplicate Labels

New in version 1.2.0.

As noted above, handling duplicates is an important feature when reading in raw data. That said, you may want to avoid introducing duplicates as part of a data processing pipeline (from methods like `pandas.concat()` , `rename()` , etc.). Both `Series` and `DataFrame` disallow duplicate labels by calling `.set_flags(allows_duplicate_labels=False)` . (the default is to allow them). If there are duplicate labels, an exception will be raised.

```python
In [19]: pd.Series([0, 1, 2], index=['a', 'b', 'b']).set_flags(allows_duplicate_labels=False)
---------------------------------------------------------------------------
DuplicateLabelError Traceback (most recent call last)
  File In [19], in <module>
    1 pd.Series([0, 1, 2], index=['a', 'b', 'b']).set_flags(allows_duplicate_labels=False)
  File /pandas/pandas/core/generic.py:438, in NDFrame.set_flags(self, copy, allows_duplicate_labels)
    436 df = self.copy(deep=copy)
    437 if allows_duplicate_labels is not None:
--> 438 df.flags['allows_duplicate_labels'] = allows_duplicate_labels
    439 return df
  File /pandas/pandas/core/flags.py:105, in Flags.__setitem__(self, key, value)
    90 if not key in self._keys:
    91     raise ValueError(f'Unknown flag {key}. Must be one of {self._keys}')
---> 92 setattr(self, key, value)
  File /pandas/pandas/core/indexes/base.py:715, in Index._maybe_check_unique(self)
(continues on next page)
This applies to both row and column labels for a DataFrame:

```
In [20]: df = pd.DataFrame({"A": [0, 1, 2, 3]}, index=["x", "y", "X", "Y"]).set_flags(
                 allows_duplicate_labels=False)
```

```
Out[20]:
     A
x   0
y   1
X   2
Y   3
```

```
In [23]: df.flags.allows_duplicate_labels
Out[23]: False
```

```
In [24]: df2 = df.set_flags(allow_duplicates=True)
```

```
In [25]: df2.flags.allows_duplicate_labels
Out[25]: True
```

The new DataFrame returned is a view on the same data as the old DataFrame. Or the property can just be set directly on the same object:

```
In [26]: df2.flags.allows_duplicate_labels = False
```
When processing raw, messy data you might initially read in the messy data (which potentially has duplicate labels), deduplicate, and then disallow duplicates going forward, to ensure that your data pipeline doesn’t introduce duplicates.

```python
>>> raw = pd.read_csv("...
>>> deduplicated = raw.groupby(level=0).first()  # remove duplicates
>>> deduplicated.flags.allows_duplicate_labels = False  # disallow going forward
```

Setting `allows_duplicate_labels=True` on a Series or DataFrame with duplicate labels or performing an operation that introduces duplicate labels on a Series or DataFrame that disallows duplicates will raise an `DuplicateLabelError`.

```python
In [28]: df.rename(str.upper)
```

```
Traceback (most recent call last)
Input In [28], in <module>
        1 df.rename(str.upper)

---------------------------------------------------------------------------
DuplicateLabelError Traceback (most recent call last)
Input In [31], in <module>
----> 1 s1.head().rename({"a": "b"})

File /pandas/pandas/core/series.py:4601, in Series.rename(self, index, axis, copy, _
   → inplace, level, errors)
4598     axis = self._get_axis_number(axis)
4600 if callable(index) or is_dict_like(index):
4601     return super().rename(  
4602         index, copy=copy, inplace=inplace, level=level, errors=errors
4603     )
else:
    return self._set_name(index, inplace=inplace)

File /pandas/pandas/core/generic.py:1171, in NDFrame._rename(self, mapper, index,
    _columns, axis, copy, inplace, level, errors)
  1169 return None
  1170 else:
  --> 1171 return result.__finalize__(self, method="rename")

File /pandas/pandas/core/generic.py:5549, in NDFrame.__finalize__(self, other, method, _
    **kwargs)
    5546 for name in other.attrs:
    5547     self.attrs[name] = other.attrs[name]
    --> 5549 self.flags.allows_duplicate_labels = other.flags.allows_duplicate_labels
    5550 # For subclasses using _metadata.
    5551 for name in set(self._metadata) & set(other._metadata):

File /pandas/pandas/core/flags.py:92, in Flags.allows_duplicate_labels(self, value)
  90 if not value:
  91     for ax in obj.axes:
  --> 92     ax._maybe_check_unique()
  93 self._allows_duplicate_labels = value

File /pandas/pandas/core/indexes/base.py:715, in Index._maybe_check_unique(self)
  712 duplicates = self._format_duplicate_message()
  713 msg += f'{duplicates}"
  --> 715 raise DuplicateLabelError(msg)

DuplicateLabelError: Index has duplicates.
    positions
    label
    b [0, 1]

**Warning:** This is an experimental feature. Currently, many methods fail to propagate the allows_duplicate_labels value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate allows_duplicate_labels.

### 2.12 Categorical data

This is an introduction to pandas categorical data type, including a short comparison with R’s `factor`.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (categories; levels in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, ...) are not possible.

All values of categorical data are either in categories or np.nan. Order is defined by the order of categories, not lexical order of the values. Internally, the data structure consists of a categories array and an integer array of codes which point to the real value in the categories array.
The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see here.
- The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see here.
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the *API docs on categoricals*.

## 2.12.1 Object creation

### Series creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying `dtype="category"` when constructing a Series:

```python
In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [2]: s
Out[2]:
0 a
1 b
2 c
3 a
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

By converting an existing Series or column to a category dtype:

```python
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})
In [4]: df["B"] = df["A"].astype("category")
In [5]: df
Out[5]:
   A  B
0  a  a
1  b  b
2  c  c
3  a  a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the example on tiling in the docs.

```python
In [6]: df = pd.DataFrame({"value": np.random.randint(0, 100, 20)})
In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]
In [8]: df["group"] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)
```

(continues on next page)
By passing a `pandas.Categorical` object to a `Series` or assigning it to a `DataFrame`.

```python
In [10]: raw_cat = pd.Categorical(["a", "b", "c", "a"], categories=["b", "c", "d"], ordered=False)

In [11]: s = pd.Series(raw_cat)

In [12]: s
Out[12]:
0    NaN
1     b
2     c
3    NaN
dtype: category
Categories (3, object): ['b', 'c', 'd']

In [13]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})

In [14]: df["B"] = raw_cat

In [15]: df
Out[15]:
   A    B
0   a   NaN
1   b     b
2   c     c
3   a   NaN
```

Categorical data has a specific category `dtype`:

```python
In [16]: df.dtypes
Out[16]:
A    object
B    category
dtype: object
```
DataFrame creation

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying dtype="category" in the DataFrame constructor:

```
In [17]: df = pd.DataFrame({"A": list("abca"), "B": list("bccd")}, dtype="category")
In [18]: df.dtypes
Out[18]:
A    category
B    category
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```
In [19]: df["A"]
Out[19]:
    0  a
    1  b
    2  c
    3  a
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [20]: df["B"]
Out[20]:
    0  b
    1  c
    2  c
    3  d
Name: B, dtype: category
Categories (3, object): ['b', 'c', 'd']
```

Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```
In [21]: df = pd.DataFrame({"A": list("abca"), "B": list("bccd")})
In [22]: df_cat = df.astype("category")
In [23]: df_cat.dtypes
Out[23]:
A    category
B    category
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat["A"]
Out[24]:
    0  a
    1  b
```

(continues on next page)
Controlling behavior

In the examples above where we passed dtype='category', we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing 'category', use an instance of CategoricalDtype.

Similarly, a CategoricalDtype can be used with a DataFrame to ensure that categories are consistent among all columns.
Out[35]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']

In [36]: df_cat['B']
Out[36]:
0  b
1  c
2  c
3  d
Name: B, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']

Note: To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the categories parameter can be determined programmatically by 
categories = pd.unique(df.to_numpy().ravel()).

If you already have codes and categories, you can use the from_codes() constructor to save the factorize step during normal constructor mode:

In [37]: splitter = np.random.choice([0, 1], 5, p=[0.5, 0.5])
In [38]: s = pd.Series(pd.Categorical.from_codes(splitter, categories=['train', 'test']))

Regaining original data

To get back to the original Series or NumPy array, use Series.astype(original_dtype) or np.asarray(categorical):

In [39]: s = pd.Series(['a', 'b', 'c', 'a'])
In [40]: s
Out[40]:
0  a
1  b
2  c
3  a
dtype: object
In [41]: s2 = s.astype("category")
In [42]: s2
Out[42]:
0  a
1  b
2  c
3    a
dtype: category
Categories (3, object): ['a', 'b', 'c']

In [43]: s2.astype(str)
Out[43]:
0   a
1   b
2   c
3   a
dtype: object

In [44]: np.asarray(s2)
Out[44]:
array(['a', 'b', 'c', 'a'], dtype=object)

Note: In contrast to R's `factor` function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

Note: In contrast to R's `factor` function, there is currently no way to assign/change labels at creation time. Use `categories` to change the categories after creation time.

2.12.2 CategoricalDtype

A categorical's type is fully described by

1. `categories`: a sequence of unique values and no missing values
2. `ordered`: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

In [45]: from pandas.api.types import CategoricalDtype

In [46]: CategoricalDtype(['a', 'b', 'c'])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)

In [47]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=False)

A `CategoricalDtype` can be used in any place pandas expects a `dtype`. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

Note: As a convenience, you can use the string 'category' in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words,
**pandas: powerful Python data analysis toolkit, Release 1.4.1**

dtype='category' is equivalent to dtype=CategoricalDtype().

### Equality semantics

Two instances of CategoricalDtype compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```
In [49]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)

# Equal, since order is not considered when ordered=False
In [50]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[50]: True

# Unequal, since the second CategoricalDtype is ordered
In [51]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[51]: False
```

All instances of CategoricalDtype compare equal to the string 'category'.

```
In [52]: c1 == 'category'
Out[52]: True
```

**Warning:** Since dtype='category' is essentially CategoricalDtype(None, False), and since all instances CategoricalDtype compare equal to 'category', all instances of CategoricalDtype compare equal to a CategoricalDtype(None, False), regardless of categories or ordered.

### 2.12.3 Description

Using `describe()` on categorical data will produce similar output to a Series or DataFrame of type string.

```
In [53]: cat = pd.Categorical(['a', 'c', 'c', np.nan], categories=['b', 'a', 'c'])
In [54]: df = pd.DataFrame({'cat': cat, 's': ['a', 'c', 'c', np.nan]})
In [55]: df.describe()
```

```
Out[55]:
         cat           s
Name: cat, dtype: object
     count 3 3
     unique 2 2
     top   c   c
    freq  2  2
```

```
In [56]: df['cat'].describe()
```

```
Out[56]:
     count 3
     unique 2
     top   c
    freq  2
Name: cat, dtype: object
```
2.12.4 Working with categories

Categorical data has a categories and an ordered property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don’t manually specify categories and ordering, they are inferred from the passed arguments.

```python
In [57]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [58]: s.cat.categories
Out[58]: Index(["a", "b", "c"], dtype=object)
In [59]: s.cat.ordered
Out[59]: False
```

It’s also possible to pass in the categories in a specific order:

```python
In [60]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], categories=["c", "b", "a"], ordered=True))
In [61]: s.cat.categories
Out[61]: Index(["c", "b", "a"], dtype=object)
In [62]: s.cat.ordered
Out[62]: True
```

**Note:** New categorical data are not automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered Categorical.

**Note:** The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```python
In [63]: s = pd.Series(list("babc"), dtype=CategoricalDtype(list("abcd")))
In [64]: s
Out[64]:
0   b
1   a
2   b
3   c
dtype: category
Categories (4, object): ["a", "b", "c", "d"]

# categories
In [65]: s.cat.categories
Out[65]: Index(["a", "b", "c", "d"], dtype=object)

# uniques
In [66]: s.unique()
Out[66]:
["b", "a", "c"]
Categories (4, object): ["a", "b", "c", "d"]
```
Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```
In [67]: s = pd.Series(\["a", "b", "c", "a"\], dtype=\"category\")

In [68]: s
Out[68]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): ['a', 'b', 'c']

In [69]: s.cat.categories = [\"Group %s\" % g for g in s.cat.categories]

In [70]: s
Out[70]:
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): ['Group a', 'Group b', 'Group c']

In [71]: s = s.cat.rename_categories([1, 2, 3])

In [72]: s
Out[72]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [1, 2, 3]

# You can also pass a dict-like object to map the renaming
In [73]: s = s.cat.rename_categories({1: \"x\", 2: \"y\", 3: \"z\"})

In [74]: s
Out[74]:
0    x
1    y
2    z
3    x
dtype: category
Categories (3, object): ['x', 'y', 'z']
```

**Note:** In contrast to R’s `factor`, categorical data can have categories of other types than string.
Note: Be aware that assigning new categories is an in-place operation, while most other operations under Series.cat per default return a new Series of dtype category.

Categories must be unique or a ValueError is raised:

```
In [75]: try:
....:     s.cat.categories = [1, 1, 1]
....: except ValueError as e:
....:     print("ValueError:", str(e))
....:
ValueError: Categorical categories must be unique
```

Categories must also not be NaN or a ValueError is raised:

```
In [76]: try:
....:     s.cat.categories = [1, 2, np.nan]
....: except ValueError as e:
....:     print("ValueError:", str(e))
....:
ValueError: Categorical categories cannot be null
```

Appending new categories

Appending categories can be done by using the add_categories() method:

```
In [77]: s = s.cat.add_categories([4])

In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')

In [79]: s
Out[79]:
0  x
1  y
2  z
3  x
dtype: category
Categories (4, object): ['x', 'y', 'z', 4]
```

Removing categories

Removing categories can be done by using the remove_categories() method. Values which are removed are replaced by np.nan:

```
In [80]: s = s.cat.remove_categories([4])

In [81]: s
Out[81]:
0  x
1  y
```

(continues on next page)
Removing unused categories

Removing unused categories can also be done:

```python
In [82]: s = pd.Series(pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c', 'd']))

In [83]: s
Out[83]:
0  a
1  b
2  a
dtype: category
Categories (4, object): ['a', 'b', 'c', 'd']

In [84]: s.cat.remove_unused_categories()
Out[84]:
0  a
1  b
2  a
dtype: category
Categories (2, object): ['a', 'b']
```

Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```python
In [85]: s = pd.Series(['one', 'two', 'four', '-'], dtype='category')

In [86]: s
Out[86]:
0  one
1  two
2  four
3  -
dtype: category
Categories (4, object): ['-', 'four', 'one', 'two']

In [87]: s = s.cat.set_categories(['one', 'two', 'three', 'four'])

In [88]: s
Out[88]:
0  one
1  two
2  four
```
3 NaN
dtype: category
Categories (4, object): ['one', 'two', 'three', 'four']

Note: Be aware that Categorical.set_categories() cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!

2.12.5 Sorting and order

If categorical data is ordered (s.cat.ordered == True), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, .min()/max() will raise a TypeError.

```
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))
In [90]: s.sort_values(inplace=True)
In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(CategoricalDtype(ordered=True))
In [92]: s.sort_values(inplace=True)
```

```
In [93]: s
Out[93]:
0  a
3  a
1  b
2  c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']
```

```
In [94]: s.min(), s.max()
Out[94]: ('a', 'c')
```

You can set categorical data to be ordered by using as_ordered() or unordered by using as_unordered(). These will by default return a new object.

```
In [95]: s.cat.as_ordered()
Out[95]:
0  a
3  a
1  b
2  c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']
```

```
In [96]: s.cat.as_unordered()
Out[96]:
0  a
3  a
```

(continues on next page)
Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```
In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")
In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)
In [99]: s
Out[99]:
0 1
1 2
2 3
3 1
dtype: category
Categories (3, int64): [2 < 3 < 1]
In [100]: s.sort_values(inplace=True)
In [101]: s
Out[101]:
1 2
2 3
0 1
3 1
dtype: category
Categories (3, int64): [2 < 3 < 1]
In [102]: s.min(), s.max()
Out[102]: (2, 1)
```

Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")
In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)
In [105]: s
Out[105]:
0 1
1 2
2 3
```

(continues on next page)
In [106]: s.sort_values(inplace=True)

In [107]: s
Out[107]:
1 2
2 3
0 1
3 1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [108]: s.min(), s.max()
Out[108]: (2, 1)

Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the Series, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the Series are changed.

Note: If the Categorical is not ordered, Series.min() and Series.max() will raise TypeError. Numeric operations like +, -, *, / and operations based on them (e.g. Series.median(), which would need to compute the mean between two values if the length of an array is even) do not work and raise a TypeError.

Multi column sorting

A categorical dtype column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

In [109]: dfs = pd.DataFrame(
       ....:     {
       ....:         "A": pd.Categorical(
       ....:             list("bbeebbaa"),
       ....:             categories=["e", "a", "b"],
       ....:             ordered=True,
       ....:         ),
       ....:         "B": [1, 2, 1, 2, 2, 1, 2, 1],
       ....:     }
       ....: )

In [110]: dfs.sort_values(by=["A", "B"])
Out[110]:
   A  B
  2  e  1
Reordering the categories changes a future sort.

In [111]: dfs["A"] = dfs["A"].cat.reorder_categories(["a", "b", "e"])

In [112]: dfs.sort_values(by=["A", "B"])
Out[112]:
   A  B
0  b  1
1  b  2
4  b  2
5  b  1
6  a  2
7  a  1
2  e  1
3  e  2

2.12.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (== and !=) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (==, !=, >, >=, <, and <=) of categorical data to another categorical Series, when ordered==True and the categories are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

Note: Any “non-equality” comparisons of categorical data with a `Series`, `np.array`, list or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

In [113]: cat = pd.Series([1, 2, 3]).astype(CategoricalDtype([3, 2, 1], ordered=True))

In [114]: cat_base = pd.Series([2, 2, 2]).astype(CategoricalDtype([3, 2, 1], ordered=True))

In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(CategoricalDtype(ordered=True))

In [116]: cat
Out[116]:
0  1
1  2
2  3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base
Out[117]:
0  2
1  2
2  2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [118]: cat_base2
Out[118]:
0  2
1  2
2  2
dtype: category
Categories (1, int64): [2]

Comparing to a categorical with the same categories and ordering or to a scalar works:

In [119]: cat > cat_base
Out[119]:
0   True
1   False
2   False
dtype: bool

In [120]: cat > 2
Out[120]:
0   True
1   False
2   False
dtype: bool

Equality comparisons work with any list-like object of same length and scalars:

In [121]: cat == cat_base
Out[121]:
0   False
1   True
2   False
dtype: bool

In [122]: cat == np.array([1, 2, 3])
Out[122]:
0   True
1   True
In [123]: cat == 2
Out[123]:
0   False
1    True
2   False
dtype: bool

This doesn't work because the categories are not the same:

In [124]: try:
       ...:   cat > cat_base2
       ...: except TypeError as e:
       ...:       print("TypeError:", str(e))

TypeError: Categoricals can only be compared if 'categories' are the same.

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

In [125]: base = np.array([1, 2, 3])

In [126]: try:
       ...:   cat > base
       ...: except TypeError as e:
       ...:       print("TypeError:", str(e))

TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'

In [127]: np.asarray(cat) > base
Out[127]: array([False, False, False])

When you compare two unordered categoricals with the same categories, the order is not considered:

In [128]: c1 = pd.Categorical(["a", "b"], categories=['a', 'b'], ordered=False)
In [129]: c2 = pd.Categorical(["a", "b"], categories=['b', 'a'], ordered=False)
In [130]: c1 == c2
Out[130]: array([ True,  True])
2.12.7 Operations

Apart from `Series.min()`, `Series.max()` and `Series.mode()`, the following operations are possible with categorical data:

Series methods like `Series.value_counts()` will use all categories, even if some categories are not present in the data:

```
In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"], categories=["c", "a", "b", ...
˓→"d"]))
In [132]: s.value_counts()
Out[132]:
c 2  
a 1  
b 1  
d 0  
dtype: int64
```

DataFrame methods like `DataFrame.sum()` also show “unused” categories.

```
In [133]: columns = pd.Categorical(...)  
    ....: ["One", "One", "Two"], categories=["One", "Two", "Three"], ordered=True  
    ....: )
    ....:
In [134]: df = pd.DataFrame(...)  
    ....: data=[[1, 2, 3], [4, 5, 6]],  
    ....: columns=pd.MultiIndex.from_arrays([["A", "B", "B"], columns]],  
    ....: )
    ....:
In [135]: df.groupby(axis=1, level=1).sum()  
Out[135]:
    One  Two  Three
0   3   3    0
1   9   6    0
```

Groupby will also show “unused” categories:

```
In [136]: cats = pd.Categorical(...)  
    ....: ["a", "b", "b", "b", "c", "c", "c"], categories=["a", "b", "c", "d"]  
    ....: )
    ....:
In [137]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 3, 4, 5]})
In [138]: df.groupby("cats").mean()  
Out[138]:
    values
cats   
a  1.0  
b  2.0  
c  4.0
```

(continues on next page)
In [139]: cats2 = pd.Categorical([-"a", "a", "b", "b"], categories=["a", "b", "c"])

In [140]: df2 = pd.DataFrame(
    ...
    {  
      "cats": cats2,
      "B": ["c", "d", "c", "d"],
      "values": [1, 2, 3, 4],
    }
)

In [141]: df2.groupby(["cats", "B"]).mean()

Out[141]:

<table>

</tbody>
</table>
2.12.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat` work as normal. The only difference is the return type (for getting) and that only values already in categories can be assigned.

Getting

If the slicing operation returns either a DataFrame or a column of type Series, the category dtype is preserved.

```python
In [145]: idx = pd.Index(['h', 'i', 'j', 'k', 'l', 'm', 'n'])
In [146]: cats = pd.Series(['a', 'b', 'b', 'b', 'c', 'c', 'c'], dtype='category', index=idx)
In [147]: values = [1, 2, 2, 2, 3, 4, 5]
In [148]: df = pd.DataFrame({'cats': cats, 'values': values}, index=idx)
In [149]: df.iloc[2:4, :]
Out[149]:
   cats values
  j   b     2
  k   b     2
In [150]: df.iloc[2:4, :].dtypes
Out[150]:
cats    category
values  int64
dtype: object
In [151]: df.loc['h':'j', 'cats']
Out[151]:
   h   a
  i   b
  j   b
Name: cats, dtype: category
Categories (3, object): ['a', 'b', 'c']
In [152]: df[df['cats'] == 'b']
Out[152]:
   cats values
  i   b     2
  j   b     2
  k   b     2
```

An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

```python
# get the complete "h" row as a Series
In [153]: df.loc['h', :]
Out[153]:
cats   a
```

(continues on next page)
Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```python
In [154]: df.iat[0, 0]  
Out[154]: 'a'
```

```python
In [155]: df["cats"].cat.categories = ["x", "y", "z"]
```

```python
In [156]: df.at["h", "cats"]  # returns a string  
Out[156]: 'x'
```

**Note:** The is in contrast to R’s `factor` function, where `factor(c(1,2,3))[1]` returns a single value `factor`.

To get a single value Series of type `category`, you pass in a list with a single value:

```python
In [157]: df.loc["h", "cats"]
```

```python
In [158]: str_s = pd.Series(list("aabb"))
```

```python
In [159]: str_cat = str_s.astype("category")
```

```python
In [160]: str_cat
```

```python
In [161]: str_cat.str.contains("a")
```

```python
In [162]: date_s = pd.Series(pd.date_range("1/1/2015", periods=5))
```
In [163]: date_cat = date_s.astype("category")

In [164]: date_cat
Out[164]:
0 2015-01-01
1 2015-01-02
2 2015-01-03
3 2015-01-04
4 2015-01-05
dtype: category

In [165]: date_cat.dt.day
Out[165]:
0 1
1 2
2 3
3 4
4 5
dtype: int64

Note: The returned Series (or DataFrame) is of the same type as if you used the .str.<method> / .dt.<method> on a Series of that type (and not of type category!).

That means, that the returned values from methods and properties on the accessors of a Series and the returned values from methods and properties on the accessors of this Series transformed to one of type category will be equal:

In [166]: ret_s = str_s.str.contains("a")

In [167]: ret_cat = str_cat.str.contains("a")

In [168]: ret_s.dtype == ret_cat.dtype
Out[168]: True

In [169]: ret_s == ret_cat
Out[169]:
0  True
1  True
2  True
3  True
4  True
dtype: bool

Note: The work is done on the categories and then a new Series is constructed. This has some performance implication if you have a Series of type string, where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series). In this case it can be faster to convert the original Series to one of type category and use .str.<method> or .dt.<property> on that.

2.12. Categorical data
Setting values in a categorical column (or Series) works as long as the value is included in the categories:

```
In [170]: idx = pd.Index(['h', 'i', 'j', 'k', 'l', 'm', 'n'])
In [171]: cats = pd.Categorical(['a', 'a', 'a', 'a', 'a', 'a', 'a'], categories=['a', 'b '])
In [172]: values = [1, 1, 1, 1, 1, 1, 1]
In [173]: df = pd.DataFrame({'cats': cats, 'values': values}, index=idx)
In [174]: df.iloc[2:4, :] = [['b', 2], ['b', 2]]
In [175]: df
```

```
   cats  values
  ---  ------
   h    a     1
   i    a     1
   j    b     2
   k    b     2
   l    a     1
   m    a     1
   n    a     1
```

```
In [176]: try:
       ....: df.iloc[2:4, :] = [['c', 3], ['c', 3]]
       ....: except TypeError as e:
       ....:     print("TypeError: ", str(e))
       ....: TypeError: Cannot setitem on a Categorical with a new category, set the categories first
```

Setting values by assigning categorical data will also check that the categories match:

```
In [177]: df.loc['j':'k', 'cats'] = pd.Categorical(['a', 'a'], categories=['a', 'b '])
In [178]: df
```

```
   cats  values
  ---  ------
   h    a     1
   i    a     1
   j    a     2
   k    a     2
   l    a     1
   m    a     1
   n    a     1
```

```
In [179]: try:
       ....: df.loc['j':'k', 'cats'] = pd.Categorical(['b', 'b'], categories=['a', 'b ', 'c'])
       ....: except TypeError as e:
       ....:     print("TypeError: ", str(e))
```

(continues on next page)
Assigning a Categorical to parts of a column of other types will use the values:

```python
In [180]: df = pd.DataFrame({'a': [1, 1, 1, 1, 1], 'b': ['a', 'a', 'a', 'a', 'a']})

In [181]: df.loc[1:2, 'a'] = pd.Categorical(['b', 'b'], categories=['a', 'b'])

In [182]: df.loc[2:3, 'b'] = pd.Categorical(['b', 'b'], categories=['a', 'b'])

In [183]: df
Out[183]:
   a  b
0  1  a
1  b  a
2  b  b
3  1  b
4  1  a

In [184]: df.dtypes
Out[184]:
    a  object
    b  object
dtype: object
```

**Merging / concatenation**

By default, combining Series or DataFrames which contain the same categories results in category dtype, otherwise results will depend on the dtype of the underlying categories. Merges that result in non-categorical dtypes will likely have higher memory usage. Use .astype or union_categoricals to ensure category results.

```python
In [185]: from pandas.api.types import union_categoricals

# same categories
In [186]: s1 = pd.Series(['a', 'b'], dtype='category')

In [187]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')

In [188]: pd.concat([s1, s2])
Out[188]:
0  a
1  b
2  a
dtype: category
Categories (2, object): ['a', 'b']

# different categories
In [189]: s3 = pd.Series(['b', 'c'], dtype='category')
```

(continues on next page)
In [190]: pd.concat([s1, s3])
Out[190]:
0    a
1    b
0    b
1    c
dtype: object

# Output dtype is inferred based on categories values

In [191]: int_cats = pd.Series([1, 2], dtype="category")
In [192]: float_cats = pd.Series([3.0, 4.0], dtype="category")
In [193]: pd.concat([int_cats, float_cats])
Out[193]:
0    1.0
1    2.0
0    3.0
1    4.0
dtype: float64

In [194]: pd.concat([s1, s3]).astype("category")
Out[194]:
0    a
1    b
0    b
1    c
dtype: category
Categories (3, object): ['a', 'b', 'c']

In [195]: union_categoricals([s1.array, s3.array])
Out[195]:
['a', 'b', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']

The following table summarizes the results of merging Categoricals:

<table>
<thead>
<tr>
<th>arg1</th>
<th>arg2</th>
<th>identical</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>category</td>
<td>True</td>
<td>category</td>
</tr>
<tr>
<td>category (object)</td>
<td>category (object)</td>
<td>False</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category (int)</td>
<td>category (float)</td>
<td>False</td>
<td>float (dtype is inferred)</td>
</tr>
</tbody>
</table>

See also the section on merge dtypes for notes about preserving merge dtypes and performance.
Unioning

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python
In [196]: from pandas.api.types import union_categoricals
In [197]: a = pd.Categorical(["b", "c"])
In [198]: b = pd.Categorical(["a", "b"])
In [199]: union_categoricals([a, b])
Out[199]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python
In [200]: union_categoricals([a, b], sort_categories=True)
Out[200]:
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also `append` for).

```python
In [201]: a = pd.Categorical(["a", "b"], ordered=True)
In [202]: b = pd.Categorical(["a", "b", "a"], ordered=True)
In [203]: union_categoricals([a, b])
Out[203]:
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

The below raises `TypeError` because the categories are ordered and not identical.

```python
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
In [204]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [205]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [206]: union_categoricals([a, b], ignore_order=True)
Out[206]:
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```
**union_categoricals()** also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```python
In [207]: a = pd.Series(['b', 'c'], dtype='category')
In [208]: b = pd.Series(['a', 'b'], dtype='category')
In [209]: union_categoricals([a, b])
Out[209]: ['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```python
In [210]: c1 = pd.Categorical(['b', 'c'])
In [211]: c2 = pd.Categorical(['a', 'b'])
In [212]: c1
Out[212]: ['b', 'c']
Categories (2, object): ['b', 'c']
# "b" is coded to 0
In [213]: c1.codes
Out[213]: array([0, 1], dtype=int8)
In [214]: c2
Out[214]: ['a', 'b']
Categories (2, object): ['a', 'b']
# "b" is coded to 1
In [215]: c2.codes
Out[215]: array([0, 1], dtype=int8)
In [216]: c = union_categoricals([c1, c2])
In [217]: c
Out[217]: ['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
# "b" is coded to 0 throughout, same as c1, different from c2
In [218]: c.codes
Out[218]: array([0, 1, 2, 0], dtype=int8)
```
2.12.9 Getting data in/out

You can write data that contains category dtypes to a HDFStore. See here for an example and caveats.

It is also possible to write data to and reading data from Stata format files. See here for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to category and assign the right categories and categories ordering.

```python
In [219]: import io
In [220]: s = pd.Series(pd.Categorical(["a", "b", "b", "a", "a", "d"]))

# rename the categories
In [221]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [222]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [223]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})
In [224]: csv = io.StringIO()
In [225]: df.to_csv(csv)
In [226]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))
In [227]: df2.dtypes
Out[227]:
     Unnamed: 0  int64
cats         object
vals         int64
dtype: object

In [228]: df2["cats"]
Out[228]:
   0   very good
   1       good
   2       good
   3  very good
   4  very good
   5      bad
Name: cats, dtype: object

# Redo the category
In [229]: df2["cats"] = df2["cats"].astype("category")

In [230]: df2["cats"].cat.set_categories(
         .....:    ["very bad", "bad", "medium", "good", "very good"], inplace=True
         .....: )

In [231]: df2.dtypes

(continues on next page)
```
Out[231]:
Unnamed: 0     int64
cats         category
vals         int64
dtype: object

In [232]: df2['cats']
Out[232]:
    0   very good
    1     good
    2   good
    3  very good
    4  very good
    5      bad
Name: cats, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

The same holds for writing to a SQL database with `to_sql`.

### 2.12.10 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the Missing Data section.

Missing values should **not** be included in the Categorical’s `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical’s `codes`, missing values will always have a code of -1.

```python
In [233]: s = pd.Series(['a', 'b', np.nan, 'a'], dtype='category')

# only two categories
In [234]: s
Out[234]:
    0    a
    1    b
    2   NaN
    3    a
dtype: category
Categories (2, object): ['a', 'b']

In [235]: s.cat.codes
Out[235]:
    0    0
    1    1
    2   -1
    3    0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```python
In [236]: s = pd.Series(['a', 'b', np.nan], dtype='category')
```
In [237]: s
Out[237]:
0  a
1  b
2  NaN
dtype: category
Categories (2, object): ['a', 'b']

In [238]: pd.isna(s)
Out[238]:
0  False
1  False
2   True
dtype: bool

In [239]: s.fillna("a")
Out[239]:
0  a
1  b
2  a
dtype: category
Categories (2, object): ['a', 'b']

2.12.11 Differences to R's factor

The following differences to R's factor functions can be observed:

• R's levels are named categories.
• R's levels are always of type string, while categories in pandas can be of any dtype.
• It's not possible to specify labels at creation time. Use s.cat.rename_categories(new_labels) afterwards.
• In contrast to R's factor function, using categorical data as the sole input to create a new categorical series will not remove unused categories but create a new categorical series which is equal to the passed in one!
• R allows for missing values to be included in its levels (pandas' categories). pandas does not allow NaN categories, but missing values can still be in the values.

2.12.12 Gotchas

Memory usage

The memory usage of a Categorical is proportional to the number of categories plus the length of the data. In contrast, an object dtype is a constant times the length of the data.

In [240]: s = pd.Series(["foo", "bar"] * 1000)

# object dtype
In [241]: s.nbytes
Out[241]: 16000

(continues on next page)
# category dtype

```python
In [242]: s.astype("category").nbytes
Out[242]: 2016
```

Note: If the number of categories approaches the length of the data, the `Categorical` will use nearly the same or more memory than an equivalent `object` dtype representation.

```python
In [243]: s = pd.Series(["foo%04d" % i for i in range(2000)])
# object dtype
In [244]: s.nbytes
Out[244]: 16000
# category dtype
In [245]: s.astype("category").nbytes
Out[245]: 20000
```

**Categorical is not a numpy array**

Currently, categorical data and the underlying `Categorical` is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn’t know about the new dtype:

```python
In [246]: try:
    ...:     np.dtype("category")
    ...: except TypeError as e:
    ...:     print("TypeError:", str(e))
    ...:
TypeError: data type 'category' not understood
```

```python
In [247]: dtype = pd.Categorical(["a"]).dtype
In [248]: try:
    ...:     np.dtype(dtype)
    ...: except TypeError as e:
    ...:     print("TypeError:", str(e))
    ...:
TypeError: Cannot interpret 'CategoricalDtype(categories=['a'], ordered=False)' as a_
˓data type
```

Dtype comparisons work:

```python
In [249]: dtype == np.str_
Out[249]: False
In [250]: np.str_ == dtype
Out[250]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat'):`
In [251]: `hasattr(pd.Series(["a"], dtype="category"), "cat")`
Out[251]: True

In [252]: `hasattr(pd.Series(["a"], "cat")
Out[252]: False

Using NumPy functions on a Series of type category should not work as Categoricals are not numeric data (even in the case that .categories is numeric).

In [253]: `s = pd.Series(pd.Categorical([1, 2, 3, 4]))
In [254]: try:
    .....: np.sum(s)
    .....: except TypeError as e:
    .....:     print("TypeError: ", str(e))
    .....:
TypeError: 'Categorical' with dtype category does not support reduction 'sum'

Note: If such a function works, please file a bug at https://github.com/pandas-dev/pandas!

**dtype in apply**

pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a Series of object dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use `fillna` to handle missing values before applying a function.

In [255]: `df = pd.DataFrame(
    .....:     {
    .....:         "a": [1, 2, 3, 4],
    .....:         "b": ["a", "b", "c", "d"],
    .....:         "cats": pd.Categorical([1, 2, 3, 2]),
    .....:     })`
In [256]: `df.apply(lambda row: type(row["cats"]), axis=1)
Out[256]:
0 <class 'int'>
1 <class 'int'>
2 <class 'int'>
3 <class 'int'>
dtype: object

In [257]: `df.apply(lambda col: col.dtype, axis=0)
Out[257]:
a    int64
b          object
cats      category
dtype: object

2.12. Categorical data
Categorical index

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements. See the advanced indexing docs for a more detailed explanation.

Setting the index will create a CategoricalIndex:

```python
In [258]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])
In [259]: strings = ["a", "b", "c", "d"]
In [260]: values = [4, 2, 3, 1]
In [261]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)
In [262]: df.index
Out[262]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype='category')
```

# This now sorts by the categories order
```python
In [263]: df.sort_index()
Out[263]:
   strings values
4     d     1
2     b     2
3     c     3
1     a     4
```

Side effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```python
In [264]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [265]: s = pd.Series(cat, name="cat")
In [266]: cat
Out[266]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [267]: s.iloc[0:2] = 10
In [268]: cat
Out[268]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [269]: df = pd.DataFrame(s)
In [270]: df["cat").cat.categories = [1, 2, 3, 4, 5]
```

(continues on next page)
In [271]: cat
Out[271]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

Use copy=True to prevent such a behaviour or simply don’t reuse Categoricals:

In [272]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [273]: s = pd.Series(cat, name="cat", copy=True)
In [274]: cat
Out[274]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [275]: s.iloc[0:2] = 10
In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

Note:  This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. np.array([1,2,3,4])) will exhibit the same behavior, while using a string array (e.g. np.array(['a','b','c','a'])) will not.

2.13 Nullable integer data type

Note:  IntegerArray is currently experimental. Its API or implementation may change without warning.

Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

In Working with missing data, we saw that pandas primarily uses NaN to represent missing data. Because NaN is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.
2.13.1 Construction

pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an `extension types` implemented within pandas.

```python
In [1]: arr = pd.array([1, 2, None], dtype=pd.Int64Dtype())
In [2]: arr
Out[2]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

Or the string alias "Int64" (note the capital "I", to differentiate from NumPy’s ‘int64’ dtype):

```python
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out[3]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

All NA-like values are replaced with `pandas.NA`.

```python
In [4]: pd.array([1, 2, np.nan, None, pd.NA], dtype="Int64")
Out[4]:
<IntegerArray>
[1, 2, <NA>, <NA>, <NA>]
Length: 5, dtype: Int64
```

This array can be stored in a `DataFrame` or `Series` like any NumPy array.

```python
In [5]: pd.Series(arr)
Out[5]:
0    1
1    2
2    <NA>
dtype: Int64
```

You can also pass the list-like object to the `Series` constructor with the dtype.

```python
In [6]: pd.array([1, None])
Out[6]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64
```

```python
In [7]: pd.array([1, 2])
Out[7]:
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

**Warning:** Currently `pandas.array()` and `pandas.Series()` use different rules for dtype inference. `pandas.array()` will infer a nullable-integer dtype.
For backwards-compatibility, `Series` infers these as either integer or float dtype.

```python
In [8]: pd.Series([1, None])
Out[8]:
0   1.0
1  NaN
dtype: float64
```

```python
In [9]: pd.Series([1, 2])
Out[9]:
0   1
1   2
dtype: int64
```

We recommend explicitly providing the dtype to avoid confusion.

```python
In [10]: pd.array([1, None], dtype="Int64")
Out[10]:
<IntegerArray>
[1, <NA>]  
Length: 2, dtype: Int64
```

```python
In [11]: pd.Series([1, None], dtype="Int64")
Out[11]:
0   1
1  <NA>
dtype: Int64
```

In the future, we may provide an option for `Series` to infer a nullable-integer dtype.

### 2.13.2 Operations

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and the data will be coerced to another dtype if needed.

```python
In [12]: s = pd.Series([1, 2, None], dtype="Int64")

# arithmetic
In [13]: s + 1
Out[13]:
0   2
1   3
2  <NA>
dtype: Int64

# comparison
In [14]: s == 1
Out[14]:
0   True
1  False
2  <NA>
dtype: boolean
```
# indexing

```python
In [15]: s.iloc[1:3]
Out[15]:
1  2
2 <NA>
dtype: Int64
```

# operate with other dtypes

```python
In [16]: s + s.iloc[1:3].astype("Int8")
Out[16]:
0 <NA>
1  4
2 <NA>
dtype: Int64
```

# coerce when needed

```python
In [17]: s + 0.01
Out[17]:
0  1.01
1  2.01
2 <NA>
dtype: Float64
```

These dtypes can operate as part of DataFrame.

```python
In [18]: df = pd.DataFrame({"A": s, "B": [1, 1, 3], "C": list("aab")})
In [19]: df
Out[19]:
       A  B  C
0    1  1  a
1    2  1  a
2  <NA>  3  b
```

```python
In [20]: df.dtypes
Out[20]:
       A    B   C
dtype: object
```

These dtypes can be merged & reshaped & casted.

```python
In [21]: pd.concat([df["A"], df["B", "C"]], axis=1).dtypes
Out[21]:
     A    B   C
dtype: object
```

```python
In [22]: df["A"].astype(float)
Out[22]:
```
(continues on next page)
Reduction and groupby operations such as ‘sum’ work as well.

```python
In [23]: df.sum()
Out[23]:
   A  B    C
0 1.0 2.0 NaN
Name: A, dtype: float64
```

```python
In [24]: df.groupby("B").A.sum()
Out[24]:
   B
0 1
1 3
Name: A, dtype: Int64
```

### 2.13.3 Scalar NA Value

`arrays.IntegerArray` uses `pandas.NA` as its scalar missing value. Slicing a single element that's missing will return `pandas.NA`

```python
In [25]: a = pd.array([1, None], dtype="Int64")
In [26]: a[1]
Out[26]: <NA>
```

### 2.14 Nullable Boolean data type

**Note:** BooleanArray is currently experimental. Its API or implementation may change without warning.

New in version 1.0.0.

#### 2.14.1 Indexing with NA values

`pandas` allows indexing with `NA` values in a boolean array, which are treated as `False`. Changed in version 1.0.2.

```python
In [1]: s = pd.Series([1, 2, 3])
In [2]: mask = pd.array([True, False, pd.NA], dtype="boolean")
``` (continues on next page)
In [3]: s[mask]
Out[3]:
0   1
dtype: int64

If you would prefer to keep the NA values you can manually fill them with fillna(True).

In [4]: s[mask.fillna(True)]
Out[4]:
0   1
  2   3
dtype: int64

2.14.2 Kleene logical operations

arrays.BooleanArray implements Kleene Logic (sometimes called three-value logic) for logical operations like & (and), | (or) and ^ (exclusive-or).

This table demonstrates the results for every combination. These operations are symmetrical, so flipping the left- and right-hand side makes no difference in the result.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>True &amp; True</td>
<td>True</td>
</tr>
<tr>
<td>True &amp; False</td>
<td>False</td>
</tr>
<tr>
<td>True &amp; NA</td>
<td>NA</td>
</tr>
<tr>
<td>False &amp; False</td>
<td>False</td>
</tr>
<tr>
<td>False &amp; NA</td>
<td>False</td>
</tr>
<tr>
<td>NA &amp; NA</td>
<td>NA</td>
</tr>
<tr>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>True</td>
<td>NA</td>
</tr>
<tr>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>False</td>
<td>NA</td>
</tr>
<tr>
<td>NA</td>
<td>NA</td>
</tr>
<tr>
<td>True ^ True</td>
<td>False</td>
</tr>
<tr>
<td>True ^ False</td>
<td>True</td>
</tr>
<tr>
<td>True ^ NA</td>
<td>NA</td>
</tr>
<tr>
<td>False ^ False</td>
<td>False</td>
</tr>
<tr>
<td>False ^ NA</td>
<td>NA</td>
</tr>
<tr>
<td>NA ^ NA</td>
<td>NA</td>
</tr>
</tbody>
</table>

When an NA is present in an operation, the output value is NA only if the result cannot be determined solely based on the other input. For example, True | NA is True, because both True | True and True | False are True. In that case, we don’t actually need to consider the value of the NA.

On the other hand, True & NA is NA. The result depends on whether the NA really is True or False, since True & True is True, but True & False is False, so we can’t determine the output.

This differs from how np.nan behaves in logical operations. pandas treated np.nan is always false in the output.
In [5]: pd.Series([True, False, np.nan], dtype="object") | True
Out[5]:
0   True
1   True
2   False
dtype: bool

In [6]: pd.Series([True, False, np.nan], dtype="boolean") | True
Out[6]:
0   True
1   True
2   True
dtype: boolean

In and

In [7]: pd.Series([True, False, np.nan], dtype="object") & True
Out[7]:
0   True
1   False
2   False
dtype: bool

In [8]: pd.Series([True, False, np.nan], dtype="boolean") & True
Out[8]:
0   True
1   False
2   <NA>
dtype: boolean

{{ header }}

### 2.15 Chart Visualization

This section demonstrates visualization through charting. For information on visualization of tabular data please see the section on Table Visualization.

We use the standard convention for referencing the matplotlib API:

```python
In [1]: import matplotlib.pyplot as plt
In [2]: plt.close("all")
```

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

**Note:** All calls to np.random are seeded with 123456.
2.15.1 Basic plotting: plot

We will demonstrate the basics, see the cookbook for some advanced strategies.

The plot method on Series and DataFrame is just a simple wrapper around plt.plot():

```python
In [3]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000",periods=1000))
In [4]: ts = ts.cumsum()
In [5]: ts.plot();
```

If the index consists of dates, it calls gcf().autofmt_xdate() to try to format the x-axis nicely as per above.

On DataFrame, plot() is a convenience to plot all of the columns with labels:

```python
In [6]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD"))
In [7]: df = df.cumsum()
In [8]: plt.figure();
In [9]: df.plot();
```
You can plot one column versus another using the x and y keywords in plot():

```
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
In [11]: df3['A'] = pd.Series(list(range(len(df))))
In [12]: df3.plot(x='A', y='B');
```
2.15.2 Other plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the kind keyword argument to plot(), and include:

- `‘bar’` or `‘barh’` for bar plots
- `‘hist’` for histogram
- `‘box’` for boxplot
- `‘kde’` or `‘density’` for density plots
- `‘area’` for area plots
- `‘scatter’` for scatter plots
- `‘hexbin’` for hexagonal bin plots
- `‘pie’` for pie plots

For example, a bar plot can be created the following way:
In [13]: plt.figure();

In [14]: df.iloc[5].plot(kind="bar");

You can also create these other plots using the methods DataFrame.plot.<kind> instead of providing the kind keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

In [15]: df = pd.DataFrame()

In [16]: df.plot.<TAB>  # noqa: E225, E999
   df.plot.area   df.plot.barh   df.plot.density   df.plot.hist   df.plot.line   df.plot.scatter
   df.plot.bar   df.plot.box   df.plot.hexbin   df.plot.kde   df.plot.pie

In addition to these kind s, there are the DataFrame.hist(), and DataFrame.boxplot() methods, which use a separate interface.

Finally, there are several plotting functions in pandas.plotting that take a Series or DataFrame as an argument. These include:

- Scatter Matrix
- Andrews Curves
- Parallel Coordinates
• Lag Plot
• Autocorrelation Plot
• Bootstrap Plot
• RadViz

Plots may also be adorned with errorbars or tables.

Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [17]: plt.figure();
In [18]: df.iloc[5].plot.bar();
In [19]: plt.axhline(0, color="k");
```

Calling a DataFrame’s plot.bar() method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [21]: df2.plot.bar();
```
To produce a stacked bar plot, pass `stacked=True`:

```python
In [22]: df2.plot.bar(stacked=True);
```
To get horizontal bar plots, use the `barh` method:

```python
In [23]: df2.plot.barh(stacked=True);
```
Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```python
In [24]: df4 = pd.DataFrame(
    ...:     {
    ...:         "a": np.random.randn(1000) + 1,
    ...:         "b": np.random.randn(1000),
    ...:         "c": np.random.randn(1000) - 1,
    ...:     },
    ...:     columns=["a", "b", "c"],
    ...: )

In [25]: plt.figure();

In [26]: df4.plot.hist(alpha=0.5);
```
A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```python
In [27]: plt.figure();

In [28]: df4.plot.hist(stacked=True, bins=20);
```
You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [29]: plt.figure();

In [30]: df4["a"].plot.hist(orientation="horizontal", cumulative=True);
```
See the `hist` method and the `matplotlib` `hist` documentation for more.
The existing interface `DataFrame.hist` to plot histogram still can be used.

```python
In [31]: plt.figure();
In [32]: df["A"].diff().hist();
```
DataFrame.hist() plots the histograms of the columns on multiple subplots:

```python
In [33]: plt.figure();

In [34]: df.diff().hist(color="k", alpha=0.5, bins=50);
```
The `by` keyword can be specified to plot grouped histograms:

```
In [35]: data = pd.Series(np.random.randn(1000))

In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4));
```
In addition, the by keyword can also be specified in DataFrame.plot.hist().

Changed in version 1.4.0.

```python
In [37]: data = pd.DataFrame(
    ...:     { 
    ...:         "a": np.random.choice(['x', 'y', 'z'], 1000),
    ...:         "b": np.random.choice(['e', 'f', 'g'], 1000),
    ...:         "c": np.random.randn(1000),
    ...:         "d": np.random.randn(1000) - 1,
    ...:     },
    ...: )

In [38]: data.plot.hist(by=['a', 'b'], figsize=(10, 5));
```
Box plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```python
In [39]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
In [40]: df.plot.box();
```
Boxplot can be colorized by passing `color` keyword. You can pass a dict whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the dict, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```python
In [41]: color = {
    ...:     "boxes": "DarkGreen",
    ...:     "whiskers": "DarkOrange",
    ...:     "medians": "DarkBlue",
    ...:     "caps": "Gray",
    ...: }
    ...:

In [42]: df.plot.box(color=color, sym="r+");```
Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```python
In [43]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8]);
```
See the `boxplot` method and the matplotlib boxplot documentation for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```
In [44]: df = pd.DataFrame(np.random.rand(10, 5))
In [45]: plt.figure();
In [46]: bp = df.boxplot()
```
You can create a stratified boxplot using the by keyword argument to create groupings. For instance,

```python
In [47]: df = pd.DataFrame(np.random.rand(10, 2), columns=['Col1', 'Col2'])
In [49]: plt.figure();
In [50]: bp = df.boxplot(by='X')
```
You can also pass a subset of columns to plot, as well as group by multiple columns:

```python
In [51]: df = pd.DataFrame(np.random.rand(10, 3), columns=['Col1', 'Col2', 'Col3'])
In [54]: plt.figure();
In [55]: bp = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```
You could also create groupings with `DataFrame.plot.box()`, for instance:

Changed in version 1.4.0.

```
In [56]: df = pd.DataFrame(np.random.rand(10, 3), columns=["Col1", "Col2", "Col3"])
In [58]: plt.figure();  
In [59]: bp = df.plot.box(column=["Col1", "Col2"], by="X")
```
In `boxplot`, the return type can be controlled by the `return_type` keyword. The valid choices are `{"axes", "dict", "both", None}`. Faceting, created by `DataFrame.boxplot` with the by keyword, will affect the output type as well:

<table>
<thead>
<tr>
<th>return_type</th>
<th>Faceted</th>
<th>Output type</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>None</td>
<td>Yes</td>
<td>2-D ndarray of axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>Yes</td>
<td>Series of axes</td>
</tr>
<tr>
<td>'dict'</td>
<td>No</td>
<td>dict of artists</td>
</tr>
<tr>
<td>'dict'</td>
<td>Yes</td>
<td>Series of dicts of artists</td>
</tr>
<tr>
<td>'both'</td>
<td>No</td>
<td>namedtuple</td>
</tr>
<tr>
<td>'both'</td>
<td>Yes</td>
<td>Series of namedtuples</td>
</tr>
</tbody>
</table>

Groupby.boxplot always returns a Series of return_type.

```
In [60]: np.random.seed(1234)

In [61]: df_box = pd.DataFrame(np.random.randn(50, 2))

In [62]: df_box["g"] = np.random.choice(['A', 'B'], size=50)

In [63]: df_box.loc[df_box["g"] == "B", 1] += 3
```

(continues on next page)
In [64]: bp = df_box.boxplot(by="g")

Boxplot grouped by g

The subplots above are split by the numeric columns first, then the value of the g column. Below the subplots are first split by the value of g, then by the numeric columns.

In [65]: bp = df_box.groupby("g").boxplot()
**Area plot**

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains NaN, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

In [66]: df = pd.DataFrame(np.random.rand(10, 4), columns=["a", "b", "c", "d"])

In [67]: df.plot.area();
To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [68]: df.plot.area(stacked=False);
```
Scatter plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the \texttt{x} and \texttt{y} keywords.

\begin{verbatim}
In [69]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])

In [70]: df['species'] = pd.Categorical(
   ....:     ['setosa'] * 20 + ['versicolor'] * 20 + ['virginica'] * 10
   ....:   )

In [71]: df.plot.scatter(x='a', y='b');
\end{verbatim}
To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify color and label keywords to distinguish each groups.

```python
In [72]: ax = df.plot.scatter(x="a", y="b", color="DarkBlue", label="Group 1")

In [73]: df.plot.scatter(x="c", y="d", color="DarkGreen", label="Group 2", ax=ax);
```
The keyword `c` may be given as the name of a column to provide colors for each point:

```python
In [74]: df.plot.scatter(x="a", y="b", c="c", s=50);
```
If a categorical column is passed to `c`, then a discrete colorbar will be produced:

New in version 1.3.0.

```
In [75]: df.plot.scatter(x="a", y="b", c="species", cmap="viridis", s=50);
```
You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```python
In [76]: df.plot.scatter(x="a", y="b", s=df["c"] * 200);
```
See the `scatter` method and the `matplotlib scatter documentation` for more.

**Hexagonal bin plot**

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```python
In [77]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [78]: df['b'] = df['b'] + np.arange(1000)
In [79]: df.plot.hexbin(x='a', y='b', gridsize=25);
```
A useful keyword argument is gridsize; it controls the number of hexagons in the x-direction, and defaults to 100. A larger gridsize means more, smaller bins.

By default, a histogram of the counts around each \((x, y)\) point is computed. You can specify alternative aggregations by passing values to the C and reduce_C_function arguments. C specifies the value at each \((x, y)\) point and reduce_C_function is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std). In this example the positions are given by columns \(a\) and \(b\), while the value is given by column \(z\). The bins are aggregated with NumPy's max function.

```python
In [80]: df = pd.DataFrame(np.random.randn(1000, 2), columns=["a", "b"])
In [81]: df["b"] = df["b"] + np.arange(1000)
In [82]: df["z"] = np.random.uniform(0, 3, 1000)
In [83]: df.plot.hexbin(x="a", y="b", C="z", reduce_C_function=np.max, gridsize=25);
```
See the `hexbin` method and the matplotlib hexbin documentation for more.

**Pie plot**

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any NaN, they will be automatically filled with 0. A ValueError will be raised if there are any negative values in your data.

```
In [84]: series = pd.Series(3 * np.random.rand(4), index=["a", "b", "c", "d"], name="series")

In [85]: series.plot.pie(figsize=(6, 6));
```
For pie plots it’s best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with DataFrame requires that you either specify a target column by the y argument or `subplots=True`. When y is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```python
In [86]: df = pd.DataFrame(  ....:     3 * np.random.rand(4, 2), index=['a', 'b', 'c', 'd'], columns=['x', 'y']  ....: )
In [87]: df.plot.pie(subplots=True, figsize=(8, 4));
```
You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```python
In [88]: series.plot.pie(
    ....:     labels=['AA', 'BB', 'CC', 'DD'],
    ....:     colors=['r', 'g', 'b', 'c'],
    ....:     autopct='%.2f',
    ....:     fontsize=20,
    ....:     figsize=(6, 6),
    ....: );
```
If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```python
In [89]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name="series2")
In [90]: series.plot.pie(figsize=(6, 6));
```
See the matplotlib pie documentation for more.

2.15.3 Plotting with missing data

pandas tries to be pragmatic about plotting DataFrames or Series that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.
If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

### 2.15.4 Plotting tools

These functions can be imported from `pandas.plotting` and take a Series or DataFrame as an argument.

**Scatter matrix plot**

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```python
In [91]: from pandas.plotting import scatter_matrix

In [92]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [93]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde');```
Density plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```python
In [94]: ser = pd.Series(np.random.randn(1000))
In [95]: ser.plot.kde();
```
Andrews curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the Wikipedia entry for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

Note: The “Iris” dataset is available here.

```
In [96]: from pandas.plotting import andrews_curves

In [97]: data = pd.read_csv("data/iris.data")

In [98]: plt.figure();

In [99]: andrews_curves(data, "Name");
```
Parallel coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the Wikipedia entry for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [100]: from pandas.plotting import parallel_coordinates
In [101]: data = pd.read_csv("data/iris.data")
In [102]: plt.figure();
In [103]: parallel_coordinates(data, "Name");
```
**Lag plot**

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```python
In [104]: from pandas.plotting import lag_plot

In [105]: plt.figure();

In [106]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)

In [107]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))

In [108]: lag_plot(data);
```
Autocorrelation plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the Wikipedia entry for more about autocorrelation plots.

```
In [109]: from pandas.plotting import autocorrelation_plot

In [110]: plt.figure();

In [111]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)

In [112]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))

In [113]: autocorrelation_plot(data);
```
Bootstrap plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [114]: from pandas.plotting import bootstrap_plot

In [115]: data = pd.Series(np.random.rand(1000))

In [116]: bootstrap_plot(data, size=50, samples=500, color="grey");
```
RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package Radviz for more information.

Note: The “Iris” dataset is available here.

```python
In [117]: from pandas.plotting import radviz

In [118]: data = pd.read_csv("data/iris.data")

In [119]: plt.figure();

In [120]: radviz(data, "Name");
```
2.15.5 Plot formatting

Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it’s very easy to try them out.

General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [121]: plt.figure();
In [122]: ts.plot(style="k--", label="Series");
```
For each kind of plot (e.g. `line`, `bar`, `scatter`) any additional arguments keywords are passed along to the corresponding matplotlib function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

**Controlling the legend**

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [123]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD"))

In [124]: df = df.cumsum()

In [125]: df.plot(legend=False);
```
Controlling the labels

New in version 1.1.0.

You may set the xlabel and ylabel arguments to give the plot custom labels for x and y axis. By default, pandas will pick up index name as xlabel, while leaving it empty for ylabel.

\[
\begin{align*}
\text{In [126]} & : \text{df.plot();} \\
\text{In [127]} & : \text{df.plot(xlabel="new x", ylabel="new y");}
\end{align*}
\]
Scales

You may pass `logy` to get a log-scale Y axis.

```
In [128]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
In [129]: ts = np.exp(ts.cumsum())
In [130]: ts.plot(logy=True);
```
See also the logx and loglog keyword arguments.

### Plotting on a secondary y-axis

To plot data on a secondary y-axis, use the secondary_y keyword:

```python
In [131]: df["A"].plot();
In [132]: df["B"].plot(secondary_y=True, style="g");
```
To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```python
In [133]: plt.figure();
In [134]: ax = df.plot(secondary_y=['A', 'B'])
In [135]: ax.set_ylabel("CD scale");
In [136]: ax.right_ax.set_ylabel("AB scale");
```
Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```python
In [137]: plt.figure();
In [138]: df.plot(secondary_y=['A', 'B'], mark_right=False);
```
Custom formatters for timeseries plots

Changed in version 1.0.0.

pandas provides custom formatters for timeseries plots. These change the formatting of the axis labels for dates and times. By default, the custom formatters are applied only to plots created by pandas with DataFrame.plot() or Series.plot(). To have them apply to all plots, including those made by matplotlib, set the option pd.options.plotting.matplotlib.register_converters = True or use pandas.plotting.register_matplotlib_converters().

Suppressing tick resolution adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created twinx), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

In [139]: plt.figure();
In [140]: df["A"].plot();
Using the `x_compat` parameter, you can suppress this behavior:

```python
In [141]: plt.figure();
In [142]: df["A"].plot(x_compat=True);
```
If you have more than one plot that needs to be suppressed, the `use` method in `pandas.plotting.plot_params` can be used in a `with` statement:

```
In [143]: plt.figure();

In [144]: with pd.plotting.plot_params.use("x_compat", True):
    ....:     df["A"].plot(color="r")
    ....:     df["B"].plot(color="g")
    ....:     df["C"].plot(color="b")
    ....:
```
**Automatic date tick adjustment**

TimedeltaIndex now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the matplotlib documentation for more.
Subplots

Each Series in a DataFrame can be plotted on a different axis with the subplots keyword:

```
In [145]: df.plot(subplots=True, figsize=(6, 6));
```
Using layout and targeting multiple axes

The layout of subplots can be specified by the layout keyword. It can accept (rows, columns). The layout keyword can be used in hist and boxplot also. If the input is invalid, a ValueError will be raised.

The number of axes which can be contained by rows x columns specified by layout must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array’s reshape method, you can use -1 for one dimension to automatically calculate the number of rows or columns needed, given the other.

In [146]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);

The above example is identical to using:

In [147]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).
You can pass multiple axes created beforehand as list-like via ax keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the ax keyword, layout, sharex and sharey keywords don’t affect to the output. You should explicitly pass sharex=False and sharey=False, otherwise you will see a warning.

```python
In [148]: fig, axes = plt.subplots(4, 4, figsize=(9, 9))
In [149]: plt.subplots_adjust(wspace=0.5, hspace=0.5)
In [150]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
In [151]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]
In [152]: df.plot(subplots=True, ax=target1, legend=False, sharex=False, sharey=False);
In [153]: (-df).plot(subplots=True, ax=target2, legend=False, sharex=False, sharey=False);
```
Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```python
In [154]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [155]: plt.subplots_adjust(wspace=0.2, hspace=0.5)
In [156]: df["A"] plot(ax=axes[0, 0]);
In [157]: axes[0, 0]. set_title("A");
In [158]: df["B"] plot(ax=axes[0, 1]);
In [159]: axes[0, 1]. set_title("B");
```

(continues on next page)
Plotting with error bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or dict of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (`list`, `tuple`, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Here is an example of one way to easily plot group means with standard deviations from the raw data.
# Generate the data
In [164]: ix3 = pd.MultiIndex.from_arrays(
   ....:     ["a", "a", "a", "a", "b", "b", "b", "b", "b"],
   ....:     ["foo", "foo", "foo", "bar", "bar", "foo", "foo", "bar", "bar"],
   ....:     names=["letter", "word"],
   ....: )

In [165]: df3 = pd.DataFrame(
   ....:     {"data1": [9, 3, 2, 4, 3, 2, 4, 6, 3, 2],
   ....:      "data2": [9, 6, 5, 7, 5, 4, 5, 6, 5, 1],
   ....:   },
   ....:     index=ix3,
   ....: )

# Group by index labels and take the means and standard deviations
# for each group
In [166]: gp3 = df3.groupby(level=("letter", "word"))

In [167]: means = gp3.mean()

In [168]: errors = gp3.std()

In [169]: means
Out[169]:

<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>3.50000</td>
<td>6.00000</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>4.66667</td>
<td>6.66667</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>3.66667</td>
<td>4.00000</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>3.00000</td>
<td>4.50000</td>
</tr>
</tbody>
</table>

In [170]: errors
Out[170]:

<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>0.70710</td>
<td>1.41421</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>0.70710</td>
<td>1.41421</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>2.08166</td>
<td>2.64575</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>1.41421</td>
<td>0.70710</td>
</tr>
</tbody>
</table>

# Plot
In [171]: fig, ax = plt.subplots()

In [172]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a $N$ length Series, a $2 \times N$ array should be provided indicating lower and upper (or left and right) errors. For a $M \times N$ DataFrame, asymmetrical errors should be in a $M \times 2 \times N$ array.

Here is an example of one way to plot the min/max range using asymmetrical error bars.

```python
In [173]: mins = gp3.min()
In [174]: maxs = gp3.max()

# errors should be positive, and defined in the order of lower, upper
In [175]: errors = [[means[c] - mins[c], maxs[c] - means[c]] for c in df3.columns]

# Plot
In [176]: fig, ax = plt.subplots()

In [177]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
```
Plotting tables

Plotting with matplotlib table is now supported in DataFrame.plot() and Series.plot() with a table keyword. The table keyword can accept bool, DataFrame or Series. The simple way to draw a table is to specify table=True. Data will be transposed to meet matplotlib’s default layout.

```
In [178]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.5))

In [179]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [180]: ax.xaxis.tick_top() # Display x-axis ticks on top.

In [181]: df.plot(table=True, ax=ax);
```
Also, you can pass a different DataFrame or Series to the table keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [182]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.75))

In [183]: ax.xaxis.tick_top()  # Display x-axis ticks on top.

In [184]: df.plot(table=np.round(df.T, 2), ax=ax);
```
There also exists a helper function `pandas.plotting.table`, which creates a table from DataFrame or Series, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib.table` has.

```python
In [185]: from pandas.plotting import table
In [186]: fig, ax = plt.subplots(1, 1)
In [187]: table(ax, np.round(df.describe(), 2), loc="upper right", colWidths=[0.2, 0.2, 0.2]);
In [188]: df.plot(ax=ax, ylim=(0, 2), legend=None);
```

2.15. Chart Visualization 743
A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, DataFrame plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available here.

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the DataFrame. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```
In [189]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)

In [190]: df = df.cumsum()

In [191]: plt.figure();

In [192]: df.plot(colormap="cubehelix");
```
Alternatively, we can pass the colormap itself:

```
In [193]: from matplotlib import cm
In [194]: plt.figure();
In [195]: df.plot(colormap=cm.cubehelix);
```
Colormaps can also be used in other plot types, like bar charts:

```python
In [196]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
In [197]: dd = dd.cumsum()
In [198]: plt.figure();
In [199]: dd.plot.bar(colormap="Greens");
```
Parallel coordinates charts:

In [200]: plt.figure();

In [201]: parallel_coordinates(data, "Name", colormap="gist_rainbow");
Andres curves charts:

```python
In [202]: plt.figure();

In [203]: andrews_curves(data, "Name", colormap="winter");```
2.15.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. Series and DataFrame objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```
In [204]: price = pd.Series(np.random.randn(150).cumsum(),
                      index=pd.date_range("2000-1-1", periods=150, freq="B"),
                      )

In [205]: ma = price.rolling(20).mean()

In [206]: mstd = price.rolling(20).std()

In [207]: plt.figure();
```

(continues on next page)
In [208]: plt.plot(price.index, price, "k");

In [209]: plt.plot(ma.index, ma, "b");

In [210]: plt.fill_between(mstd.index, ma - 2 * mstd, ma + 2 * mstd, color="b", alpha=0.2);

2.15.7 Plotting backends

Starting in version 0.25, pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib.

This can be done by passing ‘backend.module’ as the argument backend in `plot` function. For example:

```python
>>> Series([1, 2, 3]).plot(backend="backend.module")
```

Alternatively, you can also set this option globally, do you don’t need to specify the keyword in each `plot` call. For example:

```python
>>> pd.set_option("plotting.backend", "backend.module")
>>> pd.Series([1, 2, 3]).plot()
```
Or:

```python
>>> pd.options.plotting.backend = "backend.module"
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair, hvplot...) to generate the plots. Some libraries implementing a backend for pandas are listed on the ecosystem ecosystem.visualization page.

Developers guide can be found at https://pandas.pydata.org/docs/dev/development/extending.html#plotting-backends

## 2.16 Table Visualization

This section demonstrates visualization of tabular data using the **Styler** class. For information on visualization with charting please see [Chart Visualization](https://pandas.pydata.org/docs/dev/development/extending.html#chart-visualization). This document is written as a Jupyter Notebook, and can be viewed or downloaded here.

### 2.16.1 Styler Object and HTML

Styling should be performed after the data in a DataFrame has been processed. The **Styler** creates an HTML `<table>` and leverages CSS styling language to manipulate many parameters including colors, fonts, borders, background, etc. See [here](https://pandas.pydata.org/docs/dev/development/extending.html#style-objects) for more information on styling HTML tables. This allows a lot of flexibility out of the box, and even enables web developers to integrate DataFrames into their exiting user interface designs.

The DataFrame.style attribute is a property that returns a **Styler** object. It has a `__repr_html__` method defined on it so they are rendered automatically in Jupyter Notebook.

```python
[2]: import pandas as pd
    import numpy as np
    import matplotlib as mpl

df = pd.DataFrame([[38.0, 2.0, 18.0, 22.0, 21, np.nan],[19, 439, 6, 452, 226, 232]],
                  index=pd.Index(['Tumour (Positive)', 'Non-Tumour (Negative)'], name='Actual Label:'),
                  columns=pd.MultiIndex.from_product([['Decision Tree', 'Regression'],
                                             ['Tumour', 'Non-Tumour']], names=['Model:', 'Predicted:']))
df.style
```

The above output looks very similar to the standard DataFrame HTML representation. But the HTML here has already attached some CSS classes to each cell, even if we haven't yet created any styles. We can view these by calling the `__repr_html__` method, which returns the raw HTML as string, which is useful for further processing or adding to a file - read on in [More about CSS and HTML](https://pandas.pydata.org/docs/dev/development/extending.html#more-about-cs-and-html). Below we will show how we can use these to format the DataFrame to be more communicative. For example how we can build s:

```python
[4]: s
[4]: <pandas.io.formats.style.Styler at 0x7f420556dbb0>
```
2.16.2 Formatting the Display

Formatting Values

Before adding styles it is useful to show that the *Styler* can distinguish the display value from the actual value, in both datavlaues and index or columns headers. To control the display value, the text is printed in each cell as string, and we can use the `.format()` and `.format_index()` methods to manipulate this according to a format spec string or a callable that takes a single value and returns a string. It is possible to define this for the whole table, or index, or for individual columns, or MultiIndex levels.

Additionally, the format function has a **precision** argument to specifically help formatting floats, as well as **decimal** and **thousands** separators to support other locales, an **na_rep** argument to display missing data, and an **escape** argument to help displaying safe-HTML or safe-LaTeX. The default formatter is configured to adopt pandas’ styler.format.precision option, controllable using with `pd.option_context('format.precision', 2):

```python
[5]: df.style.format(precision=0, na_rep='MISSING', thousands=" ",
    formatter={('Decision Tree', 'Tumour'): '{:.2f}',
               ('Regression', 'Non-Tumour'): lambda x: '$ {:.1f}'.format(x*-
...-1e6))

[5]: <pandas.io.formats.style.Styler at 0x7f4205552b80>
```

Using Styler to manipulate the display is a useful feature because maintaining the indexing and datavlaues for other purposes gives greater control. You do not have to overwrite your DataFrame to display it how you like. Here is an example of using the formatting functions whilst still relying on the underlying data for indexing and calculations.

```python
[6]: weather_df = pd.DataFrame(np.random.rand(10,2)*5,
                            index=pd.date_range(start="2021-01-01", periods=10),
                            columns=['Tokyo', 'Beijing'])

def rain_condition(v):
    if v < 1.75:
        return "Dry"
    elif v < 2.75:
        return "Rain"
    return "Heavy Rain"

def make_pretty(styler):
    styler.set_caption("Weather Conditions")
    styler.format(rain_condition)
    styler.format_index(lambda v: v.strftime("%A"))
    styler.background_gradient(axis=None, vmin=1, vmax=5, cmap="YlGnBu")

weather_df
[6]:                Tokyo  Beijing
2021-01-01  0.511700  1.220817
2021-01-02  2.653205  3.149595

(continues on next page)
Hiding Data

The index and column headers can be completely hidden, as well subselecting rows or columns that one wishes to exclude. Both these options are performed using the same methods.

The index can be hidden from rendering by calling `.hide()` without any arguments, which might be useful if your index is integer based. Similarly column headers can be hidden by calling `.hide(axis="columns")` without any further arguments.

Specific rows or columns can be hidden from rendering by calling the same `.hide()` method and passing in a row/column label, a list-like or a slice of row/column labels to for the `subset` argument.

Hiding does not change the integer arrangement of CSS classes, e.g. hiding the first two columns of a DataFrame means the column class indexing will still start at `col2`, since `col0` and `col1` are simply ignored.

We can update our Styler object from before to hide some data and format the values.

```python
[8]: s = df.style.format('{:.0f}').hide([('Random', 'Tumour'), ('Random', 'Non-Tumour')], axis="columns")
```

```python
[8]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

### 2.16.3 Methods to Add Styles

There are 3 primary methods of adding custom CSS styles to Styler:

- Using `.set_table_styles()` to control broader areas of the table with specified internal CSS. Although table styles allow the flexibility to add CSS selectors and properties controlling all individual parts of the table, they are unwieldy for individual cell specifications. Also, note that table styles cannot be exported to Excel.

- Using `.set_td_classes()` to directly link either external CSS classes to your data cells or link the internal CSS classes created by `.set_table_styles()`. See here. These cannot be used on column header rows or indexes, and also won't export to Excel.

- Using the `.apply()` and `.applymap()` functions to add direct internal CSS to specific data cells. See here. As of v1.4.0 there are also methods that work directly on column header rows or indexes; `.apply_index()` and `.applymap_index()`. Note that only these methods add styles that will export to Excel. These methods work in a similar way to `DataFrame.apply()` and `DataFrame.applymap()`. 

---

2.16. Table Visualization 753
2.16.4 Table Styles

Table styles are flexible enough to control all individual parts of the table, including column headers and indexes. However, they can be unwieldy to type for individual data cells or for any kind of conditional formatting, so we recommend that table styles are used for broad styling, such as entire rows or columns at a time.

Table styles are also used to control features which can apply to the whole table at once such as creating a generic hover functionality. The :hover pseudo-selector, as well as other pseudo-selectors, can only be used this way.

To replicate the normal format of CSS selectors and properties (attribute value pairs), e.g.

```
tr:hover {
    background-color: #ffff99;
}
```

the necessary format to pass styles to `.set_table_styles()` is as a list of dicts, each with a CSS-selector tag and CSS-properties. Properties can either be a list of 2-tuples, or a regular CSS-string, for example:

```python
[10]: cell_hover = {
    'selector': 'td:hover',
    'props': [('background-color', '#ffffb3')]
}
index_names = {
    'selector': '.index_name',
    'props': 'font-style: italic; color: darkgrey; font-weight:normal;'
}
headers = {
    'selector': 'th:not(.index_name)',
    'props': 'background-color: #000066; color: white;'
}
s.set_table_styles([cell_hover, index_names, headers])
[10]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

Next we just add a couple more styling artifacts targeting specific parts of the table. Be careful here, since we are chaining methods we need to explicitly instruct the method not to overwrite the existing styles.

```python
[12]: s.set_table_styles([
    {'selector': 'th.col_heading', 'props': 'text-align: center;'},
    {'selector': 'th.col_heading.level0', 'props': 'font-size: 1.5em;'},
    {'selector': 'td', 'props': 'text-align: center; font-weight: bold;'},
], overwrite=False)
[12]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

As a convenience method (since version 1.2.0) we can also pass a dict to `.set_table_styles()` which contains row or column keys. Behind the scenes Styler just indexes the keys and adds relevant `.col<m>` or `.row<n>` classes as necessary to the given CSS selectors.

```python
[14]: s.set_table_styles({
    ('Regression', 'Tumour'): [{
        'selector': 'th', 'props': 'border-left: 1px solid white',
    },
    {'selector': 'td', 'props': 'border-left: 1px solid #000066'}
}, overwrite=False, axis=0)
```
2.16.5 Setting Classes and Linking to External CSS

If you have designed a website then it is likely you will already have an external CSS file that controls the styling of table and cell objects within it. You may want to use these native files rather than duplicate all the CSS in python (and duplicate any maintenance work).

**Table Attributes**

It is very easy to add a class to the main `<table>` using `set_table_attributes()`. This method can also attach inline styles - read more in [CSS Hierarchies](#).

```python
out = s.set_table_attributes('class="my-table-cls"').to_html()
print(out[out.find('<table'):][:109])
```

```html
<table id="T_xyz01" class="my-table-cls">
<thead>
<tr>
</thead>
</table>
```

**Data Cell CSS Classes**

*New in version 1.2.0*

The `.set_td_classes()` method accepts a DataFrame with matching indices and columns to the underlying Styler’s DataFrame. That DataFrame will contain strings as css-classes to add to individual data cells: the `<td>` elements of the `<table>`. Rather than use external CSS we will create our classes internally and add them to table style. We will save adding the borders until the section on tooltips.

```python
s.set_table_styles([    # create internal CSS classes
    {'selector': '.true', 'props': 'background-color: #e6ffe6;'},
    {'selector': '.false', 'props': 'background-color: #ffe6e6;'},
], overwrite=False)
cell_color = pd.DataFrame([[true', 'false', 'true', 'false'],
    ['false', 'true', 'false', 'true']],
    index=df.index,
    columns=df.columns[:4])
s.set_td_classes(cell_color)
```

```python
<pandas.io.formats.style.Styler at 0x7f417c593790>
```
2.16.6 Styler Functions

Acting on Data

We use the following methods to pass your style functions. Both of those methods take a function (and some other keyword arguments) and apply it to the DataFrame in a certain way, rendering CSS styles.

- `applymap()` (elementwise): accepts a function that takes a single value and returns a string with the CSS attribute-value pair.
- `apply()` (column-/row-/table-wise): accepts a function that takes a Series or DataFrame and returns a Series, DataFrame, or numpy array with an identical shape where each element is a string with a CSS attribute-value pair. This method passes each column or row of your DataFrame one-at-a-time or the entire table at once, depending on the axis keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

This method is powerful for applying multiple, complex logic to data cells. We create a new DataFrame to demonstrate this.

```python
[19]: np.random.seed(0)
df2 = pd.DataFrame(np.random.randn(10,4), columns=['A', 'B', 'C', 'D'])
df2.style
[19]: <pandas.io.formats.style.Styler at 0x7f42044a36d0>
```

For example we can build a function that colors text if it is negative, and chain this with a function that partially fades cells of negligible value. Since this looks at each element in turn we use `applymap`.

```python
[20]: def style_negative(v, props=''):    
        return props if v < 0 else None
s2 = df2.style.applymap(style_negative, props='color:red;')
    .applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)

[20]: <pandas.io.formats.style.Styler at 0x7f4205302b80>
```

We can also build a function that highlights the maximum value across rows, cols, and the DataFrame all at once. In this case we use `apply`. Below we highlight the maximum in a column.

```python
[22]: def highlight_max(s, props=''):    
        return np.where(s == np.nanmax(s.values), props, '')
        s2.apply(highlight_max, props='color:white;background-color:darkblue', axis=0)

[22]: <pandas.io.formats.style.Styler at 0x7f4205302b80>
```

We can use the same function across the different axes, highlighting here the DataFrame maximum in purple, and row maximums in pink.

```python
[24]: s2.apply(highlight_max, props='color:white;background-color:purple', axis=None)

[24]: <pandas.io.formats.style.Styler at 0x7f4205302b80>
```

This last example shows how some styles have been overwritten by others. In general the most recent style applied is active but you can read more in the section on CSS hierarchies. You can also apply these styles to more granular parts of the DataFrame - read more in section on subset slicing.

It is possible to replicate some of this functionality using just classes but it can be more cumbersome. See item 3) of Optimization
Debugging Tip: If you’re having trouble writing your style function, try just passing it into DataFrame.apply. Internally, Styler.apply uses DataFrame.apply so the result should be the same, and with DataFrame.apply you will be able to inspect the CSS string output of your intended function in each cell.

Acting on the Index and Column Headers

Similar application is acheived for headers by using:

• `applymap_index()` (elementwise): accepts a function that takes a single value and returns a string with the CSS attribute-value pair.

• `apply_index()` (level-wise): accepts a function that takes a Series and returns a Series, or numpy array with an identical shape where each element is a string with a CSS attribute-value pair. This method passes each level of your Index one-at-a-time. To style the index use `axis=0` and to style the column headers use `axis=1`.

You can select a level of a MultiIndex but currently no similar subset application is available for these methods.

Adding tooltips (since version 1.3.0) can be done using the `set_tooltips()` method in the same way you can add CSS classes to data cells by providing a string based DataFrame with intersecting indices and columns. You don’t have to specify a `css_class` name or any css `props` for the tooltips, since there are standard defaults, but the option is there if you want more visual control.

2.16. Table Visualization

Table captions can be added with the `.set_caption()` method. You can use table styles to control the CSS relevant to the caption.

Adding tooltips (since version 1.3.0) can be done using the `.set_tooltips()` method in the same way you can add CSS classes to data cells by providing a string based DataFrame with intersecting indices and columns. You don’t have to specify a css_class name or any css props for the tooltips, since there are standard defaults, but the option is there if you want more visual control.
The only thing left to do for our table is to add the highlighting borders to draw the audience attention to the tooltips. We will create internal CSS classes as before using table styles. **Setting classes always overwrites** so we need to make sure we add the previous classes.

```python
s.set_table_styles([  # create internal CSS classes
    {'selector': ' .border-red', 'props': ' border: 2px dashed red;'},
    {'selector': ' .border-green', 'props': ' border: 2px dashed green;'},
], overwrite=False)
cell_border = pd.DataFrame([[  # create internal CSS classes
    'border-green', '', '', 'border-red'],
    ['', '', '', '']],
    index=df.index,
    columns=df.columns[:4])
s.set_td_classes(cell_color + cell_border)
```

2.16.8 Finer Control with Slicing

The examples we have shown so far for the `Styler.apply` and `Styler.applymap` functions have not demonstrated the use of the `subset` argument. This is a useful argument which permits a lot of flexibility: it allows you to apply styles to specific rows or columns, without having to code that logic into your `style` function.

The value passed to `subset` behaves similar to slicing a DataFrame:

- A scalar is treated as a column label
- A list (or Series or NumPy array) is treated as multiple column labels
- A tuple is treated as `(row_indexer, column_indexer)`

Consider using `pd.IndexSlice` to construct the tuple for the last one. We will create a MultiIndexed DataFrame to demonstrate the functionality.

```python
[33]: df3 = pd.DataFrame(np.random.randn(4,4),
    pd.MultiIndex.from_product([['A', 'B'], ['r1', 'r2']])),
    columns=['c1','c2','c3','c4'])
```

We will use subset to highlight the maximum in the third and fourth columns with red text. We will highlight the subset sliced region in yellow.

```python
[34]: slice_ = ['c3', 'c4']
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_)
    .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
```

If combined with the `IndexSlice` as suggested then it can index across both dimensions with greater flexibility.
pandas: powerful Python data analysis toolkit, Release 1.4.1

[35]:
idx = pd.IndexSlice
slice_ = idx[idx[:, 'r1'], idx['c2':'c4']]  
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_)
  .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
[35]: <pandas.io.formats.style.Styler at 0x7f42053199a0>

This also provides the flexibility to sub select rows when used with the axis=1.

[36]:
slice_ = idx[idx[:, 'r2'], :]
   df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)
  .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
[36]: <pandas.io.formats.style.Styler at 0x7f4205319c40>

There is also scope to provide conditional filtering.

Suppose we want to highlight the maximum across columns 2 and 4 only in the case that the sum of columns 1 and 3 is less than -2.0 (essentially excluding rows (:, 'r2')).

[37]:
slice_ = idx[idx[(df3['c1'] + df3['c3']) < -2.0], ['c2', 'c4']]
   df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)
  .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
[37]: <pandas.io.formats.style.Styler at 0x7f4205319910>

Only label-based slicing is supported right now, not positional, and not callables.

If your style function uses a subset or axis keyword argument, consider wrapping your function in a functools.partial, partialing out that keyword.

my_func2 = functools.partial(my_func, subset=42)

2.16.9 Optimization

Generally, for smaller tables and most cases, the rendered HTML does not need to be optimized, and we don’t really recommend it. There are two cases where it is worth considering:

- If you are rendering and styling a very large HTML table, certain browsers have performance issues.
- If you are using Styler to dynamically create part of online user interfaces and want to improve network performance.

Here we recommend the following steps to implement:

1. Remove UUID and cell_ids

Ignore the uuid and set cell_ids to False. This will prevent unnecessary HTML.

This is sub-optimal:

[38]:
df4 = pd.DataFrame([[1,2],[3,4]])
s4 = df4.style

2.16. Table Visualization
2. Use table styles

Use table styles where possible (e.g. for all cells or rows or columns at a time) since the CSS is nearly always more efficient than other formats.

This is sub-optimal:

```python
props = 'font-family: "Times New Roman", Times, serif; color: #e83e8c; font-size:1.3em;'
df4.style.applymap(lambda x: props, subset=[1])
```

This is better:

```python
df4.style.set_table_styles([{
    'selector': 'td.col1',
    'props': props}
])
```

3. Set classes instead of using Styler functions

For large DataFrames where the same style is applied to many cells it can be more efficient to declare the styles as classes and then apply those classes to data cells, rather than directly applying styles to cells. It is, however, probably still easier to use the Styler function api when you are not concerned about optimization.

This is sub-optimal:

```python
def2.style.apply(highlight_max, props='color:white;background-color:darkblue;', axis=0)
    .apply(highlight_max, props='color:white;background-color:pink;', axis=1)
    .apply(highlight_max, props='color:white;background-color:purple', axis=None)
```

This is better:

```python
build = lambda x: pd.DataFrame(x, index=df2.index, columns=df2.columns)
cls1 = build(df2.apply(highlight_max, props='cls-1 ', axis=0))
cls2 = build(df2.apply(highlight_max, props='cls-2 ', axis=1, result_type='expand').values)
cls3 = build(highlight_max(df2, props='cls-3 '))
```
df2.style.set_table_styles([
    {'selector': '.cls-1', 'props': 'color:white;background-color:darkblue;'},
    {'selector': '.cls-2', 'props': 'color:white;background-color:pink;'},
    {'selector': '.cls-3', 'props': 'color:white;background-color:purple;'}
]).set_td_classes(cls1 + cls2 + cls3)

4. Don’t use tooltips

Tooltips require cell_ids to work and they generate extra HTML elements for every data cell.

5. If every byte counts use string replacement

You can remove unnecessary HTML, or shorten the default class names by replacing the default css dict. You can read a little more about CSS below.

my_css = {
    "row_heading": "",
    "col_heading": "",
    "index_name": "",
    "col": "c",
    "row": "r",
    "col_trim": "",
    "row_trim": "",
    "level": "1",
    "data": "",
    "blank": "",
}

html = Styler(df4, uuid_len=0, cell_ids=False)

html.set_table_styles([{
    'selector': 'td', 'props': props,
    'selector': '.c1', 'props': 'color:green;'},
    'selector': '.l0', 'props': 'color:blue;'],
    css_class_names=my_css)

print(html.to_html())

<style type="text/css">
#T_ td {
    font-family: "Times New Roman", Times, serif;
    color: #e83e8c;
    font-size: 1.3em;
}

#T_ .c1 {
    color: green;
}

#T_ .l0 {
    color: blue;
}
</style>
<table id="T_">
<thead>
2.16.10 Builtin Styles

Some styling functions are common enough that we’ve “built them in” to the `Styler`, so you don’t have to write them and apply them yourself. The current list of such functions is:

- `.highlight_null`: for use with identifying missing data.
- `.highlight_min` and `.highlight_max`: for use with identifying extremeties in data.
- `.highlight_between` and `.highlight_quantile`: for use with identifying classes within data.
- `.background_gradient`: a flexible method for highlighting cells based or their, or other, values on a numeric scale.
- `.text_gradient`: similar method for highlighting text based on their, or other, values on a numeric scale.
- `.bar`: to display mini-charts within cell backgrounds.

The individual documentation on each function often gives more examples of their arguments.

**Highlight Null**

```python
[46]: df2.iloc[0, 2] = np.nan
df2.iloc[4, 3] = np.nan
df2.loc[:4].style.highlight_null(null_color='yellow')
```

```python
[46]: <pandas.io.formats.style.Styler at 0x7f4205319d90>
```
Highlight Min or Max

```python
[47]: df2.loc[:4].style.highlight_max(axis=1, props='color:white; font-weight:bold; background-color:darkblue;')
[47]: <pandas.io.formats.style.Styler at 0x7f4205319fa0>
```

Highlight Between

This method accepts ranges as float, or NumPy arrays or Series provided the indexes match.

```python
[48]: left = pd.Series([1.0, 0.0, 1.0], index=['A', 'B', 'D'])
df2.loc[:4].style.highlight_between(left=left, right=1.5, axis=1, props='color:white; background-color:purple;')
[48]: <pandas.io.formats.style.Styler at 0x7f42052b4e50>
```

Highlight Quantile

Useful for detecting the highest or lowest percentile values

```python
[49]: df2.loc[:4].style.highlight_quantile(q_left=0.85, axis=None, color='yellow')
[49]: <pandas.io.formats.style.Styler at 0x7f42052b5580>
```

Background Gradient and Text Gradient

You can create “heatmaps” with the `background_gradient` and `text_gradient` methods. These require matplotlib, and we’ll use Seaborn to get a nice colormap.

```python
[50]: import seaborn as sns
cm = sns.light_palette("green", as_cmap=True)
df2.style.background_gradient(cmap=cm)
[50]: <pandas.io.formats.style.Styler at 0x7f42052f6ac0>
```

```python
[51]: df2.style.text_gradient(cmap=cm)
[51]: <pandas.io.formats.style.Styler at 0x7f42053136d0>
```

`background_gradient` and `text_gradient` have a number of keyword arguments to customise the gradients and colors. See the documentation.
pandas: powerful Python data analysis toolkit, Release 1.4.1

Set properties
Use Styler.set_properties when the style doesn’t actually depend on the values. This is just a simple wrapper for
.applymap where the function returns the same properties for all cells.
[52]: df2.loc[:4].style.set_properties(**{'background-color': 'black',
'color': 'lawngreen',
'border-color': 'white'})
[52]: <pandas.io.formats.style.Styler at 0x7f420556d310>

Bar charts
You can include “bar charts” in your DataFrame.
[53]: df2.style.bar(subset=['A', 'B'], color='#d65f5f')
[53]: <pandas.io.formats.style.Styler at 0x7f41da19d520>
Additional keyword arguments give more control on centering and positioning, and you can pass a list of
[color_negative, color_positive] to highlight lower and higher values or a matplotlib colormap.
To showcase an example here’s how you can change the above with the new align option, combined with setting vmin
and vmax limits, the width of the figure, and underlying css props of cells, leaving space to display the text and the
bars. We also use text_gradient to color the text the same as the bars using a matplotlib colormap (although in this
case the visualization is probably better without this additional effect).
[54]: df2.style.format('{:.3f}', na_rep="")\
.bar(align=0, vmin=-2.5, vmax=2.5, cmap="bwr", height=50,
width=60, props="width: 120px; border-right: 1px solid black;")\
.text_gradient(cmap="bwr", vmin=-2.5, vmax=2.5)
[54]: <pandas.io.formats.style.Styler at 0x7f41da19eac0>
The following example aims to give a highlight of the behavior of the new align options:
[56]: HTML(head)
[56]: <IPython.core.display.HTML object>

2.16.11 Sharing styles
Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame.
Export the style with df1.style.export, and import it on the second DataFrame with df1.style.set
[57]: style1 = df2.style\
.applymap(style_negative, props='color:red;')\
.applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)\
.set_table_styles([{"selector": "th", "props": "color: blue;"}])\
.hide(axis="index")
style1

Chapter 2. User Guide


Notice that you’re able to share the styles even though they’re data aware. The styles are re-evaluated on the new DataFrame they’ve been used upon.

### 2.16.12 Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns do not need to be unique, but certain styling functions can only work with unique indexes.
- No large repr, and construction performance isn’t great; although we have some *HTML optimizations*
- You can only apply styles, you can’t insert new HTML entities, except via subclassing.

### 2.16.13 Other Fun and Useful Stuff

Here are a few interesting examples.

#### Widgets

Styler interacts pretty well with widgets. If you’re viewing this online instead of running the notebook yourself, you’re missing out on interactively adjusting the color palette.

```python
from ipywidgets import widgets

@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
    return df2.style.background_gradient(
        cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l, as_cmap=True)
    )

interactive(children=(IntSlider(value=179, description='h_neg', max=359),
    ... IntSlider(value=179, description='h...
```

#### Magnify

```python
def magnify():
    return [dict(selector="th",
        props=[("font-size", "4pt")]),
    dict(selector="td",
        props=[('padding', '0em 0em')]),
    dict(selector="th:hover",
        props=[("font-size", "12pt")]),
    dict(selector="tr:hover td:hover",
        props=[('max-width', '200px'),
               ('font-size', '12pt')])
]
```
Sticky Headers

If you display a large matrix or DataFrame in a notebook, but you want to always see the column and row headers you can use the `set_sticky` method which manipulates the table styles CSS.

```python
bigdf = pd.DataFrame(np.random.randn(16, 100))
bigdf.style.set_sticky(axis="index")
```

It is also possible to stick MultiIndexes and even only specific levels.

```python
bigdf.index = pd.MultiIndex.from_product(["A","B"],[0,1],[0,1,2,3])
bigdf.style.set_sticky(axis="index", pixel_size=18, levels=[1,2])
```

HTML Escaping

Suppose you have to display HTML within HTML, that can be a bit of pain when the renderer can't distinguish. You can use the escape formatting option to handle this, and even use it within a formatter that contains HTML itself.

```python
df4 = pd.DataFrame([["<div></div>", "&other"],["<span></span>"]])
df4.style
```

```python
df4.style.format(escape="html")
```

```python
df4.style.format("<a href="https://pandas.pydata.org" target="_blank">{}</a>", escape="html")
```

[pandas: powerful Python data analysis toolkit, Release 1.4.1]
2.16.14 Export to Excel

Some support (since version 0.20.0) is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Currently broken: border-style, border-width, border-color and their {top, right, bottom, left variants}
- Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
  - number-format

Table level styles, and data cell CSS-classes are not included in the export to Excel: individual cells must have their properties mapped by the Styler.apply and/or Styler.applymap methods.

```python
[67]: df2.style.
    .applymap(style_negative, props='color:red;').
    .highlight_max(axis=0).
    .to_excel('styled.xlsx', engine='openpyxl')
```

A screenshot of the output:

2.16.15 Export to LaTeX

There is support (since version 1.3.0) to export Styler to LaTeX. The documentation for the .to_latex method gives further detail and numerous examples.

2.16.16 More About CSS and HTML

Cascading Style Sheet (CSS) language, which is designed to influence how a browser renders HTML elements, has its own peculiarities. It never reports errors: it just silently ignores them and doesn’t render your objects how you intend so can sometimes be frustrating. Here is a very brief primer on how Styler creates HTML and interacts with CSS, with advice on common pitfalls to avoid.

CSS Classes and Ids

The precise structure of the CSS class attached to each cell is as follows.

- Cells with Index and Column names include index_name and level<k> where k is its level in a MultiIndex
- Index label cells include
  - row_heading
  - level<k> where k is the level in a MultiIndex
  - row<m> where m is the numeric position of the row
- Column label cells include
  - col_heading
  - level<k> where k is the level in a MultiIndex
  - col<n> where n is the numeric position of the column
- Data cells include
  - data
  - row<m>, where m is the numeric position of the cell.
  - col<n>, where n is the numeric position of the cell.
- Blank cells include blank
- Trimmed cells include col_trim or row_trim

The structure of the id is T_uuid_level<k>_row<m>_col<n> where level<k> is used only on headings, and headings will only have either row<m> or col<n> whichever is needed. By default we’ve also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn’t collide with the styling from another within the same notebook or page. You can read more about the use of UUIDs in Optimization.

We can see example of the HTML by calling the .to_html() method.

```
[68]: print(pd.DataFrame([[1,2],[3,4]], index=['i1', 'i2'], columns=['c1', 'c2']).style.to_html())
```

```
[68]:<style type="text/css">
</style>
<table id="T_60ca3">
<thead>
<tr>
</tr>
</thead>
</table>
```
CSS Hierarchies

The examples have shown that when CSS styles overlap, the one that comes last in the HTML render, takes precedence. So the following yield different results:

```
[69]: df4 = pd.DataFrame([[text]])
df4.style.applymap(lambda x: 'color:green;')
     .applymap(lambda x: 'color:red;')

[69]: <pandas.io.formats.style.Styler at 0x7f41da1ba1f0>

[70]: df4.style.applymap(lambda x: 'color:red;')
     .applymap(lambda x: 'color:green;')

[70]: <pandas.io.formats.style.Styler at 0x7f41c91cd340>
```

This is only true for CSS rules that are equivalent in hierarchy, or importance. You can read more about CSS specificity here but for our purposes it suffices to summarize the key points:

A CSS importance score for each HTML element is derived by starting at zero and adding:

- 1000 for an inline style attribute
- 100 for each ID
- 10 for each attribute, class or pseudo-class
- 1 for each element name or pseudo-element

Let's use this to describe the action of the following configurations

```
[71]: df4.style.set_uuid('a_')
     .set_table_styles([{'selector': 'td', 'props': 'color:red;'}])
     .applymap(lambda x: 'color:green;')
```
This text is red because the generated selector \#T_a\_ td is worth 101 (ID plus element), whereas \#T_a_row0\_col0 is only worth 100 (ID), so is considered inferior even though in the HTML it comes after the previous.

```
[72]: df4.style.set_uuid('b_')
   .set_table_styles([{'selector': 'td', 'props': 'color:red;'},
                      {'selector': '.cls-1', 'props': 'color:blue;'}])
   .applymap(lambda x: 'color:green;')
   .set_td_classes(pd.DataFrame([['cls-1']]))
```

In the above case the text is blue because the selector \#T_b_ .cls-1 is worth 110 (ID plus class), which takes precedence.

```
[73]: df4.style.set_uuid('c_')
   .set_table_styles([{'selector': 'td', 'props': 'color:red;'},
                      {'selector': '.cls-1', 'props': 'color:blue;'},
                      {'selector': 'td.data', 'props': 'color:yellow;'}])
   .applymap(lambda x: 'color:green;')
   .set_td_classes(pd.DataFrame([['cls-1']]))
```

Now we have created another table style this time the selector T_c_ td.data (ID plus element plus class) gets bumped up to 111.

If your style fails to be applied, and its really frustrating, try the !important trump card.

```
[74]: df4.style.set_uuid('d_')
   .set_table_styles([{'selector': 'td', 'props': 'color:red;'},
                      {'selector': '.cls-1', 'props': 'color:blue;'},
                      {'selector': 'td.data', 'props': 'color:yellow;'}])
   .applymap(lambda x: 'color:green !important;')
   .set_td_classes(pd.DataFrame([['cls-1']]))
```

Finally got that green text after all!

**2.16.17 Extensibility**

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that DataFrame.style accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll link to it.
Subclassing

If the default template doesn’t quite suit your needs, you can subclass Styler and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```python
from jinja2 import Environment, ChoiceLoader, FileSystemLoader
from IPython.display import HTML
from pandas.io.formats.style import Styler

We’ll use the following template:

```jinja2
{% extends "html_table.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we’ve created a template, we need to set up a subclass of Styler that knows about it.

```python
class MyStyler(Styler):
    env = Environment(
        loader=ChoiceLoader(
            [FileSystemLoader("templates"), # contains ours
             Styler.loader, # the default
            ]
        )
    )
    template_html_table = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment’s loader. That’s because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It’s __init__ takes a DataFrame.

```python
MyStyler(df3)
```

Our custom template accepts a table_title keyword. We can provide the value in the .to_html method.

```python
HTML(MyStyler(df3).to_html(table_title="Extending Example"))
```

For convenience, we provide the Styler.from_custom_template method that does the same as the custom subclass.

```python
EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
HTML(EasyStyler(df3).to_html(table_title="Another Title"))
```
### Template Structure

Here’s the template structure for the both the style generation template and the table generation template:

**Style template:**

```
[82]: HTML(style_structure)
[82]: <IPython.core.display.HTML object>
```

**Table template:**

```
[84]: HTML(table_structure)
[84]: <IPython.core.display.HTML object>
```

See the template in the [GitHub repo](https://github.com) for more details.

## 2.17 Computational tools

### 2.17.1 Statistical functions

#### Percent change

Series and DataFrame have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values before computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))

In [2]: ser.pct_change()
Out[2]:
0    NaN
1   -1.602976
2    4.334938
3   -0.247456
4   -2.067345
5  -1.142903
6   -1.688214
7   -9.759729
dtype: float64

In [3]: df = pd.DataFrame(np.random.randn(10, 4))

In [4]: df.pct_change(periods=3)
Out[4]:
     0       1       2       3
0   NaN   NaN   NaN   NaN
1   NaN   NaN   NaN   NaN
2  NaN   NaN   NaN   NaN
3 -0.218320 -1.054001 1.987147 -0.510183
4 -0.439121 -1.816454 0.649715 -4.822809
5 -0.127833 -3.042065 -5.866604 -1.776977
```

(continues on next page)
Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).

```python
In [5]: s1 = pd.Series(np.random.randn(1000))
In [6]: s2 = pd.Series(np.random.randn(1000))
In [7]: s1.cov(s2)
Out[7]: 0.0006801088174310875
```

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

```python
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=["a", "b", "c", "d", "e"])
In [9]: frame.cov()
Out[9]:
         a      b      c      d      e
a  1.000882 -0.003177 -0.002698 -0.006889  0.031912
b -0.003177  1.024721  0.000191  0.009212  0.000857
c -0.002698  0.000191  0.950735 -0.031743 -0.005087
d -0.006889  0.009212 -0.031743  1.002983 -0.047952
e  0.031912  0.000857 -0.005087 -0.047952  1.042487
```

`DataFrame.cov` also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```python
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=["a", "b", "c"])
In [11]: frame.loc[frame.index[:5], "a"] = np.nan
In [12]: frame.loc[frame.index[5:10], "b"] = np.nan
In [13]: frame.cov()
Out[13]:
         a      b      c
a  1.123670 -0.412851  0.018169
b -0.412851  1.154141  0.305260
c  0.018169  0.305260  1.301149
```

2.17. Computational tools
In [14]: frame.cov(min_periods=12)
Out[14]:
   a    b    c
a 1.123670 NaN  0.018169
b  NaN 1.154141  0.305260
c  0.018169  0.305260 1.301149

**Correlation**

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

<table>
<thead>
<tr>
<th>Method name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pearson</td>
<td>Standard correlation coefficient</td>
</tr>
<tr>
<td>kendall</td>
<td>Kendall Tau correlation coefficient</td>
</tr>
<tr>
<td>spearman</td>
<td>Spearman rank correlation coefficient</td>
</tr>
</tbody>
</table>

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman’s rank correlation coefficient

**Note:** Please see the caveats associated with this method of calculating correlation matrices in the covariance section.

In [15]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e '])
In [16]: frame.iloc[::2] = np.nan
# Series with Series
In [17]: frame["a"].corr(frame["b"])
Out[17]: 0.013479040400098775
In [18]: frame["a"].corr(frame["b"], method="spearman")
Out[18]: -0.007289885159540637
# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
   a    b    c    d    e
a 1.000000 0.013479 -0.049269 -0.042239 -0.028525
b 0.013479 1.000000 -0.020433 -0.011139 0.005654
c -0.049269 -0.020433 1.000000 0.018587 -0.054269
d -0.042239 -0.011139 0.018587 1.000000 -0.017060
e -0.028525 0.005654 -0.054269 -0.017060 1.000000
Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```python
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [21]: frame.loc[frame.index[:5], 'a'] = np.nan
In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [23]: frame.corr()
Out[23]:
          a      b      c
a  1.000000  NaN  0.069544
b  NaN  1.000000  0.051742
c  0.069544  0.051742  1.000000
In [24]: frame.corr(min_periods=12)
Out[24]:
          a      b      c
a  1.000000  NaN  0.069544
b  NaN  1.000000  0.051742
c  0.069544  0.051742  1.000000
```

The `method` argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

```python
# histogram intersection
In [25]: def histogram_intersection(a, b):
......:     return np.minimum(np.true_divide(a, a.sum()), np.true_divide(b, b.sum())).sum()
......:
In [26]: frame.corr(method=histogram_intersection)
Out[26]:
          a      b      c
a  1.000000 -6.404882 -2.058431
b -6.404882  1.000000 -19.255743
c -2.058431 -19.255743  1.000000
```

A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```python
In [27]: index = ['a', 'b', 'c', 'd', 'e']
In [28]: columns = ['one', 'two', 'three', 'four']
In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)
In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)
In [31]: df1.corrwith(df2)
Out[31]:
```

(continues on next page)
Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```python
In [33]: s = pd.Series(np.random.randn(5), index=list("abcde"))
In [34]: s["d"] = s["b"]  # so there's a tie
In [35]: s.rank()
```

```
Out[35]:
a 5.0
b 2.5
c 1.0
d 2.5
e 4.0
dtype: float64
```

`rank()` is also a DataFrame method and can rank either the rows (`axis=0`) or the columns (`axis=1`). NaN values are excluded from the ranking.

```python
In [36]: df = pd.DataFrame(np.random.randn(10, 6))
In [38]: df
```

```
  0    1    2    3    4    5
0 -0.904948 -1.163537 -1.457187 0.135463 -1.457187 0.294650
1 -0.976288 -0.244652 -0.748406 -0.999601 -0.748406 -0.800809
2  0.401965  1.460840  1.256057  1.308127  1.256057  0.876004
3  0.205954  0.369552 -0.669304  0.383878 -0.669304  1.140296
4 -0.477586 -0.730705 -1.129149 -0.601463 -1.129149 -0.211196
5 -1.092970 -0.689246  0.908114  0.204848 NaN  0.463347
6  0.376892  0.959292  0.955572 -0.593740 NaN  0.069180

```

(continues on next page)
rank optionally takes a parameter ascending which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

rank supports different tie-breaking methods, specified with the method parameter:

- **average**: average rank of tied group
- **min**: lowest rank in the group
- **max**: highest rank in the group
- **first**: ranks assigned in the order they appear in the array

**Windowing functions**

See the window operations user guide for an overview of windowing functions.

### 2.18 Group by: split-apply-combine

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to do one of the following:

- **Aggregation**: compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.
- **Transformation**: perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.
• **Filtration**: discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  – Discard data that belongs to groups with only a few members.
  – Filter out data based on the group sum or mean.

• Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or itertools), in which you can write code like:

```sql
SELECT Column1, Column2, mean(Column3), sum(Column4) FROM SomeTable GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the *cookbook* for some advanced strategies.

### 2.18.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```python
In [1]: df = pd.DataFrame(
    ...:     [
    ...:         ("bird", "Falconiformes", 389.0),
    ...:         ("bird", "Psittaciformes", 24.0),
    ...:         ("mammal", "Carnivora", 80.2),
    ...:         ("mammal", "Primates", np.nan),
    ...:         ("mammal", "Carnivora", 58),
    ...:     ],
    ...:     index=["falcon", "parrot", "lion", "monkey", "leopard"],
    ...:     columns=("class", "order", "max_speed"),
    ...: )

In [2]: df
Out[2]:
   class  order     max_speed
  falcon  bird  Falconiformes   389.0
  parrot  bird   Psittaciformes   24.0
     lion  mammal     Carnivora    80.2
   monkey  mammal     Primates   NaN
  leopard  mammal     Carnivora    58.0

# default is axis=0
In [3]: grouped = df.groupby("class")

In [4]: grouped = df.groupby("order", axis="columns")

In [5]: grouped = df.groupby(["class", "order"])
```
The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label -> group name mapping.
- For DataFrame objects, a string indicating either a column name or an index level name to be used to group.
- `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`.
- A list of any of the above things.

Collectively we refer to the grouping objects as the **keys**. For example, consider the following DataFrame:

```
In [6]: df = pd.DataFrame(
    ...:     {
    ...:         "A": ["foo", "bar", "foo", "bar", "foo", "foo", "foo", "foo"],
    ...:         "B": ["one", "one", "two", "three", "two", "two", "one", "three"],
    ...:         "C": np.random.randn(8),
    ...:         "D": np.random.randn(8),
    ...:     }
    ...: )
```

```
In [7]: df
Out[7]:
         A   B       C      D
   0  foo  one  0.469112 -0.861849
   1  bar  one -0.282863 -2.104569
   2  foo  two -1.509059 -0.494929
   3  bar  three -1.135632  1.071804
   4  foo  two  1.212112  0.721555
   5  bar  two  0.173215 -0.706771
   6  foo  one  0.119209 -1.039575
   7  foo  three -1.044236  0.271860
```

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```
In [8]: grouped = df.groupby("A")
In [9]: grouped = df.groupby(["A", "B")]
```

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns

```
In [10]: df2 = df.set_index(["A", "B")]
In [11]: grouped = df2.groupby1level=df2.index.names.difference(["B")])
In [12]: grouped.sum()
```

(continues on next page)
These will split the DataFrame on its index (rows). We could also split by the columns:

```python
In [13]: def get_letter_type(letter):
   ....:     if letter.lower() in 'aeiou':
   ....:         return 'vowel'
   ....:     else:
   ....:         return 'consonant'
   ....:
In [14]: grouped = df.groupby(get_letter_type, axis=1)
```

`pandas Index` objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```python
In [15]: lst = [1, 2, 3, 1, 2, 3]
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [17]: grouped = s.groupby(level=0)
In [18]: grouped.first()
Out[18]:
1  1
2  2
3  3
dtype: int64
In [19]: grouped.last()
Out[19]:
1  10
2  20
3  30
dtype: int64
In [20]: grouped.sum()
Out[20]:
1   11
2   22
3   33
dtype: int64
```

Note that **no splitting occurs** until it’s needed. Creating the GroupBy object only verifies that you’ve passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can’t be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.
**GroupBy sorting**

By default the group keys are sorted during the groupby operation. You may however pass `sort=False` for potential speedups:

```python
In [21]: df2 = pd.DataFrame({"X": ["B", "B", "A", "A"], "Y": [1, 2, 3, 4]})

In [22]: df2.groupby(["X"]).sum()
Out[22]:
          Y
X          
A          7
B          3

In [23]: df2.groupby(["X"], sort=False).sum()
Out[23]:
          Y
X          
B          3
A          7
```

Note that groupby will preserve the order in which observations are sorted within each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

```python
In [24]: df3 = pd.DataFrame({"X": ["A", "B", "A", "B"], "Y": [1, 4, 3, 2]})

In [25]: df3.groupby(["X"]).get_group("A")
Out[25]:
   X  Y
0  A  1
2  A  3

In [26]: df3.groupby(["X"]).get_group("B")
Out[26]:
   X  Y
1  B  4
3  B  2
```

New in version 1.1.0.

**GroupBy dropna**

By default `NA` values are excluded from group keys during the groupby operation. However, in case you want to include `NA` values in group keys, you could pass `dropna=False` to achieve it.

```python
In [27]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]

In [28]: df_dropna = pd.DataFrame(df_list, columns=["a", "b", "c"])

In [29]: df_dropna
Out[29]:
   a  b  c
0  1  2  0
```

(continues on next page)
# Default `dropna` is set to True, which will exclude NaNs in keys

In [30]: df_dropna.groupby(by="b", dropna=True).sum()

Out[30]:

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0</td>
<td>2</td>
</tr>
<tr>
<td>2.0</td>
<td>5</td>
</tr>
</tbody>
</table>

# In order to allow NaN in keys, set `dropna` to False

In [31]: df_dropna.groupby(by="b", dropna=False).sum()

Out[31]:

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0</td>
<td>2</td>
</tr>
<tr>
<td>2.0</td>
<td>5</td>
</tr>
<tr>
<td>NaN</td>
<td>1</td>
</tr>
</tbody>
</table>

The default setting of dropna argument is True which means NA are not included in group keys.

## GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

In [32]: df.groupby("A").groups

Out[32]: {'bar': [1, 3, 5], 'foo': [0, 2, 4, 6, 7]}

In [33]: df.groupby(get_letter_type, axis=1).groups

Out[33]: {'consonant': ['B', 'C', 'D'], 'vowel': ['A']}

Calling the standard Python `len` function on the GroupBy object just returns the length of the `groups` dict, so it is largely just a convenience:

In [34]: grouped = df.groupby(['A', 'B'])

In [35]: grouped.groups

Out[35]: {('bar', 'one'): [1], ('bar', 'three'): [3], ('bar', 'two'): [5], ('foo', 'one →'): [0, 6], ('foo', 'three'): [7], ('foo', 'two'): [2, 4]}

In [36]: len(grouped)

Out[36]: 6

GroupBy will tab complete column names (and other attributes):

In [37]: df

Out[37]:

<table>
<thead>
<tr>
<th></th>
<th>height</th>
<th>weight</th>
<th>gender</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>42.849980</td>
<td>157.500553</td>
<td>male</td>
</tr>
</tbody>
</table>
In [38]: gb = df.groupby("gender")

In [39]: gb.<TAB>  # noqa: E225, E999
   gb.agg gb.boxplot gb.cummin gb.describe gb.filter gb.get_group gb.
      gb.agg gb.last gb.median gb.ngroups gb.plot gb.rank gb.
      gb.std gb.transform gb.aggregate gb.count gb.cumprod gb.dtype gb.
      gb.hist gb.max gb.min gb.nth gb.prod gb.resample gb.
      gb.sum gb.var gb.apply gb.cummmax gb.cumsum gb.fillna gb.gender gb.
      gb.indicies gb.mean gb.name gb.ohlc gb.quantile gb.size gb.
      gb.tail gb.weight

GroupBy with MultiIndex

With hierarchically-indexed data, it’s quite natural to group by one of the levels of the hierarchy.

Let’s create a Series with a two-level MultiIndex.

```
In [40]: arrays = [
   ....:      ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
   ....:      ["one", "two", "one", "two", "one", "two", "one", "two"],
   ....:      ]
   ....:
In [41]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])

In [42]: s = pd.Series(np.random.randn(8), index=index)

In [43]: s
```

```
Out[43]:
first   second
bar     one   -0.919854
   two   -0.042379
baz     one    1.247642
   two  -0.009920
foo     one    0.290213
   two    0.495767
qux     one    0.362949
   two   1.548106
dtype: float64
```

2.18. Group by: split-apply-combine
We can then group by one of the levels in `s`.

```
In [44]: grouped = s.groupby(level=0)

In [45]: grouped.sum()
Out[45]:
   first
  bar   -0.962232
  baz   1.237723
  foo    0.785980
  qux   1.911055
       dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```
In [46]: s.groupby(level="second").sum()
Out[46]:
   second
  one   0.980950
  two   1.991575
       dtype: float64
```

Grouping with multiple levels is supported.

```
In [47]: s
Out[47]:
   first   second   third
  bar   doo   one  -1.131345
         two   -0.089329
  baz   bee   one   0.337863
         two   -0.945867
  foo   bop   one  -0.932132
         two   1.956030
  qux   bop   one   0.017587
         two  -0.016692
       dtype: float64

In [48]: s.groupby(["first", "second"]).sum()
Out[48]:
   first   second
  bar   doo  -1.220674
  baz   bee  -0.608004
  foo   bop   1.023898
  qux   bop   0.000895
       dtype: float64
```

Index level names may be supplied as keys.

```
In [49]: s.groupby(["first", "second"]).sum()
Out[49]:
   first   second
  bar   doo  -1.220674
  baz   bee  -0.608004
  foo   bop   1.023898
  qux   bop   0.000895
       dtype: float64
```

(continues on next page)
More on the `sum` function and aggregation later.

**Grouping DataFrame with Index levels and columns**

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```python
In [50]: arrays = [
    ....:     ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
    ....:     ["one", "two", "one", "two", "one", "two", "one", "two"],
    ....:     ]
    ....:

In [51]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])

In [52]: df = pd.DataFrame({"A": [1, 1, 1, 1, 2, 2, 3, 3], "B": np.arange(8)},
                   index=index)

In [53]: df
Out[53]:
   A   B
first second
  bar one 1 0
     two 1 1
  baz one 1 2
     two 1 3
  foo one 2 4
     two 2 5
  qux one 3 6
     two 3 7
```

The following example groups `df` by the second index level and the `A` column.

```python
In [54]: df.groupby([pd.Grouper(level=1), "A"]).sum()
Out[54]:
    B
second A
one   1 2
     2 4
     3 6
two  1 4
     2 5
     3 7
```

Index levels may also be specified by name.

```python
In [55]: df.groupby([pd.Grouper(level="second"), "A"]).sum()
Out[55]:
    B
```

(continues on next page)
Index level names may be specified as keys directly to `groupby`.

```python
In [56]: df.groupby(["second", "A"]).sum()
Out[56]:
    B
second A
one  1  2
     2  4
     3  6
two  1  4
     2  5
     3  7
```

**DataFrame column selection in GroupBy**

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a DataFrame, you can do:

```python
In [57]: df = pd.DataFrame(
             {...
             "A": ["foo", "bar", "foo", "bar", "foo", "foo"],
             "B": ["one", "one", "two", "three", "two", "one", "three"],
             "C": np.random.randn(8),
             "D": np.random.randn(8),
             })
           ...

In [58]: df
Out[58]:
   A    B       C       D
0  foo  one -0.575247  1.346061
1  bar  one  0.254161  1.511763
2  foo  two -1.143704  1.627081
3  bar  three  0.215897 -0.990582
4  foo  two  1.193555 -0.441652
5  bar  two -0.077118  1.211526
6  foo  one -0.408530  0.268520
7  foo  three -0.862495  0.024580

In [59]: grouped = df.groupby(["A"])  

In [60]: grouped_C = grouped["C"]
```
In [61]: grouped_D = grouped["D"]

This is mainly syntactic sugar for the alternative and much more verbose:

In [62]: df["C"].groupby(df["A"])
Out[62]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7f5534f9a2b0>

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

2.18.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

In [63]: grouped = df.groupby('A')

In [64]: for name, group in grouped:
   ....:     print(name)
   ....:     print(group)
   ....:
bar
   A   B   C     D
   1 bar one 0.254161 1.511763
   3 bar three 0.215897 -0.990582
   5 bar two -0.077118 1.211526
foo
   A   B   C     D
   0 foo one -0.575247 1.346061
   2 foo two -1.143704 1.627081
   4 foo two 1.193555 -0.441652
   6 foo one -0.408530 0.268520
   7 foo three -0.862495 0.024580

In the case of grouping by multiple keys, the group name will be a tuple:

In [65]: for name, group in df.groupby(['A', 'B']):
   ....:     print(name)
   ....:     print(group)
   ....:
('bar', 'one')
   A   B   C     D
   1 bar one 0.254161 1.511763
('bar', 'three')
   A   B   C     D
   3 bar three 0.215897 -0.990582
('bar', 'two')
   A   B   C     D
   5 bar two -0.077118 1.211526
('foo', 'one')
   A   B   C     D
   0 foo one -0.575247 1.346061

(continues on next page)

<td>-0.441652</td>
<td></td>
</tr>
</tbody>
</table>

See `Iterating through groups`.

### 2.18.3 Selecting a group

A single group can be selected using `get_group()`:

```python
In [66]: grouped.get_group("bar")
Out [66]:
    A   B   C   D
1  bar  one  0.254161  1.511763
3  bar three  0.215897 -0.990582
5  bar  two -0.077118  1.211526
```

Or for an object grouped on multiple columns:

```python
In [67]: df.groupby(["A", "B"]).get_group(("bar", "one"))
Out [67]:
    A   B   C   D
1  bar  one  0.254161  1.511763
```

### 2.18.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the `aggregating API`, `window API`, and `resample API`.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```python
In [68]: grouped = df.groupby("A")
In [69]: grouped.aggregate(np.sum)
Out[69]:
    C   D
A
bar  0.392940  1.732707
foo -1.796421  2.824590
```

```python
In [70]: grouped = df.groupby(["A", "B"])  
In [71]: grouped.aggregate(np.sum)
Out[71]:
    C   D
A B
```

(continues on next page)
As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a `MultiIndex` by default, though this can be changed by using the `as_index` option:

```
As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a `MultiIndex` by default, though this can be changed by using the `as_index` option:

```
Another aggregation example is to compute the number of unique values of each group. This is similar to the `value_counts` function, except that it only counts unique values.

```
In [78]: ll = [['foo', 1], ['foo', 2], ['foo', 2], ['bar', 1], ['bar', 1]]
In [79]: df4 = pd.DataFrame(ll, columns=['A', 'B'])
In [80]: df4
Out[80]:
   A   B
0  foo  1
1  foo  2
2  foo  2
3  bar  1
4  bar  1

In [81]: df4.groupby('A')['B'].nunique()
Out[81]:
A
bar 1
foo 2
Name: B, dtype: int64
```

Note: Aggregation functions **will not** return the groups that you are aggregating over if they are named `columns`, when `as_index=True`, the default. The grouped columns will be the `indices` of the returned object.

Passing `as_index=False` will return the groups that you are aggregating over, if they are named `columns`.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean()</td>
<td>Compute mean of groups</td>
</tr>
<tr>
<td>sum()</td>
<td>Compute sum of group values</td>
</tr>
<tr>
<td>size()</td>
<td>Compute group sizes</td>
</tr>
<tr>
<td>count()</td>
<td>Compute count of group</td>
</tr>
<tr>
<td>std()</td>
<td>Standard deviation of groups</td>
</tr>
<tr>
<td>var()</td>
<td>Compute variance of groups</td>
</tr>
<tr>
<td>sem()</td>
<td>Standard error of the mean of groups</td>
</tr>
<tr>
<td>describe()</td>
<td>Generates descriptive statistics</td>
</tr>
<tr>
<td>first()</td>
<td>Compute first of group values</td>
</tr>
<tr>
<td>last()</td>
<td>Compute last of group values</td>
</tr>
<tr>
<td>nth()</td>
<td>Take nth value, or a subset if n is a list</td>
</tr>
<tr>
<td>min()</td>
<td>Compute min of group values</td>
</tr>
<tr>
<td>max()</td>
<td>Compute max of group values</td>
</tr>
</tbody>
</table>

The aggregating functions above will exclude NA values. Any function which reduces a Series to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that nth() can act as a reducer or a filter, see here.

### Applying multiple functions at once

With grouped Series you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```python
In [82]: grouped = df.groupby("A")

In [83]: grouped["C"].agg([np.sum, np.mean, np.std])
```

```
Out[83]:
          sum     mean  std
    A
  bar  0.392940  0.130980 0.181231
  foo -1.796421 -0.359284 0.912265
```

On a grouped DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```python
In [84]: grouped["C", "D"].agg([np.sum, np.mean, np.std])
```

```
Out[84]:
         C         D
          sum     mean     std    sum     mean     std
    A
  bar  0.392940  0.130980  0.181231  1.732707  0.577569  1.366330
  foo -1.796421 -0.359284  0.912265  2.824590  0.564918  0.884785
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a Series like this:

```python
In [85]:
       (  
       ....:  grouped["C"]
       ....:     .agg([np.sum, np.mean, np.std])
       ....:     .rename(columns={"sum": "foo", "mean": "bar", "std": "baz"})
       ....:  )
```

(continues on next page)
For a grouped DataFrame, you can rename in a similar manner:

```python
In [86]: (grouped[['C', 'D']].agg([np.sum, np.mean, np.std]).rename(
    ...:     columns={"sum": "foo", "mean": "bar", "std": "baz"}
    ...: ))
Out[86]:

C    D
foo  bar  baz  foo  bar  baz
A    0.392940 0.130980 0.181231 1.732707 0.577569 1.366330
foo -1.796421 -0.359284 0.912265 2.824590 0.564918 0.884785
```

- **Note:** In general, the output column names should be unique. You can’t apply the same function (or two functions with the same name) to the same column.

```python
In [87]: grouped['C'].agg(['sum', 'sum'])
Out[87]:

sum  sum
A    0.392940 0.392940
foo -1.796421 -1.796421
```

pandas does allow you to provide multiple lambdas. In this case, pandas will mangle the name of the (nameless) lambda functions, appending `_<i>` to each subsequent lambda.

```python
In [88]: grouped['C'].agg([lambda x: x.max() - x.min(), lambda x: x.median() - x.mean()])
Out[88]:

<lambda_0>  <lambda_1>
A    0.331279 0.084917
foo  2.337259 -0.215962
```
Named aggregation

New in version 0.25.0.

To support column-specific aggregation *with control over the output column names*, pandas accepts the special syntax in `GroupBy.agg()`, known as “named aggregation”, where

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. pandas provides the `pandas.NamedAgg` namedtuple with the fields `[‘column’, ‘aggfunc’]` to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

```python
In [89]: animals = pd.DataFrame(
    ....:     {
    ....:         "kind": ["cat", "dog", "cat", "dog"],
    ....:         "height": [9.1, 6.0, 9.5, 34.0],
    ....:         "weight": [7.9, 7.5, 9.9, 198.0],
    ....:     }
    ....: )

In [90]: animals
Out[90]:
   kind  height  weight
0    cat     9.1     7.9
1    dog     6.0     7.5
2    cat     9.5     9.9
3    dog    34.0   198.0

In [91]: animals.groupby("kind").agg(
    ....:     min_height=pd.NamedAgg(column="height", aggfunc="min"),
    ....:     max_height=pd.NamedAgg(column="height", aggfunc="max"),
    ....:     average_weight=pd.NamedAgg(column="weight", aggfunc=np.mean),
    ....: )

Out[91]:
    min_height  max_height  average_weight
kind
  cat       9.1       9.5          8.90
  dog       6.0       34.0        102.75
```

pandas.NamedAgg is just a namedtuple. Plain tuples are allowed as well.

```python
In [92]: animals.groupby("kind").agg(
    ....:     min_height=("height", "min"),
    ....:     max_height=("height", "max"),
    ....:     average_weight=("weight", np.mean),
    ....: )

Out[92]:
    min_height  max_height  average_weight
kind
  cat       9.1       9.5          8.90
  dog       6.0       34.0        102.75
```
If your desired output column names are not valid Python keywords, construct a dictionary and unpack the keyword arguments:

```
In [93]: animals.groupby("kind").agg(
    ....:     **{
    ....:         "total weight": pd.NamedAgg(column="weight", aggfunc=sum)
    ....:     })
```

```
Out[93]:

<table>
<thead>
<tr>
<th>kind</th>
<th>total weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>17.8</td>
</tr>
<tr>
<td>dog</td>
<td>205.5</td>
</tr>
</tbody>
</table>
```

Additional keyword arguments are not passed through to the aggregation functions. Only pairs of (column, aggfunc) should be passed as **kwargs. If your aggregation functions requires additional arguments, partially apply them with `functools.partial()`.

**Note:** For Python 3.5 and earlier, the order of **kwargs in a functions was not preserved. This means that the output column ordering would not be consistent. To ensure consistent ordering, the keys (and so output columns) will always be sorted for Python 3.5.

Named aggregation is also valid for Series groupby aggregations. In this case there’s no column selection, so the values are just the functions:

```
In [94]: animals.groupby("kind").height.agg(
    ....:     min_height="min",
    ....:     max_height="max",
    ....:     )
```

```
Out[94]:

<table>
<thead>
<tr>
<th>kind</th>
<th>min_height</th>
<th>max_height</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>9.1</td>
<td>9.5</td>
</tr>
<tr>
<td>dog</td>
<td>6.0</td>
<td>34.0</td>
</tr>
</tbody>
</table>
```

**Applying different functions to DataFrame columns**

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [95]: grouped.agg({"C": np.sum, "D": lambda x: np.std(x, ddof=1)})
```

```
Out[95]:

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>0.392940</td>
<td>1.366330</td>
</tr>
<tr>
<td>foo</td>
<td>-1.796421</td>
<td>0.884785</td>
</tr>
</tbody>
</table>
```

The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via `dispatching:`
In [96]: grouped.agg({'C': 'sum', 'D': 'std'})
Out[96]:
     C      D
A  0.392940  1.366330
bar -1.796421  0.884785

Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

In [97]: df.groupby('A').sum()
Out[97]:
     C      D
A  0.392940  1.732707
bar -1.796421  2.824590
foo -1.796421  2.824590

In [98]: df.groupby(['A', 'B']).mean()
Out[98]:
     C      D
A B
bar one  0.254161  1.511763
two  -0.077118  1.211526
three  0.215897 -0.990582
foo one  0.491888  0.807291
two  0.024925  0.592714
three  0.862495  0.024580

Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

Aggregations with User-Defined Functions

Users can also provide their own functions for custom aggregations. When aggregating with a User-Defined Function (UDF), the UDF should not mutate the provided `Series`, see Mutating with User Defined Function (UDF) methods for more information.

In [99]: animals.groupby('kind')[['height']].agg(lambda x: set(x))
Out[99]:
       height
  kind  
cat  {9.1, 9.5}
dog  {34.0, 6.0}

The resulting dtype will reflect that of the aggregating function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as `DataFrame` construction.

In [100]: animals.groupby('kind')[['height']].agg(lambda x: x.astype(int).sum())
Out[100]:
       height
  kind  
cat  2.18
(continues on next page)
2.18.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the second chunk.

Similar to Aggregations with User-Defined Functions, the resulting dtype will reflect that of the transformation function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as `DataFrame` construction.

Suppose we wished to standardize the data within each group:

```python
In [101]: index = pd.date_range("10/1/1999", periods=1100)
In [102]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)
In [103]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()
In [104]: ts.head()
Out[104]:
2000-01-08  0.779333
2000-01-09  0.778852
2000-01-10  0.786476
2000-01-11  0.782797
2000-01-12  0.798110
Freq: D, dtype: float64
In [105]: ts.tail()
Out[105]:
2002-09-30  0.660294
2002-10-01  0.631095
2002-10-02  0.673601
2002-10-03  0.709213
2002-10-04  0.719369
Freq: D, dtype: float64
In [106]: transformed = ts.groupby(lambda x: x.year).transform(
    ........: lambda x: (x - x.mean()) / x.std())
```

(continues on next page)
We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```python
# Original Data
In [107]: grouped = ts.groupby(lambda x: x.year)

In [108]: grouped.mean()
Out[108]:
2000  0.442441
2001  0.526246
2002  0.459365
dtype: float64

In [109]: grouped.std()
Out[109]:
2000  0.131752
2001  0.210945
2002  0.128753
dtype: float64

# Transformed Data
In [110]: grouped_trans = transformed.groupby(lambda x: x.year)

In [111]: grouped_trans.mean()
Out[111]:
2000  1.193722e-15
2001  1.945476e-15
2002  1.272949e-15
dtype: float64

In [112]: grouped_trans.std()
Out[112]:
2000  1.0
2001  1.0
2002  1.0
dtype: float64

We can also visually compare the original and transformed data sets.

```
Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [115]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
Out[115]:
2000-01-08  0.623893
2000-01-09  0.623893
2000-01-10  0.623893
2000-01-11  0.623893
2000-01-12  0.623893
          ...
2002-09-30  0.558275
2002-10-01  0.558275
2002-10-02  0.558275
2002-10-03  0.558275
2002-10-04  0.558275
Freq: D, Length: 1001, dtype: float64
```

Alternatively, the built-in methods could be used to produce the same outputs.

```
In [116]: max = ts.groupby(lambda x: x.year).transform("max")
In [117]: min = ts.groupby(lambda x: x.year).transform("min")
In [118]: max - min
```
Another common data transform is to replace missing data with the group mean.

```python
In [119]: data_df
Out[119]:
   A         B        C
0  1.539708 -1.166480  0.533026
1  1.302092 -0.505754   NaN
2 -1.309622  1.104803 -1.161657
3 -1.924296  0.396437  0.812436
..          ...        ...
995 -0.093110  0.683847 -0.774753
996 -0.185043  1.438572   NaN
997 -0.394469 -0.642343  0.011374
998 -1.174126  1.857148   NaN
999  0.234564  0.517098  0.393534
[1000 rows x 3 columns]
```

```python
In [120]: countries = np.array(['US', 'UK', 'GR', 'JP'])
In [121]: key = countries[np.random.randint(0, 4, 1000)]
In [122]: grouped = data_df.groupby(key)

# Non-NA count in each group
In [123]: grouped.count()
Out[123]:
   A   B   C
GR 209 217 189
JP 240 255 217
UK 216 231 193
US 239 250 217

In [124]: transformed = grouped.transform(lambda x: x.fillna(x.mean()))
```

We can verify that the group means have not changed in the transformed data and that the transformed data contains no NAs.
```python
In [125]: grouped_trans = transformed.groupby(key)

In [126]: grouped.mean()  # original group means
Out[126]:
   A         B         C
GR -0.098371 -0.015420  0.068053
JP  0.069025  0.023100 -0.077324
UK  0.034069 -0.052580 -0.116525
US  0.058664 -0.020399  0.028603

In [127]: grouped_trans.mean()  # transformation did not change group means
Out[127]:
   A         B         C
GR -0.098371 -0.015420  0.068053
JP  0.069025  0.023100 -0.077324
UK  0.034069 -0.052580 -0.116525
US  0.058664 -0.020399  0.028603

In [128]: grouped.count()  # original has some missing data points
Out[128]:
   A  B  C
GR 209 217 189
JP 240 255 217
UK 216 231 193
US 239 250 217

In [129]: grouped_trans.count()  # counts after transformation
Out[129]:
   A  B  C
GR 228 228 228
JP 267 267 267
UK 247 247 247
US 258 258 258

In [130]: grouped_trans.size()  # Verify non-NA count equals group size
Out[130]:
   GR 228
   JP 267
   UK 247
   US 258
dtype: int64

Note: Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing as_index=False will not affect these transformation methods.

For example: fillna, ffill, bfill, shift..

In [131]: grouped.ffill()
Out[131]:
   A         B         C
0  1.539708 -1.166480  0.533026
1  1.302092 -0.505754  0.533026

(continues on next page)
Window and resample operations

It is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```python

In [133]: df_re.groupby("A").rolling(4).B.mean()
Out[134]:
A       
1  NaN   
2  NaN   
3  1.5   
4  2.5   
...    
5  15.5  
16  14.5 
17  15.5 
```

(continues on next page)
The expanding() method will accumulate a given operation (sum() in the example) for all the members of each particular group.

```
In [135]: df_re.groupby("A").expanding().sum()
Out[135]:
    B
A
1  0  0.0
  1  1.0
  2  3.0
  3  6.0
  4 10.0
... ...
5 15 75.0
16 91.0
17 108.0
18 126.0
19 145.0
[20 rows x 1 columns]
```

Suppose you want to use the resample() method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the ffill() method.

```
In [136]: df_re = pd.DataFrame(
      .....:     
      .....:     
      .....:     
      .....:     
    ).set_index("date")
In [137]: df_re
Out[137]:
   group  val
date
2016-01-03  1  5
2016-01-10  1  6
2016-01-17  2  7
2016-01-24  2  8

In [138]: df_re.groupby("group").resample("1D").ffill()
Out[138]:
   group  val
group  date
1  2016-01-03  1  5
    2016-01-04  1  5
```

(continues on next page)
2.18.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```python
In [139]: sf = pd.Series([1, 1, 2, 3, 3, 3])

In [140]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[140]:
3 3
4 3
5 3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```python
In [141]: dff = pd.DataFrame({"A": np.arange(8), "B": list("aabbbbcc")})

In [142]: dff.groupby("B").filter(lambda x: len(x) > 2)
Out[142]:
   A  B
2  2  b
3  3  b
4  4  b
5  5  b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```python
In [143]: dff.groupby("B").filter(lambda x: len(x) > 2, dropna=False)
Out[143]:
   A  B
0 NaN NaN
1 NaN NaN
2  2.0  b
3  3.0  b
4  4.0  b
5  5.0  b
```

(continues on next page)
For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```python
In [144]: dff["C"] = np.arange(8)
In [145]: dff.groupby("B").filter(lambda x: len(x["C"]) > 2)
Out[145]:
   A  B  C
2  2  b  2
3  3  b  3
4  4  b  4
5  5  b  5
```

**Note:** Some functions when applied to a groupby object will act as a filter on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

```python
In [146]: dff.groupby("B").head(2)
Out[146]:
   A  B  C
0  0  a  0
1  1  a  1
2  2  b  2
3  3  b  3
6  6  c  6
7  7  c  7
```

### 2.18.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```python
In [147]: grouped = df.groupby("A")
In [148]: grouped.agg(lambda x: x.std())
Out[148]:
   C      D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

But, it’s rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:

```python
In [149]: grouped.std()
Out[149]:
```
What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```python
In [150]: tsdf = pd.DataFrame(
    ...:     np.random.randn(1000, 3),
    ...:     index=pd.date_range("1/1/2000", periods=1000),
    ...:     columns=["A", "B", "C"],
    ...: )
    
In [151]: tsdf.iloc[::2] = np.nan
In [152]: grouped = tsdf.groupby(lambda x: x.year)
In [153]: grouped.fillna(method="pad")
```

```
Out[153]:
       A       B       C
2000-01-01  NaN  NaN    NaN
2000-01-02 -0.3535  -0.0809  -0.8769
2000-01-03 -0.3535  -0.0809  -0.8769
2000-01-04  0.0509  0.0442  -0.5599
2000-01-05  0.0509  0.0442  -0.5599
          ...     ...     ...
2002-09-22  0.0050  0.0539  -1.0269
2002-09-23  0.0050  0.0539  -1.0269
2002-09-24  0.4565  -1.8490  1.5599
2002-09-25  0.4565  -1.8490  1.5599
2002-09-26  1.1231  0.3547  1.1281
[1000 rows x 3 columns]
```

In this example, we chopped the collection of time series into yearly chunks then independently called `fillna` on the groups.

The `nlargest` and `nsmallest` methods work on Series style groupbys:

```python
In [154]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
In [155]: g = pd.Series(list("abababab"))
In [156]: gb = s.groupby(g)
In [157]: gb.nlargest(3)
```

```
Out[157]:
   a  4  19.0
    0  9.0
```

(continues on next page)
2.18.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want GroupBy to infer how to combine the results. For these, use the apply function, which can be substituted for both aggregate and transform in many standard use cases. However, apply can handle some exceptional use cases, for example:

```python
In [159]: df
Out[159]:
     A     B     C         D
0  foo  one  -0.575247  1.346061
1  bar  one   0.254161  1.511763
2  foo  two  -1.143704  1.627081
3  bar  three  0.215897 -0.990582
4  foo  two   1.193555 -0.441652
5  bar  two  -0.077118  1.211526
6  foo  one  -0.408530  0.268520
7  foo  three -0.862495  0.024580

In [160]: grouped = df.groupby("A")

# could also just call .describe()
In [161]: grouped["C"].apply(lambda x: x.describe())
Out[161]:
   A
   bar count    3.000000
     mean   0.130980
     std   0.181231
     min  -0.077118
    25%   0.069390
          ...
   foo  min  -1.143704
    25%  -0.862495
    50%  -0.575247
    75%  -0.408530
```

(continues on next page)
max 1.193555
Name: C, Length: 16, dtype: float64

The dimension of the returned result can also change:

```
In [162]: grouped = df.groupby('A')['C']

In [163]: def f(group):
   .....: return pd.DataFrame({'original': group,
   .....:                           'demeaned': group - group.mean()})
   .....:

In [164]: grouped.apply(f)
Out[164]:
   original  demeaned
0 -0.575247 -0.215962
1 0.254161  0.123181
2 1.193555  1.552839
3 -1.143704 -0.784420
4 0.215897  0.084917
5 1.193555  1.552839
6 -1.143704 -0.784420
7 -0.077118 -0.208098
8 0.215897  0.084917
9 1.193555  1.552839
10 0.215897  0.084917
11 1.193555  1.552839
12 -1.143704 -0.784420
13 -0.077118 -0.208098
14 0.215897  0.084917
15 1.193555  1.552839
```

apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

```
In [165]: def f(x):
   .....: return pd.Series([x, x ** 2], index=['x', 'x^2'])
   .....:

In [166]: s = pd.Series(np.random.rand(5))

In [167]: s
Out[167]:
0   0.321438
1   0.493496
2   0.139505
3   0.910103
4   0.194158
dtype: float64

In [168]: s.apply(f)
Out[168]:
   x  x^2
0  0.321438  0.103323
1  0.493496  0.243538
2  0.139505  0.019462
3  0.910103  0.828287
4  0.194158  0.037697
```

Note: apply can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So
depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

Similar to Aggregations with User-Defined Functions, the resulting dtype will reflect that of the apply function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as DataFrame construction.

2.18.9 Numba Accelerated Routines

New in version 1.1.

If Numba is installed as an optional dependency, the transform and aggregate methods support engine='numba' and engine_kwargs arguments. See enhancing performance with Numba for general usage of the arguments and performance considerations.

The function signature must start with values, index exactly as the data belonging to each group will be passed into values, and the group index will be passed into index.

**Warning:** When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as NumPy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

2.18.10 Other useful features

Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```python
In [169]: df
Out[169]:
    A    B     C     D
0  foo  one  -0.575247  1.346061
1  bar  one   0.254161  1.511763
2  foo  two  -1.143704  1.627081
3  bar  three  0.215897  -0.990582
4  foo  two   1.193555  -0.441652
5  bar  two  -0.077118  1.211526
6  foo  one  -0.408530  0.268520
7  foo  three  -0.862495  0.024580
```

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```python
In [170]: df.groupby("A").std()
Out[170]:
        C      D
A
  bar  0.181231  1.366330
  foo  0.912265  0.884785
```
Note that `df.groupby('A').colname.std()` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered before applying the aggregation function.

**Note:** Any object column, also if it contains numerical values such as `Decimal` objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in `groupby`.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```python
In [171]: from decimal import Decimal

In [172]: df_dec = pd.DataFrame(
    ....:     {
    ....:         "id": [1, 2, 1, 2],
    ....:         "int_column": [1, 2, 3, 4],
    ....:         "dec_column": [
    ....:             Decimal("0.50"),
    ....:             Decimal("0.15"),
    ....:             Decimal("0.25"),
    ....:             Decimal("0.40"),
    ....:         ],
    ....:     }
    ....: )

# Decimal columns can be sum'd explicitly by themselves...
In [173]: df_dec.groupby(["id"])[["dec_column"]].sum()
Out[173]:
           dec_column
id
1         0.75
2         0.55

# ...but cannot be combined with standard data types or they will be excluded
In [174]: df_dec.groupby(["id"])[["int_column", "dec_column"]].sum()
Out[174]:
         int_column
id
1         4
2         6

# Use .agg function to aggregate over standard and "nuisance" data types
# at the same time
In [175]: df_dec.groupby(["id"]).agg({"int_column": "sum", "dec_column": "sum"})
Out[175]:
         int_column  dec_column
id
1         4         0.75
2         6         0.55
```
Handling of (un)observed Categorical values

When using a Categorical grouper (as a single grouper, or as part of multiple groupers), the observed keyword controls whether to return a cartesian product of all possible groupers values (observed=False) or only those that are observed groupers (observed=True).

Show all values:

```
In [176]: pd.Series([1, 1, 1]).groupby(
        ...:     pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=False
        ...:     ).count()
        ...
Out[176]:
    a 3
    b 0
    dtype: int64
```

Show only the observed values:

```
In [177]: pd.Series([1, 1, 1]).groupby(
        ...:     pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=True
        ...:     ).count()
        ...
Out[177]:
    a 3
dtype: int64
```

The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```
In [178]: s = (np
        ...:     .Series([1, 1, 1])
        ...:     .groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']),
        ...:     observed=False)
        ...:     .count()
        ...:     )
        ...
In [179]: s.index.dtype
Out[179]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```
NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

Grouping with ordered factors

Categorical variables represented as instance of pandas’s Categorical class can be used as group keys. If so, the order of the levels will be preserved:

```python
In [180]: data = pd.Series(np.random.randn(100))
In [181]: factor = pd.qcut(data, [0, 0.25, 0.5, 0.75, 1.0])
In [182]: data.groupby(factor).mean()
Out[182]:
(-2.645, -0.523]  -1.362896
(-0.523, 0.0296]  -0.260266
(0.0296, 0.654]   0.361802
(0.654, 2.21]     1.073801
dtype: float64
```

Grouping with a grouper specification

You may need to specify a bit more data to properly group. You can use the pd.Grouper to provide this local control.

```python
In [183]: import datetime
In [184]: df = pd.DataFrame(  
               {  
               "Branch": "A A A A A A A B".split(),         
               "Buyer": "Carl Mark Carl Carl Joe Joe Joe Carl".split(),  
               "Quantity": [1, 3, 5, 1, 8, 1, 9, 3],  
               "Date": [  
               datetime.datetime(2013, 1, 1, 13, 0),  
               datetime.datetime(2013, 1, 1, 13, 5),  
               datetime.datetime(2013, 10, 1, 20, 0),  
               datetime.datetime(2013, 10, 2, 10, 0),  
               datetime.datetime(2013, 10, 1, 20, 0),  
               datetime.datetime(2013, 10, 2, 10, 0),  
               datetime.datetime(2013, 12, 2, 12, 0),  
               datetime.datetime(2013, 12, 2, 14, 0),  
               ],  
               ...
               }  
               )
In [185]: df
Out[185]:
  Branch Buyer  Quantity  Date
0     A   Carl       1 2013-01-01 13:00:00
```

2.18. Group by: split-apply-combine
Groupby a specific column with the desired frequency. This is like resampling.

```
In [186]: df.groupby([pd.Grouper(freq="1M", key="Date"), "Buyer"]).sum()
Out[186]:
          Quantity
    Date Buyer
2013-01-31 Carl  1
                  Mark  3
2013-10-31 Carl  6
                  Joe  9
2013-12-31 Carl  3
                  Joe  9
```

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```
In [187]: df = df.set_index("Date")

In [188]: df["Date"] = df.index + pd.offsets.MonthEnd(2)

In [189]: df.groupby([pd.Grouper(freq="6M", key="Date"), "Buyer"]).sum()
Out[189]:
          Quantity
    Date Buyer
2013-02-28 Carl  1
                  Mark  3
2014-02-28 Carl  9
                  Joe 18

In [190]: df.groupby([pd.Grouper(freq="6M", level="Date"), "Buyer"]).sum()
Out[190]:
          Quantity
    Date Buyer
2013-01-31 Carl  1
                  Mark  3
2014-01-31 Carl  9
                  Joe 18
```
Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```
In [191]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])

In [192]: df
Out[192]:
   A  B
0  1  2
1  1  4
2  5  6

In [193]: g = df.groupby('A')

In [194]: g.head(1)
Out[194]:
   A  B
0  1  2
2  5  6

In [195]: g.tail(1)
Out[195]:
   A  B
1  1  4
2  5  6
```

This shows the first or last n rows from each group.

Taking the nth row of each group

To select from a DataFrame or Series the nth item, use nth(). This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```
In [196]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [197]: g = df.groupby('A')

In [198]: g.nth(0)
Out[198]:
   B
A
  1   NaN
  5  6.0

In [199]: g.nth(-1)
Out[199]:
   B
A
  1  4.0
  5  6.0

In [200]: g.nth(1)
```

(continues on next page)
If you want to select the nth not-null item, use the dropna kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to dropna:

```python
# nth(0) is the same as g.first()
In [201]: g.nth(0, dropna="any")
Out[201]:
   B
  A
  1  4.0
  5  6.0

In [202]: g.first()
Out[202]:
   B
  A
  1  4.0
  5  6.0

# nth(-1) is the same as g.last()
In [203]: g.nth(-1, dropna="any")  # NaNs denote group exhausted when using dropna
Out[203]:
   B
  A
  1  4.0
  5  6.0

In [204]: g.last()
Out[204]:
   B
  A
  1  4.0
  5  6.0

In [205]: g.B.nth(0, dropna="all")
Out[205]:
   A
  1  4.0
  5  6.0
Name: B, dtype: float64
```

As with other methods, passing as_index=False, will achieve a filtration, which returns the grouped row.

```python
In [206]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=["A", "B"])
In [207]: g = df.groupby("A", as_index=False)
In [208]: g.nth(0)
```
Out[208]:
A   B
0   1  NaN
2   5  6.0

In [209]: g.nth(-1)
Out[209]:
A   B
1   1  4.0
2   5  6.0

You can also select multiple rows from each group by specifying multiple nth values as a list of ints.

In [210]: business_dates = pd.date_range(start="4/1/2014", end="6/30/2014", freq="B")
In [211]: df = pd.DataFrame(1, index=business_dates, columns=["a", "b"])

# get the first, 4th, and last date index for each month
In [212]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[212]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>6</td>
<td>1</td>
</tr>
</tbody>
</table>

Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

In [213]: dfg = pd.DataFrame(list("aaabba"), columns=["A")
In [214]: dfg
Out[214]:
<table>
<thead>
<tr>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>a</td>
</tr>
<tr>
<td>a</td>
</tr>
<tr>
<td>b</td>
</tr>
<tr>
<td>b</td>
</tr>
<tr>
<td>a</td>
</tr>
</tbody>
</table>

In [215]: dfg.groupby("A").cumcount()
Out[215]:
<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>
Enumerate groups

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```python
In [217]: dfg = pd.DataFrame(list("aaabba"), columns=["A"])        
In [218]: dfg
Out[218]:     A
0    a
1    a
2    a
3    b
4    b
5    a

In [219]: dfg.groupby("A").ngroup()          
Out[219]:
0    0
1    1
2    1
3    1
4    1
5    0
dtype: int64

In [220]: dfg.groupby("A").ngroup(ascending=False)  
Out[220]:
0    1
1    1
2    1
```
Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [221]: np.random.seed(1234)
In [222]: df = pd.DataFrame(np.random.randn(50, 2))
In [223]: df["g"] = np.random.choice(["A", "B"], size=50)
In [224]: df.loc[df["g"] == "B", 1] += 3
```

We can easily visualize this with a boxplot:

```
In [225]: df.groupby("g").boxplot()
Out[225]:
A     AxesSubplot(0.1,0.15;0.363636x0.75)
B     AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```
The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` ("A" and "B"). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the visualization documentation for more.

**Warning:** For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

### Piping function calls

Similar to the functionality provided by `DataFrame` and `Series`, functions that take GroupBy objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse GroupBy objects.

As an example, imagine having a DataFrame with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of `prices` (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```python
In [226]: n = 1000
In [227]: df = pd.DataFrame(

```
In [228]: df.head(2)
Out[228]:
```
Store  Product  Revenue  Quantity
0  Store_2  Product_1  26.12    1
1  Store_2  Product_1  28.86    1
```

Now, to find prices per store/product, we can simply do:

```python
In [229]:
    ...
    ...: df.groupby(\[
    ...:     \"Store\", \"Product\"
    ...: \]).pipe(
    ...:     lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
    ...:     .unstack()
    ...:     .round(2)
    ...: 
Out[229]:
```
```
Product  Product_1  Product_2
Store
Store_1  6.82  7.05
Store_2  6.30  6.64
```
```}

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```python
In [230]: def mean(groupby):
    ...
    ...
    ...
    ...
    return groupby.mean()

In [231]: df.groupby(\[
    ...:     \"Store\", \"Product\"
    ...: \]).pipe(mean)
```
```
Revenue  Quantity
Store  Product
Store_1 Product_1  34.622727  5.075758
Product_2  35.482815  5.029630
Store_2 Product_1  32.972837  5.237589
Product_2  34.684360  5.224000
```
```}

where `mean` takes a GroupBy object and finds the mean of the Revenue and Quantity columns respectively for each Store-Product combination. The `mean` function can be any function that takes in a GroupBy object; the `.pipe` will pass the GroupBy object as a parameter into the function you specify.
### 2.18.11 Examples

#### Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

```python
In [232]: df = pd.DataFrame({'a': [1, 0, 0], 'b': [0, 1, 0], 'c': [1, 0, 0], 'd': [2, 3, 4]})

In [233]: df
Out[233]:
   a  b  c  d
0  1  0  1  2
1  0  1  0  3
2  0  0  0  4

In [234]: df.groupby(df.sum(), axis=1).sum()
Out[234]:
   1  9
   0  2  2
   1  1  3
   2  0  4
```

#### Multi-column factorization

By using `ngroup()` we can extract information about the groups in a way similar to `factorize()` (as described further in the reshaping API) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the [Categorical introduction](#) and the API documentation.)

```python
In [235]: dfg = pd.DataFrame({'A': [1, 1, 2, 3, 2], 'B': list('aaaba')})

In [236]: dfg
Out[236]:
   A  B
0  1  a
1  1  a
2  2  a
3  3  b
4  2  a

In [237]: dfg.groupby(["A", "B"]).ngroup()
Out[237]:
   0  0
   1  1
   2  1
   3  2
   4  1
dtype: int64

In [238]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
```
Groupby by indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetimelike, the following procedure can be utilized. In the following examples, \texttt{df.index // 5} returns a binary array which is used to determine what gets selected for the groupby operation.

\textbf{Note:} The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using \texttt{df.index // 5}, we are aggregating the samples in bins. By applying \texttt{std()} function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.
Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

```
In [243]: df = pd.DataFrame(
    .....:     
    .....:     
    .....: "a": [0, 0, 0, 1, 1, 1, 2, 2, 2, 2],
    .....: "b": [0, 0, 1, 1, 0, 0, 1, 1, 0, 1],
    .....: "c": [1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
    .....: "d": [0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
    .....: }
    .....:
In [244]: def compute_metrics(x):
    .....:     result = {"b_sum": x["b"].sum(), "c_mean": x["c"].mean()}
    .....:     return pd.Series(result, name="metrics")
    .....:
In [245]: result = df.groupby("a").apply(compute_metrics)
In [246]: result
```

<table>
<thead>
<tr>
<th>a</th>
<th>b_sum</th>
<th>c_mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2.0</td>
<td>0.5</td>
</tr>
<tr>
<td>1</td>
<td>2.0</td>
<td>0.5</td>
</tr>
<tr>
<td>2</td>
<td>2.0</td>
<td>0.5</td>
</tr>
</tbody>
</table>

```
In [247]: result.stack()
```

```
<table>
<thead>
<tr>
<th>a metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 metrics</td>
</tr>
<tr>
<td>b_sum 2.0</td>
</tr>
<tr>
<td>c_mean 0.5</td>
</tr>
<tr>
<td>1 metrics</td>
</tr>
<tr>
<td>b_sum 2.0</td>
</tr>
<tr>
<td>c_mean 0.5</td>
</tr>
<tr>
<td>2 metrics</td>
</tr>
<tr>
<td>b_sum 2.0</td>
</tr>
<tr>
<td>c_mean 0.5</td>
</tr>
<tr>
<td>dtype: float64</td>
</tr>
</tbody>
</table>
```

2.19 Windowing Operations

pandas contains a compact set of APIs for performing windowing operations - an operation that performs an aggregation over a sliding partition of values. The API functions similarly to the groupby API in that Series and DataFrame call the windowing method with necessary parameters and then subsequently call the aggregation function.

```
In [1]: s = pd.Series(range(5))
In [2]: s.rolling(window=2).sum()
(continues on next page)```
The windows are comprised by looking back the length of the window from the current observation. The result above can be derived by taking the sum of the following windowed partitions of data:

```python
In [3]: for window in s.rolling(window=2):
   ...:    print(window)
   ...:
0 0
dtype: int64
0 0
1 1
dtype: int64
1 1
2 2
dtype: int64
2 2
3 3
dtype: int64
3 3
4 4
dtype: int64
```

### 2.19.1 Overview

pandas supports 4 types of windowing operations:

1. **Rolling window**: Generic fixed or variable sliding window over the values.
2. **Weighted window**: Weighted, non-rectangular window supplied by the `scipy.signal` library.
3. **Expanding window**: Accumulating window over the values.
4. **Exponentially Weighted window**: Accumulating and exponentially weighted window over the values.

<table>
<thead>
<tr>
<th>Concept</th>
<th>Method</th>
<th>Returned Object</th>
<th>Supports time-based windows</th>
<th>Supports chained groupby</th>
<th>Supports table method</th>
<th>Supports online operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rolling window</td>
<td>rolling</td>
<td>Rolling</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
<tr>
<td>Weighted window</td>
<td>rolling</td>
<td>Window</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Expanding window</td>
<td>expanding</td>
<td>Expanding</td>
<td>No</td>
<td>Yes</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
<tr>
<td>Exponentially Weighted window</td>
<td>ewm</td>
<td>ExponentialMovingWindow</td>
<td>Yes (as of version 1.2)</td>
<td>No</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
</tbody>
</table>
As noted above, some operations support specifying a window based on a time offset:

```
In [4]: s = pd.Series(range(5), index=pd.date_range('2020-01-01', periods=5, freq='1D'))
In [5]: s.rolling(window='2D').sum()
Out[5]:
      2020-01-01 0.0
      2020-01-02 1.0
      2020-01-03 3.0
      2020-01-04 5.0
      2020-01-05 7.0
Freq: D, dtype: float64
```

Additionally, some methods support chaining a `groupby` operation with a windowing operation which will first group the data by the specified keys and then perform a windowing operation per group.

```
In [6]: df = pd.DataFrame({'A': ['a', 'b', 'a', 'b', 'a'], 'B': range(5)})
In [7]: df.groupby('A').expanding().sum()
Out[7]:
       B
    A
a  0  0.0
   2  2.0
   4  6.0
b  1  1.0
   3  4.0
```

Note: Windowing operations currently only support numeric data (integer and float) and will always return `float64` values.

Warning: Some windowing aggregation, `mean`, `sum`, `var` and `std` methods may suffer from numerical imprecision due to the underlying windowing algorithms accumulating sums. When values differ with magnitude \(1/\text{np.finfo(np.double).eps}\) this results in truncation. It must be noted, that large values may have an impact on windows, which do not include these values. Kahan summation is used to compute the rolling sums to preserve accuracy as much as possible.

New in version 1.3.0.

Some windowing operations also support the `method='table'` option in the constructor which performs the windowing operation over an entire `DataFrame` instead of a single column or row at a time. This can provide a useful performance benefit for a `DataFrame` with many columns or rows (with the corresponding `axis` argument) or the ability to utilize other columns during the windowing operation. The `method='table'` option can only be used if `engine='numba'` is specified in the corresponding method call.

For example, a weighted mean calculation can be calculated with `apply()` by specifying a separate column of weights.

```
In [8]: def weighted_mean(x):
   ...:     arr = np.ones((1, x.shape[1]))
   ...:     arr[:, :2] = (x[:, :2] * x[:, 2]).sum(axis=0) / x[:, 2].sum()
   ...:     return arr
```

(continues on next page)
...:

In [9]: df = pd.DataFrame([[1, 2, 0.6], [2, 3, 0.4], [3, 4, 0.2], [4, 5, 0.7]])

In [10]: df.rolling(2, method="table", min_periods=0).apply(weighted_mean, raw=True, 
˓→engine="numba") # noqa:E501
Out[10]:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.0000 2.0000 1.0</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1.8000 2.0000 1.0</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>3.3333 2.3333 1.0</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>1.5556 7.0000 1.0</td>
<td></td>
</tr>
</tbody>
</table>

New in version 1.3.

Some windowing operations also support an online method after constructing a windowing object which returns a new object that supports passing in new DataFrame or Series objects to continue the windowing calculation with the new values (i.e. online calculations).

The methods on this new windowing objects must call the aggregation method first to "prime" the initial state of the online calculation. Then, new DataFrame or Series objects can be passed in the update argument to continue the windowing calculation.

In [11]: df = pd.DataFrame([[1, 2, 0.6], [2, 3, 0.4], [3, 4, 0.2], [4, 5, 0.7]])

In [12]: df.ewm(0.5).mean()
Out[12]:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.0000 2.0000 0.6000</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1.7500 2.7500 0.4500</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>2.6154 3.6154 0.2769</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>3.5500 4.5500 0.5625</td>
<td></td>
</tr>
</tbody>
</table>

In [13]: online_ewm = df.head(2).ewm(0.5).online()

In [14]: online_ewm.mean()
Out[14]:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.00   2.00 0.60</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1.75   2.75 0.45</td>
<td></td>
</tr>
</tbody>
</table>

In [15]: online_ewm.mean(update=df.tail(1))
Out[15]:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>3.31    4.31 0.62</td>
<td></td>
</tr>
</tbody>
</table>

All windowing operations support a min_periods argument that dictates the minimum amount of non-np.nan values a window must have; otherwise, the resulting value is np.nan. min_periods defaults to 1 for time-based windows and window for fixed windows.

In [16]: s = pd.Series([np.nan, 1, 2, np.nan, np.nan, 3])

In [17]: s.rolling(window=3, min_periods=1).sum()
Additionally, all windowing operations support the `aggregate` method for returning a result of multiple aggregations applied to a window.

```
In [20]: df = pd.DataFrame({"A": range(5), "B": range(10, 15)})
In [21]: df.expanding().agg([np.sum, np.mean, np.std])
Out[21]:
   A  B
  0  A  B
    sum  mean  std  sum  mean  std
  0  0.0  0.0  NaN  10.0  10.0  NaN
  1  1.0  0.5  0.707107  21.0  10.5  0.707107
  2  3.0  1.0  1.000000  33.0  11.0  1.000000
  3  6.0  1.5  1.290994  46.0  11.5  1.290994
  4 10.0  2.0  1.581139  60.0  12.0  1.581139
```
2.19.2 Rolling window

Generic rolling windows support specifying windows as a fixed number of observations or variable number of observations based on an offset. If a time based offset is provided, the corresponding time based index must be monotonic.

In [22]: times = ['2020-01-01', '2020-01-03', '2020-01-04', '2020-01-05', '2020-01-29']

In [23]: s = pd.Series(range(5), index=pd.DatetimeIndex(times))

In [24]: s
Out[24]:
2020-01-01  0
2020-01-03  1
2020-01-04  2
2020-01-05  3
2020-01-29  4
dtype: int64

# Window with 2 observations
In [25]: s.rolling(window=2).sum()
Out[25]:
2020-01-01  NaN
2020-01-03  1.0
2020-01-04  3.0
2020-01-05  5.0
2020-01-29  7.0
dtype: float64

# Window with 2 days worth of observations
In [26]: s.rolling(window='2D').sum()
Out[26]:
2020-01-01  0.0
2020-01-03  1.0
2020-01-04  3.0
2020-01-05  5.0
2020-01-29  4.0
dtype: float64

For all supported aggregation functions, see Rolling window functions.

Centering windows

By default the labels are set to the right edge of the window, but a center keyword is available so the labels can be set at the center.

In [27]: s = pd.Series(range(10))

In [28]: s.rolling(window=5).mean()
Out[28]:
0    NaN
1    NaN
2    NaN
3    NaN

(continues on next page)
4 2.0
5 3.0
6 4.0
7 5.0
8 6.0
9 7.0
dtype: float64

```
In [29]: s.rolling(window=5, center=True).mean()
Out[29]:
0  NaN
1  NaN
2  2.0
3  3.0
4  4.0
5  5.0
6  6.0
7  7.0
8  NaN
9  NaN
dtype: float64
```

This can also be applied to datetime-like indices.

New in version 1.3.0.

```
In [30]: df = pd.DataFrame(
          ....:     {"A": [0, 1, 2, 3, 4]}, index=pd.date_range("2020", periods=5, freq="1D")
          ....: )
In [31]: df
Out[31]:
     A
2020-01-01  0
2020-01-02  1
2020-01-03  2
2020-01-04  3
2020-01-05  4

In [32]: df.rolling("2D", center=False).mean()
Out[32]:
     A
2020-01-01  0.0
2020-01-02  0.5
2020-01-03  1.5
2020-01-04  2.5
2020-01-05  3.5

In [33]: df.rolling("2D", center=True).mean()
Out[33]:
     A
2020-01-01  0.5
```

(continues on next page)
Rolling window endpoints

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

<table>
<thead>
<tr>
<th>Value</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>'right'</td>
<td>close right endpoint</td>
</tr>
<tr>
<td>'left'</td>
<td>close left endpoint</td>
</tr>
<tr>
<td>'both'</td>
<td>close both endpoints</td>
</tr>
<tr>
<td>'neither'</td>
<td>open endpoints</td>
</tr>
</tbody>
</table>

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```
In [34]: df = pd.DataFrame(
        .....:     {"x": 1},
        .....:     index=[
        .....:         pd.Timestamp("20130101 09:00:01"),
        .....:         pd.Timestamp("20130101 09:00:02"),
        .....:         pd.Timestamp("20130101 09:00:03"),
        .....:         pd.Timestamp("20130101 09:00:04"),
        .....:         pd.Timestamp("20130101 09:00:06"),
        .....:     ],
        .....: )

In [35]: df["right"] = df.rolling("2s", closed="right").x.sum() # default
In [36]: df["both"] = df.rolling("2s", closed="both").x.sum()
In [37]: df["left"] = df.rolling("2s", closed="left").x.sum()
In [38]: df["neither"] = df.rolling("2s", closed="neither").x.sum()
In [39]: df
Out[39]:
```

### 2.19. Windowing Operations
Custom window rolling

New in version 1.0.

In addition to accepting an integer or offset as a window argument, rolling also accepts a BaseIndexer subclass that allows a user to define a custom method for calculating window bounds. The BaseIndexer subclass will need to define a get_window_bounds method that returns a tuple of two arrays, the first being the starting indices of the windows and second being the ending indices of the windows. Additionally, num_values, min_periods, center, closed and will automatically be passed to get_window_bounds and the defined method must always accept these arguments.

For example, if we have the following DataFrame

```python
In [40]: use_expanding = [True, False, True, False, True]
In [41]: use_expanding
Out[41]: [True, False, True, False, True]
In [42]: df = pd.DataFrame({"values": range(5)})
In [43]: df
Out[43]:
   values
0      0
1      1
2      2
3      3
4      4
```

and we want to use an expanding window where use_expanding is True otherwise a window of size 1, we can create the following BaseIndexer subclass:

```python
In [2]: from pandas.api.indexers import BaseIndexer
In [3]: class CustomIndexer(BaseIndexer):
    ...
    def get_window_bounds(self, num_values, min_periods, center, closed):
        ...
        start = np.empty(num_values, dtype=np.int64)
        ...
        end = np.empty(num_values, dtype=np.int64)
        ...
        for i in range(num_values):
            ...
            if self.use_expanding[i]:
                start[i] = 0
                end[i] = i + 1
            ...
            else:
                start[i] = i
                end[i] = i + self.window_size
        ...
        return start, end
In [4]: indexer = CustomIndexer(window_size=1, use_expanding=use_expanding)
In [5]: df.rolling(indexer).sum()
Out[5]:
   values
0   0.0
1   1.0
2   3.0
```

(continues on next page)
You can view other examples of BaseIndexer subclasses here

New in version 1.1.

One subclass of note within those examples is the VariableOffsetWindowIndexer that allows rolling operations over a non-fixed offset like a BusinessDay.

```python
In [44]: from pandas.api.indexers import VariableOffsetWindowIndexer
In [45]: df = pd.DataFrame(range(10), index=pd.date_range("2020", periods=10))
In [46]: offset = pd.offsets.BDay(1)
In [47]: indexer = VariableOffsetWindowIndexer(index=df.index, offset=offset)
In [48]: df
Out[48]:
          0
2020-01-01  0
2020-01-02  1
2020-01-03  2
2020-01-04  3
2020-01-05  4
2020-01-06  5
2020-01-07  6
2020-01-08  7
2020-01-09  8
2020-01-10  9
In [49]: df.rolling(indexer).sum()
Out[49]:
          0
2020-01-01  0.0
2020-01-02  1.0
2020-01-03  2.0
2020-01-04  3.0
2020-01-05  7.0
2020-01-06  12.0
2020-01-07  6.0
2020-01-08  7.0
2020-01-09  8.0
2020-01-10  9.0
```

For some problems knowledge of the future is available for analysis. For example, this occurs when each data point is a full time series read from an experiment, and the task is to extract underlying conditions. In these cases it can be useful to perform forward-looking rolling window computations. FixedForwardWindowIndexer class is available for this purpose. This BaseIndexer subclass implements a closed fixed-width forward-looking rolling window, and we can use it as follows:

```python
In [50]: from pandas.api.indexers import FixedForwardWindowIndexer
```
In [51]: indexer = FixedForwardWindowIndexer(window_size=2)

In [52]: df.rolling(indexer, min_periods=1).sum()
Out[52]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>value</td>
</tr>
<tr>
<td>2020-01-01 1.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-02 3.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 5.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-04 7.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-05 9.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-06 11.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-07 13.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-08 15.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-09 17.0</td>
<td></td>
</tr>
<tr>
<td>2020-01-10 9.0</td>
<td></td>
</tr>
</tbody>
</table>

We can also achieve this by using slicing, applying rolling aggregation, and then flipping the result as shown in the example below:

In [53]: df = pd.DataFrame(
                ....:     data=[
                ....:         [pd.Timestamp("2018-01-01 00:00:00"), 100],
                ....:         [pd.Timestamp("2018-01-01 00:00:01"), 101],
                ....:         [pd.Timestamp("2018-01-01 00:00:03"), 103],
                ....:         [pd.Timestamp("2018-01-01 00:00:04"), 111],
                ....:     ],
                ....:     columns=["time", "value"],
                ....: ).set_index("time")
          
In [54]: df
Out[54]:

<table>
<thead>
<tr>
<th>time</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-01-01 00:00:00</td>
<td>100</td>
</tr>
<tr>
<td>2018-01-01 00:00:01</td>
<td>101</td>
</tr>
<tr>
<td>2018-01-01 00:00:03</td>
<td>103</td>
</tr>
<tr>
<td>2018-01-01 00:00:04</td>
<td>111</td>
</tr>
</tbody>
</table>

In [55]: reversed_df = df[::-1].rolling("2s").sum()[::-1]

In [56]: reversed_df
Out[56]:

<table>
<thead>
<tr>
<th>time</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-01-01 00:00:00</td>
<td>201.0</td>
</tr>
<tr>
<td>2018-01-01 00:00:01</td>
<td>101.0</td>
</tr>
<tr>
<td>2018-01-01 00:00:03</td>
<td>214.0</td>
</tr>
<tr>
<td>2018-01-01 00:00:04</td>
<td>111.0</td>
</tr>
</tbody>
</table>
Rolling apply

The apply() function takes an extra func argument and performs generic rolling computations. The func argument should be a single function that produces a single value from an ndarray input. raw specifies whether the windows are cast as Series objects (raw=False) or ndarray objects (raw=True).

```
In [57]: def mad(x):
    ...:     return np.fabs(x - x.mean()).mean()
    ...:

In [58]: s = pd.Series(range(10))

In [59]: s.rolling(window=4).apply(mad, raw=True)
```

```
Out[59]:
       0  NaN
       1  NaN
       2  NaN
       3  1.0
       4  1.0
       5  1.0
       6  1.0
       7  1.0
       8  1.0
       9  1.0
dtype: float64
```

Numba engine

New in version 1.0.

Additionally, apply() can leverage Numba if installed as an optional dependency. The apply aggregation can be executed using Numba by specifying engine='numba' and engine_kwargs arguments (raw must also be set to True). See enhancing performance with Numba for general usage of the arguments and performance considerations.

Numba will be applied in potentially two routines:

1. If func is a standard Python function, the engine will JIT the passed function. func can also be a JITed function in which case the engine will not JIT the function again.

2. The engine will JIT the for loop where the apply function is applied to each window.

The engine_kwargs argument is a dictionary of keyword arguments that will be passed into the numba.jit decorator. These keyword arguments will be applied to both the passed function (if a standard Python function) and the apply for loop over each window.

New in version 1.3.0.

mean, median, max, min, and sum also support the engine and engine_kwargs arguments.
Binary window functions

cov() and corr() can compute moving window statistics about two Series or any combination of DataFrame/Series or DataFrame/DataFrame. Here is the behavior in each case:

- two Series: compute the statistic for the pairing.
- DataFrame/Series: compute the statistics for each column of the DataFrame with the passed Series, thus returning a DataFrame.
- DataFrame/DataFrame: by default compute the statistic for matching column names, returning a DataFrame. If the keyword argument pairwise=True is passed then computes the statistic for each pair of columns, returning a DataFrame with a MultiIndex whose values are the dates in question (see the next section).

For example:

```python
In [60]: df = pd.DataFrame(
        ....:     np.random.randn(10, 4),
        ....:     index=pd.date_range("2020-01-01", periods=10),
        ....:     columns=["A", "B", "C", "D"],
        ....:     )
In [61]: df = df.cumsum()
In [62]: df2 = df[:4]
In [63]: df2.rolling(window=2).corr(df2["B"])
Out[63]:
     A       B      C      D
2020-01-01 NaN  NaN  NaN  NaN
2020-01-02 -1.0  1.0 -1.0  1.0
2020-01-03  1.0  1.0  1.0 -1.0
2020-01-04 -1.0  1.0  1.0 -1.0
```

Computing rolling pairwise covariances and correlations

In financial data analysis and other fields it’s common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the pairwise keyword argument, which in the case of DataFrame inputs will yield a MultiIndexed DataFrame whose index are the dates in question. In the case of a single DataFrame argument the pairwise argument can even be omitted:

```
Note: Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the covariance section for caveats associated with this method of calculating covariance and correlation matrices.
```

```python
In [64]: covs = (  
        ....:     df["B", "C", "D"]  
        ....:     .rolling(window=4)  
        ....:     .cov(df["A", "B", "C"], pairwise=True)  
        ....:     )
```

(continues on next page)
In [65]: covs
Out[65]:

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-01</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2020-01-02</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2020-01-09</td>

<td>0.469271</td>
</tr>
</tbody>
</table>

[30 rows x 3 columns]

2.19.3 Weighted window

The `win_type` argument in `.rolling` generates a weighted windows that are commonly used in filtering and spectral estimation. `win_type` must be string that corresponds to a scipy.signal window function. Scipy must be installed in order to use these windows, and supplementary arguments that the Scipy window methods take must be specified in the aggregation function.

In [66]: s = pd.Series(range(10))

In [67]: s.rolling(window=5).mean()
Out[67]:

| 0     | NaN   |
| 1     | NaN   |
| 2     | NaN   |
| 3     | NaN   |
| 4     | 2.0   |
| 5     | 3.0   |
| 6     | 4.0   |
| 7     | 5.0   |
| 8     | 6.0   |
| 9     | 7.0   |

dtype: float64

In [68]: s.rolling(window=5, win_type="triang").mean()
Out[68]:

| 0     | NaN   |
| 1     | NaN   |
| 2     | NaN   |
| 3     | NaN   |
| 4     | 2.0   |
| 5     | 3.0   |
| 6     | 4.0   |
| 7     | 5.0   |
| 8     | 6.0   |

(continues on next page)
For all supported aggregation functions, see *Weighted window functions*.

### 2.19.4 Expanding window

An expanding window yields the value of an aggregation statistic with all the data available up to that point in time. Since these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```python
In [70]: df = pd.DataFrame(range(5))
In [71]: df.rolling(window=len(df), min_periods=1).mean()
Out[71]:
   0   0.0
   1   0.5
   2   1.0
   3   1.5
   4   2.0
```

```python
In [72]: df.expanding(min_periods=1).mean()
Out[72]:
   0   0.0
   1   0.5
   2   1.0
   3   1.5
   4   2.0
```

For all supported aggregation functions, see *Expanding window functions*. 
2.19.5 Exponentially Weighted window

An exponentially weighted window is similar to an expanding window but with each prior point being exponentially weighted down relative to the current point.

In general, a weighted moving average is calculated as

\[ y_t = \frac{\sum_{i=0}^{t} w_i x_{t-i}}{\sum_{i=0}^{t} w_i}, \]

where \( x_t \) is the input, \( y_t \) is the result and the \( w_i \) are the weights.

For all supported aggregation functions, see Exponentially-weighted window functions.

The EW functions support two variants of exponential weights. The default, \( \text{adjust=True} \), uses the weights \( w_i = (1 - \alpha)^i \) which gives

\[ y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots + (1 - \alpha)^{t}x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots + (1 - \alpha)^{t}} \]

When \( \text{adjust=False} \) is specified, moving averages are calculated as

\[
\begin{align*}
y_0 &= x_0 \\
y_t &= (1 - \alpha)y_{t-1} + \alpha x_t,
\end{align*}
\]

which is equivalent to using weights

\[
 w_i = \begin{cases} 
 \alpha(1 - \alpha)^i & \text{if } i < t \\
 (1 - \alpha)^i & \text{if } i = t.
\end{cases}
\]

**Note:** These equations are sometimes written in terms of \( \alpha' = 1 - \alpha \), e.g.

\[ y_t = \alpha'y_{t-1} + (1 - \alpha')x_t. \]

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history, with \( \text{adjust=True} \):

\[ y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots} \]

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of \( 1 - \alpha \) we have

\[
\begin{align*}
y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots}{1 - (1 - \alpha)} \\
&= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots] \alpha \\
&= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots] \alpha \\
&= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \ldots] \alpha \\
&= \alpha x_t + (1 - \alpha)y_{t-1}
\end{align*}
\]

which is the same expression as \( \text{adjust=False} \) above and therefore shows the equivalence of the two variants for infinite series. When \( \text{adjust=False} \), we have \( y_0 = x_0 \) and \( y_t = \alpha x_t + (1 - \alpha)y_{t-1} \). Therefore, there is an assumption that \( x_0 \) is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.
One must have \(0 < \alpha \leq 1\), and while it is possible to pass \(\alpha\) directly, it’s often easier to think about either the **span**, **center of mass (com)** or **half-life** of an EW moment:

\[
\alpha = \begin{cases} 
\frac{2}{s+1}, & \text{for span } s \geq 1 \\
\frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\
1 - \exp\left(-\frac{\log 0.5}{h}\right), & \text{for half-life } h > 0
\end{cases}
\]

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: \(c = (s - 1)/2\).
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

New in version 1.1.0.

You can also specify **halflife** in terms of a timedelta convertible unit to specify the amount of time it takes for an observation to decay to half its value when also specifying a sequence of **times**.

```python
In [73]: df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})

In [74]: df
Out[74]:
     B
0   0.0
1   1.0
2   2.0
3   NaN
4   4.0

In [75]: times = ["2020-01-01", "2020-01-03", "2020-01-10", "2020-01-15", "2020-01-17"]

In [76]: df.ewm(halflife="4 days", times=pd.DatetimeIndex(times)).mean()
Out[76]:
     B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

The following formula is used to compute exponentially weighted mean with an input vector of times:

\[
y_t = \frac{\sum_{i=0}^{t} 0.5^{\frac{t-i}{s}} x_{t-i}}{\sum_{i=0}^{t} 0.5^{\frac{t-i}{s}}},
\]

ExponentialMovingWindow also has an **ignore_na** argument, which determines how intermediate null values affect the calculation of the weights. When **ignore_na=False** (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When **ignore_na=True**, weights are calculated by ignoring intermediate null values. For example, assuming **adjust=True**, if **ignore_na=False**, the weighted average of 3, NaN, 5 would be calculated as

\[
\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.
\]
Whereas if ignore_na=True, the weighted average would be calculated as
\[
(1 - \alpha) \cdot 3 + 1 \cdot 5
\]
\[
(1 - \alpha) + 1
\]

The var(), std(), and cov() functions have a bias argument, specifying whether the result should contain biased or unbiased statistics. For example, if bias=True, ewmvar(x) is calculated as \(\text{ewmvar}(x) = \text{ewma}(x**2) - \text{ewma}(x)**2\); whereas if bias=False (the default), the biased variance statistics are scaled by debiasing factors
\[
\frac{(\sum_{i=0}^{t} w_i)^2}{(\sum_{i=0}^{t} w_i)^2 - \sum_{i=0}^{t} w_i^2}.
\]

(For \(w_i = 1\), this reduces to the usual \(N/(N - 1)\) factor, with \(N = t+1\).) See Weighted Sample Variance on Wikipedia for further details.

### 2.20 Time series / date functionality

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy datetime64 and timedelta64 dtypes, pandas has consolidated a large number of features from other Python libraries like scikits.timeseries as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

- Parsing time series information from various sources and formats

```python
In [1]: import datetime
In [2]: dti = pd.to_datetime(
   ...:   ['1/1/2018', np.datetime64('2018-01-01'), datetime.datetime(2018, 1, 1)]
   ...: )
In [3]: dti
Out[3]: DatetimeIndex(['2018-01-01', '2018-01-01', '2018-01-01'], dtype='datetime64[ns]', freq=None)
```

- Generate sequences of fixed-frequency dates and time spans

```python
In [4]: dti = pd.date_range('2018-01-01', periods=3, freq='H')
In [5]: dti
Out[5]: DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00', '2018-01-01 02:00:00'],
                     dtype='datetime64[ns]', freq='H')
```

- Manipulating and converting date times with timezone information

```python
In [6]: dti = dti.tz_localize('UTC')
In [7]: dti
Out[7]:
```

(continues on next page)
Resampling or converting a time series to a particular frequency

```
In [9]: idx = pd.date_range("2018-01-01", periods=5, freq="H")
In [10]: ts = pd.Series(range(len(idx)), index=idx)
In [11]: ts
Out[11]:
2018-01-01 00:00:00    0
2018-01-01 01:00:00    1
2018-01-01 02:00:00    2
2018-01-01 03:00:00    3
2018-01-01 04:00:00    4
Freq: H, dtype: int64
```

```
In [12]: ts.resample("2H").mean()
Out[12]:
2018-01-01 00:00:00    0.5
2018-01-01 02:00:00    2.5
2018-01-01 04:00:00    4.0
Freq: 2H, dtype: float64
```

Performing date and time arithmetic with absolute or relative time increments

```
In [13]: friday = pd.Timestamp("2018-01-05")
In [14]: friday.day_name()
Out[14]: 'Friday'

# Add 1 day
In [15]: saturday = friday + pd.Timedelta("1 day")
In [16]: saturday.day_name()
Out[16]: 'Saturday'

# Add 1 business day (Friday --> Monday)
In [17]: monday = friday + pd.offsets.BDay()
In [18]: monday.day_name()
Out[18]: 'Monday'
```

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.
2.20.1 Overview

pandas captures 4 general time related concepts:

1. Date times: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. Time deltas: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. Time spans: A span of time defined by a point in time and its associated frequency.
4. Date offsets: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

</tbody>
</table>

For time series data, it’s conventional to represent the time component in the index of a `Series` or `DataFrame` so manipulations can be performed with respect to the time element.

```
In [19]: pd.Series(range(3), index=pd.date_range("2000", freq="D", periods=3))
Out[19]:
2000-01-01  0
2000-01-02  1
2000-01-03  2
Freq: D, dtype: int64
```

However, `Series` and `DataFrame` can directly also support the time component as data itself.

```
In [20]: pd.Series(pd.date_range("2000", freq="D", periods=3))
Out[20]:
0  2000-01-01
1  2000-01-02
2  2000-01-03
dtype: datetime64[ns]
```

`Series` and `DataFrame` have extended data type support and functionality for `datetime`, `timedelta` and `Period` data when passed into those constructors. `DateOffset` data however will be stored as object data.

```
In [21]: pd.Series(pd.period_range("1/1/2011", freq="M", periods=3))
Out[21]:
0  2011-01
1  2011-02
2  2011-03
dtype: period[M]
```

```
In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
```

(continues on next page)
Lastly, pandas represents null date times, time deltas, and time spans as NaT which is useful for representing missing or null date like values and behaves similar as np.nan does for float data.

# Equality acts as np.nan would

In [27]: pd.NaT == pd.NaT
Out[27]: False

### 2.20.2 Timestamps vs. time spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by Period can be specified explicitly, or inferred from datetime string format.

For example:
Timestamp and Period can serve as an index. Lists of Timestamp and Period are automatically coerced to DatetimeIndex and PeriodIndex respectively.

```python
In [33]: dates = [
    ....:     pd.Timestamp("2012-05-01"),
    ....:     pd.Timestamp("2012-05-02"),
    ....:     pd.Timestamp("2012-05-03"),
    ....:     ]

In [34]: ts = pd.Series(np.random.randn(3), dates)

In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex

In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

In [37]: ts
Out[37]:
2012-05-01    0.469112
2012-05-02   -0.282863
2012-05-03   -1.509059
dtype: float64

In [38]: periods = [pd.Period("2012-01"), pd.Period("2012-02"), pd.Period("2012-03")]

In [39]: ts = pd.Series(np.random.randn(3), periods)

In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex

In [41]: ts.index
Out[41]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]')

In [42]: ts
Out[42]:
2012-01    -1.135632
2012-02     1.212112
2012-03   -0.173215
Freq: M, dtype: float64
```
pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of Timestamp and sequences of timestamps using instances of DatetimeIndex. For regular time spans, pandas uses Period objects for scalar values and PeriodIndex for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.
2.20.3 Converting to timestamps

To convert a Series or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a Series, this returns a Series (with the same index), while a list-like is converted to a DatetimeIndex:

```python
In [43]: pd.to_datetime(pd.Series(["Jul 31, 2009", "2010-01-10", None]))
Out[43]:
0 2009-07-31
1 2010-01-10
2 NaT
dtype: datetime64[ns]
```

```python
In [44]: pd.to_datetime(["2005/11/23", "2010.12.31"], dayfirst=True)
Out[44]: DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

Warning: You see in the above example that `dayfirst` isn’t strict. If a date can’t be parsed with the day being first it will be parsed as if `dayfirst` were False, and in the case of parsing delimited date strings (e.g. 31-12-2012) then a warning will also be raised.

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```python
In [45]: pd.to_datetime(["04-01-2012 10:00"], dayfirst=True)
Out[45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)
```

```python
In [46]: pd.to_datetime(["14-01-2012", "01-14-2012"], dayfirst=True)
Out[46]: DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

If you pass a single string to `to_datetime`, it returns a single Timestamp. `Timestamp` can also accept string input, but it doesn’t accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```python
In [47]: pd.to_datetime("2010/11/12")
Out[47]: Timestamp('2010-11-12 00:00:00')
```

```python
In [48]: pd.Timestamp("2010/11/12")
Out[48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the DatetimeIndex constructor directly:

```python
In [49]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05")
Out[49]: DatetimeIndex(["2018-01-01", '2018-01-03', '2018-01-05'], dtype='datetime64[ns]
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```python
In [50]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05"], freq="infer")
Out[50]: DatetimeIndex(["2018-01-01", '2018-01-03', '2018-01-05'], dtype='datetime64[ns]
```
Providing a format argument

In addition to the required datetime string, a format argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```python
In [51]: pd.to_datetime("2010/11/12", format="%Y/%m/%d")
Out[51]: Timestamp('2010-11-12 00:00:00')

In [52]: pd.to_datetime("12-11-2010 00:00", format="%d-%m-%Y %H:%M")
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the format option, see the Python datetime documentation.

Assembling datetime from multiple DataFrame columns

You can also pass a DataFrame of integer or string columns to assemble into a Series of Timestamps.

```python
In [53]: df = pd.DataFrame({
        "year": [2015, 2016],
        "month": [2, 3],
        "day": [4, 5],
        "hour": [2, 3]
    })

In [54]: pd.to_datetime(df)
Out[54]:
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
```

You can pass only the columns that you need to assemble.

```python
In [55]: pd.to_datetime(df[["year", "month", "day"]])
Out[55]:
0 2015-02-04
1 2016-03-05
```

pd.to_datetime looks for standard designations of the datetime component in the column names, including:

- required: year, month, day
- optional: hour, minute, second, millisecond, microsecond, nanosecond

Invalid data

The default behavior, errors='raise', is to raise when unparsable:

```python
In [2]: pd.to_datetime(["2009/07/31", 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass errors='ignore' to return the original input when unparsable:

```python
In [56]: pd.to_datetime(["2009/07/31", 'asd'], errors='ignore')
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```
Pass `errors=’coerce’` to convert unparsable data to NaT (not a time):

```python
In [57]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[57]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

### Epoch timestamps

pandas supports converting integer or float epoch times to Timestamp and DatetimeIndex. The default unit is nanoseconds, since that is how Timestamp objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.

```python
In [58]: pd.to_datetime(
....: [1349720105, 1349806505, 1349892905, 1349979305, 1350065705], unit="s"
....: )
Out[58]: DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
                      '2012-10-10 18:15:05', '2012-10-11 18:15:05',
                      '2012-10-12 18:15:05'],
                      dtype='datetime64[ns]', freq=None)

In [59]: pd.to_datetime(
....: [1349720105100, 1349720105200, 1349720105300, 1349720105400, 1349720105500],
....: unit="ms",
....: )
Out[59]: DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000',
                      '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000',
                      '2012-10-08 18:15:05.500000'],
                      dtype='datetime64[ns]', freq=None)
```

**Note:** The `unit` parameter does not use the same strings as the `format` parameter that was discussed above. The available units are listed on the documentation for `pandas.to_datetime()`.

Changed in version 1.0.0.

Constructing a Timestamp or DatetimeIndex with an epoch timestamp with the tz argument specified will raise a ValueError. If you have epochs in wall time in another timezone, you can read the epochs as timezone-naive timestamps and then localize to the appropriate timezone:

```python
In [60]: pd.Timestamp(1262347200000000000).tz_localize("US/Pacific")
Out[60]: Timestamp('2010-01-01 12:00:00-0800', tz='US/Pacific')

In [61]: pd.DatetimeIndex([1262347200000000000]).tz_localize("US/Pacific")
Out[61]: DatetimeIndex(['2010-01-01 12:00:00-08:00'],
                      dtype='datetime64[ns, US/Pacific]',
                      freq=None)
```

**Note:** Epoch times will be rounded to the nearest nanosecond.
Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

```
In [62]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit="s")
Out[62]: DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.433502913'], dtype='datetime64[ns]', freq=None)
```

```
In [63]: pd.to_datetime(1490195805433502912, unit="ns")
Out[63]: Timestamp('2017-03-22 15:16:45.433502912')
```

See also:

Using the origin Parameter

From timestamps to epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

```
In [64]: stamps = pd.date_range("2012-10-08 18:15:05", periods=4, freq="D")
In [65]: stamps
Out[65]: DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05', '2012-10-10 18:15:05', '2012-10-11 18:15:05'], dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [66]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta("1s")
Out[66]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

Using the origin Parameter

Using the origin parameter, one can specify an alternative starting point for creation of a DatetimeIndex. For example, to use 1960-01-01 as the starting date:

```
In [67]: pd.to_datetime([1, 2, 3], unit="D", origin=pd.Timestamp("1960-01-01"))
Out[67]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq='D')
```

The default is set at origin='unix', which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [68]: pd.to_datetime([1, 2, 3], unit="D")
Out[68]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]', freq=None)
```
2.20.4 Generating ranges of timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [69]: dates = [
   ...:    datetime.datetime(2012, 5, 1),
   ...:    datetime.datetime(2012, 5, 2),
   ...:    datetime.datetime(2012, 5, 3),
   ...: ]
   ...
   
# Note the frequency information
In [70]: index = pd.DatetimeIndex(dates)

In [71]: index
Out[71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a calendar day while the default for `bdate_range` is a business day:

```
In [74]: start = datetime.datetime(2011, 1, 1)

In [75]: end = datetime.datetime(2012, 1, 1)

In [76]: index = pd.date_range(start, end)

In [77]: index
   ...:    '2011-01-09', '2011-01-10',
   ...:    '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
   ...:    '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
   ...:    '2011-12-31', '2012-01-01'],
   dtype='datetime64[ns]', length=366, freq='D')
```

```
In [78]: index = pd.bdate_range(start, end)

In [79]: index
   ...:    '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
   ...:    '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
   ...:    '2011-12-31', '2012-01-01'],
   dtype='datetime64[ns]', length=366, freq='D')
```

(continues on next page)
Convenience functions like `date_range` and `bdate_range` can utilize a variety of frequency aliases:

```python
In [80]: pd.date_range(start, periods=1000, freq="M")
Out[80]:
               '2011-09-30', '2011-10-31'],
       dtype='datetime64[ns]', length=1000, freq='M')
```

```python
In [81]: pd.bdate_range(start, periods=250, freq="BQS")
Out[81]:
               '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
               '2013-01-01', '2013-04-01',
               '2071-04-01', '2074-01-01', '2077-01-01', '2080-01-01',
               '2083-01-01', '2086-01-01', '2089-01-01', '2092-01-01',
               '2095-01-01', '2098-01-01'],
       dtype='datetime64[ns]', length=250, freq='BQS-JAN')
```

date_range and bdate_range make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```python
In [82]: pd.date_range(start, end, freq="BM")
Out[82]:
               '2011-09-30', '2011-10-31',
               '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
               '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
               '2094-03-31', '2094-04-30'],
       dtype='datetime64[ns]', length=260, freq='BM')
```

```python
In [83]: pd.date_range(start, end, freq="W")
Out[83]:
               '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
               '2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25'],
       dtype='datetime64[ns]', freq='W')
```

(continues on next page)
In [84]: pd.bdate_range(end=end, periods=20)
Out[84]:
dtype='datetime64[ns]', freq='W-SUN')

In [85]: pd.bdate_range(start=start, periods=20)
Out[85]:
dtype='datetime64[ns]', freq='B')

Specifying start, end, and periods will generate a range of evenly spaced dates from start to end inclusively, with periods number of elements in the resulting DatetimeIndex:

In [86]: pd.date_range("2018-01-01", "2018-01-05", periods=5)
Out[86]:
dtype='datetime64[ns]', freq=None)

In [87]: pd.date_range("2018-01-01", "2018-01-05", periods=10)
Out[87]:
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00', '2018-01-01 21:20:00', '2018-01-02 08:00:00', '2018-01-02 18:40:00', '2018-01-03 05:20:00', '2018-01-03 16:00:00', '2018-01-04 02:40:00', '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
dtype='datetime64[ns]', freq=None)
Custom frequency ranges

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [88]: weekmask = "Mon Wed Fri"

In [89]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]

In [90]: pd.bdate_range(start, end, freq="C", weekmask=weekmask, holidays=holidays)
Out[90]:
               '2011-01-24', '2011-01-26',
               '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
               '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
               '2011-12-28', '2011-12-30'],
dtype='datetime64[ns]', length=154, freq='C')
```

```
In [91]: pd.bdate_range(start, end, freq="CBMS", weekmask=weekmask)
Out[91]:
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
               '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
dtype='datetime64[ns]', freq='CBMS')
```

See also:

*Custom business days*

### 2.20.5 Timestamp limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [92]: pd.Timestamp.min
Out[92]: Timestamp('1677-09-21 00:12:43.145224193')

In [93]: pd.Timestamp.max
Out[93]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:

*Representing out-of-bounds spans*
2.20.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

**See also:**

*Reindexing methods*

**Note:** While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [94]: rng = pd.date_range(start, end, freq="BM")

In [95]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [96]: ts.index
                   dtype='datetime64[ns]', freq='BM')

In [97]: ts[:5].index
                       '2011-05-31'],
                       dtype='datetime64[ns]', freq='BM')

In [98]: ts[::2].index
                      '2011-09-30', '2011-11-30'],
                      dtype='datetime64[ns]', freq='2BM')
```
Partial string indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [99]: ts["1/31/2011"]
Out[99]: 0.11920871129693428

In [100]: ts[datetime.datetime(2011, 12, 25):]
Out[100]:
2011-12-30  0.56702
Freq: BM, dtype: float64

In [101]: ts["10/31/2011":"12/31/2011"]
Out[101]:
2011-10-31  0.271860
2011-11-30 -0.424972
2011-12-30  0.567020
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [102]: ts["2011"]
Out[102]:
2011-01-31  0.119209
2011-02-28 -1.044236
2011-03-31 -0.861849
2011-04-29 -2.104569
2011-05-31 -0.494929
2011-06-30  1.071804
2011-07-29  0.721555
2011-08-31 -0.706771
2011-09-30 -1.039575
2011-10-31  0.271860
2011-11-30 -0.424972
2011-12-30  0.567020
Freq: BM, dtype: float64

In [103]: ts["2011-6"]
Out[103]:
2011-06-30  1.071804
Freq: BM, dtype: float64
```

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints will be included. This would include matching times on an included date:

```
Warning: Indexing DataFrame rows with a single string with getitem (e.g. frame[dtstring]) is deprecated starting with pandas 1.2.0 (given the ambiguity whether it is indexing the rows or selecting a column) and will be removed in a future version. The equivalent with .loc (e.g. frame.loc[dtstring]) is still supported.
```

```
In [104]: dft = pd.DataFrame(
        .....:     np.random.randn(100000, 1),
        .....:     columns="A",
```

(continues on next page)
......: index=pd.date_range("20130101", periods=100000, freq="T"),
......: )
......:

In [105]: dft
Out[105]:

A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00  -1.087401

2013-03-11 10:39:00  -1.693043
[100000 rows x 1 columns]

This starts on the very first time in the month, and includes the last date and time for the month:

In [107]: dft["2013-1":"2013-2"]
Out[107]:

A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00  -1.087401
2013-01-01 00:02:00  -0.673690
2013-01-01 00:03:00  -0.113648
2013-01-01 00:04:00  -1.478427
...  ...
2013-02-28 23:55:00  0.850929
2013-02-28 23:56:00  0.976712
2013-02-28 23:57:00  -2.693884
(continues on next page)
This specifies a stop time that includes all of the times on the last day:

```python
In [108]: dft["2013-1":"2013-2-28"]
Out[108]:
   A
2013-01-01 00:00:00    0.276232
2013-01-01 00:01:00    -1.087401
2013-01-01 00:02:00    -0.673690
2013-01-01 00:03:00    0.113648
2013-01-01 00:04:00    -1.478427
2013-01-01 00:05:00    ... 
2013-02-28 23:55:00    0.850929
2013-02-28 23:56:00    0.976712
2013-02-28 23:57:00    -2.693884
2013-02-28 23:58:00    -1.575535
2013-02-28 23:59:00    -1.573517
[84960 rows x 1 columns]
```

This specifies an exact stop time (and is not the same as the above):

```python
In [109]: dft["2013-1-15":"2013-1-15 00:00:00"]
Out[109]:
   A
2013-01-15 00:00:00    0.276232
2013-01-15 00:01:00    -1.087401
2013-01-15 00:02:00    -0.673690
2013-01-15 00:03:00    0.113648
2013-01-15 00:04:00    -1.478427
2013-01-15 00:05:00    ... 
2013-02-15 23:56:00    1.197749
2013-02-15 23:57:00    0.720521
2013-02-15 23:58:00    -0.072718
2013-02-15 23:59:00    -0.681192
2013-02-28 00:00:00    -0.557501
[83521 rows x 1 columns]
```

We are stopping on the included end-point as it is part of the index:
DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [111]: dft2 = pd.DataFrame(
    ....: np.random.randn(20, 1),
    ....: columns=["A"],
    ....: index=pd.MultiIndex.from_product(
    ....:     [pd.date_range("20130101", periods=10, freq="12H"), ["a", "b"]]
    ....: ),
    ....: )
    ....:
In [112]: dft2
Out[112]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>a</td>
<td>b</td>
</tr>
<tr>
<td>2013-01-01 00:00:00</td>
<td>-0.298694</td>
<td>0.823553</td>
</tr>
<tr>
<td>2013-01-01 12:00:00</td>
<td>0.943285</td>
<td>-1.479399</td>
</tr>
<tr>
<td>2013-01-02 00:00:00</td>

<td></td>
</tr>
</tbody>
</table>
| ...       | ...| ...
| 2013-01-04 12:00:00 | 0.069036  |
| 2013-01-05 00:00:00 | 0.122297  |
| 2013-01-05 12:00:00 | 0.370079  |

[20 rows x 1 columns]
```

```
In [113]: dft2.loc["2013-01-05"]
Out[113]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-05 00:00:00</td>
<td>0.122297</td>
</tr>
<tr>
<td>2013-01-05 12:00:00</td>
<td>0.370079</td>
</tr>
</tbody>
</table>

In [114]: idx = pd.IndexSlice
```

```
In [115]: dft2 = dft2.swaplevel(0, 1).sort_index()
```

```
In [116]: dft2.loc[idx[:, "2013-01-05"], :]
Out[116]:
<p>| | |</p>
<table>
<thead>
<tr>

</tr>
<tr>
<td>2013-01-05 12:00:00</td>
<td>0.370079</td>
</tr>
</tbody>
</table>
```

(continues on next page)
New in version 0.25.0.
Slicing with string indexing also honors UTC offset.

```python
In [117]: df = pd.DataFrame([0], index=pd.DatetimeIndex(["2019-01-01"], tz="US/Pacific"))
In [118]: df
Out[118]:
   2019-01-01 00:00:00-08:00  0

In [119]: df["2019-01-01 12:00:00+04:00":"2019-01-01 13:00:00+04:00"]
Out[119]:
   2019-01-01 00:00:00-08:00  0
```

**Slice vs. exact match**

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```python
In [120]: series_minute = pd.Series([1, 2, 3],
                           pd.DatetimeIndex(["2011-12-31 23:59:00", "2012-01-01 00:00:00", "2012-01-01 00:02:00"],
                           pd.DatetimeIndex(["2011-12-31 23:59:00", "2012-01-01 00:00:00", "2012-01-01 00:02:00"]
                           ))
In [121]: series_minute.index.resolution
Out[121]: 'minute'
```

A timestamp string less accurate than a minute gives a `Series` object.

```python
In [122]: series_minute["2011-12-31 23"]
Out[122]:
2011-12-31 23:59:00    1
dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.
In [124]: series_minute["2011-12-31 23:59:00"]
Out[124]:
1

If index resolution is second, then the minute-accurate timestamp gives a Series.

In [125]: series_second = pd.Series([1, 2, 3],
....: pd.DatetimeIndex(["2011-12-31 23:59:59", "2012-01-01 00:00:00", "2012-01-01 00:00:01"])

In [126]: series_second.index.resolution
Out[126]: 'second'

In [127]: series_second["2011-12-31 23:59"]
Out[127]:
2011-12-31 23:59:59 1
dtype: int64

If the timestamp string is treated as a slice, it can be used to index DataFrame with .loc[] as well.

In [128]: dft_minute = pd.DataFrame(
    ....:     {"a": [1, 2, 3], "b": [4, 5, 6]}, index=series_minute.index
    ....: )

In [129]: dft_minute.loc["2011-12-31 23"]
Out[129]:
a  b
2011-12-31 23:59:00 1 4

Warning: However, if the string is treated as an exact match, the selection in DataFrame’s [] will be column-wise and not row-wise, see Indexing Basics. For example dft_minute["2011-12-31 23:59"] will raise KeyError as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To always have unambiguous selection, whether the row is treated as a slice or a single selection, use .loc.

In [130]: dft_minute.loc["2011-12-31 23:59"]
Out[130]:
a  1
b  4
Name: 2011-12-31 23:59:00, dtype: int64

Note also that DatetimeIndex resolution cannot be less precise than day.

In [131]: series_monthly = pd.Series([1, 2, 3], pd.DatetimeIndex(["2011-12", "2012-01", "2012-02"]))

(continues on next page)
Exact indexing

As discussed in previous section, indexing a DatetimeIndex with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with Timestamp or datetime objects is exact, because the objects have exact meaning. These also follow the semantics of including both endpoints.

These Timestamp and datetime objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```python
In [134]: dft[datetime.datetime(2013, 1, 1): datetime.datetime(2013, 2, 28)]
Out[134]:
  A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00 -1.087401
2013-01-01 00:02:00 -0.673690
2013-01-01 00:03:00  0.113648
2013-01-01 00:04:00 -1.478427
... ...  
2013-02-27 23:56:00  1.197749
2013-02-27 23:57:00  0.720521
2013-02-27 23:58:00 -0.072718
2013-02-27 23:59:00 -0.681192
2013-02-28 00:00:00 -0.557501
[83521 rows x 1 columns]
```

With no defaults.

```python
In [135]: dft[datetime.datetime(2013, 1, 1, 10, 12, 0): datetime.datetime(2013, 2, 28, 10, 12, 0)]
Out[135]:
  A
2013-01-01 10:12:00  0.565375
2013-01-01 10:13:00  0.068184
2013-01-01 10:14:00  0.788871
2013-01-01 10:15:00 -0.280343
2013-01-01 10:16:00  0.931536
... ...
```

2.20. Time series / date functionality

Truncating & fancy indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```python
In [136]: rng2 = pd.date_range("2011-01-01", "2012-01-01", freq="W")
In [137]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
In [138]: ts2.truncate(before="2011-11", after="2011-12")
Out[138]:
2011-11-06  0.437823
2011-11-13 -0.293083
2011-11-20 -0.059881
2011-11-27  1.252450
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```python
In [140]: ts2[[0, 2, 6]].index
Out[140]: DatetimeIndex(['2011-01-01', '2011-01-16', '2011-02-13'], dtype='datetime64[ns] →', freq=None)
```
2.20.7 Time/date components

There are several time/date properties that one can access from Timestamp or a collection of timestamps like a DatetimeIndex.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>The year of the datetime</td>
</tr>
<tr>
<td>month</td>
<td>The month of the datetime</td>
</tr>
<tr>
<td>day</td>
<td>The days of the datetime</td>
</tr>
<tr>
<td>hour</td>
<td>The hour of the datetime</td>
</tr>
<tr>
<td>minute</td>
<td>The minutes of the datetime</td>
</tr>
<tr>
<td>second</td>
<td>The seconds of the datetime</td>
</tr>
<tr>
<td>microsecond</td>
<td>The microseconds of the datetime</td>
</tr>
<tr>
<td>nanosecond</td>
<td>The nanoseconds of the datetime</td>
</tr>
<tr>
<td>date</td>
<td>Returns datetime.date (does not contain timezone information)</td>
</tr>
<tr>
<td>time</td>
<td>Returns datetime.time (does not contain timezone information)</td>
</tr>
<tr>
<td>timetz</td>
<td>Returns datetime.time as local time with timezone information</td>
</tr>
<tr>
<td>dayofyear</td>
<td>The ordinal day of year</td>
</tr>
<tr>
<td>day_of_year</td>
<td>The ordinal day of year</td>
</tr>
<tr>
<td>weekofyear</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>week</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>dayofweek</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>day_of_week</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>weekday</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>quarter</td>
<td>Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.</td>
</tr>
<tr>
<td>days_in_month</td>
<td>The number of days in the month of the datetime</td>
</tr>
<tr>
<td>is_month_start</td>
<td>Logical indicating if first day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_month_end</td>
<td>Logical indicating if last day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_start</td>
<td>Logical indicating if first day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_end</td>
<td>Logical indicating if last day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_year_start</td>
<td>Logical indicating if first day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_year_end</td>
<td>Logical indicating if last day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_leap_year</td>
<td>Logical indicating if the date belongs to a leap year</td>
</tr>
</tbody>
</table>

Furthermore, if you have a Series with datetimelike values, then you can access these properties via the .dt accessor, as detailed in the section on .dt accessors.

New in version 1.1.0.

You may obtain the year, week and day components of the ISO year from the ISO 8601 standard:

```
In [141]: idx = pd.date_range(start="2019-12-29", freq="D", periods=4)

In [142]: idx.isocalendar()
Out[142]:

(continues on next page)
2.20.8 DateOffset objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in `DatetimeIndex` were spaced when using `date_range()`
- the frequency of a `Period` or `PeriodIndex`

These frequency strings map to a `DateOffset` object and its subclasses. A `DateOffset` is similar to a `Timedelta` that represents a duration of time but follows specific calendar duration rules. For example, a `Timedelta` day will always increment datetimes by 24 hours, while a `DateOffset` day will increment datetimes to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all `DateOffset` subclasses that are an hour or smaller (`Hour`, `Minute`, `Second`, `Milli`, `Micro`, `Nano`) behave like `Timedelta` and respect absolute time.

The basic `DateOffset` acts similar to `dateutil.relativedelta` (relativedelta documentation) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) can be used to perform the shift.

```
# This particular day contains a day light savings time transition
In [144]: ts = pd.Timestamp("2016-10-30 00:00:00", tz="Europe/Helsinki")

# Respects absolute time
In [145]: ts + pd.Timedelta(days=1)
Out[145]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

# Respects calendar time
In [146]: ts + pd.DateOffset(days=1)
Out[146]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [147]: friday = pd.Timestamp("2018-01-05")

In [148]: friday.day_name()
Out[148]: 'Friday'

# Add 2 business days (Friday --> Tuesday)
In [149]: two_business_days = 2 * pd.offsets.BDay()

In [150]: friday + two_business_days
Out[150]: Timestamp('2018-01-09 00:00:00')

In [151]: (friday + two_business_days).day_name()
Out[151]: 'Tuesday'
```

Most `DateOffsets` have associated frequencies strings, or offset aliases, that can be passed into `freq` keyword arguments. The available date offsets and associated frequency strings can be found below:
<table>
<thead>
<tr>
<th>Date Offset</th>

</tbody>
</table>

DateOffsets additionally have `rollforward()` and `rollback()` methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```python
In [152]: ts = pd.Timestamp("2018-01-06 00:00:00")
```

(continues on next page)
In [153]: ts.day_name()
Out[153]: 'Saturday'

# BusinessHour's valid offset dates are Monday through Friday
In [154]: offset = pd.offsets.BusinessHour(start="09:00")

# Bring the date to the closest offset date (Monday)
In [155]: offset.rollforward(ts)
Out[155]: Timestamp('2018-01-08 09:00:00')

# Date is brought to the closest offset date first and then the hour is added
In [156]: ts + offset
Out[156]: Timestamp('2018-01-08 10:00:00')

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use normalize() before or after applying the operation (depending on whether you want the time information included in the operation).

In [157]: ts = pd.Timestamp("2014-01-01 09:00")
In [158]: day = pd.offsets.Day()
In [159]: day + ts
Out[159]: Timestamp('2014-01-02 09:00:00')
In [160]: (day + ts).normalize()
Out[160]: Timestamp('2014-01-02 00:00:00')
In [161]: ts = pd.Timestamp("2014-01-01 22:00")
In [162]: hour = pd.offsets.Hour()
In [163]: hour + ts
Out[163]: Timestamp('2014-01-01 23:00:00')
In [164]: (hour + ts).normalize()
Out[164]: Timestamp('2014-01-02 00:00:00')
In [165]: (hour + pd.Timestamp("2014-01-01 23:30")).normalize()
Out[165]: Timestamp('2014-01-02 00:00:00')

**Parametric offsets**

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the Week offset for generating weekly data accepts a weekday parameter which results in the generated dates always lying on a particular day of the week:

In [166]: d = datetime.datetime(2008, 8, 18, 9, 0)
In [167]: d
Out[167]: datetime.datetime(2008, 8, 18, 9, 0)
In [168]: d + pd.offsets.Week()
Out[168]: Timestamp('2008-08-25 09:00:00')

In [169]: d + pd.offsets.Week(weekday=4)
Out[169]: Timestamp('2008-08-22 09:00:00')

In [170]: (d + pd.offsets.Week(weekday=4)).weekday()
Out[170]: 4

In [171]: d - pd.offsets.Week()
Out[171]: Timestamp('2008-08-11 09:00:00')

The normalize option will be effective for addition and subtraction.

In [172]: d + pd.offsets.Week(normalize=True)
Out[172]: Timestamp('2008-08-25 00:00:00')

In [173]: d - pd.offsets.Week(normalize=True)
Out[173]: Timestamp('2008-08-11 00:00:00')

Another example is parameterizing YearEnd with the specific ending month:

In [174]: d + pd.offsets.YearEnd()
Out[174]: Timestamp('2008-12-31 09:00:00')

In [175]: d + pd.offsets.YearEnd(month=6)
Out[175]: Timestamp('2009-06-30 09:00:00')

Using offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

In [176]: rng = pd.date_range("2012-01-01", "2012-01-03")
In [177]: s = pd.Series(rng)

In [178]: rng
Out[178]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')

In [179]: rng + pd.DateOffset(months=2)
Out[179]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq=None)

In [180]: s + pd.DateOffset(months=2)
Out[180]:
0  2012-03-01
1  2012-03-02
2  2012-03-03
dtype: datetime64[ns]
In [181]: s = pd.DateOffset(months=2)  
Out[181]:  
0  2011-11-01  
1  2011-11-02  
2  2011-11-03  
dtype: datetime64[ns]  

If the offset class maps directly to a Timedelta (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a Timedelta - see the Timedelta section for more examples.

In [182]: s = pd.offsets.Day(2)  
Out[182]:  
0  2011-12-30  
1  2011-12-31  
2  2012-01-01  
dtype: datetime64[ns]  

In [183]: td = s - pd.Series(pd.date_range("2011-12-29", "2011-12-31"))  

In [184]: td  
Out[184]:  
0   3 days  
1   3 days  
2   3 days  
dtype: timedelta64[ns]  

In [185]: td + pd.offsets.Minute(15)  
Out[185]:  
0  3 days 00:15:00  
1  3 days 00:15:00  
2  3 days 00:15:00  
dtype: timedelta64[ns]  

Note that some offsets (such as BQuarterEnd) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a PerformanceWarning.

In [186]: rng + pd.offsets.BQuarterEnd()  
Out[186]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype='datetime64[ns]', freq=None)  

Custom business days

The CDay or CustomBusinessDay class provides a parametric BusinessDay class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

In [187]: weekmask_egypt = "Sun Mon Tue Wed Thu"  

# They also observe International Workers' Day so let's  
# add that for a couple of years  
In [188]: holidays = [  

(continues on next page)
In [189]: bday_egypt = pd.offsets.CustomBusinessDay(
    ...:     holidays=holidays,
    ...:     weekmask=weekmask_egypt,
    ...: )

In [190]: dt = datetime.datetime(2013, 4, 30)

In [191]: dt + 2 * bday_egypt
Out[191]: Timestamp('2013-05-05 00:00:00')

Let's map to the weekday names:

In [192]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [193]: pd.Series(dts.weekday, dts).map(pd.Series("Mon Tue Wed Thu Fri Sat Sun".split()))
Out[193]:
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object

Holiday calendars can be used to provide the list of holidays. See the holiday calendar section for more information.

In [194]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [195]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [196]: dt = datetime.datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [197]: dt + bday_us
Out[197]: Timestamp('2014-01-21 00:00:00')

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

In [198]: bmth_us = pd.offsets.CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())

# Skip new years
In [199]: dt = datetime.datetime(2013, 12, 17)

In [200]: dt + bmth_us

(continues on next page)
Out[200]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [201]: pd.date_range(start="20100101", end="20120101", freq=bmth_us)
Out[201]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
              '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
              '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
              '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
dtype='datetime64[ns]', freq='CBMS')

Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to
note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is
not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used
consistently within the user’s application.

Business hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and
der end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp
by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it.
If the result exceeds the business hours end, the remaining hours are added to the next business day.

In [202]: bh = pd.offsets.BusinessHour()

In [203]: bh
Out[203]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [204]: pd.Timestamp("2014-08-01 10:00").weekday()
Out[204]: 4

In [205]: pd.Timestamp("2014-08-01 10:00") + bh
Out[205]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00')+ bh
In [206]: pd.Timestamp("2014-08-01 08:00") + bh
Out[206]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [207]: pd.Timestamp("2014-08-01 16:00") + bh
Out[207]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [208]: pd.Timestamp("2014-08-01 16:30") + bh
Out[208]: Timestamp('2014-08-04 09:30:00')
# Adding 2 business hours

```
In [209]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(2)
Out[209]: Timestamp('2014-08-01 12:00:00')
```

# Subtracting 3 business hours

```
In [210]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(-3)
Out[210]: Timestamp('2014-07-31 15:00:00')
```

You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

```
In [211]: bh = pd.offsets.BusinessHour(start="11:00", end=datetime.time(20, 0))
In [212]: bh
Out[212]: <BusinessHour: BH=11:00-20:00>
In [213]: pd.Timestamp("2014-08-01 13:00") + bh
Out[213]: Timestamp('2014-08-01 14:00:00')
In [214]: pd.Timestamp("2014-08-01 09:00") + bh
Out[214]: Timestamp('2014-08-01 12:00:00')
In [215]: pd.Timestamp("2014-08-01 18:00") + bh
Out[215]: Timestamp('2014-08-01 19:00:00')
```

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid BusinessDay.

```
In [216]: bh = pd.offsets.BusinessHour(start="17:00", end="09:00")
In [217]: bh
Out[217]: <BusinessHour: BH=17:00-09:00>
In [218]: pd.Timestamp("2014-08-01 17:00") + bh
Out[218]: Timestamp('2014-08-01 18:00:00')
In [219]: pd.Timestamp("2014-08-01 23:00") + bh
Out[219]: Timestamp('2014-08-02 00:00:00')
```

# Although 2014-08-02 is Saturday,
# it is valid because it starts from 08-01 (Friday).
```
In [220]: pd.Timestamp("2014-08-02 04:00") + bh
Out[220]: Timestamp('2014-08-02 05:00:00')
```

# Although 2014-08-04 is Monday,
# it is out of business hours because it starts from 08-03 (Sunday).
```
In [221]: pd.Timestamp("2014-08-04 04:00") + bh
Out[221]: Timestamp('2014-08-04 18:00:00')
```

Applying BusinessHour.rollforward and rollback to out of business hours results in the next business hour start or previous day’s end. Different from other offsets, BusinessHour.rollforward may output different results from
apply by definition.

This is because one day’s business hour end is equal to next day’s business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

```
# This adjusts a Timestamp to business hour edge
In [222]: pd.offsets.BusinessHour().rollback(pd.Timestamp("2014-08-02 15:00"))
Out[222]: Timestamp('2014-08-01 17:00:00')

In [223]: pd.offsets.BusinessHour().rollforward(pd.Timestamp("2014-08-02 15:00"))
Out[223]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour() + pd.Timestamp('2014-08-01 17:00').
# And it is the same as BusinessHour() + pd.Timestamp('2014-08-04 09:00')
In [224]: pd.offsets.BusinessHour() + pd.Timestamp("2014-08-02 15:00")
Out[224]: Timestamp('2014-08-04 10:00:00')

# BusinessDay results (for reference)
In [225]: pd.offsets.BusinessHour().rollforward(pd.Timestamp("2014-08-02"))
Out[225]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessDay() + pd.Timestamp('2014-08-01')
# The result is the same as rollforward because BusinessDay never overlap.
In [226]: pd.offsets.BusinessHour() + pd.Timestamp("2014-08-02")
Out[226]: Timestamp('2014-08-04 10:00:00')
```

BusinessHour regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use CustomBusinessHour offset, as explained in the following subsection.

**Custom business hour**

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. CustomBusinessHour works as the same as BusinessHour except that it skips specified custom holidays.

```
In [227]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [228]: bhour_us = pd.offsets.CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [229]: dt = datetime.datetime(2014, 1, 17, 15)

In [230]: dt + bhour_us
Out[230]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [231]: dt + bhour_us * 2
Out[231]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either BusinessHour and CustomBusinessDay.

```
In [232]: bhour_mon = pd.offsets.CustomBusinessHour(start="10:00", weekmask="Tue Wed Thu...
˓→Fri")
```

(continues on next page)
# Monday is skipped because it's a holiday, business hour starts from 10:00

```python
In [233]: dt + bhour_mon * 2
Out[233]: Timestamp('2014-01-21 10:00:00')
```

## Offset aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as *offset aliases*.

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>business day frequency</td>
</tr>
<tr>
<td>C</td>
<td>custom business day frequency</td>
</tr>

<tr>
<td>L, ms</td>
<td>millisecond</td>
</tr>
<tr>
<td>U, us</td>
<td>microsecond</td>
</tr>
<tr>
<td>N</td>
<td>nanosecond</td>
</tr>
</tbody>
</table>

**Note:**

When using the offset aliases above, it should be noted that functions such as `date_range()`, `bdate_range()`, will only return timestamps that are in the interval defined by `start_date` and `end_date`. If the `start_date` does not correspond to the frequency, the returned timestamps will start at the next valid timestamp, same for `end_date`, the returned timestamps will stop at the previous valid timestamp.

For example, for the offset `MS`, if the `start_date` is not the first of the month, the returned timestamps will start with the first day of the next month. If `end_date` is not the first day of a month, the last returned timestamp will be the first day of the corresponding month.
In [234]: dates_lst_1 = pd.date_range("2020-01-06", "2020-04-03", freq="MS")

In [235]: dates_lst_1
Out[235]:
DatetimeIndex(['2020-02-01', '2020-03-01', '2020-04-01'], dtype='datetime64[ns]', freq='MS')

In [236]: dates_lst_2 = pd.date_range("2020-01-01", "2020-04-01", freq="MS")

In [237]: dates_lst_2
Out[237]:
DatetimeIndex(['2020-01-01', '2020-02-01', '2020-03-01', '2020-04-01'], dtype='datetime64[ns]', freq='MS')

We can see in the above example `date_range()` and `bdate_range()` will only return the valid timestamps between the `start_date` and `end_date`. If these are not valid timestamps for the given frequency it will roll to the next value for `start_date` (respectively previous for the `end_date`).

### Combining aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

In [238]: pd.date_range(start, periods=5, freq="B")
Out[238]:
                  '2011-01-07'],
              dtype='datetime64[ns]', freq='B')

In [239]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
Out[239]:
                  '2011-01-07'],
              dtype='datetime64[ns]', freq='B')

You can combine together day and intraday offsets:

In [240]: pd.date_range(start, periods=10, freq="2h20min")
Out[240]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
                  '2011-01-01 04:40:00', '2011-01-01 07:00:00',
                  '2011-01-01 09:20:00', '2011-01-01 11:40:00',
                  '2011-01-01 14:00:00', '2011-01-01 16:20:00',
                  '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
              dtype='datetime64[ns]', freq='140T')

In [241]: pd.date_range(start, periods=10, freq="1D10U")
Out[241]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
                  '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
                  '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
                  '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
                  '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
              dtype='datetime64[ns]', freq='86400000010U')
Anchored offsets

For some frequencies you can specify an anchoring suffix:

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W-SUN</td>
<td>weekly frequency (Sundays). Same as ‘W’</td>
</tr>
<tr>
<td>W-MON</td>
<td>weekly frequency (Mondays)</td>
</tr>
<tr>
<td>W-TUE</td>
<td>weekly frequency (Tuesdays)</td>
</tr>
<tr>
<td>W-WED</td>
<td>weekly frequency (Wednesdays)</td>
</tr>
<tr>
<td>W-THU</td>
<td>weekly frequency (Thursdays)</td>
</tr>
<tr>
<td>W-FRI</td>
<td>weekly frequency (Fridays)</td>
</tr>
<tr>
<td>W-SAT</td>
<td>weekly frequency (Saturdays)</td>
</tr>
<tr>
<td>(B)Q(S)-DEC</td>
<td>quarterly frequency, year ends in December. Same as ‘Q’</td>
</tr>
<tr>
<td>(B)Q(S)-JAN</td>
<td>quarterly frequency, year ends in January</td>
</tr>
<tr>
<td>(B)Q(S)-FEB</td>
<td>quarterly frequency, year ends in February</td>
</tr>
<tr>
<td>(B)Q(S)-MAR</td>
<td>quarterly frequency, year ends in March</td>
</tr>
<tr>
<td>(B)Q(S)-APR</td>
<td>quarterly frequency, year ends in April</td>
</tr>
<tr>
<td>(B)Q(S)-MAY</td>
<td>quarterly frequency, year ends in May</td>
</tr>
<tr>
<td>(B)Q(S)-JUN</td>
<td>quarterly frequency, year ends in June</td>
</tr>
<tr>
<td>(B)Q(S)-JUL</td>
<td>quarterly frequency, year ends in July</td>
</tr>
<tr>
<td>(B)Q(S)-AUG</td>
<td>quarterly frequency, year ends in August</td>
</tr>
<tr>
<td>(B)Q(S)-SEP</td>
<td>quarterly frequency, year ends in September</td>
</tr>
<tr>
<td>(B)Q(S)-OCT</td>
<td>quarterly frequency, year ends in October</td>
</tr>
<tr>
<td>(B)Q(S)-NOV</td>
<td>quarterly frequency, year ends in November</td>
</tr>
<tr>
<td>(B)A(S)-DEC</td>
<td>annual frequency, anchored end of December. Same as ‘A’</td>
</tr>
<tr>
<td>(B)A(S)-JAN</td>
<td>annual frequency, anchored end of January</td>
</tr>
<tr>
<td>(B)A(S)-FEB</td>
<td>annual frequency, anchored end of February</td>
</tr>
<tr>
<td>(B)A(S)-MAR</td>
<td>annual frequency, anchored end of March</td>
</tr>
<tr>
<td>(B)A(S)-APR</td>
<td>annual frequency, anchored end of April</td>
</tr>
<tr>
<td>(B)A(S)-MAY</td>
<td>annual frequency, anchored end of May</td>
</tr>
<tr>
<td>(B)A(S)-JUN</td>
<td>annual frequency, anchored end of June</td>
</tr>
<tr>
<td>(B)A(S)-JUL</td>
<td>annual frequency, anchored end of July</td>
</tr>
</tbody>
</table>

continues on next page
Table 4 – continued from previous page

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(B)A(S)-AUG</td>
<td>annual frequency, anchored end of August</td>
</tr>
<tr>
<td>(B)A(S)-SEP</td>
<td>annual frequency, anchored end of September</td>
</tr>
<tr>
<td>(B)A(S)-OCT</td>
<td>annual frequency, anchored end of October</td>
</tr>
<tr>
<td>(B)A(S)-NOV</td>
<td>annual frequency, anchored end of November</td>
</tr>
</tbody>
</table>

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

**Anchored offset semantics**

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When \( n \) is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved \(|n| - 1\) additional steps forwards or backwards.

```
In [242]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=1)
Out[242]: Timestamp('2014-02-01 00:00:00')

In [243]: pd.Timestamp("2014-01-31") + pd.offsets.MonthEnd(n=1)
Out[243]: Timestamp('2014-02-28 00:00:00')

In [244]: pd.Timestamp("2014-01-01") - pd.offsets.MonthBegin(n=1)
Out[244]: Timestamp('2013-12-01 00:00:00')

In [245]: pd.Timestamp("2014-01-31") - pd.offsets.MonthEnd(n=1)
Out[245]: Timestamp('2013-12-31 00:00:00')
```

If the given date is on an anchor point, it is moved \(|n|\) points forwards or backwards.

```
In [248]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=1)
Out[248]: Timestamp('2014-02-01 00:00:00')

In [249]: pd.Timestamp("2014-01-31") + pd.offsets.MonthEnd(n=1)
Out[249]: Timestamp('2014-02-28 00:00:00')

In [250]: pd.Timestamp("2014-01-01") - pd.offsets.MonthBegin(n=1)
Out[250]: Timestamp('2013-12-01 00:00:00')

In [251]: pd.Timestamp("2014-01-31") - pd.offsets.MonthEnd(n=1)
Out[251]: Timestamp('2013-12-31 00:00:00')
```
In [252]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=4)
Out[252]: Timestamp('2014-05-01 00:00:00')

In [253]: pd.Timestamp("2014-01-31") - pd.offsets.MonthBegin(n=4)
Out[253]: Timestamp('2013-10-01 00:00:00')

For the case when n=0, the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

In [254]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=0)
Out[254]: Timestamp('2014-02-01 00:00:00')

In [255]: pd.Timestamp("2014-01-02") + pd.offsets.MonthEnd(n=0)
Out[255]: Timestamp('2014-01-31 00:00:00')

In [256]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=0)
Out[256]: Timestamp('2014-01-01 00:00:00')

In [257]: pd.Timestamp("2014-01-31") + pd.offsets.MonthEnd(n=0)
Out[257]: Timestamp('2014-01-31 00:00:00')

**Holidays / holiday calendars**

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearest_workday</td>
<td>move Saturday to Friday and Sunday to Monday</td>
</tr>
<tr>
<td>sun-to-monday</td>
<td>move Sunday to following Monday</td>
</tr>
<tr>
<td>next_monday_or_tue</td>
<td>Saturday to Monday and Sunday/Monday to Tuesday</td>
</tr>
<tr>
<td>previous_friday</td>
<td>move Saturday and Sunday to previous Friday</td>
</tr>
<tr>
<td>next_monday</td>
<td>move Saturday and Sunday to following Monday</td>
</tr>
</tbody>
</table>

An example of how holidays and holiday calendars are defined:

In [258]: from pandas.tseries.holiday import (   
        Holiday,   
        USMemorialDay,   
        AbstractHolidayCalendar,   
        nearest_workday,   
        MO,

(continues on next page)
In [259]: class ExampleCalendar(AbstractHolidayCalendar):
    ....:     rules = [
    ....:         USMemorialDay,
    ....:         Holiday("July 4th", month=7, day=4, observance=nearest_workday),
    ....:         Holiday("Columbus Day",
    ....:             month=10,
    ....:             day=1,
    ....:             offset=pd.DateOffset(weekday=MO(2)),
    ....:         ),
    ....:     ]

In [260]: cal = ExampleCalendar()

In [261]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
Out[261]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]')

hint weekday=MO(2) is same as 2 * Week(weekday=2)

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the ExampleCalendar. Like any other offset, it can be used to create a DatetimeIndex or added to datetime or Timestamp objects.

In [262]: pd.date_range(
    ....:     start="7/1/2012", end="7/10/2012", freq=pd.offsets.CDay(calendar=cal)
    ....: ).to_pydatetime()

Out[262]: array([datetime.datetime(2012, 7, 2, 0, 0),
    datetime.datetime(2012, 7, 3, 0, 0),
    datetime.datetime(2012, 7, 5, 0, 0),
    datetime.datetime(2012, 7, 6, 0, 0),
    datetime.datetime(2012, 7, 9, 0, 0),
    datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)

In [263]: offset = pd.offsets.CustomBusinessDay(calendar=cal)

In [264]: datetime.datetime(2012, 5, 25) + offset
Out[264]: Timestamp('2012-05-29 00:00:00')

In [265]: datetime.datetime(2012, 7, 3) + offset
Out[265]: Timestamp('2012-07-05 00:00:00')

In [266]: datetime.datetime(2012, 7, 3) + 2 * offset
Out[266]: Timestamp('2012-07-06 00:00:00')

In [267]: datetime.datetime(2012, 7, 6) + offset
Out[267]: Timestamp('2012-07-09 00:00:00')
Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [268]: AbstractHolidayCalendar.start_date
Out[268]: Timestamp('1970-01-01 00:00:00')

In [269]: AbstractHolidayCalendar.end_date
Out[269]: Timestamp('2200-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.

```
In [270]: AbstractHolidayCalendar.start_date = datetime.datetime(2012, 1, 1)
In [271]: AbstractHolidayCalendar.end_date = datetime.datetime(2012, 12, 31)
In [272]: cal.holidays()
Out[272]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [273]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory, USLaborDay
In [274]: cal = get_calendar("ExampleCalendar")
In [275]: cal.rules
Out[275]: [Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
          Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x7f54ed1375e0>),
          Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
In [276]: new_cal = HolidayCalendarFactory("NewExampleCalendar", cal, USLaborDay)
In [277]: new_cal.rules
Out[277]: [Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
          Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
          Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x7f54ed1375e0>),
          Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
```
2.20.9 Time series-related instance methods

Shifting / lagging

One may want to shift or lag the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```python
In [278]: ts = pd.Series(range(len(rng)), index=rng)
In [279]: ts = ts[:5]
In [280]: ts.shift(1)
Out[280]:
2012-01-01    NaN
2012-01-02    0.0
2012-01-03    1.0
Freq: D, dtype: float64
```

The shift method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an `offset alias`.

When `freq` is specified, `shift` method changes all the dates in the index rather than changing the alignment of the data and the index:

```python
In [281]: ts.shift(5, freq="D")
Out[281]:
2012-01-06    0
2012-01-07    1
2012-01-08    2
Freq: D, dtype: int64

In [282]: ts.shift(5, freq=pd.offsets.BDay())
Out[282]:
2012-01-06    0
2012-01-09    1
2012-01-10    2
dtype: int64

In [283]: ts.shift(5, freq="BM")
Out[283]:
2012-05-31    0
2012-05-31    1
2012-05-31    2
dtype: int64
```

Note that with when `freq` is specified, the leading entry is no longer NaN because the data is not being realigned.
Frequency conversion

The primary function for changing frequencies is the \texttt{asfreq()} method. For a \texttt{DatetimeIndex}, this is basically just a thin, but convenient wrapper around \texttt{reindex()} which generates a date_range and calls \texttt{reindex}.

\begin{Verbatim}
In [284]: dr = pd.date_range("1/1/2010", periods=3, freq=3 * pd.offsets.BDay())
In [285]: ts = pd.Series(np.random.randn(3), index=dr)
In [286]: ts
Out[286]:
2010-01-01    1.494522
2010-01-06   -0.778425
2010-01-11   -0.253355
Freq: 3B, dtype: float64
In [287]: ts.asfreq(pd.offsets.BDay())
Out[287]:
2010-01-01    1.494522
2010-01-04    NaN
2010-01-05    NaN
2010-01-06   -0.778425
2010-01-07    NaN
2010-01-08    NaN
2010-01-11   -0.253355
Freq: B, dtype: float64
\end{Verbatim}

\texttt{asfreq} provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

\begin{Verbatim}
In [288]: ts.asfreq(pd.offsets.BDay(), method="pad")
Out[288]:
2010-01-01    1.494522
2010-01-04    1.494522
2010-01-05    1.494522
2010-01-06   -0.778425
2010-01-07   -0.778425
2010-01-08   -0.778425
2010-01-11   -0.253355
Freq: B, dtype: float64
\end{Verbatim}
Filling forward / backward

Related to asfreq and reindex is `fillna()`, which is documented in the missing data section.

Converting to Python datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

2.20.10 Resampling

`pandas` has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some cookbook examples for some advanced strategies.

The `resample()` method can be used directly from DataFrameGroupBy objects, see the groupby docs.

Basics

```
In [289]: rng = pd.date_range("1/1/2012", periods=100, freq="S")
In [290]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [291]: ts.resample("5Min").sum()
Out[291]:
2012-01-01    25103
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via `dispatching` is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [292]: ts.resample("5Min").mean()
Out[292]:
2012-01-01    251.03
Freq: 5T, dtype: float64
```

```
In [293]: ts.resample("5Min").ohlc()
Out[293]:
          open  high  low  close
2012-01-01  308    460    9   205
```

```
In [294]: ts.resample("5Min").max()
Out[294]:
2012-01-01    460
Freq: 5T, dtype: int64
```

For downsampling, `closed` can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:
Parameters like `label` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval.

```python
In [297]: ts.resample("5Min", label="left").mean()
Out[297]:
2012-01-01 251.03
Freq: 5T, dtype: float64
```

Warning: The default values for `label` and `closed` is `left` for all frequency offsets except for `M`, `A`, `Q`, `BM`, `BA`, `BQ`, and `W` which all have a default of `right`. This might unintendly lead to looking ahead, where the value for a later time is pulled back to a previous time as in the following example with the `BusinessDay` frequency:

```python
In [298]: s.dt.day_name()
Out[298]:
2000-01-01 Saturday
2000-01-02 Sunday
2000-01-03 NaN
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: D, dtype: object
```

Notice how the value for Sunday got pulled back to the previous Friday. To get the behavior where the value for

---

2.20. Time series / date functionality
Sunday is pushed to Monday, use instead

```python
In [303]: s.resample("B", label="right", closed="right").last().dt.day_name()
Out[303]:
2000-01-03 Sunday
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: B, dtype: object
```

The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a DataFrame. The `kind` can be set to ‘timestamp’ or ‘period’ to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation.

The `convention` can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

### Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```python
# from secondly to every 250 milliseconds
In [304]: ts[:2].resample("250L").asfreq()
Out[304]:
2012-01-01 00:00:00.000    308.0
2012-01-01 00:00:00.250      NaN
2012-01-01 00:00:00.500      NaN
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64
```

```python
In [305]: ts[:2].resample("250L").ffill()
Out[305]:
2012-01-01 00:00:00.000    308
2012-01-01 00:00:00.250    308
2012-01-01 00:00:00.500    308
2012-01-01 00:00:00.750    308
2012-01-01 00:00:01.000    204
Freq: 250L, dtype: int64
```

```python
In [306]: ts[:2].resample("250L").ffill(limit=2)
Out[306]:
2012-01-01 00:00:00.000    308.0
2012-01-01 00:00:00.250    308.0
2012-01-01 00:00:00.500    308.0
2012-01-01 00:00:00.750     NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64
```
Sparse resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don’t want to use a method to fill these values, e.g. fill_method is None, then intermediate values will be filled with NaN.

Since resample is a time-based groupby, the following is a method to efficiently resample only the groups that are not all NaN.

```
In [307]: rng = pd.date_range("2014-1-1", periods=100, freq="D") + pd.Timedelta("1s")
In [308]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [309]: ts.resample("3T").sum()
Out[309]:
2014-01-01 00:00:00 0
2014-01-01 00:03:00 0
2014-01-01 00:06:00 0
2014-01-01 00:09:00 0
2014-01-01 00:12:00 0
..       
2014-04-09 23:48:00 0
2014-04-09 23:51:00 0
2014-04-09 23:54:00 0
2014-04-09 23:57:00 0
2014-04-10 00:00:00 99
Freq: 3T, Length: 47521, dtype: int64
```

We can instead only resample those groups where we have points as follows:

```
In [310]: from functools import partial
In [311]: from pandas.tseries.frequencies import to_offset
In [312]: def round(t, freq):
.....:   freq = to_offset(freq)
.....:   return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)
.....:
In [313]: ts.groupby(partial(round, freq="3T")).sum()
Out[313]:
2014-01-01    0
2014-01-02    1
2014-01-03    2
2014-01-04    3
2014-01-05    4
..       
2014-04-06   95
2014-04-07   96
2014-04-08   97
2014-04-09   98
2014-04-10   99
Length: 100, dtype: int64
```
### Aggregation

Similar to the aggregating API, groupby API, and the window API, a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

```python
In [314]: df = pd.DataFrame(
    ......:     np.random.randn(1000, 3),
    ......:     index=pd.date_range("1/1/2012", freq="S", periods=1000),
    ......:     columns=["A", "B", "C"],
    ......: )
    ......:
In [315]: r = df.resample("3T")

In [316]: r.mean()

Out[316]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-0.033823</td>
<td>-0.121514</td>
<td>-0.081447</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>0.056909</td>
<td>0.146731</td>
<td>-0.024320</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>-0.058837</td>
<td>0.047046</td>
<td>-0.052021</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>0.063123</td>
<td>-0.026158</td>
<td>-0.066533</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>0.186340</td>
<td>-0.003144</td>
<td>0.074752</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>-0.085954</td>
<td>-0.016287</td>
<td>-0.050046</td>
</tr>
</tbody>
</table>

Freq: 3T, Name: A, dtype: float64
```

We can select a specific column or columns using standard getitem.

```python
In [317]: r["A"].mean()

Out[317]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-0.033823</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>0.056909</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>-0.058837</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>0.063123</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>0.186340</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>-0.085954</td>
</tr>
</tbody>
</table>

Freq: 3T, Name: A, dtype: float64
```

```python
In [318]: r[["A", "B"]].mean()

Out[318]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-0.033823</td>
<td>-0.121514</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>0.056909</td>
<td>0.146731</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>-0.058837</td>
<td>0.047046</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>0.063123</td>
<td>-0.026158</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>0.186340</td>
<td>-0.003144</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>-0.085954</td>
<td>-0.016287</td>
</tr>
</tbody>
</table>
```

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```python
In [319]: r["A"].agg([np.sum, np.mean, np.std])

Out[319]:

<table>
<thead>
<tr>
<th></th>
<th>sum</th>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.088060</td>
<td>-0.033823</td>
<td>1.043263</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>10.243678</td>
<td>0.056909</td>
<td>1.058534</td>
</tr>
</tbody>
</table>
```

00:09:00 11.362228 0.063123
00:12:00 33.541257 0.186340
00:15:00 -8.595393 -0.085954

0.949264
1.028096
0.884586
1.035476

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated
result with a hierarchical index:
In [320]: r.agg([np.sum, np.mean])
Out[320]:
A
B
C
sum
mean
sum
mean
sum
mean
2012-01-01 00:00:00 -6.088060 -0.033823 -21.872530 -0.121514 -14.660515 -0.081447
2012-01-01 00:03:00 10.243678 0.056909 26.411633 0.146731 -4.377642 -0.024320
2012-01-01 00:06:00 -10.590584 -0.058837
8.468289 0.047046 -9.363825 -0.052021
2012-01-01 00:09:00 11.362228 0.063123 -4.708526 -0.026158 -11.975895 -0.066533
2012-01-01 00:12:00 33.541257 0.186340 -0.565895 -0.003144 13.455299 0.074752
2012-01-01 00:15:00 -8.595393 -0.085954 -1.628689 -0.016287 -5.004580 -0.050046
By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:
In [321]: r.agg({"A": np.sum, "B": lambda x: np.std(x, ddof=1)})
Out[321]:
A
B
2012-01-01 00:00:00 -6.088060 1.001294
2012-01-01 00:03:00 10.243678 1.074597
2012-01-01 00:06:00 -10.590584 0.987309
2012-01-01 00:09:00 11.362228 0.944953
2012-01-01 00:12:00 33.541257 1.095025
2012-01-01 00:15:00 -8.595393 1.035312
The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:
In [322]: r.agg({"A": "sum", "B": "std"})
Out[322]:
A
B
2012-01-01 00:00:00 -6.088060 1.001294
2012-01-01 00:03:00 10.243678 1.074597
2012-01-01 00:06:00 -10.590584 0.987309
2012-01-01 00:09:00 11.362228 0.944953
2012-01-01 00:12:00 33.541257 1.095025
2012-01-01 00:15:00 -8.595393 1.035312
Furthermore, you can also specify multiple aggregation functions for each column separately.
In [323]: r.agg({"A": ["sum", "std"], "B": ["mean",
Out[323]:
A
B
sum
std
mean
2012-01-01 00:00:00 -6.088060 1.043263 -0.121514
2012-01-01 00:03:00 10.243678 1.058534 0.146731
2012-01-01 00:06:00 -10.590584 0.949264 0.047046
2012-01-01 00:09:00 11.362228 1.028096 -0.026158

"std"]})

std
1.001294
1.074597
0.987309
0.944953
(continues on next page)

2.20. Time series / date functionality

885


If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can passed to the on keyword.

In [324]: df = pd.DataFrame(
    .....:   "date": pd.date_range("2015-01-01", freq="W", periods=5), "a": np.
    .....:   arange(5),
    .....:   index=pd.MultiIndex.from_arrays(
    .....:   [[1, 2, 3, 4, 5], pd.date_range("2015-01-01", freq="W", periods=5)],
    .....:   names=["v", "d"],
    .....: ),
    .....:
    .....:
In [325]: df
Out[325]:
   date       a
v    d
1  2015-01-04 2015-01-04 0
2  2015-01-11 2015-01-11 1
3  2015-01-18 2015-01-18 2
4  2015-01-25 2015-01-25 3
5  2015-02-01 2015-02-01 4

In [326]: df.resample("M", on="date").sum()
Out[326]:
   a
date
2015-01-31 6
2015-02-28 4

Similarly, if you instead want to resample by a datetimelike level of MultiIndex, its name or location can be passed to the level keyword.

In [327]: df.resample("M", level="d").sum()
Out[327]:
   a
d
2015-01-31 6
2015-02-28 4
Iterating through groups

With the Resampler object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```python
In [328]: small = pd.Series(
    .....:     range(6),
    .....:     index=pd.to_datetime(
    .....:         [  
    .....:             "2017-01-01T00:00:00",
    .....:             "2017-01-01T00:30:00",
    .....:             "2017-01-01T00:31:00",
    .....:             "2017-01-01T01:00:00",
    .....:             "2017-01-01T03:00:00",
    .....:             "2017-01-01T03:05:00",
    .....:         ])
    .....:     ),
    .....: )
    .....: 

In [329]: resampled = small.resample("H")

In [330]: for name, group in resampled:
    .....:     print("Group: ", name)
    .....:     print("-" * 27)
    .....:     print(group, end="\n\n")

Group: 2017-01-01 00:00:00
------------------------
2017-01-01 00:00:00 0
2017-01-01 00:30:00 1
2017-01-01 00:31:00 2
dtype: int64

Group: 2017-01-01 01:00:00
------------------------
2017-01-01 01:00:00 3
dtype: int64

Group: 2017-01-01 02:00:00
------------------------
Series([], dtype: int64)

Group: 2017-01-01 03:00:00
------------------------
2017-01-01 03:00:00 4
2017-01-01 03:05:00 5
dtype: int64
```

See Iterating through groups or Resampler.__iter__ for more.
Use `origin` or `offset` to adjust the start of the bins

New in version 1.1.0.

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like `30D`) or that divide a day evenly (like `90s` or `1min`). This can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can specify a fixed Timestamp with the argument `origin`.

For example:

```python
In [331]: start, end = "2000-10-01 23:30:00", "2000-10-02 00:30:00"
In [332]: middle = "2000-10-02 00:00:00"
In [333]: rng = pd.date_range(start, end, freq="7min")
In [334]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
In [335]: ts
Out[335]:
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64
```

Here we can see that, when using `origin` with its default value (`'start_day'`), the result after `'2000-10-02 00:00:00'` are not identical depending on the start of time series:

```python
In [336]: ts.resample("17min", origin="start_day").sum()
Out[336]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64
```

```python
In [337]: ts[middle:end].resample("17min", origin="start_day").sum()
Out[337]:
2000-10-02 00:00:00   33
2000-10-02 00:17:00   45
Freq: 17T, dtype: int64
```

Here we can see that, when setting `origin` to `'epoch'`, the result after `'2000-10-02 00:00:00'` are identical depending on the start of time series:

```python
In [338]: ts.resample("17min", origin="epoch").sum()
Out[338]:
(continues on next page)
```
In [339]: ts[middle:end].resample("17min", origin="epoch").sum()
Out[339]:
2000-10-01 23:52:00 15
2000-10-02 00:09:00 39
2000-10-02 00:26:00 24
Freq: 17T, dtype: int64

If needed you can use a custom timestamp for origin:

In [340]: ts.resample("17min", origin="2001-01-01").sum()
Out[340]:
2000-10-01 23:52:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64

In [341]: ts[middle:end].resample("17min", origin=pd.Timestamp("2001-01-01")).sum()
Out[341]:
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64

If needed you can just adjust the bins with an offset Timedelta that would be added to the default origin. Those two examples are equivalent for this time series:

In [342]: ts.resample("17min", origin="start").sum()
Out[342]:
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64

In [343]: ts.resample("17min", offset="23h30min").sum()
Out[343]:
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64

Note the use of 'start' for origin on the last example. In that case, origin will be set to the first value of the timeseries.
**Backward resample**

New in version 1.3.0.

Instead of adjusting the beginning of bins, sometimes we need to fix the end of the bins to make a backward resample with a given `freq`. The backward resample sets closed to 'right' by default since the last value should be considered as the edge point for the last bin.

We can set `origin` to 'end'. The value for a specific `Timestamp` index stands for the resample result from the current `Timestamp` minus `freq` to the current `Timestamp` with a right close.

```
In [344]: ts.resample('17min', origin='end').sum()
Out[344]:
2000-10-01 23:35:00   0
2000-10-01 23:52:00   18
2000-10-02 00:09:00   27
2000-10-02 00:26:00   63
Freq: 17T, dtype: int64
```

Besides, in contrast with the 'start_day' option, `end_day` is supported. This will set the origin as the ceiling midnight of the largest `Timestamp`.

```
In [345]: ts.resample('17min', origin='end_day').sum()
Out[345]:
2000-10-01 23:38:00   3
2000-10-01 23:55:00   15
2000-10-02 00:12:00   45
2000-10-02 00:29:00   45
Freq: 17T, dtype: int64
```

The above result uses 2000-10-02 00:29:00 as the last bin's right edge since the following computation.

```
In [346]: ceil_mid = rng.max().ceil('D')
In [347]: freq = pd.offsets.Minute(17)
In [348]: bin_res = ceil_mid - freq * ((ceil_mid - rng.max()) // freq)
In [349]: bin_res
Out[349]: Timestamp('2000-10-02 00:29:00')
```
2.20.11 Time span representation

Regular intervals of time are represented by Period objects in pandas while sequences of Period objects are collected in a PeriodIndex, which can be created with the convenience function period_range.

Period

A Period represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via freq keyword using a frequency alias like below. Because freq represents a span of Period, it cannot be negative like “-3D”.

```python
In [350]: pd.Period("2012", freq="A-DEC")
Out[350]: Period('2012', 'A-DEC')

In [351]: pd.Period("2012-1-1", freq="D")
Out[351]: Period('2012-01-01', 'D')

In [352]: pd.Period("2012-1-1 19:00", freq="H")
Out[352]: Period('2012-01-01 19:00', 'H')

In [353]: pd.Period("2012-1-1 19:00", freq="5H")
Out[353]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between Period with different freq (span).

```python
In [354]: p = pd.Period("2012", freq="A-DEC")

In [355]: p + 1
Out[355]: Period('2013', 'A-DEC')

In [356]: p - 3
Out[356]: Period('2009', 'A-DEC')

In [357]: p = pd.Period("2012-01", freq="2M")

In [358]: p + 2
Out[358]: Period('2012-05', '2M')

In [359]: p - 1
Out[359]: Period('2011-11', '2M')

In [360]: p == pd.Period("2012-01", freq="3M")
Out[360]: False
```

If Period freq is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, ValueError will be raised.

```python
In [361]: p = pd.Period("2014-07-01 09:00", freq="H")

In [362]: p + pd.offsets.Hour(2)
Out[362]: Period('2014-07-01 11:00', 'H')

In [363]: p + datetime.timedelta(minutes=120)
```

(continues on next page)
Out[363]: Period('2014-07-01 11:00', 'H')

In [364]: p + np.timedelta64(7200, "s")
Out[364]: Period('2014-07-01 11:00', 'H')

In [1]: p + pd.offsets.Minute(5)
Traceback...
ValueError: Input has different freq from Period(freq=H)

If Period has other frequencies, only the same offsets can be added. Otherwise, ValueError will be raised.

In [365]: p = pd.Period("2014-07", freq="M")
In [366]: p + pd.offsets.MonthEnd(3)
Out[366]: Period('2014-10', 'M')

In [1]: p + pd.offsets.MonthBegin(3)
Traceback...
ValueError: Input has different freq from Period(freq=M)

Taking the difference of Period instances with the same frequency will return the number of frequency units between them:

Out[367]: <10 * YearEnds: month=12>

PeriodIndex and period_range

Regular sequences of Period objects can be collected in a PeriodIndex, which can be constructed using the period_range convenience function:

In [368]: prng = pd.period_range("1/1/2011", "1/1/2012", freq="M")
In [369]: prng
  "2012-01"],
dtype='period[M]')

The PeriodIndex constructor can also be used directly:

In [370]: pd.PeriodIndex(["2011-1", "2011-2", "2011-3"], freq="M")
Out[370]: PeriodIndex(["2011-01", "2011-02", "2011-03"], dtype='period[M]')

Passing multiplied frequency outputs a sequence of Period which has multiplied span.

In [371]: pd.period_range(start="2014-01", freq="3M", periods=4)
If start or end are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the PeriodIndex constructor.

```
In [372]: pd.period_range(       
       .....: start=pd.Period("2017Q1", freq="Q"), end=pd.Period("2017Q2", freq="Q"),  
       .....: freq="M"  
       .....: )  
Out[372]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]')
```

Just like DatetimeIndex, a PeriodIndex can also be used to index pandas objects:

```
In [373]: ps = pd.Series(np.random.randn(len(prng)), prng)  
In [374]: ps  
Out[374]: 2011-01 -2.916901  
          2011-02 0.514474  
          2011-03 1.346470  
          2011-04 0.816397  
          2011-05 2.258648  
          2011-06 0.494789  
          2011-07 0.301239  
          2011-08 0.464776  
          2011-09 -1.393581  
          2011-10 0.056780  
          2011-11 0.197035  
          2011-12 2.261385  
          2012-01 -0.329583  
Freq: M, dtype: float64
```

PeriodIndex supports addition and subtraction with the same rule as Period.

```
In [375]: idx = pd.period_range("2014-07-01 09:00", periods=5, freq="H")  
In [376]: idx  
Out[376]: PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',  
           '2014-07-01 12:00', '2014-07-01 13:00'],  
           dtype='period[H]')
In [377]: idx + pd.offsets.Hour(2)  
Out[377]: PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',  
           '2014-07-01 14:00', '2014-07-01 15:00'],  
           dtype='period[H]')
In [378]: idx = pd.period_range("2014-07", periods=5, freq="M")  
In [379]: idx  
               'period[M]')
In [380]: idx + pd.offsets.MonthEnd(3)  
```

(continues on next page)
PeriodIndex has its own dtype named period, refer to *Period Dtypes*.

**Period dtypes**

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using *frequency strings*.

```python
In [381]: pi = pd.period_range("2016-01-01", periods=3, freq="M")

In [382]: pi
Out[382]: PeriodIndex(['2016-01', '2016-02', '2016-03'], dtype='period[M]')

In [383]: pi.dtype
Out[383]: period[M]
```

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like to_period():

```python
# change monthly freq to daily freq
In [384]: pi.astype("period[D]")
Out[384]: PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'], dtype='period[D]')

# convert to DatetimeIndex
In [385]: pi.astype("datetime64[ns]")
Out[385]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'], dtype='datetime64[ns]', freq='MS')

# convert to PeriodIndex
In [386]: dti = pd.date_range("2011-01-01", freq="M", periods=3)

In [387]: dti
Out[387]: DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01'], dtype='datetime64[ns]', freq='M')

In [388]: dti.astype("period[M]")
Out[388]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]')
```
**PeriodIndex partial string indexing**

PeriodIndex now supports partial string slicing with non-monotonic indexes.

New in version 1.1.0.

You can pass in dates and strings to `Series` and `DataFrame` with PeriodIndex, in the same manner as `DatetimeIndex`. For details, refer to `DatetimeIndex Partial String Indexing`.

```
In [389]: ps["2011-01"]
Out[389]: -2.9169013294054507

In [390]: ps[datetime.datetime(2011, 12, 25):]
Out[390]:
2011-12  2.261385
2012-01 -0.329583
Freq: M, dtype: float64

In [391]: ps["10/31/2011":"12/31/2011"]
Out[391]:
2011-10  0.056780
2011-11  0.197035
2011-12  2.261385
Freq: M, dtype: float64
```

Passing a string representing a lower frequency than `PeriodIndex` returns partial sliced data.

```
In [392]: ps["2011"]
Out[392]:
2011-01  -2.916901
2011-02   0.514474
2011-03  1.346470
2011-04  0.816397
2011-05  2.258648
2011-06  0.494789
2011-07  0.301239
2011-08  0.464776
2011-09 -1.393581
2011-10  0.056780
2011-11  0.197035
2011-12  2.261385
Freq: M, dtype: float64

In [393]: dfp = pd.DataFrame(
       ....:     np.random.randn(600, 1),
       ....:     columns=["A"],
       ....:     index=pd.period_range("2013-01-01 9:00", periods=600, freq="T"),
       ....:     )
       ....:

In [394]: dfp
Out[394]:
     A
2013-01-01  09:00 -0.538468
2013-01-01  09:01 -1.365819
```

(continues on next page)
In [395]: dfp.loc["2013-01-01 10H"]

Out[395]:

    A
2013-01-01 10:00  -0.308975
2013-01-01 10:01   0.542520
2013-01-01 10:02   1.061068
2013-01-01 10:03   0.754005
2013-01-01 10:04   0.352933
... ... 
2013-01-01 10:55  -0.865621
2013-01-01 10:56  -1.167818
2013-01-01 10:57  -2.081748
2013-01-01 10:58  -0.527146
2013-01-01 10:59   0.802298

[60 rows x 1 columns]

As with DatetimeIndex, the endpoints will be included in the result. The example below slices data starting from 10:00 to 11:59.

In [396]: dfp["2013-01-01 10H":"2013-01-01 11H"]

Out[396]:

    A
2013-01-01 10:00  -0.308975
2013-01-01 10:01   0.542520
2013-01-01 10:02   1.061068
2013-01-01 10:03   0.754005
2013-01-01 10:04   0.352933
... ... 
2013-01-01 11:55  -0.590204
2013-01-01 11:56   1.539990
2013-01-01 11:57  -1.224826
2013-01-01 11:58   0.578798
2013-01-01 11:59  -0.685496

[120 rows x 1 columns]
**Frequency conversion and resampling with PeriodIndex**

The frequency of Period and PeriodIndex can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

In [397]: p = pd.Period("2011", freq="A-DEC")

In [398]: p
Out[398]: Period('2011', 'A-DEC')

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or ending month:

In [399]: p.asfreq("M", how="start")
Out[399]: Period('2011-01', 'M')

In [400]: p.asfreq("M", how="end")
Out[400]: Period('2011-12', 'M')

The shorthands 's' and 'e' are provided for convenience:

In [401]: p.asfreq("M", "s")
Out[401]: Period('2011-01', 'M')

In [402]: p.asfreq("M", "e")
Out[402]: Period('2011-12', 'M')

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

In [403]: p = pd.Period("2011-12", freq="M")

In [404]: p.asfreq("A-NOV")
Out[404]: Period('2012', 'A-NOV')

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

In [405]: p = pd.Period("2012Q1", freq="Q-DEC")

In [406]: p.asfreq("Q", "s")
Out[406]: Period('2012-01-01', 'D')

In [407]: p.asfreq("Q", "e")
Out[407]: Period('2012-03-31', 'D')

Q-MAR defines fiscal year end in March:
pandas: powerful Python data analysis toolkit, Release 1.4.1

In [408]: p = pd.Period("2011Q4", freq="Q-MAR")

In [409]: p.asfreq("D", "s")
Out[409]: Period('2011-01-01', 'D')

In [410]: p.asfreq("D", "e")
Out[410]: Period('2011-03-31', 'D')

2.20.12 Converting between representations

Timestamped data can be converted to PeriodIndex-ed data using to_period and vice-versa using to_timestamp:

In [411]: rng = pd.date_range("1/1/2012", periods=5, freq="M")

In [412]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [413]: ts
Out[413]:
2012-01-31  1.931253
2012-02-29 -0.184594
2012-03-31  0.249656
2012-04-30 -0.978151
2012-05-31 -0.873389
Freq: M, dtype: float64

In [414]: ps = ts.to_period()

In [415]: ps
Out[415]:
2012-01  1.931253
2012-02 -0.184594
2012-03  0.249656
2012-04 -0.978151
2012-05 -0.873389
Freq: M, dtype: float64

In [416]: ps.to_timestamp()
Out[416]:
2012-01-01  1.931253
2012-02-01 -0.184594
2012-03-01  0.249656
2012-04-01 -0.978151
2012-05-01 -0.873389
Freq: MS, dtype: float64

Remember that 's' and 'e' can be used to return the timestamps at the start or end of the period:

In [417]: ps.to_timestamp("D", how="s")
Out[417]:
2012-01-01 1.931253
2012-02-01 -0.184594
2012-03-01 0.249656

(continues on next page)
Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [418]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")
In [419]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [420]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9
In [421]: ts.head()
Out[421]:
1990-03-01 09:00 -0.109291
1990-06-01 09:00 -0.637235
1990-09-01 09:00 -1.735925
1990-12-01 09:00 2.096946
1991-03-01 09:00 -1.039926
Freq: H, dtype: float64
```

2.20.13 Representing out-of-bounds spans

If you have data that is outside of the Timestamp bounds, see Timestamp limitations, then you can use a PeriodIndex and/or Series of Periods to do computations.

```
In [422]: span = pd.period_range("1215-01-01", "1381-01-01", freq="D")
In [423]: span
Out[423]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
           '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
           '1215-01-09', '1215-01-10',
           ...
           '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
           '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
           '1380-12-31', '1381-01-01'],
dtype='period[D]', length=60632)
```

To convert from an int64 based YYYYMMDD representation.

```
In [424]: s = pd.Series([20121231, 20141130, 99991231])
In [425]: s
Out[425]:
0   20121231
1   20141130
2   99991231
dtype: int64
```
In [426]: def conv(x):
   .....:     return pd.Period(year=x // 10000, month=x // 100 % 100, day=x % 100, freq="D")
   .....:
In [427]: s.apply(conv)
Out[427]:
0  2012-12-31
1  2014-11-30
2  9999-12-31
dtype: period[D]
In [428]: s.apply(conv)[2]
Out[428]: Period('9999-12-31', 'D')

These can easily be converted to a PeriodIndex:

In [429]: span = pd.PeriodIndex(s.apply(conv))
In [430]: span
Out[430]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'], dtype='period[D'])

2.20.14 Time zone handling

pandas provides rich support for working with timestamps in different time zones using the pytz and dateutil libraries or datetime.timezone objects from the standard library.

Working with time zones

By default, pandas objects are time zone unaware:

In [431]: rng = pd.date_range("3/6/2012 00:00", periods=15, freq="D")
In [432]: rng.tz
Out[432]: None

To localize these dates to a time zone (assign a particular time zone to a naive date), you can use the tz_localize method or the tz keyword argument in date_range(), Timestamp, or DatetimeIndex. You can either pass pytz or dateutil time zone objects or Olson time zone database strings. Olson time zone strings will return pytz time zone objects by default. To return dateutil time zone objects, append dateutil/ before the string.

- In pytz you can find a list of common (and less common) time zones using from pytz import common_timezones, all_timezones.
- dateutil uses the OS time zones so there isn’t a fixed list available. For common zones, the names are the same as pytz.

In [433]: import dateutil
# pytz
(continues on next page)
In [434]: rng_pytz = pd.date_range("3/6/2012 00:00", periods=3, freq="D", tz="Europe/London")

In [435]: rng_pytz.tz
Out[435]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [436]: rng_dateutil = pd.date_range("3/6/2012 00:00", periods=3, freq="D")

In [437]: rng_dateutil = rng_dateutil.tz_localize("dateutil/Europe/London")

In [438]: rng_dateutil.tz
Out[438]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [439]:
   ...: rng_utc = pd.date_range(
   ...:     "3/6/2012 00:00",
   ...:     periods=3,
   ...:     freq="D",
   ...:     tz=dateutil.tz.tzutc(),
   ...: )
   ...

In [440]: rng_utc.tz
Out[440]: tzutc()

New in version 0.25.0.

# datetime.timezone
In [441]: rng_utc = pd.date_range(
   ...:     "3/6/2012 00:00",
   ...:     periods=3,
   ...:     freq="D",
   ...:     tz=datetime.timezone.utc,
   ...: )
   ...

In [442]: rng_utc.tz
Out[442]: datetime.timezone.utc

Note that the UTC time zone is a special case in dateutil and should be constructed explicitly as an instance of dateutil.tz.tzutc. You can also construct other time zones objects explicitly first.

In [443]: import pytz

# pytz
In [444]: tz_pytz = pytz.timezone("Europe/London")

In [445]: rng_pytz = pd.date_range("3/6/2012 00:00", periods=3, freq="D")

In [446]: rng_pytz = rng_pytz.tz_localize(tz_pytz)

(continues on next page)
In [447]: rng_pytz.tz == tz_pytz
   Out[447]: True

# dateutil
In [448]: tz_dateutil = dateutil.tz.gettz("Europe/London")
In [449]: rng_dateutil = pd.date_range("3/6/2012 00:00", periods=3, freq="D", tz=tz_˓→dateutil)
In [450]: rng_dateutil.tz == tz_dateutil
   Out[450]: True

To convert a time zone aware pandas object from one time zone to another, you can use the tz_convert method.

In [451]: rng_pytz.tz_convert("US/Eastern")
   Out[451]:
   DatetimeIndex(['2012-03-05 19:00:00-05:00', '2012-03-06 19:00:00-05:00', '2012-03-07 19:00:00-05:00'],
               dtype='datetime64[ns, US/Eastern]', freq=None)

Note: When using pytz time zones, DatetimeIndex will construct a different time zone object than a Timestamp for the same time zone input. A DatetimeIndex can hold a collection of Timestamp objects that may have different UTC offsets and cannot be succinctly represented by one pytz time zone instance while one Timestamp represents one point in time with a specific UTC offset.

In [452]: dti = pd.date_range("2019-01-01", periods=3, freq="D", tz="US/Pacific")
In [453]: dti.tz
   Out[453]: <DstTzInfo 'US/Pacific' LMT-1 day, 16:07:00 STD>
In [454]: ts = pd.Timestamp("2019-01-01", tz="US/Pacific")
In [455]: ts.tz
   Out[455]: <DstTzInfo 'US/Pacific' PST-1 day, 16:00:00 STD>

Warning: Be wary of conversions between libraries. For some time zones, pytz and dateutil have different definitions of the zone. This is more of a problem for unusual time zones than for 'standard' zones like US/Eastern.

Warning: Be aware that a time zone definition across versions of time zone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See here for how to handle such a situation.

Warning: For pytz time zones, it is incorrect to pass a time zone object directly into the datetime.datetime constructor (e.g., datetime.datetime(2011, 1, 1, tzinfo=pytz.timezone('US/Eastern'))). Instead, the datetime needs to be localized using the localize method on the pytz time zone object.
**Warning:** Be aware that for times in the future, correct conversion between time zones (and UTC) cannot be guaranteed by any time zone library because a timezone’s offset from UTC may be changed by the respective government.

**Warning:** If you are using dates beyond 2038-01-18, due to current deficiencies in the underlying libraries caused by the year 2038 problem, daylight saving time (DST) adjustments to timezone aware dates will not be applied. If and when the underlying libraries are fixed, the DST transitions will be applied.

For example, for two dates that are in British Summer Time (and so would normally be GMT+1), both the following asserts evaluate as true:

```python
In [456]: d_2037 = "2037-03-31T010101"
In [457]: d_2038 = "2038-03-31T010101"
In [458]: DST = "Europe/London"
In [459]: assert pd.Timestamp(d_2037, tz=DST) != pd.Timestamp(d_2037, tz="GMT")
In [460]: assert pd.Timestamp(d_2038, tz=DST) == pd.Timestamp(d_2038, tz="GMT")
```

Under the hood, all timestamps are stored in UTC. Values from a time zone aware `DatetimeIndex` or `Timestamp` will have their fields (day, hour, minute, etc.) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```python
In [461]: rng_eastern = rng_utc.tz_convert("US/Eastern")
In [462]: rng_berlin = rng_utc.tz_convert("Europe/Berlin")
In [463]: rng_eastern[2]
Out[463]: Timestamp('2012-03-07 19:00:00-0500', tz='US/Eastern', freq='D')
In [464]: rng_berlin[2]
Out[464]: Timestamp('2012-03-08 01:00:00+0100', tz='Europe/Berlin', freq='D')
Out[465]: True
```

Operations between `Series` in different time zones will yield UTC `Series`, aligning the data on the UTC timestamps:

```python
In [466]: ts_utc = pd.Series(range(3), pd.date_range("20130101", periods=3, tz="UTC"))
In [467]: eastern = ts_utc.tz_convert("US/Eastern")
In [468]: berlin = ts_utc.tz_convert("Europe/Berlin")
In [469]: result = eastern + berlin
In [470]: result
Out[470]:
2013-01-01 00:00:00+00:00    0
```

(continues on next page)
To remove time zone information, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove the time zone yielding the local time representation. `tz_convert(None)` will remove the time zone after converting to UTC time.

```python
In [472]: didx = pd.date_range(start="2014-08-01 09:00", freq="H", periods=3, tz="US/Eastern")

In [473]: didx
Out[473]:
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00', '2014-08-01 11:00:00-04:00'],  
dtype='datetime64[ns, US/Eastern]', freq='H')

In [474]: didx.tz_localize(None)
Out[474]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00', '2014-08-01 11:00:00'],  
dtype='datetime64[ns]', freq=None)

In [475]: didx.tz_convert(None)
Out[475]:
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00', '2014-08-01 15:00:00'],  
dtype='datetime64[ns]', freq='H')

# tz_convert(None) is identical to tz_convert('UTC').tz_localize(None)
In [476]: didx.tz_convert("UTC").tz_localize(None)
Out[476]:
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00', '2014-08-01 15:00:00'],  
dtype='datetime64[ns]', freq=None)
```
Fold

New in version 1.1.0.

For ambiguous times, pandas supports explicitly specifying the keyword-only fold argument. Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time. Fold is supported only for constructing from naive \texttt{datetime.datetime} (see \texttt{datetime} documentation for details) or from \texttt{Timestamp} or for constructing from components (see below). Only \texttt{dateutil} timezones are supported (see \texttt{dateutil} documentation for dateutil methods that deal with ambiguous datetimes) as pytz timezones do not support fold (see \texttt{pytz} documentation for details on how \texttt{pytz} deals with ambiguous datetimes). To localize an ambiguous datetime with \texttt{pytz}, please use \texttt{Timestamp.tz_localize()}.

In general, we recommend to rely on \texttt{Timestamp.tz_localize()} when localizing ambiguous datetimes if you need direct control over how they are handled.

```
In [477]: pd.Timestamp(
    .....:      datetime.datetime(2019, 10, 27, 1, 30, 0, 0),
    .....:      tz="dateutil/Europe/London",
    .....:      fold=0,
    .....:      )
Out[477]: Timestamp('2019-10-27 01:30:00+0100', tz='dateutil//usr/share/zoneinfo/Europe/London')

In [478]: pd.Timestamp(
    .....:      year=2019,
    .....:      month=10,
    .....:      day=27,
    .....:      hour=1,
    .....:      minute=30,
    .....:      tz="dateutil/Europe/London",
    .....:      fold=1,
    .....:      )
Out[478]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil//usr/share/zoneinfo/Europe/London')
```

Ambiguous times when localizing

\texttt{tz_localize} may not be able to determine the UTC offset of a timestamp because daylight savings time (DST) in a local time zone causes some times to occur twice within one day (“clocks fall back”). The following options are available:

- 'raise': Raises a \texttt{pytz.AmbiguousTimeError} (the default behavior)
- 'infer': Attempt to determine the correct offset base on the monotonicity of the timestamps
- 'NaT': Replaces ambiguous times with \texttt{NaT}
- \texttt{bool}: True represents a DST time, False represents non-DST time. An array-like of bool values is supported for a sequence of times.

```
In [479]: rng_hourly = pd.DatetimeIndex(
    .....:      ["11/06/2011 00:00", "11/06/2011 01:00", "11/06/2011 01:00", "11/06/2011...
    .....:      02:00"]
```
This will fail as there are ambiguous times ('11/06/2011 01:00')

```python
In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try...
```

Handle these ambiguous times by specifying the following.

```python
In [480]: rng_hourly.tz_localize("US/Eastern", ambiguous="infer")
Out[480]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
               '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
          dtype='datetime64[ns, US/Eastern]', freq=None)

In [481]: rng_hourly.tz_localize("US/Eastern", ambiguous="NaT")
Out[481]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', 'NaT', 'NaT',
               '2011-11-06 02:00:00-05:00'],
          dtype='datetime64[ns, US/Eastern]', freq=None)

In [482]: rng_hourly.tz_localize("US/Eastern", ambiguous=[True, True, False, False])
Out[482]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
               '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
          dtype='datetime64[ns, US/Eastern]', freq=None)
```

### Nonexistent times when localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times (“clocks spring forward”). The behavior of localizing a timeseries with nonexistent times can be controlled by the `nonexistent` argument. The following options are available:

- 'raise': Raises a `pytz.NonExistentTimeError` (the default behavior)
- 'NaT': Replaces nonexistent times with NaT
- 'shift_forward': Shifts nonexistent times forward to the closest real time
- 'shift_backward': Shifts nonexistent times backward to the closest real time
- timedelta object: Shifts nonexistent times by the timedelta duration

```python
In [483]: dti = pd.date_range(start="2015-03-29 02:30:00", periods=3, freq="H")

# 2:30 is a nonexistent time
```

Localization of nonexistent times will raise an error by default.

```python
In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00
```

Transform nonexistent times to NaT or shift the times.
In [484]: dti
Out[484]:
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00', '2015-03-29 04:30:00'],
dtype='datetime64[ns]', freq='H')

In [485]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_forward")
Out[485]:
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00', '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [486]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_backward")
Out[486]:
DatetimeIndex(['2015-03-29 01:59:59.999999999+01:00', '2015-03-29 03:30:00+02:00', '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [487]: dti.tz_localize("Europe/Warsaw", nonexistent=pd.Timedelta(1, unit="H"))
Out[487]:
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00', '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [488]: dti.tz_localize("Europe/Warsaw", nonexistent="NaT")
Out[488]:
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00', '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

Time zone series operations

A Series with time zone naive values is represented with a dtype of datetime64[ns].

In [489]: s_naive = pd.Series(pd.date_range("20130101", periods=3))

In [490]: s_naive
Out[490]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
dtype: datetime64[ns]

A Series with a time zone aware values is represented with a dtype of datetime64[ns, tz] where tz is the time zone

In [491]: s_aware = pd.Series(pd.date_range("20130101", periods=3, tz="US/Eastern"))

In [492]: s_aware
Out[492]:
0  2013-01-01 00:00:00-05:00
(continues on next page)
Both of these `Series` time zone information can be manipulated via the `.dt` accessor, see the `dt accessor section`.
For example, to localize and convert a naive stamp to time zone aware.

```
In [493]: s_naive.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")
Out[493]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Time zone information can also be manipulated using the `astype` method. This method can convert between different time zone aware dtypes.

```
# convert to a new time zone
In [494]: s_aware.astype("datetime64[ns, CET"])
Out[494]:
0  2013-01-01 06:00:00+01:00
1  2013-01-02 06:00:00+01:00
2  2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

**Note:** Using `Series.to_numpy()` on a Series, returns a NumPy array of the data. NumPy does not currently support time zones (even though it is printing in the local time zone!), therefore an object array of Timestamps is returned for time zone aware data:

```
In [495]: s_naive.to_numpy()
Out[495]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
In [496]: s_aware.to_numpy()
Out[496]:
array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern'),
       Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern'),
       Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern')],
       dtype=object)
```

By converting to an object array of Timestamps, it preserves the time zone information. For example, when converting back to a Series:

```
In [497]: pd.Series(s_aware.to_numpy())
Out[497]:
0  2013-01-01 00:00:00-05:00
1  2013-01-02 00:00:00-05:00
2  2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

However, if you want an actual NumPy `datetime64[ns]` array (with the values converted to UTC) instead of an array
of objects, you can specify the `dtype` argument:

```python
In [498]: s_aware.to_numpy(dtype="datetime64[ns]"
Out[498]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

## 2.21 Time deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

Timedelta is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

### 2.21.1 Parsing

You can construct a Timedelta scalar through various arguments, including ISO 8601 Duration strings.

```python
In [1]: import datetime
# strings
In [2]: pd.Timedelta("1 days")
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta("1 days 00:00:00")
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta("1 days 2 hours")
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta("-1 days 2 min 3us")
Out[5]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit="d")
Out[7]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')

In [9]: pd.Timedelta(np.timedelta64(1, "ms"))
Out[9]: Timedelta('0 days 00:00:00.001000')
```

(continues on next page)
# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta("-1us")
Out[10]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta("nan")
Out[11]: NaT

In [12]: pd.Timedelta("nat")
Out[12]: NaT

# ISO 8601 Duration strings
In [13]: pd.Timedelta("P0DT0H1M0S")
Out[13]: Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta("P0DT0H0M0.000000123S")
Out[14]: Timedelta('0 days 00:00:00.000000123')

*DateOffsets* (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

In [15]: pd.Timedelta(pd.offsets.Second(2))
Out[15]: Timedelta('0 days 00:00:02')

Further, operations among the scalars yield another scalar Timedelta.

→Timedelta(
   .....:     "00:00:00.000123"
   .....: )
   .....:
Out[16]: Timedelta('2 days 00:00:02.000123')

to_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or Series from a recognized timedelta format / value into a Timedelta type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a TimedeltaIndex.

You can parse a single string to a Timedelta:

In [17]: pd.to_timedelta("1 days 06:05:01.00003")
Out[17]: Timedelta('1 days 06:05:01.000030')

In [18]: pd.to_timedelta("15.5us")
Out[18]: Timedelta('0 days 00:00:00.000015500')

or a list/array of strings:

In [19]: pd.to_timedelta(['"1 days 06:05:01.00003", "15.5us", "nan"'])
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
   dtype='timedelta64[ns]', freq=None)
The unit keyword argument specifies the unit of the Timedelta if the input is numeric:

```
In [20]: pd.to_timedelta(np.arange(5), unit="s")
Out[20]:
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
                '0 days 00:00:03', '0 days 00:00:04'],
               dtype='timedelta64[ns]', freq=None)
```

```
In [21]: pd.to_timedelta(np.arange(5), unit="d")
Out[21]:
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

**Warning:** If a string or array of strings is passed as an input then the `unit` keyword argument will be ignored. If a string without units is passed then the default unit of nanoseconds is assumed.

### Timedelta limitations

pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

```
In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224193')
```

```
In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days 23:47:16.854775807')
```

#### 2.21.2 Operations

You can operate on Series/DataFrames and construct timedelta64[ns] Series through subtraction operations on datetime64[ns] Series, or Timestamps.

```
In [24]: s = pd.Series(pd.date_range("2012-1-1", periods=3, freq="D"))
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
In [26]: df = pd.DataFrame({"A": s, "B": td})
```

```
In [27]: df
Out[27]:
   A         B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days
```

```
In [28]: df["C"] = df["A"] + df["B"]
```

```
In [29]: df
Out[29]:
   A         B    C
0 2012-01-01 0 days 2012-01-01
```
In [30]: df.dtypes
Out[30]:
A  datetime64[ns]
B  timedelta64[ns]
C  datetime64[ns]
dtype: object

In [31]: s - s.max()
Out[31]:
0   -2 days
1   -1 days
2    0 days
dtype: timedelta64[ns]

In [32]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[32]:
0  364 days 20:55:00
1  365 days 20:55:00
2  366 days 20:55:00
dtype: timedelta64[ns]

In [33]: s + pd.offsets.Minute(5)
Out[33]:
0  2012-01-01 00:05:00
1  2012-01-02 00:05:00
2  2012-01-03 00:05:00
dtype: datetime64[ns]

In [34]: s + pd.offsets.Minute(5) + pd.offsets.Milli(5)
Out[34]:
0  2012-01-01 00:05:00.005
1  2012-01-02 00:05:00.005
2  2012-01-03 00:05:00.005
dtype: datetime64[ns]

Operations with scalars from a timedelta64[ns] series:

In [36]: y = s - s[0]

In [37]: y
Out[37]:
0   0 days

Series of timedeltas with NaT values are supported:

```
In [38]: y = s - s.shift()

In [39]: y
Out[39]:
    0   NaT
    1   1 days
    2   1 days
 dtype: timedelta64[ns]
```

Elements can be set to NaT using np.nan analogously to datetimes:

```
In [40]: y[1] = np.nan

In [41]: y
Out[41]:
    0   NaT
    1   NaT
    2   1 days
 dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```
In [42]: s.max() - s
Out[42]:
    0   2 days
    1   1 days
    2    0 days
 dtype: timedelta64[ns]
```

```
In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[43]:
    0  -365 days +03:05:00
    1  -366 days +03:05:00
    2  -367 days +03:05:00
 dtype: timedelta64[ns]
```

```
In [44]: datetime.timedelta(minutes=5) + s
Out[44]:
    0 2012-01-01 00:05:00
    1 2012-01-02 00:05:00
    2 2012-01-03 00:05:00
 dtype: datetime64[ns]
```

min, max and the corresponding idxmin, idxmax operations are supported on frames:

```
In [45]: A = s - pd.Timestamp("20120101") - pd.Timedelta("00:05:05")
```

(continues on next page)
In [46]: B = s - pd.Series(pd.date_range("2012-1-2", periods=3, freq="D"))

In [47]: df = pd.DataFrame({"A": A, "B": B})

In [48]: df
Out[48]:
   A      B
0 -1 days +23:54:55 -1 days
1  0 days 23:54:55 -1 days
2  1 days 23:54:55 -1 days

In [49]: df.min()
Out[49]:
   A      B
0 -1 days +23:54:55
1 -1 days +00:00:00
dtype: timedelta64[ns]

In [50]: df.min(axis=1)
Out[50]:
0 -1 days
1 -1 days
2 -1 days
dtype: timedelta64[ns]

In [51]: df.idxmin()
Out[51]:
   A 0
   B 0
dtype: int64

In [52]: df.idxmax()
Out[52]:
   A 2
   B 0
dtype: int64

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

In [53]: df.min().max()
Out[53]: Timedelta('-1 days +23:54:55')

In [54]: df.min(axis=1).min()
Out[54]: Timedelta('-1 days +00:00:00')

In [55]: df.min().idxmax()
Out[55]: 'A'

In [56]: df.min(axis=1).idxmin()
Out[56]: 0

You can fillna on timedeltas, passing a timedelta to get a particular value.
You can also negate, multiply and use abs on Timedeltas:

```
In [60]: td1 = pd.Timedelta("-1 days 2 hours 3 seconds")
In [61]: td1
Out[61]: Timedelta('-2 days +21:59:57')
In [62]: -1 * td1
Out[62]: Timedelta('1 days 02:00:03')
In [63]: -td1
Out[63]: Timedelta('1 days 02:00:03')
In [64]: abs(td1)
Out[64]: Timedelta('1 days 02:00:03')
```

### 2.21.3 Reductions

Numeric reduction operation for timedelta64[ns] will return Timedelta objects. As usual NaT are skipped during evaluation.

```
In [65]: y2 = pd.Series(
    ....:     pd.to_timedelta(["-1 days +00:00:05", "nat", "-1 days +00:00:05", "1 days"])
    ....: )
    ....:
In [66]: y2
Out[66]:
0     -1 days +00:00:05
1       NaT
2     -1 days +00:00:05
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

3 1 days 00:00:00
dtype: timedelta64[ns]

In [67]: y2.mean()
Out[67]: Timedelta('-1 days +16:00:03.333333334')

In [68]: y2.median()
Out[68]: Timedelta('-1 days +00:00:05')

In [69]: y2.quantile(0.1)
Out[69]: Timedelta('-1 days +00:00:05')

In [70]: y2.sum()
Out[70]: Timedelta('-1 days +00:00:10')

2.21.4 Frequency conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

In [71]: december = pd.Series(pd.date_range("20121201", periods=4))
In [72]: january = pd.Series(pd.date_range("20130101", periods=4))
In [73]: td = january - december
In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)
In [75]: td[3] = np.nan
In [76]: td
Out[76]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3  NaT
dtype: timedelta64[ns]

# to days
In [77]: td / np.timedelta64(1, "D")
Out[77]:
0  31.000000
1  31.000000
2  31.003507
3  NaN
dtype: float64

In [78]: td.astype("timedelta64[D]"")
Out[78]:
0  31.0

(continues on next page)
1 31.0
2 31.0
3 NaN
dtype: float64

# to seconds
In [79]: td / np.timedelta64(1, "s")
Out[79]:
0 2678400.0
1 2678400.0
2 2678703.0
3 NaN
dtype: float64

In [80]: td.astype(\"timedelta64[s]\")
Out[80]:
0 2678400.0
1 2678400.0
2 2678703.0
3 NaN
dtype: float64

# to months (these are constant months)
In [81]: td / np.timedelta64(1, "M")
Out[81]:
0 1.018501
1 1.018501
2 1.018617
3 NaN
dtype: float64

Dividing or multiplying a timedelta64[ns] Series by an integer or integer Series yields another timedelta64[ns] dtypes Series.

In [82]: td * -1
Out[82]:
0 -31 days +00:00:00
1 -31 days +00:00:00
2 -32 days +23:54:57
3 NaN
dtype: timedelta64[ns]

In [83]: td * pd.Series([1, 2, 3, 4])
Out[83]:
0 31 days 00:00:00
1 62 days 00:00:00
2 93 days 00:15:09
3 NaN
dtype: timedelta64[ns]

Rounded division (floor-division) of a timedelta64[ns] Series by a scalar Timedelta gives a series of integers.
The mod (%) and divmod operations are defined for Timedelta when operating with another timedelta-like or with a numeric argument.

```python
In [86]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[86]: Timedelta('0 days 01:00:00')
```

```python
# divmod against a timedelta-like returns a pair (int, Timedelta)
In [87]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[87]: (10, Timedelta('0 days 00:10:00'))
```

```python
# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [88]: divmod(pd.Timedelta(hours=25), 86400000000000)
Out[88]: (Timedelta('0 days 00:00:00.000000001'), Timedelta('0 days 01:00:00'))
```

### 2.21.5 Attributes

You can access various components of the Timedelta or TimedeltaIndex directly using the attributes `days`, `seconds`, `microseconds`, `nanoseconds`. These are identical to the values returned by `datetime.timedelta`, in that, for example, the `.seconds` attribute represents the number of seconds >= 0 and < 1 day. These are signed according to whether the Timedelta is signed.

These operations can also be directly accessed via the `.dt` property of the Series as well.

**Note:** Note that the attributes are NOT the displayed values of the Timedelta. Use `.components` to retrieve the displayed values.

For a Series:

```python
In [89]: td.dt.days
Out[89]:
   0   31.0
   1   31.0
   2   31.0
   3  NaN
dtype: float64
```
You can access the value of the fields for a scalar Timedelta directly.

```python
In [91]: tds = pd.Timedelta("31 days 5 min 3 sec")

In [92]: tds.days
Out[92]: 31

In [93]: tds.seconds
Out[93]: 303

In [94]: (-tds).seconds
Out[94]: 86097
```

You can use the `.components` property to access a reduced form of the timedelta. This returns a DataFrame indexed similarly to the Series. These are the displayed values of the Timedelta.

```python
In [95]: tds.dt.components
Out[95]:
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0   31.0     0.0       0.0       0.0            0             0            0
1   31.0     0.0       0.0       0.0            0             0            0
2   31.0     0.0       5.0       3.0            0             0            0
3    NaN     NaN       NaN       NaN            NaN            NaN            NaN
```

You can convert a Timedelta to an ISO 8601 Duration string with the `.isoformat` method.

```python
In [97]: pd.Timedelta(
   ....:   days=6, minutes=50, seconds=3, milliseconds=10, microseconds=10,
   ....:   nanoseconds=12)
   ....: ).isoformat()
Out[97]: 'P6DT0H50M3.010010012S'
```
2.21.6 TimedeltaIndex

To generate an index with time delta, you can use either the TimedeltaIndex or the timedelta_range() constructor.

Using TimedeltaIndex you can pass string-like, Timedelta, timedelta, or np.timedelta64 objects. Passing np.nan/pd.NaT/nat will represent missing values.

```python
In [98]: pd.TimedeltaIndex(
   ....: ['1 days',
   ....:  '1 days, 00:00:05',
   ....:  np.timedelta64(2, "D"),
   ....:  datetime.timedelta(days=2, seconds=2),
   ....: ]
   ....: )
Out[98]: TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05',
   '2 days 00:00:00', '2 days 00:00:02'],
   dtype='timedelta64[ns]', freq=None)
```

The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```python
In [99]: pd.TimedeltaIndex(['0 days', '10 days', '20 days'], freq="infer")
Out[99]: TimedeltaIndex(['0 days', '10 days', '20 days'],
   dtype='timedelta64[ns]', freq='10D')
```

Generating ranges of time deltas

Similar to date_range(), you can construct regular ranges of a TimedeltaIndex using timedelta_range(). The default frequency for timedelta_range is calendar day:

```python
In [100]: pd.timedelta_range(start="1 days", periods=5)
Out[100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
   dtype='timedelta64[ns]', freq='D')
```

Various combinations of start, end, and periods can be used with timedelta_range:

```python
In [101]: pd.timedelta_range(start="1 days", end="5 days")
Out[101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
   dtype='timedelta64[ns]', freq='D')
```

```python
In [102]: pd.timedelta_range(end="10 days", periods=4)
Out[102]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'],
   dtype='timedelta64[ns]', freq='D')
```

The freq parameter can passed a variety of frequency aliases:

```python
In [103]: pd.timedelta_range(start="1 days", end="2 days", freq="30T")
Out[103]: TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
   '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
   '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
   '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00'],
   dtype='timedelta64[ns]', freq='30T')
```

(continues on next page)
1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
'1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
'1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
'1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
'1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
'1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
'1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
'1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
'1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
'1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
'1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
'1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
'1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
'2 days 00:00:00'],
dtype='timedelta64[ns]', freq='30T')

In [104]: pd.timedelta_range(start="1 days", periods=5, freq="2D5H")
Out[104]:
TimedeltaIndex(["1 days 00:00:00", '3 days 05:00:00', '5 days 10:00:00',
'7 days 15:00:00', '9 days 20:00:00'],
dtype='timedelta64[ns]', freq='53H')

Specifying start, end, and periods will generate a range of evenly spaced timedeltas from start to end inclusively, with periods number of elements in the resulting TimedeltaIndex:

In [105]: pd.timedelta_range("0 days", "4 days", periods=5)
Out[105]:
TimedeltaIndex(["0 days", '1 days', '2 days', '3 days', '4 days'], dtype=
˓to'timedelta64[ns]', freq=None)

In [106]: pd.timedelta_range("0 days", "4 days", periods=10)
Out[106]:
TimedeltaIndex(["0 days 00:00:00", '0 days 10:40:00', '0 days 21:20:00',
'1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
'2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
'4 days 00:00:00'],
dtype='timedelta64[ns]', freq=None)

Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

In [107]: s = pd.Series(
      ......: np.arange(100),
      ......: index=pd.timedelta_range("1 days", periods=100, freq="h"),
      ......: )
      ......:

In [108]: s
Out[108]:
1 days 00:00:00  0

(continues on next page)
Selections work similarly, with coercion on string-likes and slices:

```python
In [109]: s["1 day":"2 day"]
Out[109]:
1 days 00:00:00 0
1 days 01:00:00 1
1 days 02:00:00 2
1 days 03:00:00 3
1 days 04:00:00 4
...
2 days 19:00:00 43
2 days 20:00:00 44
2 days 21:00:00 45
2 days 22:00:00 46
2 days 23:00:00 47
Freq: H, Length: 48, dtype: int64
```

```python
In [110]: s["1 day 01:00:00"]
Out[110]: 1
```

```python
In [111]: s[pd.Timedelta("1 day 1h")]
Out[111]: 1
```

Furthermore you can use partial string selection and the range will be inferred:

```python
In [112]: s["1 day":"1 day 5 hours"]
Out[112]:
1 days 00:00:00 0
1 days 01:00:00 1
1 days 02:00:00 2
1 days 03:00:00 3
1 days 04:00:00 4
1 days 05:00:00 5
Freq: H, dtype: int64
```
Operations

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```python
In [113]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])
Out[113]: TimedeltaIndex(['1 days', NaT, '2 days'], dtype='timedelta64[ns]', freq=None)

In [114]: tdi.to_list()
Out[114]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [115]: dti = pd.date_range('20130101', periods=3)
Out[115]: [Timestamp('2013-01-01 00:00:00', freq='D'),
           Timestamp('2013-01-02 00:00:00', freq='D'),
           Timestamp('2013-01-03 00:00:00', freq='D')]

In [117]: (dti + tdi).to_list()
Out[117]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [118]: (dti - tdi).to_list()
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

Conversions

Similarly to frequency conversion on a Series above, you can convert these indices to yield another Index.

```python
In [119]: tdi / np.timedelta64(1, 's')
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

In [120]: tdi.astype('timedelta64[s]')
Out[120]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

Scalars type ops work as well. These can potentially return a different type of index.

```python
# adding or timedelta and date -> datelike
In [121]: tdi + pd.Timestamp('20130101')
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]', freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [122]: (pd.Timestamp('20130101') - tdi).to_list()
Out[122]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [123]: tdi + pd.Timedelta('10 days')
Out[123]: TimedeltaIndex(['10 days', NaT, '12 days'], dtype='timedelta64[ns]', freq=None)

# division can result in a Timedelta if the divisor is an integer
In [124]: tdi / 2
Out[124]: TimedeltaIndex(['0 days 12:00:00', 'NaT', '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)
```

(continues on next page)
2.21.7 Resampling

Similar to timeseries resampling, we can resample with a TimedeltaIndex.

```
In [126]: s.resample("D").mean()
Out[126]:
1 days    11.5
2 days    35.5
3 days    59.5
4 days    83.5
5 days    97.5
Freq: D, dtype: float64
```

2.22 Options and settings

2.22.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```
In [1]: import pandas as pd
In [2]: pd.options.display.max_rows
Out[2]: 15
In [3]: pd.options.display.max_rows = 999
In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

Note: Developers can check out `pandas/core/config_init.py` for more information.

All of the functions above accept a regexp pattern (re.search style) as an argument, and so passing in a substring will work - as long as it is unambiguous:
In [5]: pd.get_option("display.chop_threshold")

In [6]: pd.set_option("display.chop_threshold", 2)

In [7]: pd.get_option("display.chop_threshold")
Out[7]: 2

In [8]: pd.set_option("chop", 4)

In [9]: pd.get_option("display.chop_threshold")
Out[9]: 4

The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```python
In [10]: try:
    ....:     pd.get_option("max")
    ....: except KeyError as e:
    ....:     print(e)
    ....:
'Pattern matched multiple keys'
```

**Note:** Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

### 2.22.2 Getting and setting options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`.

```python
In [11]: pd.get_option("mode.sim_interactive")
Out[11]: False

In [12]: pd.set_option("mode.sim_interactive", True)

In [13]: pd.get_option("mode.sim_interactive")
Out[13]: True
```

**Note:** The option 'mode.sim_interactive' is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```python
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999
```

(continues on next page)
In [17]: pd.reset_option("display.max_rows")
In [18]: pd.get_option("display.max_rows")
Out[18]: 60

It's also possible to reset multiple options at once (using a regex):

In [19]: pd.reset_option("^display")

option_context context manager has been exposed through the top-level API, allowing you to execute code with
given option values. Option values are restored automatically when you exit the with block:

In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
   ....:   print(pd.get_option("display.max_rows"))
   ....:   print(pd.get_option("display.max_columns"))
   ....: 10
   5
In [21]: print(pd.get_option("display.max_rows"))
60
In [22]: print(pd.get_option("display.max_columns"))
0

2.22.3 Setting startup options in Python/IPython environment

Using startup scripts for the Python/IPython environment to import pandas and set options makes working with pandas
more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where
the startup folder is in a default IPython profile can be found at:

$IPYTHONDIR/profile_default/startup

More information can be found in the IPython documentation. An example startup script for pandas is displayed below:

import pandas as pd
pd.set_option("display.max_rows", 999)
pd.set_option("display.precision", 5)

2.22.4 Frequently used options

The following is a walk-through of the more frequently used display options.
display.max_rows and display.max_columns sets the maximum number of rows and columns displayed when a
frame is pretty-printed. Truncated lines are replaced by an ellipsis.
In [25]: df
Out[25]:
       0      1
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771

In [26]: pd.set_option("display.max_rows", 5)

In [27]: df
Out[27]:
       0      1
0  0.469112 -0.282863
1 -1.509059 -1.135632
...     ...     ...
5 -0.494929  1.071804
6  0.721555 -0.706771
[7 rows x 2 columns]

In [28]: pd.reset_option("display.max_rows")

Once the display.max_rows is exceeded, the display.min_rows options determines how many rows are shown in the truncated repr.

In [29]: pd.set_option("display.max_rows", 8)

In [30]: pd.set_option("display.min_rows", 4)

# below max_rows -> all rows shown
In [31]: df = pd.DataFrame(np.random.randn(7, 2))

In [32]: df
Out[32]:
       0      1
0 -1.039575  0.271860
1 -0.424972  0.567020
2  0.276232 -1.087401
3 -0.673690  0.113648
4 -1.478427  0.524988
5  0.404705  0.577046
6 -1.715002 -1.039268

# above max_rows -> only min_rows (4) rows shown
In [33]: df = pd.DataFrame(np.random.randn(9, 2))

In [34]: df
Out[34]:
(continues on next page)
0 1
0 -0.370647 -1.157892 1 -1.344312 0.844885 
. . . 
7 0.276662 -0.472035 8 -0.013960 -0.362543

[9 rows x 2 columns]

In [35]: pd.reset_option("display.max_rows")
In [36]: pd.reset_option("display.min_rows")

display.expand_frame_repr allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

In [37]: df = pd.DataFrame(np.random.randn(5, 10))
In [38]: pd.set_option("expand_frame_repr", True)
In [39]: df
Out[39]:
   0     1     2     3     4     5     6     7

memory usage: 928.0 bytes

In [62]: pd.reset_option("max_info_columns")

display.max_info_rows: df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. Note that you can specify the option df.info(null_counts=True) to override on showing a particular frame.

In [63]: df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))

### 2.22.5 Available options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>display.chop_threshold</td>
<td>None</td>
<td>If set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends.</td>
</tr>
<tr>
<td>display.colheader_justify</td>
<td>right</td>
<td>Controls the justification of column headers. used by DataFrameFormatter.</td>
</tr>
<tr>
<td>display.column_space</td>
<td>12</td>
<td>No description available.</td>
</tr>
<tr>
<td>display.date_dayfirst</td>
<td>False</td>
<td>When True, prints and parses dates with the day first, eg 20/01/2005</td>
</tr>
<tr>
<td>display.date_yearfirst</td>
<td>False</td>
<td>When True, prints and parses dates with the year first, eg 2005/01/20</td>
</tr>
<tr>
<td>display.encoding</td>
<td>UTF-8</td>
<td>Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console.</td>
</tr>
<tr>
<td>display.expand_frame_repr</td>
<td>True</td>
<td>Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width.</td>
</tr>
</tbody>
</table>

<td>If set to True will render \toprule, \midrule, and \bottomrule by default.</td>
</tr>
</tbody>
</table>
2.22.6 Number formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the set_options API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```
In [87]: import numpy as np
In [88]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)
In [89]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
In [90]: s / 1.0e3
Out[90]:
a  303.638u
b - 721.084u
c - 622.696u
d  648.250u
e  -1.945m
dtype: float64
In [91]: s / 1.0e6
Out[91]:
a  303.638n
b - 721.084n
c - 622.696n
d  648.250n
e  -1.945u
dtype: float64
```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

2.22.7 Unicode formatting

**Warning**: Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note**: Screen captures are attached for each output to show the actual results.

```
In [92]: df = pd.DataFrame({'"UK": ["UK", ""], """: ["Alice", ""]})
In [93]: df
Out[93]:
```

(continues on next page)
Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to True. However, this will result in longer render times than the standard `len` function.

```python
In [94]: pd.set_option("display.unicode.east_asian_width", True)
In [95]: df
Out[95]:
    0  UK  Alice
    1

>>> df = pd.DataFrame({u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
    名前  国籍
     0  Alice  UK
     1  しのぶ  日本
```

Enabling `display.unicode.east_asian_width` makes pandas interpret these characters' widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

```python
In [96]: df
Out[96]:
    0  UK  Alice
    1
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```python
In [97]: df = pd.DataFrame({"a": ["xxx", "¡¡"], "b": ["yyy", "¡¡"]})
In [98]: df
Out[98]:
    a     b
    0  xxx  yyy
    1   ¡¡  ¡¡
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```python
In [99]: df
```

(continues on next page)
2.22.8 Table schema display

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [100]: pd.set_option("display.html.table_schema", True)
```

Only 'display.max_rows' are serialized and published.

2.23 Enhancing performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas `DataFrame` using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the `DataFrame`. Using `pandas.eval()` we will speed up a sum by an order of ~2.

**Note:** In addition to following the steps in this tutorial, users interested in enhancing performance are highly encouraged to install the recommended dependencies for pandas. These dependencies are often not installed by default, but will offer speed improvements if present.

2.23.1 Cython (writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to Cython.

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It’s always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an example from the Cython documentation but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.
Pure Python

We have a DataFrame to which we want to apply a function row-wise.

```python
In [1]: df = pd.DataFrame(
    ...:     {
    ...:         "a": np.random.randn(1000),
    ...:         "b": np.random.randn(1000),
    ...:         "N": np.random.randint(100, 1000, (1000)),
    ...:         "x": "x",
    ...:     }
    ...: )
    ...

In [2]: df
Out[2]:
       a       b       N   x
0  0.469112 -0.218470  585  x
1 -0.282863 -0.061645  841  x
2 -1.509059 -0.723780  251  x
3 -1.135632  0.551225  972  x
4  1.212112 -0.497767  181  x
   ...     ...     ... ...
995 -1.512743  0.874737  374  x
996  0.933753  1.120790  246  x
997 -0.308013  0.198768  157  x
998 -0.079915  1.757555  977  x
999 -1.010589  1.115680  770  x
[1000 rows x 4 columns]
```

Here's the function in pure Python:

```python
In [3]: def f(x):
    ...:     return x * (x - 1)
    ...

In [4]: def integrate_f(a, b, N):
    ...:     s = 0
    ...:     dx = (b - a) / N
    ...:     for i in range(N):
    ...:         s += f(a + i * dx)
    ...:     return s * dx
    ...
```

We achieve our result by using apply (row-wise):

```python
In [7]: %timeit df.apply(lambda x: integrate_f(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 174 ms per loop
```

But clearly this isn’t fast enough for us. Let’s take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the prun ipython magic function:
By far the majority of time is spent inside either `integrate_f` or `f`, hence we’ll concentrate our efforts cythonizing these two functions.

### Plain Cython

First we’re going to need to import the Cython magic function to IPython:

```
In [6]: %load_ext Cython
```

Now, let’s simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```
In [7]: %%cython
    ...: def f_plain(x):
    ...:     return x * (x - 1)
    ...: def integrate_f_plain(a, b, N):
    ...:     s = 0
    ...:     dx = (b - a) / N
    ...:     for i in range(N):
    ...:         s += f_plain(a + i * dx)
    ...:     return s * dx
```

**Note:** If you’re having trouble pasting the above into your ipython, you may need to be using bleeding edge IPython for paste to play well with cell magics.

```
In [4]: %timeit df.apply(lambda x: integrate_f_plain(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 85.5 ms per loop
```

Already this has shaved a third off, not too bad for a simple copy and paste.
Adding type

We get another huge improvement simply by providing type information:

```python
In [8]: %cython
cdef double f_typed(double x) except? -2:
    return x * (x - 1)
cdef double integrate_f_typed(double a, double b, int N):
    cdef int i
    cdef double s, dx
    s = 0
dx = (b - a) / N
for i in range(N):
    s += f_typed(a + i * dx)
return s * dx
```

```python
In [4]: %timeit df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 20.3 ms per loop
```

Now, we’re talking! It’s now over ten times faster than the original Python implementation, and we haven’t really modified the code. Let’s have another look at what’s eating up time:

```python
In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
85918 function calls (85900 primitive calls) in 0.052 seconds
Ordered by: internal time
List reduced from 221 to 4 due to restriction <4>
ncalls tottime percall cumtime percall filename:lineno(function)
3000 0.006 0.000 0.031 0.000 series.py:943(__getitem__)
3000 0.004 0.000 0.018 0.000 series.py:1052(_get_value)
16189 0.003 0.000 0.004 0.000 {built-in method builtins.isinstance}
3000 0.003 0.000 0.005 0.000 base.py:5646(_get_values_for_loc)
```

Using ndarray

It’s calling series... a lot! It’s creating a Series from each row, and get-ting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

**Note:** We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```python
In [10]: %cython
cimport numpy as np
cdef double f_typed(double x) except? -2:
    return x * (x - 1)
cdef double integrate_f_typed(double a, double b, int N):
    cdef int i
    cdef double s, dx
```

(continues on next page)
The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the zeros array.

**Warning:** You can not pass a `Series` directly as a `ndarray` typed parameter to a Cython function. Instead pass the actual `ndarray` using the `Series.to_numpy()`. The reason is that the Cython definition is specific to an `ndarray` and not the passed `Series`.

So, do not do this:

```
apply_integrate_f(df["a"], df["b"], df["N"])
```

But rather, use `Series.to_numpy()` to get the underlying `ndarray`:

```
apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
```

**Note:** Loops like this would be extremely slow in Python, but in Cython looping over NumPy arrays is fast.

```
In [4]: %timeit apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
1000 loops, best of 3: 1.25 ms per loop
```

We’ve gotten another big improvement. Let’s check again where the time is spent:

```
In [11]: %prun -l 4 apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
200 function calls in 0.002 seconds

Ordered by: internal time
List reduced from 53 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
      1    0.001    0.001    0.000    0.000 {built-in method _cython_magic_
...ddc107c474f1147882a8a0afe7a24e2.apply_integrate_f}
```
As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

**More advanced techniques**

There is still hope for improvement. Here’s an example of using some more advanced Cython techniques:

```cython
In [12]: %cython
    ....: cimport cython
    ....: cimport numpy as np
    ....: import numpy as np
    ....: cdef double f_typed(double x) except? -2:
    ....:     return x * (x - 1)
    ....: cpdef double integrate_f_typed(double a, double b, int N):
    ....:     cdef int i
    ....:     cdef double s, dx
    ....:     s = 0
    ....:     dx = (b - a) / N
    ....:     for i in range(N):
    ....:         s += f_typed(a + i * dx)
    ....:     return s * dx
    ....: @cython.boundscheck(False)
    ....: @cython.wraparound(False)
    ....: cpdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
    ....:                                             np.ndarray[double] col_b,
    ....:                                             np.ndarray[int] col_N):
    ....:     cdef int i, n = len(col_N)
    ....:     assert len(col_a) == len(col_b) == n
    ....:     cdef np.ndarray[double] res = np.empty(n)
    ....:     for i in range(n):
    ....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
    ....:     return res

In [4]: %timeit apply_integrate_f_wrap(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
1000 loops, best of 3: 987 us per loop
```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn’t checked. For more about boundscheck and wraparound, see the Cython docs on compiler directives.
2.23.2 Numba (JIT compilation)

An alternative to statically compiling Cython code is to use a dynamic just-in-time (JIT) compiler with Numba.

Numba allows you to write a pure Python function which can be JIT compiled to native machine instructions, similar in performance to C, C++ and Fortran, by decorating your function with @jit.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycc tool). Numba supports compilation of Python to run on either CPU or GPU hardware and is designed to integrate with the Python scientific software stack.

Note: The @jit compilation will add overhead to the runtime of the function, so performance benefits may not be realized especially when using small data sets. Consider caching your function to avoid compilation overhead each time your function is run.

Numba can be used in 2 ways with pandas:

1. Specify the engine="numba" keyword in select pandas methods
2. Define your own Python function decorated with @jit and pass the underlying NumPy array of Series or DataFrame (using to_numpy()) into the function

pandas Numba Engine

If Numba is installed, one can specify engine="numba" in select pandas methods to execute the method using Numba. Methods that support engine="numba" will also have an engine_kwargs keyword that accepts a dictionary that allows one to specify "nogil", "nopython" and "parallel" keys with boolean values to pass into the @jit decorator. If engine_kwargs is not specified, it defaults to {"nogil": False, "nopython": True, "parallel": False} unless otherwise specified.

In terms of performance, the first time a function is run using the Numba engine will be slow as Numba will have some function compilation overhead. However, the JIT compiled functions are cached, and subsequent calls will be fast. In general, the Numba engine is performant with a larger amount of data points (e.g. 1+ million).

In [1]: data = pd.Series(range(1_000_000))  # noqa: E225
In [2]: roll = data.rolling(10)
In [3]: def f(x):
    ...:     return np.sum(x) + 5
# Run the first time, compilation time will affect performance
In [4]: %timeit -r 1 -n 1 roll.apply(f, engine='numba', raw=True)
1.23 s ± 0 ns per loop (mean ± std. dev. of 1 run, 1 loop each)
# Function is cached and performance will improve
In [5]: %timeit roll.apply(f, engine='numba', raw=True)
188 ms ± 1.93 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)
In [6]: %timeit roll.apply(f, engine='cython', raw=True)
3.92 s ± 59 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
Custom Function Examples

A custom Python function decorated with @jit can be used with pandas objects by passing their NumPy array representations with to_numpy().

```python
import numba

def double_every_value_nonumba(x):
    return x * 2
```

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following example of doubling each observation:

```python
import numba

def double_every_value_numba(x):
    return x * 2
```

In this example, using Numba was faster than Cython.

In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop

(continues on next page)
@numba.vectorize
def double_every_value_withnumba(x): # noqa E501
    return x * 2

# Custom function without numba
In [5]: %timeit df["col1_doubled"] = df["a"].apply(double_every_value_nonumba) # noqa
   →
    1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df["col1_doubled"] = df["a"] * 2
    1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit df["col1_doubled"] = double_every_value_withnumba(df["a"].to_numpy())
    1000 loops, best of 3: 145 us per loop

Caveats

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. If you try to @jit a function that contains unsupported Python or NumPy code, compilation will revert object mode which will mostly likely not speed up your function. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument nopython=True (e.g. @jit(nopython=True)). For more on troubleshooting Numba modes, see the Numba troubleshooting page.

Using parallel=True (e.g. @jit(parallel=True)) may result in a SIGABRT if the threading layer leads to unsafe behavior. You can first specify a safe threading layer before running a JIT function with parallel=True.

Generally if the you encounter a segfault (SIGSEGV) while using Numba, please report the issue to the Numba issue tracker.

2.23.3 Expression evaluation via eval()

The top-level function pandas.eval() implements expression evaluation of Series and DataFrame objects.

Note: To benefit from using eval() you need to install numexpr. See the recommended dependencies section for more details.

The point of using eval() for expression evaluation rather than plain Python is two-fold: 1) large DataFrame objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default numexpr is used for evaluation).

Note: You should not use eval() for simple expressions or for expressions involving small DataFrames. In fact, eval() is many orders of magnitude slower for smaller expressions/objects than plain ol’ Python. A good rule of thumb is to only use eval() when you have a DataFrame with more than 10,000 rows.

eval() supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.
Note: The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

Supported syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (<<) and right shift (>>) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4 or not df_bool`
- List and tuple literals, e.g., `[1, 2]` or `(1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval("df")` (this is not very useful)
- Math functions: `sin`, `cos`, `exp`, `expm1`, `log`, `log1p`, `sqrt`, `cosh`, `tanh`, `arcsin`, `arccos`, `arctan`, `arccosh`, `arcsinh`, `arctanh`, `abs`, `arctan2` and `log10`.

This Python syntax is not allowed:

- Expressions
  - Function calls other than math functions.
  - `is/is not` operations
  - `if` expressions
  - `lambda` expressions
  - `list/set/dict` comprehensions
  - `Literal dict and set` expressions
  - `yield` expressions
  - `Generator expressions`
  - Boolean expressions consisting of only scalar values

- Statements
  - Neither `simple` nor `compound` statements are allowed. This includes things like `for`, `while`, and `if`.

`eval()` examples

`pandas.eval()` works well with expressions containing large arrays.

First let’s create a few decent-sized arrays to play with:

```
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in range(4)]
```

Now let’s compare adding them together using plain ol’ Python versus `eval()`:
In [15]: %timeit df1 + df2 + df3 + df4
8.34 ms +- 147 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [16]: %timeit pd.eval("df1 + df2 + df3 + df4")
5.71 ms +- 121 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

Now let’s do the same thing but with comparisons:

In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
7.47 ms +- 199 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [18]: %timeit pd.eval("(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"")
6.64 ms +- 62.7 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

eval() also works with unaligned pandas objects:

In [19]: s = pd.Series(np.random.randn(50))

In [20]: %timeit df1 + df2 + df3 + df4 + s
23.8 ms +- 697 us per loop (mean +- std. dev. of 7 runs, 10 loops each)

In [21]: %timeit pd.eval("df1 + df2 + df3 + df4 + s")
6.3 ms +- 67.3 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

Note: Operations such as

1 and 2  # would parse to 1 & 2, but should evaluate to 2
3 or 4  # would parse to 3 | 4, but should evaluate to 3
-1  # this is okay, but slower when using eval

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type bool or np.bool_. Again, you should perform these kinds of operations in plain Python.

The DataFrame.eval method

In addition to the top level pandas.eval() function you can also evaluate an expression in the “context” of a DataFrame.

In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=\["a", "b"\])

In [23]: df.eval("a + b")
Out[23]:
    0  -0.246747
    1   0.867786
    2  -1.626063
    3  -1.134978
    4  -1.027798
dtype: float64
Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don’t have to prefix the name of the `DataFrame` to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for formulaic evaluation. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

The `inplace` keyword determines whether this assignment will performed on the original `DataFrame` or return a copy with the new column.

```
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [25]: df.eval("c = a + b", inplace=True)
In [26]: df.eval("d = a + b + c", inplace=True)
In [27]: df.eval("a = 1", inplace=True)
In [28]: df
Out[28]:
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26
```

When `inplace` is set to `False`, the default, a copy of the `DataFrame` with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
Out[29]:
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26

In [30]: df.eval("e = a - c", inplace=False)
Out[30]:
   a  b  c  d  e
0  1  5  5 10 -4
1  1  6  7 14 -6
2  1  7  9 18 -8
3  1  8 11 22 -10
4  1  9 13 26 -12
```

2.23. Enhancing performance
As a convenience, multiple assignments can be performed by using a multi-line string.

```python
In [32]: df.eval(
    .....:     ""
    .....:     c = a + b
    .....:     d = a + b + c
    .....:     a = 1",
    .....:     inplace=False,
    .....:     )
```

```
Out[32]:
    a  b  c  d
0  1  5  6  12
1  1  6  7  14
2  1  7  8  16
3  1  8  9  18
4  1  9 10  20
```

The equivalent in standard Python would be

```python
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [34]: df["c"] = df["a"] + df["b"]
In [35]: df["d"] = df["a"] + df["b"] + df["c"]
In [36]: df["a"] = 1

In [37]: df
Out[37]:
    a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  8  18
3  1  8 11  22
4  1  9 13  26
```

The query method has a `inplace` keyword which determines whether the query modifies the original frame.

```python
In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [39]: df.query("a > 2")
Out[39]:
    a  b
3  3  8
4  4  9

In [40]: df.query("a > 2", inplace=True)
In [41]: df
Out[41]:
    a  b
3  3  8
4  4  9
```
Local variables

You must *explicitly reference* any local variable that you want to use in an expression by placing the `@` character in front of the name. For example,

```python
In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list("ab"))

In [43]: newcol = np.random.randn(len(df))

In [44]: df.eval("b + @newcol")
Out[44]:
          0     1     2     3     4
0  -0.173926  2.493083 -0.881831 -0.691045 1.334703
dtype: float64

In [45]: df.query("b < @newcol")
Out[45]:
     a    b
0  0.863987 -0.115998
2 -2.621419 -1.297879
```

If you don’t prefix the local variable with `@`, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```python
In [46]: a = np.random.randn()

In [47]: df.query("@a < a")
Out[47]:
     a    b
0  0.863987 -0.115998
```

With `pandas.eval()` you cannot use the `@` prefix *at all*, because it isn’t defined in that context. pandas will let you know this if you try to use `@` in a top-level call to `pandas.eval()`. For example,

```python
In [49]: a, b = 1, 2

In [50]: pd.eval("@a + b")
Traceback (most recent call last):
     py:3251 in run_code
       exec(code_obj, self.user_global_ns, self.user_ns)

Input In [50] in <module>
```

(continues on next page)
pd.eval("@a + b")

File /pandas/pandas/core/computation/eval.py:339 in eval
    _check_for_locals(expr, level, parser)

File /pandas/pandas/core/computation/eval.py:163 in _check_for_locals
    raise SyntaxError(msg)

File <string>
SyntaxError: The '@' prefix is not allowed in top-level eval calls.
please refer to your variables by name without the '@' prefix.

In this case, you should simply refer to the variables like you would in standard Python.

In [51]: pd.eval("a + b")
Out[51]: 3

pandas.eval() parsers

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

In [52]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"
In [53]: x = pd.eval(expr, parser="python")
In [54]: expr_no_parens = "df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0"
In [55]: y = pd.eval(expr_no_parens, parser="pandas")
In [56]: np.all(x == y)
Out[56]: True

The same expression can be “anded” together with the word and as well:

In [57]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"
In [58]: x = pd.eval(expr, parser="python")
In [59]: expr_with_ands = "df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0"
In [60]: y = pd.eval(expr_with_ands, parser="pandas")
In [61]: np.all(x == y)
Out[61]: True

The and and or operators here have the same precedence that they would in vanilla Python.
**pandas.eval() backends**

There’s also the option to make `eval()` operate identical to plain ol’ Python.

**Note:** Using the ‘python’ engine is generally *not* useful, except for testing other evaluation engines against it. You will achieve no performance benefits using `eval()` with `engine='python'` and in fact may incur a performance hit.

You can see this by using `pandas.eval()` with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python:

```python
In [62]: %timeit df1 + df2 + df3 + df4
8.31 ms +- 544 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```python
In [63]: %timeit pd.eval("df1 + df2 + df3 + df4", engine="python")
9.31 ms +- 354 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**pandas.eval() performance**

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame/Series` objects should see a significant performance benefit. Here is a plot showing the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

![DataFrame.eval()](image)

**Note:** Operations with smallish objects (around 15k-20k rows) are faster using plain Python:
This plot was created using a DataFrame with 3 columns each containing floating point values generated using numpy.random.randn().

Technical minutia regarding expression evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to ndarray.astype(str) will truncate any strings that are more than 60 characters in length. Second, we can’t pass object arrays to numexpr thus string comparisons must be evaluated in Python space.

The upshot is that this only applies to object-dtype expressions. So, if you have an expression—for example

```
In [64]: df = pd.DataFrame(
    ....:     {"strings": np.repeat(list("cba"), 3), "nums": np.repeat(range(3), 3)}
    ....: )
    ....:
In [65]: df
Out[65]:
   strings  nums
0      c    0
1      c    0
2      c    0
3      b    1
4      b    1
5      b    1
6      a    2
7      a    2
8      a    2
```

```
In [66]: df.query("strings == 'a' and nums == 1")
Out[66]:
(continues on next page)
the numeric part of the comparison (`nums == 1`) will be evaluated by `numexpr`.

In general, `DataFrame.query()`/`pandas.eval()` will evaluate the subexpressions that can be evaluated by `numexpr` and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.

## 2.24 Scaling to large datasets

pandas provides data structures for in-memory analytics, which makes using pandas to analyze datasets that are larger than memory datasets somewhat tricky. Even datasets that are a sizable fraction of memory become unwieldy, as some pandas operations need to make intermediate copies.

This document provides a few recommendations for scaling your analysis to larger datasets. It’s a complement to *Enhancing performance*, which focuses on speeding up analysis for datasets that fit in memory.

But first, it’s worth considering *not using pandas*. pandas isn’t the right tool for all situations. If you’re working with very large datasets and a tool like PostgreSQL fits your needs, then you should probably be using that. Assuming you want or need the expressiveness and power of pandas, let’s carry on.

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```

### 2.24.1 Load less data

Suppose our raw dataset on disk has many columns:

<table>
<thead>

2000-12-30 23:59:00  1019 Ingrid   0.322208 -0.615974
2000-12-31 00:00:00  937 Ursula  -0.906523  0.943178

[525601 rows x 4 columns]

If we were to measure the memory usage of the two calls, we'd see that specifying columns uses about 1/10th the memory in this case.

With pandas.read_csv(), you can specify usecols to limit the columns read into memory. Not all file formats that can be read by pandas provide an option to read a subset of columns.

960 Chapter 2. User Guide
### 2.24.2 Use efficient datatypes

The default pandas data types are not the most memory efficient. This is especially true for text data columns with relatively few unique values (commonly referred to as “low-cardinality” data). By using more efficient data types, you can store larger datasets in memory.

```python
In [6]: ts = pd.read_parquet("timeseries.parquet")

In [7]: ts
Out[7]:
   id    name     x      y
0  1029  Michael  0.278837  0.247932
1  1010  Patricia  0.077144  0.490260
2  1001    Victor  0.214525  0.258635
3  1018    Alice  -0.646866  0.822104
4  991      Dan   0.902389  0.466665
```

Now, let’s inspect the data types and memory usage to see where we should focus our attention.

```python
In [8]: ts.dtypes
Out[8]:
   id     name      x      y
0  int64   object  float64 float64

In [9]: ts.memory_usage(deep=True)  # memory usage in bytes
Out[9]:
   Index 8409608
   id  8409608
   name  6553768
   x  8409608
   y  8409608
   dtype: int64
```

The `name` column is taking up much more memory than any other. It has just a few unique values, so it’s a good candidate for converting to a `Categorical`. With a Categorical, we store each unique name once and use space-efficient integers to know which specific name is used in each row.

```python
In [10]: ts2 = ts.copy()

In [11]: ts2["name"] = ts2["name"].astype("category")
```

(continues on next page)
In [12]: ts2.memory_usage(deep=True)
Out[12]:
<table>
<thead>
<tr>
<th></th>
<th>8409608</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>8409608</td>
</tr>
<tr>
<td>id</td>
<td>8409608</td>
</tr>
<tr>
<td>name</td>
<td>1053894</td>
</tr>
<tr>
<td>x</td>
<td>8409608</td>
</tr>
<tr>
<td>y</td>
<td>8409608</td>
</tr>
<tr>
<td>dtype</td>
<td>int64</td>
</tr>
</tbody>
</table>

We can go a bit further and downcast the numeric columns to their smallest types using `pandas.to_numeric()`.

In [13]: ts2["id"] = pd.to_numeric(ts2["id"], downcast="unsigned")
In [14]: ts2[["x", "y"]].apply(pd.to_numeric, downcast="float")
In [15]: ts2.dtypes
Out[15]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>uint16</td>
</tr>
<tr>
<td>name</td>
<td>category</td>
</tr>
<tr>
<td>x</td>
<td>float32</td>
</tr>
<tr>
<td>y</td>
<td>float32</td>
</tr>
<tr>
<td>dtype</td>
<td>object</td>
</tr>
</tbody>
</table>

In [16]: ts2.memory_usage(deep=True)
Out[16]:
<table>
<thead>
<tr>
<th></th>
<th>8409608</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>8409608</td>
</tr>
<tr>
<td>id</td>
<td>2102402</td>
</tr>
<tr>
<td>name</td>
<td>1053894</td>
</tr>
<tr>
<td>x</td>
<td>4204804</td>
</tr>
<tr>
<td>y</td>
<td>4204804</td>
</tr>
<tr>
<td>dtype</td>
<td>int64</td>
</tr>
</tbody>
</table>

In [17]: reduction = ts2.memory_usage(deep=True).sum() / ts.memory_usage(deep=True).sum()
In [18]: print(f"{reduction:.2f}")
0.20

In all, we’ve reduced the in-memory footprint of this dataset to 1/5 of its original size.

See *Categorical data* for more on *Categorical* and *dtypes* for an overview of all of pandas’ dtypes.

### 2.24.3 Use chunking

Some workloads can be achieved with chunking: splitting a large problem like “convert this directory of CSVs to parquet” into a bunch of small problems (“convert this individual CSV file into a Parquet file. Now repeat that for each file in this directory.”). As long as each chunk fits in memory, you can work with datasets that are much larger than memory.

**Note:** Chunking works well when the operation you’re performing requires zero or minimal coordination between chunks. For more complicated workflows, you’re better off using another library.
Suppose we have an even larger “logical dataset” on disk that’s a directory of parquet files. Each file in the directory represents a different year of the entire dataset.

```
data
└── timeseries
    ├── ts-00.parquet
    ├── ts-01.parquet
    ├── ts-02.parquet
    ├── ts-03.parquet
    ├── ts-04.parquet
    ├── ts-05.parquet
    ├── ts-06.parquet
    ├── ts-07.parquet
    ├── ts-08.parquet
    ├── ts-09.parquet
    └── ts-10.parquet
```

Now we’ll implement an out-of-core `value_counts`. The peak memory usage of this workflow is the single largest chunk, plus a small series storing the unique value counts up to this point. As long as each individual file fits in memory, this will work for arbitrary-sized datasets.

```
In [19]: %%time
...: files = pathlib.Path("data/timeseries/").glob("ts*.parquet")
...: counts = pd.Series(dtype=int)
...: for path in files:
...:   df = pd.read_parquet(path)
...:   counts = counts.add(df["name"].value_counts(), fill_value=0)
...: counts.astype(int)
...:
CPU times: user 622 ms, sys: 110 ms, total: 733 ms
Wall time: 684 ms
Out[19]:
Alice    229802
Bob      229211
Charlie  229303
Dan      230621
Edith    230349
...  
Victor   230502
Wendy    230038
Xavier   229553
Yvonne   228766
Zelda    229909
Length: 26, dtype: int64
```

Some readers, like `pandas.read_csv()`, offer parameters to control the `chunksize` when reading a single file.

Manually chunking is an OK option for workflows that don’t require too sophisticated of operations. Some operations, like `groupby`, are much harder to do chunkwise. In these cases, you may be better switching to a different library that implements these out-of-core algorithms for you.
2.24.4 Use other libraries

pandas is just one library offering a DataFrame API. Because of its popularity, pandas’ API has become something of a standard that other libraries implement. The pandas documentation maintains a list of libraries implementing a DataFrame API in our ecosystem page.

For example, Dask, a parallel computing library, has `dask.dataframe`, a pandas-like API for working with larger than memory datasets in parallel. Dask can use multiple threads or processes on a single machine, or a cluster of machines to process data in parallel.

We’ll import `dask.dataframe` and notice that the API feels similar to pandas. We can use Dask’s `read_parquet` function, but provide a globstring of files to read in.

```python
In [20]: import dask.dataframe as dd

In [21]: ddf = dd.read_parquet("data/timeseries/ts*.parquet", engine="pyarrow")

In [22]: ddf
Out[22]:
Dask DataFrame Structure:
 id  name  x  y
npartitions=12
   int64  object  float64  float64
   ...  ...  ...  ...
   ...  ...  ...  ...
   ...  ...  ...  ...
   ...  ...  ...  ...
Dask Name: read-parquet, 12 tasks
```

Inspecting the `ddf` object, we see a few things

- There are familiar attributes like `.columns` and `.dtypes`
- There are familiar methods like `.groupby`, `.sum`, etc.
- There are new attributes like `.npartitions` and `.divisions`

The partitions and divisions are how Dask parallelizes computation. A Dask DataFrame is made up of many pandas DataFrames. A single method call on a Dask DataFrame ends up making many pandas method calls, and Dask knows how to coordinate everything to get the result.

```python
In [23]: ddf.columns
Out[23]: Index(['id', 'name', 'x', 'y'], dtype='object')

In [24]: ddf.dtypes
Out[24]:
 id  int64
name  object
 x  float64
 y  float64
dtype: object

In [25]: ddf.npartitions
Out[25]: 12
```

One major difference: the `dask.dataframe` API is lazy. If you look at the repr above, you’ll notice that the values aren’t actually printed out; just the column names and dtypes. That’s because Dask hasn’t actually read the data yet.
Rather than executing immediately, doing operations build up a task graph.

```
In [26]: ddf
Out[26]:
Dask DataFrame Structure:
   id  name  x  y
npartitions=12
   int64  object  float64  float64
   ...  ...  ...  ...
Dask Name: read-parquet, 12 tasks

In [27]: ddf["name"]
Out[27]:
Dask Series Structure:
npartitions=12
   object
   ...  ...
   ...  ...
   ...
Name: name, dtype: object
Dask Name: getitem, 24 tasks

In [28]: ddf["name"].value_counts()
Out[28]:
Dask Series Structure:
npartitions=1
   int64
   ...  ...
   ...  ...
   ...
Name: name, dtype: int64
Dask Name: value-counts-agg, 39 tasks
```

Each of these calls is instant because the result isn’t being computed yet. We’re just building up a list of computation to do when someone needs the result. Dask knows that the return type of a pandas.Series.value_counts is a pandas Series with a certain dtype and a certain name. So the Dask version returns a Dask Series with the same dtype and the same name.

To get the actual result you can call .compute().

```
In [29]: %time ddf["name"].value_counts().compute()
CPU times: user 885 ms, sys: 77.5 ms, total: 962 ms
Wall time: 526 ms
Out[29]:
Laura  230906
Ingrid 230838
Kevin  230698
Dan    230621
Frank  230595
   ...  ...
Ray    229603
Xavier 229553
(continues on next page)
```
At that point, you get back the same thing you’d get with pandas, in this case a concrete pandas Series with the count of each name.

Calling `.compute` causes the full task graph to be executed. This includes reading the data, selecting the columns, and doing the `value_counts`. The execution is done in parallel where possible, and Dask tries to keep the overall memory footprint small. You can work with datasets that are much larger than memory, as long as each partition (a regular pandas DataFrame) fits in memory.

By default, `dask.dataframe` operations use a threadpool to do operations in parallel. We can also connect to a cluster to distribute the work on many machines. In this case we’ll connect to a local “cluster” made up of several processes on this single machine.

```python
>>> from dask.distributed import Client, LocalCluster

>>> cluster = LocalCluster()

>>> client = Client(cluster)

>>> client
<Client: 'tcp://127.0.0.1:53349' processes=4 threads=8, memory=17.18 GB>
```

Once this `client` is created, all of Dask’s computation will take place on the cluster (which is just processes in this case).

Dask implements the most used parts of the pandas API. For example, we can do a familiar groupby aggregation.

```python
In [30]: time ddf.groupby("name")[['x', "y"]].mean().compute().head()
CPU times: user 1.88 s, sys: 302 ms, total: 2.18 s
Wall time: 899 ms

Out[30]:
   x         y
name
Alice 0.000086 -0.001170
Bob   -0.000843 -0.000799
Charlie 0.000564 -0.000038
Dan    0.000584  0.000818
Edith -0.000116 -0.000044
```

The grouping and aggregation is done out-of-core and in parallel.

When Dask knows the divisions of a dataset, certain optimizations are possible. When reading parquet datasets written by dask, the divisions will be known automatically. In this case, since we created the parquet files manually, we need to supply the divisions manually.

```python
In [31]: N = 12

In [32]: starts = [f"20{i:02d}-01-01" for i in range(N)]

In [33]: ends = [f"20{i:02d}-12-13" for i in range(N)]

In [34]: divisions = tuple(pd.to_datetime(starts)) + (pd.Timestamp(ends[-1]),)
```
In [35]: ddf.divisions = divisions

In [36]: ddf

Out[36]:  
Dask DataFrame Structure:
   id   name    x      y
npartitions=12
2000-01-01  int64  object  float64  float64
2001-01-01    ...     ...      ...    ...
...    ...     ...      ...    ...
2011-01-01    ...     ...      ...    ...
2011-12-13    ...     ...      ...    ...
Dask Name: read-parquet, 12 tasks

Now we can do things like fast random access with .loc.

In [37]: ddf.loc["2002-01-01 12:01":"2002-01-01 12:05"].compute()

Out[37]:  
<table>
<thead>
<tr>
<th>timestamp</th>
<th>id</th>
<th>name</th>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>2002-01-01 12:01:00</td>
<td>983</td>
<td>Laura</td>
<td>0.243985</td>
<td>-0.079392</td>
</tr>
<tr>
<td>2002-01-01 12:02:00</td>
<td>1001</td>
<td>Laura</td>
<td>-0.523119</td>
<td>-0.226026</td>
</tr>
<tr>
<td>2002-01-01 12:03:00</td>
<td>1059</td>
<td>Oliver</td>
<td>0.612886</td>
<td>0.405680</td>
</tr>
<tr>
<td>2002-01-01 12:04:00</td>
<td>993</td>
<td>Kevin</td>
<td>0.451977</td>
<td>0.332947</td>
</tr>
<tr>
<td>2002-01-01 12:05:00</td>
<td>1014</td>
<td>Yvonne</td>
<td>-0.948681</td>
<td>0.361748</td>
</tr>
</tbody>
</table>

Dask knows to just look in the 3rd partition for selecting values in 2002. It doesn’t need to look at any other data.

Many workflows involve a large amount of data and processing it in a way that reduces the size to something that fits in memory. In this case, we’ll resample to daily frequency and take the mean. Once we’ve taken the mean, we know the results will fit in memory, so we can safely call compute without running out of memory. At that point it’s just a regular pandas object.

In [38]: ddf["x", "y"].resample("1D").mean().cumsum().compute().plot()

Out[38]: <AxesSubplot:xlabel='timestamp'>
2.25 Sparse data structures

pandas provides data structures for efficiently storing sparse data. These are not necessarily sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (NaN / missing value, though any value can be chosen, including 0) is omitted. The compressed values are not actually stored in the array.

```
In [1]: arr = np.random.randn(10)
In [2]: arr[2:-2] = np.nan
In [3]: ts = pd.Series(pd.arrays.SparseArray(arr))
In [4]: ts
Out[4]:
0   0.469112
1 -0.282863
```
2 NaN
3 NaN
4 NaN
5 NaN
6 NaN
7 NaN
8 -0.861849
9 -2.104569
dtype: Sparse[ recoil64, nan]

Notice the dtype, Sparse[ recoil64, nan]. The nan means that elements in the array that are nan aren’t actually stored, only the non-nan elements are. Those non-nan elements have a float64 dtype.

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```python
In [5]: df = pd.DataFrame(np.random.randn(10000, 4))
In [6]: df.iloc[:9998] = np.nan
In [7]: sdf = df.astype(pd.SparseDtype("float", np.nan))
In [8]: sdf.head()
Out[8]:
      0  1  2  3
0  NaN NaN NaN NaN
1  NaN NaN NaN NaN
2  NaN NaN NaN NaN
3  NaN NaN NaN NaN
4  NaN NaN NaN NaN

In [9]: sdf.dtypes
Out[9]:
0  Sparse[ recoil64, nan]
1  Sparse[ recoil64, nan]
2  Sparse[ recoil64, nan]
3  Sparse[ recoil64, nan]
dtype: object

In [10]: sdf.sparse.density
Out[10]: 0.0002
```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter.

```python
In [11]: '{:0.2f} bytes'.format(df.memory_usage().sum() / 1e3)
Out[11]: 'dense : 320.13 bytes'
In [12]: '{:0.2f} bytes'.format(sdf.memory_usage().sum() / 1e3)
Out[12]: 'sparse: 0.22 bytes'
```

Functionally, their behavior should be nearly identical to their dense counterparts.

2.25. Sparse data structures
2.25.1 SparseArray

`arrays.SparseArray` is a `ExtensionArray` for storing an array of sparse values (see `dtypes` for more on extension arrays). It is a 1-dimensional ndarray-like object storing only values distinct from the `fill_value`:

```python
In [13]: arr = np.random.randn(10)
In [14]: arr[2:5] = np.nan
In [15]: arr[7:8] = np.nan
In [16]: sparr = pd.arrays.SparseArray(arr)
In [17]: sparr
Out[17]:
[[-1.9556635297215477, -1.6588664275960427, nan, nan, nan, 1.1589328886422277, 0.14529711373305043, nan, 0.6060271905134522, 1.3342113401317768]
```

A sparse array can be converted to a regular (dense) ndarray with `numpy.asarray()`

```python
In [18]: np.asarray(sparr)
Out[18]:
array([-1.9557, -1.6589, nan, nan, nan, 1.1589, 0.1453, nan, 0.606 , 1.3342])
```

2.25.2 SparseDtype

The `SparseArray.dtype` property stores two pieces of information

1. The dtype of the non-sparse values
2. The scalar fill value

```python
In [19]: sparr.dtype
Out[19]: Sparse[float64, nan]
```

A `SparseDtype` may be constructed by passing only a dtype

```python
In [20]: pd.SparseDtype(np.dtype('datetime64[ns]'))
Out[20]: Sparse[datetime64[ns], numpy.datetime64('NaT')]
```

in which case a default fill value will be used (for NumPy dtypes this is often the “missing” value for that dtype). To override this default an explicit fill value may be passed instead

```python
In [21]: pd.SparseDtype(np.dtype('datetime64[ns]'),
                fill_value=pd.Timestamp('2017-01-01'))
Out[21]: Sparse[datetime64[ns], Timestamp('2017-01-01 00:00:00')]
```

Finally, the string alias 'Sparse[dtype]' may be used to specify a sparse dtype in many places
In [22]: pd.array([1, 0, 0, 2], dtype='Sparse[int]')
Out[22]:
[1, 0, 0, 2]
Fill: 0
IntIndex
Indices: array([0, 3], dtype=int32)

2.25.3 Sparse accessor

pandas provides a .sparse accessor, similar to .str for string data, .cat for categorical data, and .dt for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

In [23]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int"]")
In [24]: s.sparse.density
Out[24]: 0.5
In [25]: s.sparse.fill_value
Out[25]: 0

This accessor is available only on data with SparseDtype, and on the Series class itself for creating a Series with sparse data from a scipy COO matrix with.

New in version 0.25.0.

A .sparse accessor has been added for DataFrame as well. See Sparse accessor for more.

2.25.4 Sparse calculation

You can apply NumPy ufuncs to SparseArray and get a SparseArray as a result.

In [26]: arr = pd.arrays.SparseArray([1., np.nan, np.nan, -2., np.nan])
In [27]: np.abs(arr)
Out[27]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)

The ufunc is also applied to fill_value. This is needed to get the correct dense result.

In [28]: arr = pd.arrays.SparseArray([1., -1, -1, -2., -1], fill_value=-1)
In [29]: np.abs(arr)
Out[29]:
[1, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([3], dtype=int32)

(continues on next page)
2.25.5 Migrating

Note: SparseSeries and SparseDataFrame were removed in pandas 1.0.0. This migration guide is present to aid in migrating from previous versions.

In older versions of pandas, the SparseSeries and SparseDataFrame classes (documented below) were the preferred way to work with sparse data. With the advent of extension arrays, these subclasses are no longer needed. Their purpose is better served by using a regular Series or DataFrame with sparse values instead.

Note: There's no performance or memory penalty to using a Series or DataFrame with sparse values, rather than a SparseSeries or SparseDataFrame.

This section provides some guidance on migrating your code to the new style. As a reminder, you can use the Python warnings module to control warnings. But we recommend modifying your code, rather than ignoring the warning.

Construction

From an array-like, use the regular Series or DataFrame constructors with SparseArray values.

# Previous-like
```python
>>> pd.SparseDataFrame({'A': [0, 1]})
```

# New way
```python
In [31]: pd.DataFrame({'A': pd.arrays.SparseArray([0, 1])})
```

From a SciPy sparse matrix, use DataFrame.sparse.from_spmatrix().

# Previous way
```python
>>> from scipy import sparse
>>> mat = sparse.eye(3)
>>> df = pd.SparseDataFrame(mat, columns=['A', 'B', 'C'])
```

# New way
```python
In [32]: from scipy import sparse

In [33]: mat = sparse.eye(3)

In [34]: df = pd.DataFrame.sparse.from_spmatrix(mat, columns=['A', 'B', 'C'])

In [35]: df.dtypes
```

Out[35]:
```
A  Sparse[float64, 0]
```

(continues on next page)
Conversion

From sparse to dense, use the `.sparse` accessors

```
In [36]: df.sparse.to_dense()
Out[36]:
     A   B   C
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

```
In [37]: df.sparse.to_coo()
Out[37]:
<3x3 sparse matrix of type 'numpy.float64'>
    with 3 stored elements in COOrdinate format
```

From dense to sparse, use `DataFrame.astype()` with a `SparseDtype`.

```
In [38]: dense = pd.DataFrame({'A': [1, 0, 0, 1]})
In [39]: dtype = pd.SparseDtype(int, fill_value=0)
In [40]: dense.astype(dtype)
Out[40]:
    A
0  1
1  0
2  0
3  1
```

Sparse Properties

Sparse-specific properties, like density, are available on the `.sparse` accessor.

```
In [41]: df.sparse.density
Out[41]: 0.3333333333333333
```

General differences

In a `SparseDataFrame`, all columns were sparse. A `DataFrame` can have a mixture of sparse and dense columns. As a consequence, assigning new columns to a `DataFrame` with sparse values will not automatically convert the input to be sparse.

```
# Previous Way
>>> df = pd.SparseDataFrame({'A': [0, 1]})
>>> df['B'] = [0, 0]  # implicitly becomes Sparse
>>> df['B'].dtype
Sparse[int64, nan]
```

Instead, you’ll need to ensure that the values being assigned are sparse
In [42]: df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1])})

In [43]: df['B'] = [0, 0]  # remains dense

In [44]: df['B'].dtype
Out[44]: dtype('int64')

In [45]: df['B'] = pd.arrays.SparseArray([0, 0])

In [46]: df['B'].dtype
Out[46]: Sparse[int64, 0]

The SparseDataFrame.default_kind and SparseDataFrame.default_fill_value attributes have no replacement.

2.25.6 Interaction with scipy.sparse

Use DataFrame.sparse.from_spmatrix() to create a DataFrame with sparse values from a sparse matrix.

New in version 0.25.0.

In [47]: from scipy.sparse import csr_matrix

In [48]: arr = np.random.random(size=(1000, 5))

In [49]: arr[arr < .9] = 0

In [50]: sp_arr = csr_matrix(arr)

In [51]: sp_arr
Out[51]:<1000x5 sparse matrix of type '<class 'numpy.float64'>'
          with 517 stored elements in Compressed Sparse Row format>

In [52]: sdf = pd.DataFrame.sparse.from_spmatrix(sp_arr)

In [53]: sdf.head()
Out[53]:
   0  1  2    3    4
0 0.956380 0.0 0.0 0.000000 0.0
1 0.000000 0.0 0.0 0.000000 0.0
2 0.000000 0.0 0.0 0.000000 0.0
3 0.000000 0.0 0.0 0.000000 0.0
4 0.999552 0.0 0.0 0.956153 0.0

In [54]: sdf.dtypes
Out[54]:
0 Sparse[float64, 0]
1 Sparse[float64, 0]
2 Sparse[float64, 0]
3 Sparse[float64, 0]
4 Sparse[float64, 0]
dtype: object
All sparse formats are supported, but matrices that are not in COOrdinate format will be converted, copying data as needed. To convert back to sparse SciPy matrix in COO format, you can use the `DataFrame.sparse.to_coo()` method:

```python
In [55]: sdf.sparse.to_coo()
Out[55]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
    with 517 stored elements in COOrdinate format>
```

`Series.sparse.to_coo()` is implemented for transforming a `Series` with sparse values indexed by a `MultiIndex` to a `scipy.sparse.coo_matrix`.

The method requires a `MultiIndex` with two or more levels.

```python
In [56]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
In [57]: s.index = pd.MultiIndex.from_tuples(
                   [(1, 2, "a", 0),
                    (1, 2, "a", 1),
                    (1, 1, "b", 0),
                    (1, 1, "b", 1),
                    (2, 1, "b", 0),
                    (2, 1, "b", 1),
                   ],
                names=["A", "B", "C", "D"],
            )
In [58]: ss = s.astype('Sparse')
In [59]: ss
Out[59]:
   A  B  C  D
0  1  2  a  0  3.0
   1  NaN
1  1  b  0  1.0
   1  3.0
2  1  b  0  NaN
   1  NaN
dtype: Sparse[float64, nan]
```

In the example below, we transform the `Series` to a sparse representation of a 2-d array by specifying that the first and second `MultiIndex` levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

```python
In [60]: A, rows, columns = ss.sparse.to_coo(
                   row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
            )
In [61]: A
Out[61]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'>
```

(continues on next page)
with 3 stored elements in COOrdinate format>

In [62]: A.todense()
Out[62]:
matrix([[0., 0., 1., 3.],
       [3., 0., 0., 0.],
       [0., 0., 0., 0.]])

In [63]: rows
Out[63]: [(1, 1), (1, 2), (2, 1)]

In [64]: columns
Out[64]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

In [65]: A, rows, columns = ss.sparse.to_coo(...: row_levels=['A', 'B', 'C'], column_levels=['D'], sort_labels=False)
.....:)
.....:

In [66]: A
Out[66]:
<3x2 sparse matrix of type '<class 'numpy.float64'>'
   with 3 stored elements in COOrdinate format>

In [67]: A.todense()
Out[67]:
matrix([[3., 0.],
       [1., 3.],
       [0., 0.]])

In [68]: rows
Out[68]: [(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]

In [69]: columns
Out[69]: [(0,), (1,)]

A convenience method `Series.sparse.from_coo()` is implemented for creating a Series with sparse values from a scipy.sparse.coo_matrix.

In [70]: from scipy import sparse

In [71]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4))

In [72]: A
Out[72]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
   with 3 stored elements in COOrdinate format>

In [73]: A.todense()
Out[73]:
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

The default behaviour (with dense_index=False) simply returns a Series containing only the non-null entries.

```python
In [74]: ss = pd.Series.sparse.from_coo(A)

In [75]: ss
Out[75]:
0  2  1.0
3  2.0
1  0  3.0
dtype: Sparse[float64, nan]
```

Specifying dense_index=True will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to dense_index=False) if the sparse matrix is large (and sparse) enough.

```python
In [76]: ss_dense = pd.Series.sparse.from_coo(A, dense_index=True)

In [77]: ss_dense
Out[77]:
 0  0  NaN
 1  NaN
 2  1.0
 3  2.0
 1  0  3.0
 1  NaN
 2  NaN
 3  NaN
 2  0  NaN
 1  NaN
 2  NaN
 3  NaN
dtype: Sparse[float64, nan]
```

### 2.26 Frequently Asked Questions (FAQ)

#### 2.26.1 DataFrame memory usage

The memory usage of a DataFrame (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see the list of options), specifies if the DataFrame’s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the DataFrame below is shown when calling `info()`:

```python
In [1]: dtypes = [
   ...:     "int64",
   ...:     "float64",
   ...:     "datetime64[ns]",
   ...
]
```
In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)

In [5]: df["categorical"] = df["object"].astype("category")

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
# Column Non-Null Count Dtype
--- ------ -------------- ----- 
0 int64 5000 non-null int64 
1 float64 5000 non-null float64 
2 datetime64[ns] 5000 non-null datetime64[ns] 
3 timedelta64[ns] 5000 non-null timedelta64[ns] 
4 complex128 5000 non-null complex128 
5 object 5000 non-null object 
6 bool 5000 non-null bool 
7 categorical 5000 non-null category 
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
˓→ object(1), timedelta64[ns](1)
memory usage: 288.2+ KB

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used
by values in columns with dtype=object.

Passing memory_usage='deep' will enable a more accurate memory usage report, accounting for the full usage of
the contained objects. This is optional as it can be expensive to do this deeper introspection.
By default the display option is set to True but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a `Series` with an index represented by column names and memory usage of each column shown in bytes. For the `DataFrame` above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```
In [8]: df.memory_usage()
Out[8]:
Index    128
int64    40000
float64  40000
datetime64[ns]  40000
timedelta64[ns]  40000
complex128  80000
object     40000
bool       5000
categorical 9968
dtype: int64
```

```
# total memory usage of dataframe
In [9]: df.memory_usage().sum()
Out[9]: 295096
```

By default the memory usage of the `DataFrame`’s index is shown in the returned `Series`, the memory usage of the index can be suppressed by passing the `index=False` argument:

```
In [10]: df.memory_usage(index=False)
Out[10]:
int64    40000
float64  40000
datetime64[ns]  40000
timedelta64[ns]  40000
complex128  80000
object     40000
bool       5000
categorical 9968
dtype: int64
```

The memory usage displayed by the `info()` method utilizes the `memory_usage()` method to determine the memory usage of a `DataFrame` while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also `Categorical Memory Usage`.
2.26.2 Using if/truth statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a bool. This happens in an if-statement or when using the boolean operations: and, or, and not. It is not clear what the result of the following code should be:

```python
>>> if pd.Series([False, True, False]):
...     pass
```

Should it be True because it’s not zero-length, or False because there are False values? It is unclear, so instead, pandas raises a ValueError:

```python
>>> if pd.Series([False, True, False]):
...     print("I was true")
```

```
Traceback...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the DataFrame, e.g. use any(), all() or empty(). Alternatively, you might want to compare if the pandas object is None:

```python
>>> if pd.Series([False, True, False]) is not None:
...     print("I was not None")
```

```
I was not None
```

Below is how to check if any of the values are True:

```python
>>> if pd.Series([False, True, False]).any():
...     print("I am any")
```

```
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method bool():

```python
In [11]: pd.Series([True]).bool()
Out[11]: True

In [12]: pd.Series([False]).bool()
Out[12]: False

In [13]: pd.DataFrame([[True]]).bool()
Out[13]: True

In [14]: pd.DataFrame([[False]]).bool()
Out[14]: False
```
Bitwise boolean

Bitwise boolean operators like == and != return a boolean Series, which is almost always what you want anyways.

```python
>>> s = pd.Series(range(5))
>>> s == 4
0    False
1    False
2    False
3    False
4     True
dtype: bool
```

See boolean comparisons for more examples.

Using the in operator

Using the Python in operator on a Series tests for membership in the index, not membership among the values.

```python
In [15]: s = pd.Series(range(5), index=list("abcde"))
In [16]: 2 in s
Out[16]: False
In [17]: 'b' in s
Out[17]: True
```

If this behavior is surprising, keep in mind that using in on a Python dictionary tests keys, not values, and Series are dict-like. To test for membership in the values, use the method isin():

```python
In [18]: s.isin([2])
Out[18]:
    a  False
    b  False
    c   True
    d  False
    e  False
dtype: bool
In [19]: s.isin([2]).any()
Out[19]: True
```

For DataFrames, likewise, in applies to the column axis, testing for membership in the list of column names.
Mutating with User Defined Function (UDF) methods

This section applies to pandas methods that take a UDF. In particular, the methods `.apply`, `.aggregate`, `.transform`, and `.filter`.

It is a general rule in programming that one should not mutate a container while it is being iterated over. Mutation will invalidate the iterator, causing unexpected behavior. Consider the example:

```
In [20]: values = [0, 1, 2, 3, 4, 5]
In [21]: n_removed = 0
In [22]: for k, value in enumerate(values):
   ....:     idx = k - n_removed
   ....:     if value % 2 == 1:
   ....:         del values[idx]
   ....:         n_removed += 1
   ....:     else:
   ....:         values[idx] = value + 1

In [23]: values
Out[23]: [1, 4, 5]
```

One probably would have expected that the result would be [1, 3, 5]. When using a pandas method that takes a UDF, internally pandas is often iterating over the DataFrame or other pandas object. Therefore, if the UDF mutates (changes) the DataFrame, unexpected behavior can arise.

Here is a similar example with `DataFrame.apply()`:

```
In [24]: def f(s):
   ....:     s.pop("a")
   ....:     return s
   ....:

In [25]: df = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6]})
In [26]: try:
   ....:     df.apply(f, axis="columns")
   ....:     except Exception as err:
   ....:         print(repr(err))
   ....:
KeyError('a')
```

To resolve this issue, one can make a copy so that the mutation does not apply to the container being iterated over.

```
In [27]: values = [0, 1, 2, 3, 4, 5]
In [28]: n_removed = 0
In [29]: for k, value in enumerate(values.copy()):
   ....:     idx = k - n_removed
   ....:     if value % 2 == 1:
   ....:         del values[idx]
   ....:         n_removed += 1
```

(continues on next page)
2.26.4 NaN, Integer NA values and NA type promotions

Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A masked array solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value NaN (Not-A-Number) is used everywhere as the NA value, and there are API functions isnan and notna which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [34]: s = pd.Series([1, 2, 3, 4, 5], index=list("abcde"))

In [35]: s
Out[35]:
   a    1
   b    2
```

(continues on next page)
c 3
d 4
e 5
dtype: int64

In [36]: s.dtype
Out[36]: dtype('int64')

In [37]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])

In [38]: s2
Out[38]:
   a  1.0
   b  2.0
   c  3.0
   f   NaN
   u   NaN

dtype: float64

In [39]: s2.dtype
Out[39]: dtype('float64')

This trade-off is made largely for memory and performance reasons, and also so that the resulting Series continues to be “numeric”.

If you need to represent integers with possibly missing values, use one of the nullable-integer extension dtypes provided by pandas

- Int8Dtype
- Int16Dtype
- Int32Dtype
- Int64Dtype

In [40]: s_int = pd.Series([1, 2, 3, 4, 5], index=list('abcde'), dtype=pd.Int64Dtype())

In [41]: s_int
Out[41]:
   a  1
   b  2
   c  3
   d  4
   e  5
dtype: Int64

In [42]: s_int.dtype
Out[42]: Int64Dtype()

In [43]: s2_int = s_int.reindex(['a', 'b', 'c', 'f', 'u'])

In [44]: s2_int
Out[44]:
a  1
See Nullable integer data type for more.

**NA type promotions**

When introducing NAs into an existing Series or DataFrame via `reindex()` or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Promotion dtype for storing NAs</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating</td>
<td>no change</td>
</tr>
<tr>
<td>object</td>
<td>no change</td>
</tr>
<tr>
<td>integer</td>
<td>cast to float64</td>
</tr>
<tr>
<td>boolean</td>
<td>cast to object</td>
</tr>
</tbody>
</table>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than $2^{53}$. Some explanation for the motivation is in the next section.

**Why not make NumPy like R?**

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy.floating</td>
<td>float16, float32, float64, float128</td>
</tr>
<tr>
<td>numpy.integer</td>
<td>int8, int16, int32, int64</td>
</tr>
<tr>
<td>numpy.unsignedinteger</td>
<td>uint8, uint16, uint32, uint64</td>
</tr>
<tr>
<td>numpy.object_</td>
<td>object_</td>
</tr>
<tr>
<td>numpy.bool_</td>
<td>bool_</td>
</tr>
<tr>
<td>numpy.character</td>
<td>string_, unicode_</td>
</tr>
</tbody>
</table>

The R language, by contrast, only has a handful of built-in data types: integer, numeric (floating-point), character, and boolean. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean mask denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using NaN. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.
2.26.5 Differences with NumPy

For Series and DataFrame objects, `var()` normalizes by \(N-1\) to produce unbiased estimates of the sample variance, while NumPy's `var` normalizes by \(N\), which measures the variance of the sample. Note that `cov()` normalizes by \(N-1\) in both pandas and NumPy.

2.26.6 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the `copy()` method. If you are doing a lot of copying of DataFrame objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See this link for more information.

2.26.7 Byte-ordering issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like:

```
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order before passing it to Series or DataFrame constructors using something similar to the following:

```
In [46]: x = np.array(list(range(10)), ">i4")  # big endian
In [47]: newx = x.byteswap().newbyteorder()   # force native byteorder
In [48]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details.

2.27 Cookbook

This is a repository for short and sweet examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great First Pull Request.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the StackOverflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer. pandas (pd) and NumPy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.
2.27.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

$$
\begin{align*}
\text{In [1]: } & \text{ df = pd.DataFrame(} \\
& \quad \quad \quad \quad \quad \quad \{"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]\} \\
& \quad \quad \quad \quad \quad \quad ) \\
& \text{...: } \\
\end{align*}
$$

$$
\begin{align*}
\text{In [2]: } & \text{ df} \\
\text{Out[2]: } \\
& \quad \quad \quad \quad \quad AAA BBB CCC \\
& \quad 0 4 10 100 \\
& \quad 1 5 20 50 \\
& \quad 2 6 30 -30 \\
& \quad 3 7 40 -50 \\
\end{align*}
$$

if-then...

An if-then on one column

$$
\begin{align*}
\text{In [3]: } & \text{ df.loc[df.AAA >= 5, "BBB"] = -1} \\
\end{align*}
$$

$$
\begin{align*}
\text{In [4]: } & \text{ df} \\
\text{Out[4]: } \\
& \quad \quad \quad \quad \quad AAA BBB CCC \\
& \quad 0 4 10 100 \\
& \quad 1 5 -1 50 \\
& \quad 2 6 -1 -30 \\
& \quad 3 7 -1 -50 \\
\end{align*}
$$

An if-then with assignment to 2 columns:

$$
\begin{align*}
\text{In [5]: } & \text{ df.loc[df.AAA >= 5, ["BBB", "CCC"]] = 555} \\
\end{align*}
$$

$$
\begin{align*}
\text{In [6]: } & \text{ df} \\
\text{Out[6]: } \\
& \quad \quad \quad \quad \quad AAA BBB CCC \\
& \quad 0 4 10 100 \\
& \quad 1 5 555 555 \\
& \quad 2 6 555 555 \\
& \quad 3 7 555 555 \\
\end{align*}
$$

Add another line with different logic, to do the -else

$$
\begin{align*}
\text{In [7]: } & \text{ df.loc[df.AAA < 5, ["BBB", "CCC"]] = 2000} \\
\end{align*}
$$

$$
\begin{align*}
\text{In [8]: } & \text{ df} \\
\text{Out[8]: } \\
& \quad \quad \quad \quad \quad AAA BBB CCC \\
& \quad 0 4 2000 2000 \\
\end{align*}
$$

(continues on next page)
Or use pandas where after you’ve set up a mask

```python
In [9]: df_mask = pd.DataFrame(
    ...:     {"AAA": [True] * 4, "BBB": [False] * 4, "CCC": [True, False] * 2}
    ...: )
    ...

In [10]: df.where(df_mask, -1000)
Out[10]:
    AAA  BBB  CCC
0   4   555  555
1   6   555  555
2   7   555  555
```

if-then-else using NumPy’s where()

```python
In [11]: df = pd.DataFrame(
    ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    ....: )
    ....:

In [12]: df
Out[12]:
     AAA  BBB  CCC
0   4    5  100
1   5    2   50
2   6    3  -30
3   7    4  -50
```

```python
In [13]: df["logic"] = np.where(df["AAA"] > 5, "high", "low")
In [14]: df
Out[14]:
     AAA  BBB  CCC    logic
0   4    5  100  low
1   5    2   50  low
2   6    3  -30  high
3   7    4  -50  high
```
## Splitting

Split a frame with a boolean criterion

```
In [15]: df = pd.DataFrame(
    .....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    .....: )
    .....:

In [16]: df
Out[16]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>30</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>40</td>
</tr>
</tbody>
</table>

In [17]: df[df.AAA <= 5]
Out[17]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
</tr>
</tbody>
</table>

In [18]: df[df.AAA > 5]
Out[18]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>6</td>
<td>30</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>40</td>
</tr>
</tbody>
</table>
```

## Building criteria

Select with multi-column criteria

```
In [19]: df = pd.DataFrame(
    .....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    .....: )
    .....:

In [20]: df
Out[20]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>30</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>40</td>
</tr>
</tbody>
</table>

...and (without assignment returns a Series)

In [21]: df.loc[(df["BBB"] < 25) & (df["CCC"] >= -40), "AAA"]
Out[21]:
<table>
<thead>
<tr>
<th>AAA</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
Name: AAA, dtype: int64
```
...or (without assignment returns a Series)

```
In [22]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= -40), "AAA"]
Out[22]:
0  4
1  5
2  6
3  7
Name: AAA, dtype: int64
```

...or (with assignment modifies the DataFrame.)

```
In [23]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= 75), "AAA"] = 0.1
In [24]: df
Out[24]:
     AAA  BBB  CCC
0  0.10  10.0 100.0
1  5.00  20.0  50.0
2  0.10  30.0 -30.0
3  0.10  40.0 -50.0
```

Select rows with data closest to certain value using argsort

```
In [25]: df = pd.DataFrame(
    .....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    .....: )
    .....:
In [26]: df
Out[26]:
     AAA  BBB  CCC
0     4.0  10.0 100.0
1     5.0  20.0  50.0
2     6.0  30.0 -30.0
3     7.0  40.0 -50.0
In [27]: aValue = 43.0
In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out[28]:
     AAA  BBB  CCC
1  5.00  20.0  50.0
0  4.10  10.0 100.0
2  6.00  30.0 -30.0
3  7.00  40.0 -50.0
```

Dynamically reduce a list of criteria using a binary operators

```
In [29]: df = pd.DataFrame(
    .....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    .....: )
    .....:
(continues on next page)
```
In [30]: df
Out[30]:
    AAA  BBB  CCC
0    4    10  100
1    5    20   50
2    6    30  -30
3    7    40  -50

In [31]: Crit1 = df.AAA <= 5.5
In [32]: Crit2 = df.BBB == 10.0
In [33]: Crit3 = df.CCC > -40.0

One could hard code:

In [34]: AllCrit = Crit1 & Crit2 & Crit3

...Or it can be done with a list of dynamically built criteria

In [35]: import functools
In [36]: CritList = [Crit1, Crit2, Crit3]
In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)
In [38]: df[AllCrit]
Out[38]:
    AAA  BBB  CCC
0    4    10  100

2.27.2 Selection

Dataframes

The indexing docs.

Using both row labels and value conditionals

In [39]: df = pd.DataFrame(
   ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
   ....: )
   ....:

In [40]: df
Out[40]:
    AAA  BBB  CCC
0    4    10  100
1    5    20   50
2    6    30  -30
3    7    40  -50
In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
Out[41]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>–30</td>
</tr>
</tbody>
</table>

Use loc for label-oriented slicing and iloc positional slicing GH2904

In [42]: df = pd.DataFrame(
   ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50],
   ....:     index=['foo', 'bar', 'boo', 'kar'],
   ....:     )
   ....: 
There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style: exclusive of end)
2. Label-oriented (Non-Python slicing style: inclusive of end)
3. General (Either slicing style: depends on if the slice contains labels or positions)

In [43]: df.loc["bar":"kar"]  # Label
Out[43]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>–30</td>
</tr>
<tr>
<td>kar</td>
<td>7</td>
<td>–50</td>
</tr>
</tbody>
</table>

# Generic
In [44]: df[0:3]
Out[44]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>–30</td>
</tr>
</tbody>
</table>

In [45]: df["bar":"kar"]
Out[45]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>–30</td>
</tr>
<tr>
<td>kar</td>
<td>7</td>
<td>–50</td>
</tr>
</tbody>
</table>

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

In [46]: data = {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}

In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4])  # Note index starts at 1.

In [48]: df2.iloc[1:3]  # Position-oriented
Out[48]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>6</td>
<td>30</td>
<td>–30</td>
</tr>
</tbody>
</table>
In [49]: df2.loc[1:3]  # Label-oriented
Out[49]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>-30</td>
</tr>
</tbody>
</table>

Using inverse operator (~) to take the complement of a mask

In [50]: df = pd.DataFrame(
    ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50],
    ....:     })

In [51]: df
Out[51]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>-30</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>-50</td>
</tr>
</tbody>
</table>

In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]
Out[52]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>-50</td>
</tr>
</tbody>
</table>

New columns

Efficiently and dynamically creating new columns using applymap

In [53]: df = pd.DataFrame({"AAA": [1, 2, 1, 3], "BBB": [1, 1, 2, 2], "CCC": [2, 1, 3, 1]})

In [54]: df
Out[54]:
<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

In [55]: source_cols = df.columns  # Or some subset would work too

In [56]: new_cols = [str(x) + "_cat" for x in source_cols]
In [57]: categories = {1: "Alpha", 2: "Beta", 3: "Charlie"}

In [58]: df[new_cols] = df[source_cols].applymap(categories.get)

In [59]: df
Out[59]:
   AAA  BBB  CCC  AAA_cat  BBB_cat  CCC_cat
0   1    1    2      Alpha    Alpha   Beta
1   2    1    1      Beta     Alpha   Alpha
2   1    2    3      Alpha    Beta    Charlie
3   3    2    1     Charlie    Beta    Alpha

Keep other columns when using min() with groupby

In [60]: df = pd.DataFrame(
   ...:     {"AAA": [1, 1, 1, 2, 2, 2, 3, 3], "BBB": [2, 1, 3, 4, 5, 1, 2, 3]}
   ...: )
   ...

In [61]: df
Out[61]:
   AAA  BBB
0   1    2
1   1    1
2   1    3
3   2    4
4   2    5
5   2    1
6   3    2
7   3    3

Method 1 : idxmin() to get the index of the minimums

In [62]: df.loc[df.groupby("AAA")["BBB"].idxmin()]
Out[62]:
   AAA  BBB
1   1    1
5   2    1
6   3    2

Method 2 : sort then take first of each

In [63]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
Out[63]:
   AAA  BBB
0   1    1
1   2    1
2   3    2

Notice the same results, with the exception of the index.
2.27.3 Multiindexing

The `multindexing` docs.

Creating a MultiIndex from a labeled frame

```python
In [64]: df = pd.DataFrame(
    ....:     {
    ....:         "row": [0, 1, 2],
    ....:         "One_X": [1.1, 1.1, 1.1],
    ....:         "One_Y": [1.2, 1.2, 1.2],
    ....:         "Two_X": [1.11, 1.11, 1.11],
    ....:         "Two_Y": [1.22, 1.22, 1.22],
    ....:     }
    ....: )

In [65]: df
Out[65]:
   row  One_X  One_Y  Two_X  Two_Y
  0    0    1.1    1.2    1.11   1.22
  1    1    1.1    1.2    1.11   1.22
  2    2    1.1    1.2    1.11   1.22

# As Labelled Index
In [66]: df = df.set_index("row")

In [67]: df
Out[67]:
   One_X  One_Y  Two_X  Two_Y
row
  0    1.1    1.2    1.11   1.22
  1    1.1    1.2    1.11   1.22
  2    1.1    1.2    1.11   1.22

# With Hierarchical Columns
In [68]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split("_")) for c in df.columns])

In [69]: df
Out[69]:
   One    Two
row
  0    1.1   1.2
  1    1.1   1.2
  2    1.1   1.2

# Now stack & Reset
In [70]: df = df.stack(0).reset_index(1)

In [71]: df
Out[71]:
   level_1  X  Y
  0          1.1  1.2
  1          1.1  1.2
  2          1.1  1.2
```

(continues on next page)
row
0 One 1.10 1.20
0 Two 1.11 1.22
1 One 1.10 1.20
1 Two 1.11 1.22
2 One 1.10 1.20
2 Two 1.11 1.22

# And fix the labels (Notice the label 'level_1' got added automatically)
In [72]: df.columns = ["Sample", "All_X", "All_Y"

In [73]: df
Out[73]:
       Sample  All_X  All_Y
row
0   One   1.10   1.20
0   Two   1.11   1.22
1   One   1.10   1.20
1   Two   1.11   1.22
2   One   1.10   1.20
2   Two   1.11   1.22

Arithmetic
Performing arithmetic with a MultiIndex that needs broadcasting

In [74]: cols = pd.MultiIndex.from_tuples(
    ....:     [(x, y) for x in ["A", "B", "C"] for y in ["O", "I"]]
    ....:   )

In [75]: df = pd.DataFrame(np.random.randn(2, 6), index=["n", "m"], columns=cols)

In [76]: df
Out[76]:
      A     B     C
n  0.469  0.283 -1.509
m  0.119 -1.044 -0.862

In [77]: df = df.div(df["C"], level=1)

In [78]: df
Out[78]:
      A     B     C
n  0.387  1.633 -1.245
m -0.241  0.974  1.741
Slicing

Slicing a MultiIndex with xs

In [79]: coords = [("AA", "one"), ("AA", "six"), ("BB", "one"), ("BB", "two"), ("BB", "six")]

In [80]: index = pd.MultiIndex.from_tuples(coords)

In [81]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ["MyData"])

In [82]: df

Out[82]:
        MyData
AA one 11
    six 22
BB one 33
two 44
    six 55

To take the cross section of the 1st level and 1st axis the index:

# Note : level and axis are optional, and default to zero
In [83]: df.xs("BB", level=0, axis=0)

Out[83]:
        MyData
one 33
    two 44
    six 55

...and now the 2nd level of the 1st axis.

In [84]: df.xs("six", level=1, axis=0)

Out[84]:
        MyData
AA 22
    BB 55

Slicing a MultiIndex with xs, method #2

In [85]: import itertools

In [86]: index = list(itertools.product(["Ada", "Quinn", "Violet"], ["Comp", "Math", "Sci"]))

In [87]: headr = list(itertools.product(["Exams", "Labs"], ["I", "II"]))

2.27.4 Missing data

The `missing data` docs.

Fill forward a reversed timeseries

In [100]: df = pd.DataFrame(
       np.random.randn(6, 1),
       index=pd.date_range("2013-08-01", periods=6, freq="B"),
       columns=list("A"),
       )

(continues on next page)
In [101]: df.loc[df.index[3], "A"] = np.nan

In [102]: df
Out[102]:
   A
2013-08-01  0.721555
2013-08-02 -0.706771
2013-08-05 -1.039575
2013-08-06  NaN
2013-08-07 -0.424972
2013-08-08  0.567020

In [103]: df.reindex(df.index[::-1]).ffill()
Out[103]:
   A
2013-08-08  0.567020
2013-08-07 -0.424972
2013-08-06 -0.424972
2013-08-05 -1.039575
2013-08-02 -0.706771
2013-08-01  0.721555

cumsum reset at NaN values

Replace

Using replace with backrefs

2.27.5 Grouping

The grouping docs.

Basic grouping with apply

Unlike agg, apply’s callable is passed a sub-DataFrame which gives you access to all the columns

In [104]: df = pd.DataFrame(
    .....:       {
    .....:           "animal": "cat dog cat fish dog cat cat".split(),
    .....:           "size": list("SSMMMLL"),
    .....:           "weight": [8, 10, 11, 1, 20, 12, 12],
    .....:           "adult": [False] * 5 + [True] * 2,
    .....:       }
    .....:   )
    .....:)

In [105]: df
Out[105]:
   animal  size  weight  adult
0       cat   S      8     False
1       dog   S     10     False
2       cat   M     11     False
3  fish  M  1  False
4  dog  M  20  False
5  cat  L  12  True
6  cat  L  12  True

# List the size of the animals with the highest weight.
In [106]: df.groupby("animal").apply(lambda subf: subf["size"] [subf["weight"].idxmax()])
Out[106]:
   animal
5   cat L
6   cat L

Using get_group

In [107]: gb = df.groupby(["animal"])

In [108]: gb.get_group("cat")
Out[108]:
   animal  size  weight  adult
0   cat  S     8  False
2   cat  M    11  False
5   cat  L    12  True
6   cat  L    12  True

Apply to different items in a group

In [109]: def GrowUp(x):
....:     avg_weight = sum(x[x["size"] == "S"].weight * 1.5)
....:     avg_weight += sum(x[x["size"] == "M"].weight * 1.25)
....:     avg_weight += sum(x[x["size"] == "L"].weight)
....:     avg_weight /= len(x)
....:     return pd.Series(["L", avg_weight, True], index=['size', 'weight', 'adult']

In [110]: expected_df = gb.apply(GrowUp)

In [111]: expected_df
Out[111]:
   size   weight  adult
animal
  cat  L  12.4375  True
dog  L  20.0000  True
  fish L  1.2500  True

Expanding apply

In [112]: S = pd.Series([i / 100.0 for i in range(1, 11)])

In [113]: def cum_ret(x, y):
....:     return x * (1 + y)
In [114]: def red(x):
   .....:     return functools.reduce(cum_ret, x, 1.0)
   .....:
In [115]: S.expanding().apply(red, raw=True)
Out[115]:
   0    1.010000
   1    1.030200
   2    1.061106
   3    1.103550
   4    1.158728
   5    1.228251
   6    1.314229
   7    1.419367
   8    1.547110
   9    1.701821
   dtype: float64

Replacing some values with mean of the rest of a group

In [116]: df = pd.DataFrame({"A": [1, 1, 2, 2], "B": [1, -1, 1, 2]})
In [117]: gb = df.groupby("A")
In [118]: def replace(g):
   .....:     mask = g < 0
   .....:     return g.where(mask, g[~mask].mean())
   .....:
In [119]: gb.transform(replace)
Out[119]:
   B
   0  1.0
   1 -1.0
   2  1.5
   3  1.5

Sort groups by aggregated data

In [120]: df = pd.DataFrame(
   .....:     {
   .....:         "code": ["foo", "bar", "baz"] * 2,
   .....:         "data": [0.16, -0.21, 0.33, 0.45, -0.59, 0.62],
   .....:         "flag": [False, True] * 3,
   .....:     }
   .....: )
   .....:
In [121]: code_groups = df.groupby("code")
In [122]: agg_n_sort_order = code_groups["data"].transform(sum).sort_values(by="data")

In [123]: sorted_df = df.loc[agg_n_sort_order.index]

In [124]: sorted_df
Out[124]:
   code  data  flag
0   foo  0.16 False
1   bar -0.21  True
2   baz  0.33 False
3   foo  0.45  True
4   bar -0.59 False
5   baz  0.62  True

Create multiple aggregated columns

In [125]: rng = pd.date_range(start="2014-10-07", periods=10, freq="2min")

In [126]: ts = pd.Series(data=list(range(10)), index=rng)

In [127]: def MyCust(x):
   ....:     if len(x) > 2:
   ....:         return x[1] * 1.234
   ....:     return pd.NaT
   ....:

In [128]: mhc = {"Mean": np.mean, "Max": np.max, "Custom": MyCust}

In [129]: ts.resample("5min").apply(mhc)
Out[129]:
   Mean   Max  Custom
2014-10-07 00:00:00  1.0   2  1.234
2014-10-07 00:05:00  3.5   4    NaN
2014-10-07 00:10:00  6.0   7  7.404
2014-10-07 00:15:00  8.5   9    NaN

In [130]: ts
Out[130]:

Freq: 2T, dtype: int64

Create a value counts column and reassign back to the DataFrame
In [131]: df = pd.DataFrame(
          .....:   {"Color": "Red Red Red Blue".split(), "Value": [100, 150, 50, 50]}
          .....:
          .....:
          .....:

In [132]: df
Out[132]:
         Color  Value
0      Red   100
1      Red   150
2      Red    50
3      Blue    50

In [133]: df["Counts"] = df.groupby(["Color"]).transform(len)

In [134]: df
Out[134]:
         Color  Value  Counts
0      Red   100     3
1      Red   150     3
2      Red    50     3
3      Blue    50     1

Shift groups of the values in a column based on the index

In [135]: df = pd.DataFrame(
          .....:   {"line_race": [10, 10, 8, 10, 10, 8], "beyer": [99, 102, 103, 103, 88,
          .....:   100]},
          .....:   index=[
          .....:     "Last Gunfighter",
          .....:     "Last Gunfighter",
          .....:     "Last Gunfighter",
          .....:     "Paynter",
          .....:     "Paynter",
          .....:     "Paynter",
          .....:     ],
          .....:   )
          .....:

In [136]: df
Out[136]:
      line_race  beyer
Last Gunfighter   10    99
Last Gunfighter   10  102
Last Gunfighter    8  103
    Paynter    10  103
    Paynter    10    88
    Paynter    8  100

In [137]: df["beyer_shifted"] = df.groupby(level=0)["beyer"].shift(1)

In [138]: df
Out[138]:
Select row with maximum value from each group

```python
In [139]: df = pd.DataFrame(......:  ......:     "host": ["other", "other", "that", "this", "this"],
......:     "service": ["mail", "web", "mail", "mail", "web"],
......:     "no": [1, 2, 1, 2, 1],
......:  ).set_index(["host", "service"])
......:

In [140]: mask = df.groupby(level=0).agg("idxmax")

How to set the index and join

KDB like asof join
Join with a criteria based on the values
Using searchsorted to merge based on values inside a range

2.27.8 Plotting

The **Plotting** docs.

Make Matplotlib look like R

Setting x-axis major and minor labels

Plotting multiple charts in an IPython Jupyter notebook

Creating a multi-line plot

Plotting a heatmap

Annotate a time-series plot

Generate Embedded plots in excel files using Pandas, Vincent and xlsxwriter

Boxplot for each quartile of a stratifying variable

```
In [186]: df = pd.DataFrame(
    ...:     
    ...:     
    ...:     "stratifying_var": np.random.uniform(0, 100, 20),
    ...:     "price": np.random.normal(100, 5, 20),
    ...:     )
    ...:     
    ...:     

In [187]: df["quartiles"] = pd.qcut(
    ...:     df["stratifying_var"], 4, labels=["0-25%", "25-50%", "50-75%", "75-100%"]
    ...:     )
    ...:     

In [188]: df.boxplot(column="price", by="quartiles")
Out[188]: <AxesSubplot:title={'center':'price'}, xlabel='quartiles'>
2.27.9 Data in/out

Performance comparison of SQL vs HDF5

CSV

The CSV docs

read_csv in action

appending to a csv

Reading a csv chunk-by-chunk

Reading only certain rows of a csv chunk-by-chunk

Reading the first few lines of a frame

Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which read_csv understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here

Inferring dtypes from a file

Dealing with bad lines GH2886
Write a multi-row index CSV without writing duplicates

**Reading multiple files to create a single DataFrame**

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```python
In [189]: for i in range(3):
      ....:     data = pd.DataFrame(np.random.randn(10, 4))
      ....:     data.to_csv("file_{}.csv".format(i))
      ....:

In [190]: files = ["file_0.csv", "file_1.csv", "file_2.csv"]

In [191]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```python
In [192]: import glob

In [193]: import os

In [194]: files = glob.glob("file_*.csv")

In [195]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*(...)` functions described in the `io docs`.

**Parsing date components in multi-columns**

Parsing date components in multi-columns is faster with a format:

```python
In [196]: i = pd.date_range("20000101", periods=10000)

In [197]: df = pd.DataFrame({"year": i.year, "month": i.month, "day": i.day})

In [198]: df.head()
Out[198]:
   year  month  day
0   2000     1     1
1   2000     1     2
2   2000     1     3
3   2000     1     4
4   2000     1     5

In [199]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format="%Y%m%d")
       1 loop, best of 3: 1.43 s per loop

       ....: ds = df.apply(lambda x: "%04d%02d%02d" % (x["year"], x["month"], x["day"]), axis=1)
       ....: ds.head()
       ....: %timeit pd.to_datetime(ds)
       ....:
```

(continues on next page)
Skip row between header and data

```python
In [200]: data = """";
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....: 
   ....:
   ....: date;Param1;Param2;Param4;Param5
   ....: ;m²;°C;m²;m
   ....: ....
   ....: 01.01.1990 00:00:00;1;1;2;3
   ....: 01.01.1990 01:00:00;5;3;4;5
   ....: 01.01.1990 02:00:00;9;5;6;7
   ....: 01.01.1990 03:00:00;13;7;8;9
   ....: 01.01.1990 04:00:00;17;9;10;11
   ....: 01.01.1990 05:00:00;21;11;12;13
   ....:
   ....:
```

Option 1: pass rows explicitly to skip rows

```python
In [201]: from io import StringIO

In [202]: pd.read_csv(  
   ....:     StringIO(data),  
   ....:     sep=";",  
   ....:     skiprows=[11, 12],  
   ....:     index_col=0,  
   ....:     parse_dates=True,  
   ....:     header=10,  
   ....: )
```

```
Out[202]:
```
<table>
<thead>
<tr>
<th></th>
<th>Param1</th>
<th>Param2</th>
<th>Param4</th>
<th>Param5</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>

Counting with a HDFStore
Troubleshoot HDFStore exceptions
Setting min_itemsize with strings
Using ptrepack to create a completely-sorted-index on a store

Storing Attributes to a group node

```python
In [206]: df = pd.DataFrame(np.random.randn(8, 3))
In [207]: store = pd.HDFStore("test.h5")
In [208]: store.put("df", df)
# you can store an arbitrary Python object via pickle
In [209]: store.get_storer("df").attrs.my_attribute = {"A": 10}
In [210]: store.get_storer("df").attrs.my_attribute
Out[210]: {'A': 10}
```

You can create or load a HDFStore in-memory by passing the `driver` parameter to PyTables. Changes are only written to disk when the HDFStore is closed.

```python
In [211]: store = pd.HDFStore("test.h5", "w", driver="H5FD_CORE")
In [212]: df = pd.DataFrame(np.random.randn(8, 3))
In [213]: store["test"] = df
# only after closing the store, data is written to disk:
In [214]: store.close()
```
Binary files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called main.c compiled with gcc main.c -std=gnu99 on a 64-bit machine,

```c
#include <stdio.h>
#include <stdint.h>

typedef struct _Data {
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[]) {
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i) {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }

    FILE *file = fopen("binary.dat", "wb");
    fwrite(&d, sizeof(Data), n, file);
    fclose(file);

    return 0;
}
```

the following Python code will read the binary file ‘binary.dat’ into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```python
names = "count", "avg", "scale"

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = "i4", "f8", "f4"
dt = np.dtype({"names": names, "offsets": offsets, "formats": formats}, align=True)
df = pd.DataFrame(np.fromfile("binary.dat", dt))
```

Note: The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommend either HDF5 or parquet, both of which are supported by pandas’ IO facilities.
2.27.10 Computation

Numerical integration (sample-based) of a time series

Correlation

Often it’s useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from DataFrame.corr(). This can be achieved by passing a boolean mask to where as follows:

In [215]: df = pd.DataFrame(np.random.random(size=(100, 5)))
In [216]: corr_mat = df.corr()
In [217]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool_), k=-1)
In [218]: corr_mat.where(mask)
Out[218]:
   0  1  2  3  4
0   NaN NaN NaN NaN NaN
1 -0.079861 NaN NaN NaN NaN
2 -0.236573 0.183801 NaN NaN NaN
3 -0.013795 -0.051975 0.037235 NaN NaN
4 -0.031974 0.118342 -0.073499 -0.02063 NaN

The method argument within DataFrame.corr can accept a callable in addition to the named correlation types. Here we compute the distance correlation matrix for a DataFrame object.

In [219]: def distcorr(x, y):
   ....:     n = len(x)
   ....:     a = np.zeros(shape=(n, n))
   ....:     b = np.zeros(shape=(n, n))
   ....:     for i in range(n):
   ....:         for j in range(i + 1, n):
   ....:             a[i, j] = abs(x[i] - x[j])
   ....:             b[i, j] = abs(y[i] - y[j])
   ....:     a += a.T
   ....:     b += b.T
   ....:     a_bar = np.vstack([np.nanmean(a, axis=0)] * n)
   ....:     b_bar = np.vstack([np.nanmean(b, axis=0)] * n)
   ....:     A = a - a_bar - a_bar.T + np.full(shape=(n, n), fill_value=a_bar.mean())
   ....:     B = b - b_bar - b_bar.T + np.full(shape=(n, n), fill_value=b_bar.mean())
   ....:     cov_ab = np.sqrt(np.nansum(A * B)) / n
   ....:     std_a = np.sqrt(np.sqrt(np.nansum(A ** 2)) / n)
   ....:     std_b = np.sqrt(np.sqrt(np.nansum(B ** 2)) / n)
   ....:     return cov_ab / std_a / std_b

In [220]: df = pd.DataFrame(np.random.normal(size=(100, 3)))
In [221]: df.corr(method=distcorr)
Out[221]:
   0   1   2
0 1.000000 0.197613 0.216328
(continues on next page)
2.27.11 Timedeltas

The *Timedeltas* docs.

Using timedeltas

In [222]: import datetime

In [223]: s = pd.Series(pd.date_range("2012-1-1", periods=3, freq="D"))

In [224]: s - s.max()
Out[224]:
0   -2 days
1   -1 days
2    0 days
dtype: timedelta64[ns]

In [225]: s.max() - s
Out[225]:
0    2 days
1    1 days
2    0 days
dtype: timedelta64[ns]

In [226]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[226]:
0  364 days 20:55:00
1  365 days 20:55:00
2  366 days 20:55:00
dtype: timedelta64[ns]

In [227]: s + datetime.timedelta(minutes=5)
Out[227]:
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]

In [228]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[228]:
0 -365 days +03:05:00
1 -366 days +03:05:00
2 -367 days +03:05:00
dtype: timedelta64[ns]

In [229]: datetime.timedelta(minutes=5) + s
Out[229]:
0 2012-01-01 00:05:00
(continues on next page)
Adding and subtracting deltas and dates

In [230]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])

In [231]: df = pd.DataFrame({'A': s, 'B': deltas})

In [232]: df
Out[232]:
   A          B
0 2012-01-02 00:05:00 2012-01-01 0 days
1 2012-01-03 00:05:00 2012-01-02 1 days
2 2012-01-03 00:05:00 2012-01-03 2 days

In [233]: df['New Dates'] = df['A'] + df['B']

In [234]: df['Delta'] = df['A'] - df['New Dates']

In [235]: df
Out[235]:
   A          B  New Dates  Delta
0 2012-01-02 00:05:00 2012-01-01 0 days       0 days
1 2012-01-03 00:05:00 2012-01-02 1 days       -1 days
2 2012-01-03 00:05:00 2012-01-03 2 days       -2 days

In [236]: df.dtypes
Out[236]:
A object
B object
New Dates object
Delta object

Another example

Values can be set to NaT using np.nan, similar to datetime

In [237]: y = s - s.shift()

In [238]: y
Out[238]:
0 NaT
1 1 days
2 1 days
dtype: timedelta64[ns]

In [239]: y[1] = np.nan

In [240]: y
Out[240]:
0 NaT
1 NaT
2 NaT
(continues on next page)
2.27.12 Creating example data

To create a dataframe from every combination of some given values, like R’s `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```python
In [241]: def expand_grid(data_dict):
    ....:     rows = itertools.product(*data_dict.values())
    ....:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
    ....:

In [242]: df = expand_grid(
    ....:     {"height": [60, 70], "weight": [100, 140, 180], "sex": ["Male", "Female"]}
    ....: )
    ....:

In [243]: df
Out[243]:
   height  weight  sex
0      60      100  Male
1      60      100  Female
2      60      140   Male
3      60      140  Female
4      60      180  Male
5      60      180  Female
6      70      100  Male
7      70      100  Female
8      70      140   Male
9      70      140  Female
10     70      180  Male
11     70      180  Female
```
CHAPTER
THREE

API REFERENCE

This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in pandas.* namespace are public.

Some subpackages are public which include pandas.errors, pandas.plotting, and pandas.testing. Public functions in pandas.io and pandas.tseries submodules are mentioned in the documentation. pandas.api.types subpackage holds some public functions related to data types in pandas.

Warning: The pandas.core, pandas.compat, and pandas.util top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

3.1 Input/output

3.1.1 Pickling

read_pickle(filepath_or_buffer[, ...]) Load pickled pandas object (or any object) from file.
DataFrame.to_pickle(path[, compression, ...]) Pickle (serialize) object to file.

pandas.read_pickle

pandas.read_pickle(filepath_or_buffer, compression='infer', storage_options=None)
Load pickled pandas object (or any object) from file.

Warning: Loading pickled data received from untrusted sources can be unsafe. See here.

Parameters

filepath_or_buffer [str, path object, or file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a binary readlines() function.

Changed in version 1.0.0: Accept URL. URL is not limited to S3 and GCS.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘filepath_or_buffer’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2',

1027
'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary:

```python
compression={'method': 'zstd', 'dict_data': my_compression_dict}
```

Changed in version 1.4.0: Zstandard support.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://” and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**Returns**

**unpickled** [same type as object stored in file]

See also:

*DataFrame.to_pickle* Pickle (serialize) DataFrame object to file.

*Series.to_pickle* Pickle (serialize) Series object to file.

*read_hdf* Read HDF5 file into a DataFrame.

*read_sql* Read SQL query or database table into a DataFrame.

*read_parquet* Load a parquet object, returning a DataFrame.

**Notes**

read_pickle is only guaranteed to be backwards compatible to pandas 0.20.3.

**Examples**

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> pd.to_pickle(original_df, ".\dummy.pkl")

>>> unpickled_df = pd.read_pickle(".\dummy.pkl")
>>> unpickled_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9
```
pandas.DataFrame.to_pickle

DataFrame.to_pickle(path, compression='infer', protocol=5, storage_options=None)

Pickle (serialize) object to file.

Parameters

- **path** [str] File path where the pickled object will be stored.
- **compression** [str or dict, default 'infer'] For on-the-fly compression of the output data. If 'infer' and 'path' path-like, then detect compression from the following extensions: .gz, .bz2, .zip, .xz, or .zst (otherwise no compression). Set to None for no compression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile,.bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}.
- **protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

- **read_pickle** Load pickled pandas object (or any object) from file.
- **DataFrame.to_hdf** Write DataFrame to an HDF5 file.
- **DataFrame.to_sql** Write DataFrame to a SQL database.
- **DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

Examples

```python
>>> original_df = pd.DataFrame({'foo': range(5), 'bar': range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle('./dummy.pkl')

>>> unpickled_df = pd.read_pickle('./dummy.pkl')
>>> unpickled_df
   foo  bar
0    0    5
(continues on next page)
```
3.1.2 Flat file

<table>
<thead>
<tr>
<th>pandas.read_table</th>
<th>Read general delimited file into DataFrame.</th>
</tr>
</thead>
<tbody>
<tr>
<td>read_table(filepath_or_buffer[, sep, ...])</td>
<td>Read general delimited file into DataFrame.</td>
</tr>
<tr>
<td>read_csv(filepath_or_buffer[, sep, ...])</td>
<td>Read a comma-separated values (csv) file into DataFrame.</td>
</tr>
<tr>
<td>DataFrame.to_csv([path_or_buf, sep, na_rep, ...])</td>
<td>Write object to a comma-separated values (csv) file.</td>
</tr>
<tr>
<td>read_fwf(filepath_or_buffer[, colspecs, ...])</td>
<td>Read a table of fixed-width formatted lines into DataFrame.</td>
</tr>
</tbody>
</table>

pandas.read_table

pandas.read_table(filepath_or_buffer, sep=NoDefault.no_default, delimiter=None, header='infer', names=NoDefault.no_default, index_col=None, usecols=None, squeeze=None, prefix=NoDefault.no_default, mangle_dupe_cols=True, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skipinitialspace=False, skiprows=None, skipfooter=0, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False, infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False, cache_dates=True, iterator=False, chunksize=None, compression=NoDefault.infer, thousands=None, decimal=’,’, lineterminator=None, quotechar=’”’, quoting=0, doublequote=True, escapechar=None, comment=None, encoding=None, encoding_errors=strict, dialect=None, error_bad_lines=None, warn_bad_lines=None, on_bad_lines=None, delim_whitespace=False, low_memory=True, memory_map=False, float_precision=None, storage_options=None)

Read general delimited file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

If you want to pass in a path object, pandas accepts any os.PathLike.

By file-like object, we refer to objects with a read() method, such as a file handle (e.g. via builtin open function) or StringIO.

sep [str, default ‘t’ (tab-stop)] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from ‘\s+’ will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: ‘\r\t’.
delimiter  [str, default None]  Alias for sep.

header  [int, list of int, None, default ‘infer’]  Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names  [array-like, optional]  List of column names to use. If the file contains a header row, then you should explicitly pass header=0 to override the column names. Duplicates in this list are not allowed.

index_col  [int, str, sequence of int/str, or False, optional, default None]  Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols  [list-like or callable, optional]  Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). If names are given, the document header row(s) are not taken into account. For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order. If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze  [bool, default False]  If the parsed data only contains one column then return a Series.

Depreciated since version 1.4.0: Append .squeeze("columns") to the call to read_table to squeeze the data.

prefix  [str, optional]  Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

Depreciated since version 1.4.0: Use a list comprehension on the DataFrame’s columns after calling read_csv.

mangle_dupe_cols  [bool, default True]  Duplicate columns will be specified as ‘X’, ‘X.1’, … ’X.N’, rather than ‘X’...’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype  [Type name or dict of column -> type, optional]  Data type for data or columns. E.g. {‘a’: np.float64, ‘b’: np.int32, ‘c’: ‘Int64’} Use str or object together with suitable na_values settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine  [‘c’, ‘python’, ‘pyarrow’], optional]  Parser engine to use. The C and pyarrow engines are faster, while the python engine is currently more feature-complete. Multithreading is
currently only supported by the pyarrow engine.

New in version 1.4.0: The “pyarrow” engine was added as an experimental engine, and some features are unsupported, or may not work correctly, with this engine.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, optional] Values to consider as True.

**false_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skips spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: '', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', '<NA>', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

- If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
- If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
- If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

**na_filter** [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip_blank_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

**parse_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
• list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
• dict, e.g. { ‘foo’ : [1, 3] } -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an un-parsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use pd.to_datetime after pd.
read_csv. To parse an index or column with a mixture of timezones, specify date_parser to be a partially-applied pandas.to_datetime() with utc=True. See Parsing a CSV with mixed timezones for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and parse_dates is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses dateutil.parser.parser to do the conversion. Pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return TextFileReader object for iteration or getting chunks with get_chunk().

Changed in version 1.2: TextFileReader is a context manager.

chunksize [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on iterator and chunksize.

Changed in version 1.2: TextFileReader is a context manager.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘%s’ is path-like, then detect compression from the following extensions: .gz’, .bz2’, .zip’, .xz’, or .zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of { ‘zip’, ‘gzip’, ‘bz2’, ‘zstd’ } and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard. ZstdDecompressor, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: compression=’zstd’, ‘dict_data’: my_compression_dict).

Changed in version 1.4.0: Zstandard support.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).
lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='#', parsing #empty
a,b,c
1,2,3 with header=0 will result in ‘a,b,c’ being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. `utf-8`). List of Python standard encodings.

Changed in version 1.2: When encoding is None, errors="replace" is passed to open(). Otherwise, errors="strict" is passed to open(). This behavior was previously only the case for engine="python".

Changed in version 1.3.0: encoding_errors is a new argument. encoding has no longer an influence on how encoding errors are handled.

encoding_errors [str, optional, default “strict”) How encoding errors are treated. List of possible values.

New in version 1.3.0.

dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines [bool, optional, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

warn_bad_lines [bool, optional, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

on_bad_lines [{'error', ‘warn’, ‘skip’} or callable, default ‘error’) Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are:

- ‘error’, raise an Exception when a bad line is encountered.
- ‘warn’, raise a warning when a bad line is encountered and skip that line.
- ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0:

- callable, function with signature \(\text{bad_line: list[str]} \rightarrow \text{list[str]} | \text{None}\) that will process a single bad line. \text{bad_line} is a list of strings split by the \text{sep}. If the function returns \text{None}, the bad line will be ignored. If the function returns a new list of strings with more elements than expected, a \text{ParserWarning} will be emitted while dropping extra elements. Only supported when \text{engine=\"python\"}

New in version 1.4.0.

\text{delim_whitespace} [bool, default False] Specifies whether or not whitespace (e.g. ‘ ’ or ‘ ’) will be used as the \text{sep}. Equivalent to setting \text{sep='\s+'}. If this option is set to True, nothing should be passed in for the \text{delimiter} parameter.

\text{low_memory} [bool, default True] Internally process the file in chunks, resulting in lower memory usage while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the \text{dtype} parameter. Note that the entire file is read into a single DataFrame regardless, use the \text{chunksize} or \text{iterator} parameter to return the data in chunks. (Only valid with C parser).

\text{memory_map} [bool, default False] If a filepath is provided for \text{filepath_or_buffer}, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

\text{float_precision} [str, optional] Specifies which converter the C engine should use for floating-point values. The options are \text{None} or ‘high’ for the ordinary converter, ‘legacy’ for the original lower precision pandas converter, and ‘round_trip’ for the round-trip converter.

Changed in version 1.2.

\text{storage_options} [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to \text{urllib} as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to \text{fsspec}. Please see \text{fsspec} and \text{urllib} for more details.

New in version 1.2.

Returns

\text{DataFrame or TextParser} A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

\text{DataFrame.to_csv} Write DataFrame to a comma-separated values (csv) file.

\text{read_csv} Read a comma-separated values (csv) file into DataFrame.

\text{read_fwf} Read a table of fixed-width formatted lines into DataFrame.
Examples

```python
>>> pd.read_table('data.csv')
```

`pandas.read_csv` is used to read a comma-separated values (csv) file into DataFrame. It also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

- **filepath_or_buffer** (str, path object or file-like object) Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv. If you want to pass in a path object, pandas accepts any `os.PathLike`.

- **sep** (str, default ',') Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin `sniffer` tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

- **delimiter** (str, default None) Alias for sep.

- **header** (int, list of int, None, default 'infer') Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so header=0 denotes the first line of data rather than the first line of the file.

- **names** (array-like, optional) List of column names to use. If the file contains a header row, then you should explicitly pass header=0 to override the column names. Duplicates in this list are not allowed.
index_col [int, str, sequence of int / str, or False, optional, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). If names are given, the document header row(s) are not taken into account. For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

Deprecated since version 1.4.0: Append .squeeze("columns") to the call to read_csv to squeeze the data.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

Deprecated since version 1.4.0: Use a list comprehension on the DataFrame’s columns after calling read_csv.

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, … ’X.N’, rather than ‘X’...’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Typename or dict of column -> type, optional] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32, 'c': 'Int64'} Use str or object together with suitable na_values settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine [{'c', 'python', 'pyarrow'}, optional] Parser engine to use. The C and pyarrow engines are faster, while the python engine is currently more feature-complete. Multithreading is currently only supported by the pyarrow engine.

New in version 1.4.0: The “pyarrow” engine was added as an experimental engine, and some features are unsupported, or may not work correctly, with this engine.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.
If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘‘, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘null’.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

- If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
- If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
- If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

**na_filter** [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip_blank_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

**parse_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an unparsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See Parsing a CSV with mixed timezones for more.

Note: A fast-path exists for iso8601-formatted dates.

**infer_datetime_format** [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred,
switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep_date_col** [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**date_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parse` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [bool, default False] DD/MM format dates, international and European format.

**cache_dates** [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

**iterator** [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

Changed in version 1.2: TextFileReader is a context manager.

**chunksize** [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on `iterator` and `chunksize`.

Changed in version 1.2: TextFileReader is a context manager.

**compression** [str or dict, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer' and '%s' is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', '.xz', or '.zst' (otherwise no compression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to `None` for no decompression. Can also be a dict with key 'method' set to one of ['zip', 'gzip', 'bz2', 'zstd'] and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: `compression={'method': 'zstd', 'dict_data': my_compression_dict}`.

Changed in version 1.4.0: Zstandard support.

**thousands** [str, optional] Thousands separator.

**decimal** [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

**lineterminator** [str (length 1), optional] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

**doublequote** [bool, default True] When `quotechar` is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

**escapechar** [str (length 1), optional] One-character string used to escape other characters.
comment  [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='#', parsing #empty\na,b,c\n1,2,3 with header=0 will result in ‘a,b,c’ being treated as the header.

encoding  [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings.

Changed in version 1.2: When encoding is None, errors="replace" is passed to open(). Otherwise, errors="strict" is passed to open(). This behavior was previously only the case for engine="python".

Changed in version 1.3.0: encoding_errors is a new argument. encoding has no longer an influence on how encoding errors are handled.

encoding_errors  [str, optional, default “strict”] How encoding errors are treated. List of possible values.

New in version 1.3.0.

dialect  [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines  [bool, optional, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

warn_bad_lines  [bool, optional, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

on_bad_lines  [{‘error’, ‘warn’, ‘skip’} or callable, default ‘error’] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are:

- ‘error’, raise an Exception when a bad line is encountered.
- ‘warn’, raise a warning when a bad line is encountered and skip that line.
- ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0:

- callable, function with signature (bad_line: list[str]) -> list[str] | None that will process a single bad line. bad_line is a list of strings split by the sep. If the function returns None, the bad line will be ignored. If the function returns a new list of strings with more elements than expected, a ParserWarning will be emitted while dropping extra elements. Only supported when engine="python"

New in version 1.4.0.

delim_whitespace  [bool, default False] Specifies whether or not whitespace (e.g. ‘ ‘ or ‘ ’) will be used as the sep. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the delimiter parameter.
**low_memory** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtye parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser).

**memory_map** [bool, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are None or ‘high’ for the ordinary converter, ‘legacy’ for the original lower precision pandas converter, and ‘round_trip’ for the round-trip converter. Changed in version 1.2.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details. New in version 1.2.

**Returns**

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

**See also:**

DataFrame.to_csv Write DataFrame to a comma-separated values (csv) file.
read_csv Read a comma-separated values (csv) file into DataFrame.
read_fwf Read a table of fixed-width formatted lines into DataFrame.

**Examples**

```python
>>> pd.read_csv('data.csv')
```

**pandas.DataFrame.to_csv**

DataFrame.to_csv(path_or_buf=None, sep=',', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, mode='w', encoding=None, compression='infer', quoting=None, quotechar='"', line_terminator=None, chunksize=None, date_format=None, doublequote=True, escapechar=None, decimal='.', errors='strict', storage_options=None)

Write object to a comma-separated values (csv) file.

**Parameters**

**path_or_buf** [str, path object, file-like object, or None, default None] String, path object (implementing os.PathLike[str]), or file-like object implementing a write() function. If None, the result is returned as a string. If a non-binary file object is passed, it should be opened with newline='', disabling universal newlines. If a binary file object is passed, mode might need to contain a ‘b’.

Changed in version 1.2.0: Support for binary file objects was introduced.
sep [str, default ','] String of length 1. Field delimiter for the output file.

na_rep [str, default ''] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use index_label=False for easier importing in R.

mode [str] Python write mode, default 'w'.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'. encoding is not supported if path_or_buf is a non-binary file object.

 compression [str or dict, default 'infer'] For on-the-fly compression of the output data. If 'infer' and '%s' path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', '.xz', or '.zst' (otherwise no compression). Set to None for no compression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}.

 Changed in version 1.0.0: May now be a dict with key ‘method’ as compression mode and other entries as additional compression options if compression mode is ‘zip’.

 Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes ‘gzip’, ‘bz2’, ‘zstd’, and ‘zip’.

 Changed in version 1.2.0: Compression is supported for binary file objects.

 Changed in version 1.2.0: Previous versions forwarded dict entries for ‘gzip’ to gzip.open instead of gzip.GzipFile which prevented setting mtime.

 quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a float_format then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

 quotechar [str, default ‘’] String of length 1. Character used to quote fields.

 line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to os.linesep, which depends on the OS in which this method is called (’\n’ for linux, ‘\r\n’ for Windows, i.e.).

 chunksize [int or None] Rows to write at a time.

 date_format [str, default None] Format string for datetime objects.

 doublequote [bool, default True] Control quoting of quotechar inside a field.

 escapechar [str, default None] String of length 1. Character used to escape sep and quotechar when appropriate.

 decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.
errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.
New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.
New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.
to_excel Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff

Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
...                       archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...            compression=compression_opts)

To write a csv file to a new folder or nested folder you will first need to create it using either Pathlib or os:

```python
>>> from pathlib import Path
>>> filepath = Path('folder/subfolder/out.csv')
>>> filepath.parent.mkdir(parents=True, exist_ok=True)
>>> df.to_csv(filepath)

>>> import os
>>> os.makedirs('folder/subfolder', exist_ok=True)
>>> df.to_csv('folder/subfolder/out.csv')
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

**pandas.read_fwf**

`pandas.read_fwf(filepath_or_buffer, colspecs='infer', widths=None, infer_nrows=100, **kwds)`

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

- `filepath_or_buffer` [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a `text.read()` function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

- `colspecs` [list of tuple(int, int) or 'infer'. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via skiprows (default='infer').

- `widths` [list of int, optional] A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

- `infer_nrows` [int, default 100] The number of rows to consider when letting the parser determine the `colspecs`.

- `**kwds` [optional] Optional keyword arguments can be passed to `TextFileReader`.

**Returns**

- `DataFrame` or `TextFileReader` A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

**See also:**

- `DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.
- `read_csv` Read a comma-separated values (csv) file into DataFrame.

**Examples**

```python
>>> pd.read_fwf('data.csv')
```

### 3.1.3 Clipboard

**read_clipboard([sep])**

Read text from clipboard and pass to `read_csv`.

**DataFrame.to_clipboard([excel, sep])**

Copy object to the system clipboard.
**pandas.read_clipboard**

`pandas.read_clipboard(sep='\s+', **kwargs)`

Read text from clipboard and pass to `read_csv`.

**Parameters**

- `sep` [str, default 's+'] A string or regex delimiter. The default of 's+' denotes one or more whitespace characters.

- **kwargs** See `read_csv` for the full argument list.

**Returns**

- `DataFrame` A parsed DataFrame object.

**pandas.DataFrame.to_clipboard**

`DataFrame.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- `excel` [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
  - False, write a string representation of the object to the clipboard.

- `sep` [str, default '\t'] Field delimiter.

- **kwargs** These parameters will be passed to `DataFrame.to_csv`.

**See also:**

- `DataFrame.to_csv` Write a DataFrame to a comma-separated values (csv) file.
- `read_clipboard` Read text from clipboard and pass to `read_csv`.

**Notes**

Requirements for your platform.

- Linux: `xclip`, or `xsel` (with PyQt4 modules)
- Windows: none
- macOS: none
Examples

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])

>>> df.to_clipboard(sep=',
...                  # Wrote the following to the system clipboard:
...                  # 0,A,B,C
...                  # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',
...                  index=False)
...                  # Wrote the following to the system clipboard:
...                  # A,B,C
...                  # 1,2,3
...                  # 4,5,6
```

### 3.1.4 Excel

<table>
<thead>
<tr>
<th>pandas.read_excel</th>
<th>Read an Excel file into a pandas DataFrame.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.to_excel</td>
<td>Write object to an Excel sheet.</td>
</tr>
<tr>
<td>ExcelFile.parse</td>
<td>Parse specified sheet(s) into a DataFrame.</td>
</tr>
</tbody>
</table>

**pandas.read_excel**

Read an Excel file into a pandas DataFrame.

Supports `.xls`, `.xlsx`, `.xlsm`, `.xlsm`, `.odf`, `.ods` and `.odt` file extensions read from a local filesystem or URL. Supports an option to read a single sheet or a list of sheets.

**Parameters**

- `io` [str, bytes, ExcelFile, xlrd.Book, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.xlsx`.
  - If you want to pass in a path object, pandas accepts any `os.PathLike`.
  - By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via built-in `open` function) or `StringIO`.

- `sheet_name` [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions (chart sheets do not count as a sheet position). Lists of strings/integers are used to request multiple sheets. Specify None to get all worksheets.
Available cases:

- Defaults to 0: 1st sheet as a DataFrame
- 1: 2nd sheet as a DataFrame
- "Sheet1": Load sheet with name “Sheet1”
- [0, 1, "Sheet5"]: Load first, second and sheet named “Sheet5” as a dict of DataFrame
- None: All worksheets.

**header** [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a MultiIndex. Use None if there is no header.

**names** [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None.

**index_col** [int, list of int, default None] Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a MultiIndex. If a subset of data is selected with usecols, index_col is based on the subset.

**usecols** [int, str, list-like, or callable default None]

- If None, then parse all columns.
- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. “A:E” or “A,C,E:F”). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.
- If callable, then evaluate each column name against it and parse the column if the callable returns True.

Returns a subset of the columns according to behavior above.

**squeeze** [bool, default False] If the parsed data only contains one column then return a Series.

Deprecated since version 1.4.0: Append .squeeze("columns") to the call to read_excel to squeeze the data.

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {‘a’: np.float64, ‘b’: np.int32} Use object to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [str, default None] If io is not a buffer or path, this must be set to identify io. Supported engines: “xlrd”, “openpyxl”, “odf”, “pyxlsb”. Engine compatibility:

- “xlrd” supports old-style Excel files (.xls).
- “openpyxl” supports newer Excel file formats.
- “odf” supports OpenDocument file formats (.odf, .ods, .odt).
- “pyxlsb” supports Binary Excel files.

Changed in version 1.2.0: The engine xlrd now only supports old-style .xls files. When engine=None, the following logic will be used to determine the engine:

- If path_or_buffer is an OpenDocument format (.odf, .ods, .odt), then odf will be used.
- Otherwise if path_or_buffer is an xls format, xlrd will be used.
• Otherwise if `path_or_buffer` is in xlsb format, `pyxlsb` will be used.
  New in version 1.3.0.
• Otherwise `openpyxl` will be used.
  Changed in version 1.3.0.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

**true_values** [list, default None] Values to consider as True.

**false_values** [list, default None] Values to consider as False.

**skiprows** [list-like, int, or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file. If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**nrows** [int, default None] Number of rows to parse.

**na_values** [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘‘, ‘‘#N/A’, ‘‘#N/A N/A’, ‘‘#NA’, ‘‘-1.#IND’, ‘‘-1.#QNAN’, ‘‘-NaN’, ‘‘-nan’, ‘‘1.#IND’, ‘‘1.#QNAN’, ‘‘<NaN>’, ‘‘N/A’, ‘‘NA’, ‘‘NULL’, ‘‘NaN’, ‘‘n/a’, ‘‘nan’, ‘‘null’.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:
  • If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
  • If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
  • If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
  • If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

**na_filter** [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**parse_dates** [bool, list-like, or dict, default False] The behavior is as follows:
  • bool. If True -> try parsing the index.
  • list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
  • list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
  • dict, e.g. { ‘foo’ : [1, 3] } -> parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. If you don’t want to parse some cells as date just change...
their type in Excel to “Text”. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_excel`.

Note: A fast-path exists for iso8601-formatted dates.

`date_parser` [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

`thousands` [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

`decimal` [str, default ‘.’] Character to recognize as decimal point for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format. (e.g. use ‘,’ for European data).

New in version 1.4.0.

`comment` [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

`skipfooter` [int, default 0] Rows at the end to skip (0-indexed).

`convert_float` [bool, default True] Convert integral floats to int (i.e., 1.0 –> 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

Deprecated since version 1.3.0: `convert_float` will be removed in a future version

`mangle_dupe_cols` [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’…‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

`storage_options` [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a local path or a file-like buffer. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

See also:

`DataFrame.to_excel` Write DataFrame to an Excel file.

`DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

`read_fwf` Read a table of fixed-width formatted lines into DataFrame.
Examples

The file can be read using the file name as string or an open file object:

```python
>>> pd.read_excel('tmp.xlsx', index_col=0)
Name   Value
0  string1  1
1  string2  2
2   #Comment  3
```

```python
>>> pd.read_excel(open('tmp.xlsx', 'rb'),
                 sheet_name='Sheet3')
   Unnamed: 0  Name   Value
     0          0  string1  1
     1          1  string2  2
     2          2   #Comment  3
```

Index and header can be specified via the `index_col` and `header` arguments

```python
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None)
  0  1  2
0 NaN Value
1  0.0 string1  1
2  1.0  string2  2
3  2.0   #Comment  3
```

Column types are inferred but can be explicitly specified

```python
>>> pd.read_excel('tmp.xlsx', index_col=0,
                 dtype={'Name': str, 'Value': float})
Name   Value
0  string1  1.0
1  string2  2.0
2   #Comment  3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```python
>>> pd.read_excel('tmp.xlsx', index_col=0,
                 na_values=['string1', 'string2'])
Name   Value
0     NaN  1
1     NaN  2
2   #Comment  3
```

Comment lines in the excel input file can be skipped using the `comment` kwarg

```python
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#')
Name   Value
0  string1  1.0
1  string2  2.0
2    None   NaN
```
pandas.DataFrame.to_excel

DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None, storage_options=None)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

- excel_writer [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- sheet_name [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- na_rep [str, default ‘’] Missing data representation.
- float_format [str, optional] Format string for floating point numbers. For example float_format="%.2f" will format 0.1234 to 0.12.
- columns [sequence or list of str, optional] Columns to write.
- header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- index [bool, default True] Write row names (index).
- index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- startrow [int, default 0] Upper left cell row to dump data frame.
- startcol [int, default 0] Upper left cell column to dump data frame.

Deprecation since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.
- merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).
- verbose [bool, default True] Display more information in the error logs.
- freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.
- storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are

3.1. Input/output
forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

See also:

- `to_csv` Write DataFrame to a comma-separated values (csv) file.
- `ExcelWriter` Class for writing DataFrame objects into excel sheets.
- `read_excel` Read an Excel file into a pandas DataFrame.
- `read_csv` Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                     index=['row 1', 'row 2'],
...                     columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
...               sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx',
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```
pandas.ExcelFile.parse

ExcelFile.parse(sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=None, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=None, mangle_dupe_cols=True, **kwds)

Parse specified sheet(s) into a DataFrame.

Equivalent to read_excel(ExcelFile, …) See the read_excel docstring for more info on accepted parameters.

Returns

DataFrame or dict of DataFrames  DataFrame from the passed in Excel file.

Styler.to_excel(excel_writer[, sheet_name, …])  Write Styler to an Excel sheet.

pandas.io.formats.style.Styler.to_excel

Styler.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)

Write Styler to an Excel sheet.

To write a single Styler to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer  [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.

sheet_name  [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.

na_rep  [str, default ‘’] Missing data representation.

float_format  [str, optional] Format string for floating point numbers. For example 
float_format="%.2f" will format 0.1234 to 0.12.

columns  [sequence or list of str, optional] Columns to write.

header  [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index  [bool, default True] Write row names (index).

index_label  [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow  [int, default 0] Upper left cell row to dump data frame.

startcol  [int, default 0] Upper left cell column to dump data frame.

groupby  [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this
Deprecation since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.

**merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

**encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

**inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

**verbose** [bool, default True] Display more information in the error logs.

**freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://” and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**See also:**

**to_csv** Write DataFrame to a comma-separated values (csv) file.

**ExcelWriter** Class for writing DataFrame objects into excel sheets.

**read_excel** Read an Excel file into a pandas DataFrame.

**read_csv** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

**Examples**

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd'],
...                      index=['row 1', 'row 2'],
...                      columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx', mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

### ExcelWriter(path[, engine, date_format, ...])
Class for writing DataFrame objects into excel sheets.

#### pandas.ExcelWriter

class pandas.ExcelWriter(path, engine=None, date_format=None, datetime_format=None, mode='w', storage_options=None, if_sheet_exists=None, engine_kwargs=None, **kwargs)

Class for writing DataFrame objects into excel sheets.

Default is to use: * xlwt for xls * xlsxwriter for xlsx if xlsxwriter is installed otherwise openpyxl * odf for ods.

See DataFrame.to_excel for typical usage.

The writer should be used as a context manager. Otherwise, call `close()` to save and close any opened file handles.

**Parameters**

- **path** [str or typing.BinaryIO] Path to xls or xlsx or ods file.
- **engine** [str (optional)] Engine to use for writing. If None, defaults to `io.excel.<extension>`. `writer`. NOTE: can only be passed as a keyword argument.

  Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.

- **date_format** [str, default None] Format string for dates written into Excel files (e.g. ‘YYYY-MM-DD’).
- **datetime_format** [str, default None] Format string for datetime objects written into Excel files. (e.g. ‘YYYY-MM-DD HH:MM:SS’).
- **mode** [‘w’, ‘a’], default ‘w’] File mode to use (write or append). Append does not work with fsspec URLs.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”,”gs://”.

  New in version 1.2.0.

- **if_sheet_exists** [‘error’, ‘new’, ‘replace’, ‘overlay’], default ‘error’] How to behave when trying to write to a sheet that already exists (append mode only).

  - error: raise a ValueError.

3.1. Input/output
• new: Create a new sheet, with a name determined by the engine.
• replace: Delete the contents of the sheet before writing to it.
• overlay: Write contents to the existing sheet without removing the old contents.

New in version 1.3.0.

Changed in version 1.4.0: Added overlay option

**engine_kwargs** [dict, optional] Keyword arguments to be passed into the engine. These will be passed to the following functions of the respective engines:

• xlsxwriter: xlsxwriter.Workbook(file, **engine_kwargs)
• openpyxl (write mode): openpyxl.Workbook(**engine_kwargs)
• openpyxl (append mode): openpyxl.load_workbook(file, **engine_kwargs)
• odswriter: odf.opendocument.OpenDocumentSpreadsheet(**engine_kwargs)

New in version 1.3.0.

**kwargs** [dict, optional] Keyword arguments to be passed into the engine.

Deprecated since version 1.3.0: Use engine_kwargs instead.

Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

Examples

Default usage:

```python
df = pd.DataFrame(["ABC", "XYZ"], columns=["Foo", "Bar"])
with pd.ExcelWriter("path_to_file.xlsx") as writer:
    df.to_excel(writer)
```

To write to separate sheets in a single file:

```python
df1 = pd.DataFrame(["AAA", "BBB"], columns=["Spam", "Egg"])
df2 = pd.DataFrame(["ABC", "XYZ"], columns=["Foo", "Bar"])
with pd.ExcelWriter("path_to_file.xlsx") as writer:
    df1.to_excel(writer, sheet_name="Sheet1")
    df2.to_excel(writer, sheet_name="Sheet2")
```

You can set the date format or datetime format:

```python
from datetime import date, datetime
df = pd.DataFrame(
    ...
    [date(2014, 1, 31), date(1999, 9, 24)],
    ...
    ...
),
index=["Date", "Datetime"],
columns=["X", "Y"],
```

(continues on next page)
... )
>>> with pd.ExcelWriter(
    ... "path_to_file.xlsx",
    ... date_format="YYYY-MM-DD",
    ... datetime_format="YYYY-MM-DD HH:MM:SS"
    ...
) as writer:
    ...
    df.to_excel(writer)

You can also append to an existing Excel file:

```python
>>> with pd.ExcelWriter("path_to_file.xlsx", mode="a", engine="openpyxl") as writer:
    ...
    df.to_excel(writer, sheet_name="Sheet3")
```

Here, the `if_sheet_exists` parameter can be set to replace a sheet if it already exists:

```python
>>> with ExcelWriter(
    ... "path_to_file.xlsx",
    ... mode="a",
    ... engine="openpyxl",
    ... if_sheet_exists="replace",
    ...
) as writer:
    ...
    df.to_excel(writer, sheet_name="Sheet1")
```

You can also write multiple DataFrames to a single sheet. Note that the `if_sheet_exists` parameter needs to be set to `overlay`:

```python
>>> with ExcelWriter("path_to_file.xlsx",
    ... mode="a",
    ... engine="openpyxl",
    ... if_sheet_exists="overlay",
    ...
) as writer:
    ...
    df1.to_excel(writer, sheet_name="Sheet1")
    ...
    df2.to_excel(writer, sheet_name="Sheet1", startcol=3)
```

You can store Excel file in RAM:

```python
>>> import io
>>> df = pd.DataFrame([["ABC", "XYZ"]], columns=["Foo", "Bar"])
>>> buffer = io.BytesIO()
>>> with pd.ExcelWriter(buffer) as writer:
        ...
        df.to_excel(writer)
```

You can pack Excel file into zip archive:

```python
>>> import zipfile
>>> df = pd.DataFrame([["ABC", "XYZ"]], columns=["Foo", "Bar"])
>>> with zipfile.ZipFile("path_to_file.zip", "w") as zf:
        ...
        with zf.open("filename.xlsx", "w") as buffer:
            ...
            with pd.ExcelWriter(buffer) as writer:
                ...
                df.to_excel(writer)
```

You can specify additional arguments to the underlying engine:
>>> with pd.ExcelWriter(
... "path_to_file.xlsx",
... engine="xlsxwriter",
... engine_kwargs={"options": {"nan_inf_to_errors": True}}
... ) as writer:
... df.to_excel(writer)

In append mode, engine_kwargs are passed through to openpyxl’s load_workbook:

>>> with pd.ExcelWriter(
... "path_to_file.xlsx",
... engine="openpyxl",
... mode="a",
... engine_kwargs={"keep_vba": True}
... ) as writer:
... df.to_excel(writer, sheet_name="Sheet2")

3.1.5 JSON

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_json(path_or_buf, orient, typ, dtype, ...)</code>)</td>
<td>Convert a JSON string to pandas object.</td>
</tr>
<tr>
<td><code>json_normalize(data[, record_path, meta, ...])</code></td>
<td>Normalize semi-structured JSON data into a flat table.</td>
</tr>
<tr>
<td><code>DataFrame.to_json([path_or_buf, orient, ...])</code></td>
<td>Convert the object to a JSON string.</td>
</tr>
</tbody>
</table>

**pandas.read_json**

`pandas.read_json(path_or_buf=None, orient=None, typ='frame', dtype=None, convert_axes=None, convert_dates=True, keep_default_dates=True, numpy=False, precise_float=False, date_unit=None, encoding=None, encoding_errors='strict', lines=False, chunksize=None, compression='infer', nrows=None, storage_options=None)`

Convert a JSON string to pandas object.

**Parameters**

- **path_or_buf** [a valid JSON str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file:///localhost/path/to/table.json.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.
By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via `builtin open` function) or `StringIO`.

orient [str] Indication of expected JSON string format. Compatible JSON strings can be produced by `to_json()` with a corresponding orient value. The set of possible orients is:

- 'split': dict like `{index -> [index], columns -> [columns], data -> [values]}`
- 'records': list like `[{column -> value}, ... , {column -> value}]`
- 'index': dict like `{index -> {column -> value}}`
- 'columns': dict like `{column -> {index -> value}}`
- 'values': just the values array

The allowed and default values depend on the value of the `typ` parameter.

- when typ == 'series',
  - allowed orients are {'split', 'records', 'index'}
  - default is 'index'
  - The Series index must be unique for orient 'index'.
- when typ == 'frame',
  - allowed orients are {'split', 'records', 'index', 'columns', 'values', 'table'}
  - default is 'columns'
  - The DataFrame index must be unique for orients 'index' and 'columns'.
  - The DataFrame columns must be unique for orients 'index', 'columns', and 'records'.

typ [{'frame', 'series'}, default 'frame'] The type of object to recover.

dtype [bool or dict, default None] If True, infer dtypes; if a dict of column to dtype, then use those; if False, then don’t infer dtypes at all, applies only to the data.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_axes [bool, default None] Try to convert the axes to the proper dtypes.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_dates [bool or list of str, default True] If True then default datelike columns may be converted (depending on keep_default_dates). If False, no dates will be converted. If a list of column names, then those columns will be converted and default datelike columns may also be converted (depending on keep_default_dates).

keep_default_dates [bool, default True] If parsing dates (convert_dates is not False), then try to parse the default datelike columns. A column label is datelike if

- it ends with '_at',
- it ends with '_time',
- it begins with 'timestamp',

3.1. Input/output
• it is 'modified', or
• it is 'date'.

**numpy** [bool, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

Deprecated since version 1.0.0.

**precise_float** [bool, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise built-in functionality.

**date_unit** [str, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

**encoding** [str, default is 'utf-8'] The encoding to use to decode py3 bytes.

**encoding_errors** [str, optional, default “strict”] How encoding errors are treated. List of possible values.

New in version 1.3.0.

**lines** [bool, default False] Read the file as a json object per line.

**chunksize** [int, optional] Return JsonReader object for iteration. See the line-delimited json docs for more information on chunksize. This can only be passed if lines=True. If this is None, the file will be read into memory all at once.

Changed in version 1.2: JsonReader is a context manager.

**compression** [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘path_or_buf’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of ['zip', 'gzip', 'bz2', 'zstd'] and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: compression={‘method’: ‘zstd’, ‘dict_data’: my_compression_dict}.

Changed in version 1.4.0: Zstandard support.

**nrows** [int, optional] The number of lines from the line-delimited json file that has to be read. This can only be passed if lines=True. If this is None, all the rows will be returned.

New in version 1.1.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**Returns**

Series or DataFrame The type returned depends on the value of typ.

See also:
**DataFrame.to_json**  Convert a DataFrame to a JSON string.

**Series.to_json**  Convert a Series to a JSON string.

**json_normalize**  Normalize semi-structured JSON data into a flat table.

**Notes**

Specific to orient='table', if a DataFrame with a literal Index name of index gets written with to_json(), the subsequent read operation will incorrectly set the Index name to None. This is because index is also used by DataFrame.to_json() to denote a missing Index name, and the subsequent read_json() operation cannot distinguish between the two. The same limitation is encountered with a MultiIndex and any names beginning with 'level_'.

**Examples**

```python
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
                   index=['row 1', 'row 2'],
                   columns=['col 1', 'col 2'])
```

Encoding/decoding a Dataframe using 'split' formatted JSON:

```python
>>> df.to_json(orient='split')
'{"columns": ["col 1", "col 2"], "index": ["row 1", "row 2"], "data": ["a", "b", "c", "d"]}'
```

```python
>>> pd.read_json(_, orient='split')
  col 1  col 2
row 1  a    b
row 2  c    d
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> df.to_json(orient='index')
'{"row 1": {"col 1": "a", "col 2": "b"}, "row 2": {"col 1": "c", "col 2": "d"}}'
```

```python
>>> pd.read_json(_, orient='index')
  col 1  col 2
row 1  a    b
row 2  c    d
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> df.to_json(orient='records')
'[{"col 1": "a", "col 2": "b"}, {"col 1": "c", "col 2": "d"}]'
```

```python
>>> pd.read_json(_, orient='records')
  col 1  col 2
0    a    b
1    c    d
```

Encoding with Table Schema
pandas: powerful Python data analysis toolkit, Release 1.4.1

```python
>>> df.to_json(orient='table')
"{"schema":{"fields": [{"name":"index","type":"string"}, {"name":"col 1","type":"string"}, {"name":"col 2","type":"string"} ]}, "primaryKey": ["index"], "pandas_version": "1.4.0"}, "data": [{"index": "row 1", "col 1": "a", "col 2": "b"}, {"index": "row 2", "col 1": "c", "col 2": "d"}]
```

**pandas.json_normalize**

*pandas.*

**pandas.json_normalize**(data, record_path=None, meta=None, meta_prefix=None, record_prefix=None, errors='raise', sep='.', max_level=None)

Normalize semi-structured JSON data into a flat table.

**Parameters**

- **data** [dict or list of dicts] Unserialized JSON objects.
- **record_path** [str or list of str, default None] Path in each object to list of records. If not passed, data will be assumed to be an array of records.
- **meta** [list of paths (str or list of str), default None] Fields to use as metadata for each record in resulting table.
- **meta_prefix** [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if meta is [‘foo’, ‘bar’].
- **record_prefix** [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if path to records is [‘foo’, ‘bar’].
- **errors** [{‘raise’, ‘ignore’}, default ‘raise’] Configures error handling.
  - ‘ignore’: will ignore KeyError if keys listed in meta are not always present.
  - ‘raise’: will raise KeyError if keys listed in meta are not always present.
- **sep** [str, default ‘.’] Nested records will generate names separated by sep. e.g., for sep=’.’, {‘foo’: {‘bar’: 0}} -> foo.bar.
- **max_level** [int, default None] Max number of levels(depth of dict) to normalize. If None, normalizes all levels.

New in version 0.25.0.

**Returns**

- **frame** [DataFrame]

Normalize semi-structured JSON data into a flat table.

**Examples**

```python
>>> data = [
... {"id": 1, "name": {"first": "Coleen", "last": "Volk"}},
... {"name": {"given": "Mark", "family": "Regner"}},
... {"id": 2, "name": "Faye Raker"},
... ]
```

```python
>>> pd.json_normalize(data)
   id name.first name.last name.given name.family
0   1.0    Coleen   Volk       NaN        NaN        NaN
```
(continues on next page)
>>> data = [
...   {"id": 1,
...    "name": "Cole Volk",
...    "fitness": {
...      "height": 130,
...      "weight": 60
...    },
...   },
...   {"name": "Mark Reg", "fitness": {
...      "height": 130,
...      "weight": 60
...    }
...   },
...   {"id": 2,
...    "name": "Faye Raker",
...    "fitness": {
...      "height": 130,
...      "weight": 60
...    }
...   }
... ]
>>> pd.json_normalize(data, max_level=0)

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>fitness</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Cole Volk</td>
<td>{'height': 130, 'weight': 60}</td>
</tr>
<tr>
<td>1</td>
<td>Mark Reg</td>
<td>{'height': 130, 'weight': 60}</td>
</tr>
<tr>
<td>2</td>
<td>Faye Raker</td>
<td>{'height': 130, 'weight': 60}</td>
</tr>
</tbody>
</table>

Normalizes nested data up to level 1.

>>> data = [
...   {"id": 1,
...    "name": "Cole Volk",
...    "fitness": {
...      "height": 130,
...      "weight": 60
...    },
...   },
...   {"name": "Mark Reg", "fitness": {
...      "height": 130,
...      "weight": 60
...    }
...   },
...   {"id": 2,
...    "name": "Faye Raker",
...    "fitness": {
...      "height": 130,
...      "weight": 60
...    }
...   }
... ]
>>> pd.json_normalize(data, max_level=1)

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>fitness.height</th>
<th>fitness.weight</th>
</tr>
</thead>
<tbody>
<tr>

...   ],
... },
... ]
>>> result = pd.json_normalize(data, "counties", 
... data, ["state", "shortname", ["info", "governor"]]
... )
>>> result
    name  population  state  shortname          info.governor
0  Dade  12345  Florida  FL      Rick Scott
1  Broward  40000  Florida  FL      Rick Scott
2  Palm Beach  60000  Florida  FL      Rick Scott
3  Summit  1234  Ohio  OH   John Kasich
4  Cuyahoga  1337  Ohio  OH   John Kasich

>>> data = {"A": [1, 2]}
>>> pd.json_normalize(data, "A", record_prefix="Prefix.")
  Prefix.0
0     1
1     2

Returns normalized data with columns prefixed with the given string.

**pandas.DataFrame.to_json**

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

**Parameters**

- **path_or_buf** [str, path object, file-like object, or None, default None] String, path object (implementing os.PathLike[str]), or file-like object implementing a write() function. If None, the result is returned as a string.

- **orient** [str] Indication of expected JSON string format.
  - Series:
    - default is ‘index’
    - allowed values are: {‘split’, ‘records’, ‘index’, ‘table’}.
  - DataFrame:
- default is 'columns'
- allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.

- The format of the JSON string:
  - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records' : list like [{column -> value}, ..., {column -> value}]
  - 'index' : dict like {index -> {column -> value}}
  - 'columns' : dict like {column -> {index -> value}}
  - 'values' : just the values array
  - 'table' : dict like {'schema': {schema}, 'data': {data}}

  Describing the data, where data component is like orient='records'.

date_format [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the orient. For orient='table', the default is 'iso'. For all other orients, the default is 'epoch'.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If 'orient' is 'records' write out line-delimited json format. Will throw ValueError if incorrect 'orient' since others are not list-like.

compression [str or dict, default 'infer'] For on-the-fly compression of the output data. If 'infer' and 'path_or BUT' path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', '.xz', or '.zst' (otherwise no compression). Set to None for no compression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2', 'zst'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}.

  Changed in version 1.4.0: Zstandard support.

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is 'split' or 'table'.

indent [int, optional] Length of whitespace used to indent each record.

  New in version 1.0.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with s3://, and "gs://") the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

  New in version 1.2.0.
Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.

Notes

The behavior of indent=0 varies from the stdlib, which does not indent the output but does insert newlines. Currently, indent=0 and the default indent=None are equivalent in pandas, though this may change in a future release.

orient='table' contains a 'pandas_version' field under 'schema'. This stores the version of pandas used in the latest revision of the schema.

Examples

```python
>>> import json
>>> df = pd.DataFrame( ...
...     [["a", "b"], ["c", "d"], ...
...     index=["row 1", "row 2"], ...
...     columns=["col 1", "col 2"], ...
... )

>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
    [
        "a",
        "b"
    ],
    ["c","d"
    ]
    ]
}
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.
Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
        "col 1": "a",
        "col 2": "b"
    },
    "row 2": {
        "col 1": "c",
        "col 2": "d"
    }
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "col 1": {
        "row 1": "a",
        "row 2": "c"
    },
    "col 2": {
        "row 1": "b",
        "row 2": "d"
    }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[ ]
```

(continues on next page)
Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
                "type": "string"
            },
            {
                "name": "col 1",
                "type": "string"
            },
            {
                "name": "col 2",
                "type": "string"
            }
        ],
        "primaryKey": ["index"],
        "pandas_version": "1.4.0"
    },
    "data": [
        {
            "index": "row 1",
            "col 1": "a",
            "col 2": "b"
        },
        {
            "index": "row 2",
            "col 1": "c",
            "col 2": "d"
        }
    ]
}
```

`build_table_schema(data[, index, ...])` Create a Table schema from `data`.  

1068 Chapter 3. API reference
**pandas.io.json.build_table_schema**

Create a Table schema from `data`.

**Parameters**

- `data` [Series, DataFrame]:
  - `index` [bool, default True]: Whether to include `data.index` in the schema.
  - `primary_key` [bool or None, default True]: Column names to designate as the primary key. The default `None` will set 'primaryKey' to the index level or levels if the index is unique.
  - `version` [bool, default True]: Whether to include a field `pandas_version` with the version of pandas that last revised the table schema. This version can be different from the installed pandas version.

**Returns**

- `schema` [dict]

**Notes**

See Table Schema for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the *any* dtype, and use the *enum* field constraint to list the allowed values. The *ordered* attribute is included in an *ordered* field.

**Examples**

```python
>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...     }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'}, {'name': 'A', 'type': 'integer'},
            {'name': 'B', 'type': 'string'}, {'name': 'C', 'type': 'datetime'}],
            'primaryKey': ['idx'],
            'pandas_version': '1.4.0'}
```

### 3.1.6 HTML

- `read_html(io[, match, flavor, header, ...])`: Read HTML tables into a list of DataFrame objects.
- `DataFrame.to_html([buf, columns, col_space, ...])`: Render a DataFrame as an HTML table.
pandas.read_html

pandas.read_html(io, match='.+', flavor=None, header=None, index_col=None, skiprows=None, attrs=None, 
aparse_dates=False, thousands=',', encoding=None, decimal='.', converters=None, 
na_values=None, keep_default_na=True, displayed_only=True)

Read HTML tables into a list of DataFrame objects.

Parameters

io [str, path object, or file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a string read() function. The string can represent a URL or the HTML itself. Note that lxml only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.

match [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to '.+' (match any non-empty string). This value is converted to a regular expression so that there is consistent behavior between Beautiful Soup and lxml.

flavor [str, optional] The parsing engine to use. ‘bs4’ and ‘html5lib’ are synonymous with each other, they are both there for backwards compatibility. The default of None tries to use lxml to parse and if that fails it falls back on bs4 + html5lib.

header [int or list-like, optional] The row (or list of rows for a MultiIndex) to use to make the columns headers.

index_col [int or list-like, optional] The column (or list of columns) to use to create the index.

skiprows [int, list-like or slice, optional] Number of rows to skip after parsing the column integer. 0-based. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.

attrs [dict, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or Beautiful Soup. However, these attributes must be valid HTML table attributes to work correctly. For example,

\[
\text{attrs} = \{\text{'id': 'table'}\}
\]

is a valid attribute dictionary because the ‘id’ HTML tag attribute is a valid HTML attribute for any HTML tag as per this document.

\[
\text{attrs} = \{\text{'asdf': 'table'}\}
\]

is not a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found here. A working draft of the HTML 5 spec can be found here. It contains the latest information on table attributes for the modern web.

parse_dates [bool, optional] See read_csv() for more details.

thousands [str, optional] Separator to use to parse thousands. Defaults to ‘,’.

encoding [str, optional] The encoding used to decode the web page. Defaults to None.”None” preserves the previous encoding behavior, which depends on the underlying parser library (e.g., the parser library will try to use the encoding provided by the document).
decimal [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

na_values [iterable, default None] Custom NA values.

keep_default_na [bool, default True] If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they’re appended to.

displayed_only [bool, default True] Whether elements with “display: none” should be parsed.

Returns

dfs A list of DataFrames.

See also:

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

Before using this function you should read the gotchas about the HTML parsing libraries.

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the header=0 argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for <table> elements and only for <tr> and <th> rows and <td> elements within each <tr> or <th> element in the table. <td> stands for “table data”. This function attempts to properly handle colspan and rowspan attributes. If the function has a <thead> argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only <th> elements into the header).

Similar to read_csv() the header argument is applied after skiprows is applied.

This function will always return a list of DataFrame or it will fail, e.g., it will not return an empty list.

Examples

See the read_html documentation in the IO section of the docs for some examples of reading in HTML tables.

pandas.DataFrame.to_html

Dataframe.to_html(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, max_cols=None, show_dimensions=False, decimal='.', bold_rows=True, classes=None, escape=True, notebook=False, border=None, table_id=None, render_links=False, encoding=None)

Render a DataFrame as an HTML table.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
columns [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

col_space [str or int, list or dict of int or str, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.

New in version 0.25.0: Ability to use str.

header [bool, optional] Whether to print column labels, default True.

index [bool, optional, default True] Whether to print index (row) labels.

na_rep [str, optional, default ‘NaN’] String representation of NaN to use.

formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by na_rep.

Changed in version 1.2.0.

sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names [bool, optional, default True] Prints the names of the indexes.

justify [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

max_rows [int, optional] Maximum number of rows to display in the console.

max_cols [int, optional] Maximum number of columns to display in the console.

show_dimensions [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

bold_rows [bool, default True] Make the row labels bold in the output.

classes [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

escape [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.
notebook  
[True, False], default False  Whether the generated HTML is for IPython Notebook.

border  [int]  A border=border attribute is included in the opening <table> tag. Default
pd.options.display.html.border.

table_id  [str, optional]  A css id is included in the opening <table> tag if specified.

render_links  [bool, default False]  Convert URLs to HTML links.

encoding  [str, default “utf-8”]  Set character encoding.

New in version 1.0.

Returns

str or None  If buf is None, returns the result as a string. Otherwise returns None.

See also:

to_string  Convert DataFrame to a string.

Styler.to_html(buf=None,
*,
table_uuid=None,
table_attributes=None,
sparse_index=None,
sparse_columns=None,
bold_headers=False,
caption=None,
max_rows=None,
max_columns=None,
encoding=None,
doctype_html=False,
exclude_styles=False,
**kwargs)

Write Styler to a file, buffer or string in HTML-CSS format.

New in version 1.3.0.

Parameters

buf  [str, path object, file-like object, or None, default None]  String, path object (implementing os.PathLike[str]), or file-like object implementing a string write() function. If None, the result is returned as a string.

table_uuid  [str, optional]  Id attribute assigned to the <table> HTML element in the format:

<table id="T_\_table_uuid"  ..>

If not given uses Styler’s initially assigned value.

table_attributes  [str, optional]  Attributes to assign within the <table> HTML element in the format:

<table .. <table_attributes>  >

If not given defaults to Styler’s preexisting value.

sparse_index  [bool, optional]  Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to pandas.options.styler.sparse.index value.

New in version 1.4.0.

sparse_columns  [bool, optional]  Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each column. Defaults to pandas.options.styler.sparse.columns value.
New in version 1.4.0.

**bold_headers** [bool, optional] Adds “font-weight: bold;” as a CSS property to table style header cells.

New in version 1.4.0.

**caption** [str, optional] Set, or overwrite, the caption on Styler before rendering.

New in version 1.4.0.

**max_rows** [int, optional] The maximum number of rows that will be rendered. Defaults to pandas.options.styler.render.max_rows/max_columns.

New in version 1.4.0.

**max_columns** [int, optional] The maximum number of columns that will be rendered. Defaults to pandas.options.styler.render.max_columns, which is None.

Rows and columns may be reduced if the number of total elements is large. This value is set to pandas.options.styler.render.max_elements, which is 262144 (18 bit browser rendering).

New in version 1.4.0.

**encoding** [str, optional] Character encoding setting for file output, and HTML meta tags. Defaults to pandas.options.styler.render.encoding value of “utf-8”.

**doctype_html** [bool, default False] Whether to output a fully structured HTML file including all HTML elements, or just the core <style> and <table> elements.

**exclude_styles** [bool, default False] Whether to include the <style> element and all associated element class and id identifiers, or solely the <table> element without styling identifiers.

**kwargs** Any additional keyword arguments are passed through to the jinja2 self. template.render process. This is useful when you need to provide additional variables for a custom template.

Returns

str or None If *buf* is None, returns the result as a string. Otherwise returns *None*.

See also:

DataFrame.to_html Write a DataFrame to a file, buffer or string in HTML format.

### 3.1.7 XML

<table>
<thead>
<tr>
<th>read_xml(path_or_buffer[, xpath, ...])</th>
<th>Read XML document into a DataFrame object.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.to_xml([path_or_buffer, index, ...])</td>
<td>Render a DataFrame to an XML document.</td>
</tr>
</tbody>
</table>
pandas.read_xml

pandas.read_xml(path_or_buffer=xpath='/*', namespaces=None, elems_only=False, attrs_only=False, names=None, encoding='utf-8', parser='lxml', stylesheet=None, compression='infer', storage_options=None)

Read XML document into a DataFrame object.

New in version 1.3.0.

Parameters

path_or_buffer [str, path object, or file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a read() function. The string can be any valid XML string or a path. The string can further be a URL. Valid URL schemes include http, ftp, s3, and file.

xpath [str, optional, default ‘/’] The XPath to parse required set of nodes for migration to DataFrame. XPath should return a collection of elements and not a single element. Note: The etree parser supports limited XPath expressions. For more complex XPath, use lxml which requires installation.

namespaces [dict, optional] The namespaces defined in XML document as dicts with key being namespace prefix and value the URI. There is no need to include all namespaces in XML, only the ones used in xpath expression. Note: if XML document uses default namespace denoted as xmlns={<URI>} without a prefix, you must assign any temporary namespace prefix such as ‘doc’ to the URI in order to parse underlying nodes and/or attributes. For example,

```python
namespaces = {"doc": "https://example.com"}
```

elems_only [bool, optional, default False] Parse only the child elements at the specified xpath. By default, all child elements and non-empty text nodes are returned.

attrs_only [bool, optional, default False] Parse only the attributes at the specified xpath. By default, all attributes are returned.

names [list-like, optional] Column names for DataFrame of parsed XML data. Use this parameter to rename original element names and distinguish same named elements.

encoding [str, optional, default ‘utf-8’] Encoding of XML document.

parser [{'lxml','etree'},default ‘lxml’] Parser module to use for retrieval of data. Only ‘lxml’ and ‘etree’ are supported. With ‘lxml’ more complex XPath searches and ability to use XSLT stylesheet are supported.

stylesheet [str, path object or file-like object] A URL, file-like object, or a raw string containing an XSLT script. This stylesheet should flatten complex, deeply nested XML documents for easier parsing. To use this feature you must have lxml module installed and specify ‘lxml’ as parser. The xpath must reference nodes of transformed XML document generated after XSLT transformation and not the original XML document. Only XSLT 1.0 scripts and not later versions is currently supported.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘path_or_buffer’ is path-like, then detect compression from the following extensions: ‘gz’, ‘bz2’, ‘zip’, ‘xz’, or ‘zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the follow-
ing could be passed for Zstandard decompression using a custom compression dictionary:
```
compression={'method': 'zstd', 'dict_data': my_compression_dict}.
```

Changed in version 1.4.0: Zstandard support.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

**Returns**

* df A DataFrame.

**See also:**

* **read_json** Convert a JSON string to pandas object.
* **read_html** Read HTML tables into a list of DataFrame objects.

**Notes**

This method is best designed to import shallow XML documents in following format which is the ideal fit for the two-dimensions of a DataFrame (row by column).

```xml
<root>
  <row>
    <column1>data</column1>
    <column2>data</column2>
    <column3>data</column3>
    ...
  </row>
  <row>
    ...
  </row>
  ...
</root>
```

As a file format, XML documents can be designed any way including layout of elements and attributes as long as it conforms to W3C specifications. Therefore, this method is a convenience handler for a specific flatter design and not all possible XML structures.

However, for more complex XML documents, **stylesheet** allows you to temporarily redesign original document with XSLT (a special purpose language) for a flatter version for migration to a DataFrame.

This function will always return a single **DataFrame** or raise exceptions due to issues with XML document, xpath, or other parameters.
Examples

```python
>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <data xmlns="http://example.com">
... <row>
...   <shape>square</shape>
...   <degrees>360</degrees>
...   <sides>4.0</sides>
... </row>
... <row>
...   <shape>circle</shape>
...   <degrees>360</degrees>
...   <sides/>
... </row>
... <row>
...   <shape>triangle</shape>
...   <degrees>180</degrees>
...   <sides>3.0</sides>
... </row>
... </data>'''

>>> df = pd.read_xml(xml)
>>> df
shape   degrees  sides
0  square     360    4.0
1  circle     360   NaN
2  triangle    180    3.0

>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <data>
... <row shape="square" degrees="360" sides="4.0"/>
... <row shape="circle" degrees="360"/>
... <row shape="triangle" degrees="180" sides="3.0"/>
... </data>'''

>>> df = pd.read_xml(xml, xpath='.//row')
>>> df
shape   degrees  sides
0  square     360    4.0
1  circle     360   NaN
2  triangle    180    3.0

>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <doc:row>
...   <doc:shape>square</doc:shape>
...   <doc:degrees>360</doc:degrees>
...   <doc:sides>4.0</doc:sides>
... </doc:row>
... <doc:row>
...   <doc:shape>circle</doc:shape>
...   <doc:degrees>360</doc:degrees>
...   <doc:sides>
... ...  ...
... </doc:row>
... </doc:row>
... </doc:row>
... </doc:row>
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

>>> df = pd.read_xml(xml, path_or_buffer=None, index=True, root_name='data', row_name='row', namespaces={}, na_rep=None, elem_cols=None, attr_cols=None, xml_declaration=True, pretty_print=True, parser='lxml', stylesheet=None, compression='infer', storage_options=None)

Render a DataFrame to an XML document.

New in version 1.3.0.

Parameters

path_or_buffer [str, path object, file-like object, or None, default None] String, path object (implementing os.PathLike[str]), or file-like object implementing a write() function. If None, the result is returned as a string.

index [bool, default True] Whether to include index in XML document.

root_name [str, default ‘data’] The name of root element in XML document.

row_name [str, default ‘row’] The name of row element in XML document.

attr_cols [list-like, optional] List of columns to write as attributes in row element. Hierarchical columns will be flattened with underscore delimiting the different levels.

elem_cols [list-like, optional] List of columns to write as children in row element. By default, all columns output as children of row element. Hierarchical columns will be flattened with underscore delimiting the different levels.

namespaces [dict, optional] All namespaces to be defined in root element. Keys of dict should be prefix names and values of dict corresponding URIs. Default namespaces should be given empty string key. For example,

```python
namespaces = {"": "https://example.com"}
```
prefix  [str, optional] Namespace prefix to be used for every element and/or attribute in document. This should be one of the keys in namespaces dict.

encoding  [str, default ‘utf-8’] Encoding of the resulting document.

xml_declaration  [bool, default True] Whether to include the XML declaration at start of document.

pretty_print  [bool, default True] Whether output should be pretty printed with indentation and line breaks.

parser  [[‘ lxml’, ‘ etree ’], default ‘ lxml ’] Parser module to use for building of tree. Only ‘ lxml ’ and ‘ etree ’ are supported. With ‘ lxml ’, the ability to use XSLT stylesheet is supported.

stylesheet  [str, path object or file-like object, optional] A URL, file-like object, or a raw string containing an XSLT script used to transform the raw XML output. Script should use layout of elements and attributes from original output. This argument requires lxml to be installed. Only XSLT 1.0 scripts and not later versions is currently supported.

compression  [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path_or_buffer’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘ method ’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}.

Changed in version 1.4.0: Zstandard support.

storage_options  [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

Returns

None or str  If io is None, returns the resulting XML format as a string. Otherwise returns None.

See also:

to_json  Convert the pandas object to a JSON string.

to_html  Convert DataFrame to a html.

Examples

```python
>>> df = pd.DataFrame({'shape': ['square', 'circle', 'triangle'],
...                     'degrees': [360, 360, 180],
...                     'sides': [4, np.nan, 3]})

>>> df.to_xml()
<?xml version='1.0' encoding='utf-8'?><data>
  <row/>
</data>
```

(continues on next page)
<row index="0" shape="square" degrees="360" sides="4.0"/>
<row index="1" shape="circle" degrees="360"></row>
<row index="2" shape="triangle" degrees="180" sides="3.0"/>

>>> df.to_xml(attr_cols=['index', 'shape', 'degrees', 'sides'])
<?xml version='1.0' encoding='utf-8'?>
<row index="0" shape="square" degrees="360" sides="4.0"/>
<row index="1" shape="circle" degrees="360"></row>
<row index="2" shape="triangle" degrees="180" sides="3.0"/>

>>> df.to_xml(namespaces={'doc': 'https://example.com'},
              prefix='doc')
<?xml version='1.0' encoding='utf-8'?>
<row index="0" shape="square" degrees="360" sides="4.0"/>
<row index="1" shape="circle" degrees="360"></row>
<row index="2" shape="triangle" degrees="180" sides="3.0"/>
### 3.1.8 Latex

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.to_latex([buf, columns, ...])</code></td>
<td>Render object to a LaTeX tabular, longtable, or nested table.</td>
</tr>
</tbody>
</table>

#### `pandas.DataFrame.to_latex`

```python
DataFrame.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal=',', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None)
```

Render object to a LaTeX tabular, longtable, or nested table.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or read from an external file with `\input{table.tex}`.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- **col_space** [int, optional] The minimum width of each column.
- **header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **na_rep** [str, default ‘NaN’] Missing data representation.
- **formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.
- **float_format** [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="%.2f"` and `float_format="{:0.2f}"`. `format` will both result in 0.1234 being formatted as 0.12.
- **sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.
- **index_names** [bool, default True] Prints the names of the indexes.
- **bold_rows** [bool, default False] Make the row labels bold in the output.
- **column_format** [str, optional] The columns format as specified in LaTeX table format e.g. ‘rcl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.
- **longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a `usepackage{longtable}` to your LaTeX preamble.
**escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to `utf-8`.

**decimal** [str, default `.`] Character recognized as decimal separator, e.g. `.` in Europe.

**multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

**multicolumn_format** [str, default `l`] The alignment for multicolumns, similar to `column_format` The default will be read from the config module.

**multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

**caption** [str or tuple, optional] Tuple (full_caption, short_caption), which results in \caption[short_caption]{full_caption}; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

**label** [str, optional] The LaTeX label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

New in version 1.0.0.

**position** [str, optional] The LaTeX positional argument for tables, to be placed after \begin{} in the output.

New in version 1.2.0.

**Returns**

str or None If buf is None, returns the result as a string. Otherwise returns None.

**See also:**

* Styler.to_latex Render a DataFrame to LaTeX with conditional formatting.

* DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

* DataFrame.to_html Render a DataFrame as an HTML table.

**Examples**

```python
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
...                     mask=['red', 'purple'],
...                     weapon=['sai', 'bo staff']))
```

```latex
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
Raphael & red & sai \\
\midrule
(continues on next page)
```
Styler.to_latex([buf, column_format, ...]) Write Styler to a file, buffer or string in LaTeX format.

pandas.io.formats.style.Styler.to_latex

Styler.to_latex(buf=None, *, column_format=None, position=None, position_float=None, hrules=None, clines=None, label=None, caption=None, sparse_index=None, sparse_columns=None, multirow_align=None, multicol_align=None, siunitx=False, environment=None, encoding=None, convert_css=False)

Write Styler to a file, buffer or string in LaTeX format.
New in version 1.3.0.

Parameters

- **buf** [str, path object, file-like object, or None, default None] String, path object (implementing os.PathLike[str]), or file-like object implementing a string write() function. If None, the result is returned as a string.

- **column_format** [str, optional] The LaTeX column specification placed in location:

  \begin{tabular}{<column_format>}

  Defaults to ‘l’ for index and non-numeric data columns, and, for numeric data columns, to ‘r’ by default, or ‘S’ if siunitx is True.

- **position** [str, optional] The LaTeX positional argument (e.g. ‘h!’) for tables, placed in location:

  \begin{table}[^<position>].

- **position_float** [{“centering”, “raggedleft”, “raggedright”}, optional] The LaTeX float command placed in location:

  \begin{table}[^<position>];<position_float>

  Cannot be used if environment is “longtable”.

- **hrules** [bool] Set to True to add \toprule, \midrule and \bottomrule from the {booktabs} LaTeX package. Defaults to pandas.options.styler.latex.hrules, which is False.

  Changed in version 1.4.0.

- **clines** [str, optional] Use to control adding \cline commands for the index labels separation. Possible values are:

  - *None*: no cline commands are added (default).
  - *"all:data"*: a cline is added for every index value extending the width of the table, including data entries.
  - *"all:index"*: as above with lines extending only the width of the index entries.
  - *"skip-last:data"*: a cline is added for each index value except the last level (which is never sparsified), extending the width of the table.
- "skip-last:index": as above with lines extending only the width of the index entries.

    New in version 1.4.0.

**label** [str, optional] The LaTeX label included as: \label{<label>}. This is used with
\ref{<label>} in the main .tex file.

**caption** [str, tuple, optional] If string, the LaTeX table caption included as: \caption{<caption>}. If tuple, i.e ("full caption", "short caption"), the caption included as:
\caption[<caption[1]>][<caption[0]>].

**sparse_index** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting
to False will display each explicit level element in a hierarchical key for each row. Defaults
to pandas.options.styler.sparse.index, which is True.

**sparse_columns** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting
to False will display each explicit level element in a hierarchical key for each column.
Defaults to pandas.options.styler.sparse.columns, which is True.

**multirow_align** [{"c", "t", "b", "naive"}, optional] If sparsifying hierarchical MultiIndexes
whether to align text centrally, at the top or bottom using the multivrow package. If not
given defaults to pandas.options.styler.latex.multirow_align, which is "c".
If "naive" is given renders without multirow.

    Changed in version 1.4.0.

**multicol_align** [{"r", "c", "l", "naive-l", "naive-r"}, optional] If sparsifying hierarchical MultiIndex columns whether to align text at the left, centrally, or at the right. If not
given defaults to pandas.options.styler.latex.multicol_align, which is "r". If a naive
option is given renders without multicol. Pipe decorators can also be added to non-naive
values to draw vertical rules, e.g. "|r" will draw a rule on the left side of right aligned
merged cells.

    Changed in version 1.4.0.

**siunitx** [bool, default False] Set to True to structure LaTeX compatible with the \{siunitx\}
package.

**environment** [str, optional] If given, the environment that will replace ‘table’ in \begin{table}. If ‘longtable’ is specified then a more suitable template is rendered. If
not given defaults to pandas.options.styler.latex.environment, which is None.

    New in version 1.4.0.

**encoding** [str, optional] Character encoding setting. Defaults to pandas.options.styler.
render.encoding, which is “utf-8”.

**convert_css** [bool, default False] Convert simple cell-styles from CSS to LaTeX format. Any
CSS not found in conversion table is dropped. A style can be forced by adding option
--latex. See notes.

**Returns**

- **str** or None If buf is None, returns the result as a string. Otherwise returns None.

**See also:**

- **Styler.format** Format the text display value of cells.
Notes

LaTeX Packages

For the following features we recommend the following LaTeX inclusions:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Inclusion</th>
</tr>
</thead>
<tbody>
<tr>
<td>sparse columns</td>
<td>\usepackage{multirow}</td>
</tr>
<tr>
<td>sparse rows</td>
<td>\usepackage{booktabs}</td>
</tr>
<tr>
<td>hrules</td>
<td>\usepackage{siunitx}</td>
</tr>
<tr>
<td>colors</td>
<td>\usepackage{table{xcolor}}</td>
</tr>
<tr>
<td>siunitx</td>
<td>\usepackage{siunitx}</td>
</tr>
<tr>
<td>bold (with siunitx)</td>
<td>\usepackage{etoolbox} \robustify\bfseries \sisetup{detect-all = true} (within {document})</td>
</tr>
<tr>
<td>italic (with siunitx)</td>
<td>\usepackage{etoolbox} \robustify\itshape \sisetup{detect-all = true} (within {document})</td>
</tr>
<tr>
<td>environment</td>
<td>\usepackage{longtable} if arg is “longtable”</td>
</tr>
<tr>
<td>hyperlinks</td>
<td>\usepackage{hyperref}</td>
</tr>
</tbody>
</table>

Cell Styles

LaTeX styling can only be rendered if the accompanying styling functions have been constructed with appropriate LaTeX commands. All styling functionality is built around the concept of a CSS (<attribute>, <value>) pair (see Table Visualization), and this should be replaced by a LaTeX (<command>, <options>) approach. Each cell will be styled individually using nested LaTeX commands with their accompanied options.

For example the following code will highlight and bold a cell in HTML-CSS:

```python
>>> df = pd.DataFrame([[1,2], [3,4]])
>>> s = df.style.highlight_max(axis=None, ... props='background-color:red; font-weight:bold;')
>>> s.to_html()
```

The equivalent using LaTeX only commands is the following:

```python
>>> s = df.style.highlight_max(axis=None, ... props='cellcolor:red; bfseries;')
>>> s.to_latex()
```

Internally these structured LaTeX (<command>, <options>) pairs are translated to the display_value with the default structure: <command><options> <display_value>. Where there are multiple commands the latter is nested recursively, so that the above example highlighted cell is rendered as \cellcolor{red} \bfseries 4.

Occasionally this format does not suit the applied command, or combination of LaTeX packages that is in use, so additional flags can be added to the <options>, within the tuple, to result in different positions of required braces (the default being the same as --nowrap):
Tuple Format | Output Structure
---|---
(\textbf{command}, \textbf{options}) | \textbf{command}\textbf{options} \textbf{display_value}
(\textbf{command}, \textbf{options} --nowrap) | \textbf{command}\textbf{options} \textbf{display_value}
(\textbf{command}, \textbf{options} --rwrap) | \{\textbf{command}\textbf{options}\} \textbf{display_value}
(\textbf{command}, \textbf{options} --lwrap) | \{\textbf{command}\textbf{options}\} \textbf{display_value}
(\textbf{command}, \textbf{options} --dwrap) | \{\textbf{command}\textbf{options}\} \{\textbf{display_value}\}

For example the \textbf{command} for font-weight should always be used with \textit{--rwrap} so ('\textbf{command}', '--rwrap') will render a working cell, wrapped with braces, as \textbf{command}{\textbf{display_value}}.

A more comprehensive example is as follows:

```python
>>> df = pd.DataFrame([[1, 2.2, 'dogs'], [3, 4.4, 'cats'], [2, 6.6, 'cows']],
                   index=["ix1", "ix2", "ix3"],
                   columns=["Integers", "Floats", "Strings"])
>>> s = df.style.highlight_max(
... props='cellcolor:[HTML]{FFFF00}; color:{red};'
... 'textit:--rwrap; textbf:--rwrap,'
... )
>>> s.to_latex()

<table>
<thead>
<tr>
<th>Integers</th>
<th>Floats</th>
<th>Strings</th>
</tr>
</thead>
<tbody>
<tr>
<td>ix1</td>
<td>1</td>
<td>2.200000</td>
</tr>
<tr>
<td>ix2</td>
<td>3</td>
<td>4.400000</td>
</tr>
<tr>
<td>ix3</td>
<td>2 6.600000</td>
<td>cows</td>
</tr>
</tbody>
</table>
```

Table Styles

Internally Styler uses its table_styles object to parse the column_format, position, position_float, and label input arguments. These arguments are added to table styles in the format:

```python
set_table_styles([
    {'selector': 'column_format', 'props': f':{column_format}';}
    ,
    {'selector': 'position', 'props': f':{position}';}
    ,
    {'selector': 'position_float', 'props': f':{position_float}';}
    ,
    {'selector': 'label', 'props': f':{{(label.replace((':', '')\})};''}
    ]
]
```

Exception is made for the hrules argument which, in fact, controls all three commands: toprule, bottomrule and midrule simultaneously. Instead of setting hrules to True, it is also possible to set each individual rule definition, by manually setting the table_styles, for example below we set a regular toprule, set an hline for bottomrule and exclude the midrule:

```python
set_table_styles([
    {'selector': 'toprule', 'props': ':toprule;'},
    {'selector': 'bottomrule', 'props': ':hline;'},
    ], overwrite=False)
```

If other commands are added to table styles they will be detected, and positioned immediately above the \texttt{begin{tabular}} command. For example to add odd and even row coloring, from the \texttt{colortbl} package, in format \texttt{rowcolors{1}{pink}{red}}, use:
A more comprehensive example using these arguments is as follows:

```python
>>> df.columns = pd.MultiIndex.from_tuples(
...     [(...
...         "Numeric", "Integers"), (...)
...         "Numeric", "Floats"), (...)
...         "Non-Numeric", "Strings")
...     ])
>>> df.index = pd.MultiIndex.from_tuples(
...     [(...
...         "L0", "ix1"), (...)
...         "L0", "ix2"), (...)
...     ])
>>> s = df.style.highlight_max(
...     props='cellcolor:[HTML]{FFFF00}; color:red; itshape:; bfseries:'
... )
>>> s.to_latex(
...     column_format="rrrrr", position="h", position_float="centering",
...     hrules=True, label="table:5", caption="Styled \LaTeX Table",
...     multirow_align="t", multicolumn_align="r"
... )
```

![Table 1: Styled \LaTeX Table](image)

### Formatting

To format values `Styler.format()` should be used prior to calling `Styler.to_latex`, as well as other methods such as `Styler.hide()` for example:

```python
>>> s.clear()
>>> s.table_styles = []
>>> s.caption = None
>>> s.format(
...     ("Numeric", "Integers"): '\$\{\}$',
...     ("Numeric", "Floats"): '{:.3f}',
...     ("Non-Numeric", "Strings"): str.upper
... )
```

```
\begin{tabular}{llrrl}
  L0 & ix1 & 1 & 2.20000 & dogs \\
  ix2 & 3 & 4.40000 & cats \\
  L1 & ix3 & 2 & 6.60000 & cows \\
\end{tabular}
```

(continues on next page)
{} & {} & \multicolumn{2}{r}{Numeric} & {Non-Numeric} \\ 
{} & {} & {Integers} & {Floats} & {Strings} \\
\multirow[0]{2}{*}{L0} & ix1 & \$1 & 2.200 & DOGS \\
& ix2 & \$3 & 4.400 & CATS \\
L1 & ix3 & \$2 & 6.600 & COWS \\
\end{tabular}

### CSS Conversion

This method can convert a Styler constructed with HTML-CSS to LaTeX using the following limited conversions.

<table>
<thead>
<tr>
<th>CSS Attribute</th>
<th>CSS value</th>
<th>LaTeX Command</th>
<th>LaTeX Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>font-weight</td>
<td>bold</td>
<td>bfseries</td>
<td></td>
</tr>
<tr>
<td></td>
<td>bolder</td>
<td></td>
<td></td>
</tr>
<tr>
<td>font-style</td>
<td>italic</td>
<td>itshape</td>
<td></td>
</tr>
<tr>
<td></td>
<td>oblique</td>
<td>slshape</td>
<td></td>
</tr>
<tr>
<td>background-color</td>
<td>red</td>
<td></td>
<td>{red}–lwrap</td>
</tr>
<tr>
<td></td>
<td>#fe01ea</td>
<td></td>
<td>[HTML]{FE01EA}–lwrap</td>
</tr>
<tr>
<td></td>
<td>#f0e</td>
<td></td>
<td>[HTML]{FF00EE}–lwrap</td>
</tr>
<tr>
<td></td>
<td>rgb(128,255,0)</td>
<td></td>
<td>[rgb]{0.5,1,0}–lwrap</td>
</tr>
<tr>
<td></td>
<td>rgba(128,0,0,0.5)</td>
<td></td>
<td>[rgb]{0.5,0,0}–lwrap</td>
</tr>
<tr>
<td></td>
<td>rgb(25%,255,50%)</td>
<td></td>
<td>[rgb]{0.25,1,0.5}–lwrap</td>
</tr>
<tr>
<td>color</td>
<td>red</td>
<td>color</td>
<td>{red}</td>
</tr>
<tr>
<td></td>
<td>#fe01ea</td>
<td></td>
<td>[HTML]{FE01EA}</td>
</tr>
<tr>
<td></td>
<td>#f0e</td>
<td></td>
<td>[HTML]{FF00EE}</td>
</tr>
<tr>
<td></td>
<td>rgb(128,255,0)</td>
<td></td>
<td>[rgb]{0.5,1,0}</td>
</tr>
<tr>
<td></td>
<td>rgba(128,0,0,0.5)</td>
<td></td>
<td>[rgb]{0.5,0,0}</td>
</tr>
<tr>
<td></td>
<td>rgb(25%,255,50%)</td>
<td></td>
<td>[rgb]{0.25,1,0.5}</td>
</tr>
</tbody>
</table>

It is also possible to add user-defined LaTeX only styles to a HTML-CSS Styler using the --latex flag, and to add LaTeX parsing options that the converter will detect within a CSS-comment.

```python
>>> df = pd.DataFrame([[1]])
>>> df.style.set_properties(
...     **"font-weight": "bold /* --dwrap */", "Huge": "--latex--rwrap"**
... ).to_latex(convert_css=True)
\begin{tabular}{lr}
\end{tabular}
```

(continues on next page)
Examples

Below we give a complete step by step example adding some advanced features and noting some common gotchas.

First we create the DataFrame and Styler as usual, including MultiIndex rows and columns, which allow for more advanced formatting options:

```python
>>> cidx = pd.MultiIndex.from_arrays([...
... ['Equity', 'Equity', 'Equity', 'Equity',
... 'Stats', 'Stats', 'Stats', 'Stats', 'Rating'],
... ['Energy', 'Energy', 'Consumer', 'Consumer', '', '', '', '', ''],
... 'BP', 'Shell', 'H&M', 'Unilever',
... 'Std Dev', 'Variance', '52w High', '52w Low', ''][...
... ])
>>> iidx = pd.MultiIndex.from_arrays([...
... ['Equity', 'Equity', 'Equity', 'Equity'],
... ['Energy', 'Energy', 'Consumer', 'Consumer'],
... 'BP', 'Shell', 'H&M', 'Unilever'][...
... ])
>>> styler = pd.DataFrame([...
... [1, 0.8, 0.66, 0.72, 32.1678, 32.1678**2, 335.12, 240.89, 'Buy'],
... [0.8, 1.0, 0.69, 0.79, 1.876, 1.876**2, 14.12, 19.78, 'Hold'],
... [0.66, 0.69, 1.0, 0.86, 7, 7**2, 210.9, 140.6, 'Buy'],
... [0.72, 0.79, 0.86, 1.0, 213.76, 213.76**2, 2807, 3678, 'Sell'][...
... ], columns=cidx, index=iidx).style
```

Second we will format the display and, since our table is quite wide, will hide the repeated level-0 of the index:

```python
>>> styler.format(subset="Equity", precision=2)
```

Note that one of the string entries of the index and column headers is “H&M". Without applying the escape="latex" option to the format_index method the resultant LaTeX will fail to render, and the error returned is quite difficult to debug. Using the appropriate escape the “&“ is converted to “\&“.

Thirdly we will apply some (CSS-HTML) styles to our object. We will use a builtin method and also define our own method to highlight the stock recommendation:

```python
>>> def rating_color(v):
... if v == "Buy": color = "#33ff85"
... elif v == "Sell": color = "#ff5933"
... else: color = "#ffdd33"
... return f"color: {color}; font-weight: bold;"
>>> styler.background_gradient(cmap="inferno", subset="Equity", vmin=0, vmax=1)
```

3.1. Input/output
All the above styles will work with HTML (see below) and LaTeX upon conversion:

```python
>>> styler.applymap_index(
    ... lambda v: "rotatebox:{45}--rwrap--latex;", level=2, axis=1
    ...
)
```

Finally we render our LaTeX adding in other options as required:

```python
>>> styler.to_latex(
    ... caption="Selected stock correlation and simple statistics.",
    ... clines="skip-last:data",
    ... convert_css=True,
    ... position_float="centering",
    ... multicolumn_align="|c|",
    ... hrules=True,
    ... )
```

(continues on next page)
Table 1: Selected stock correlation and simple statistics.

<table>
<thead>
<tr>

</tbody>
</table>

3.1.9 HDFStore: PyTables (HDF5)

- `read_hdf(path_or_buf[, key, mode, errors, ...])`: Read from the store, close it if we opened it.
- `HDFStore.put(key, value[, format, index, ...])`: Store object in HDFStore.
- `HDFStore.append(key, value[, format, axes, ...])`: Append to Table in file.
- `HDFStore.get(key)`: Retrieve pandas object stored in file.
- `HDFStore.select(key[, where, start, stop, ...])`: Retrieve pandas object stored in file, optionally based on where criteria.
- `HDFStore.info()` : Print detailed information on the store.
- `HDFStore.keys([include])`: Return a list of keys corresponding to objects stored in HDFStore.
- `HDFStore.groups()`: Return a list of all the top-level nodes.
- `HDFStore.walk([where])`: Walk the pytables group hierarchy for pandas objects.
**pandas.read_hdf**

`pandas.read_hdf(path_or_buf, key=None, mode='r', errors='strict', where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, **kwargs)`

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria.

**Warning:** Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe. See: https://docs.python.org/3/library/pickle.html for more.

**Parameters**

- `path_or_buf` [str, path object, pandas.HDFStore] Any valid string path is acceptable. Only supports the local file system, remote URLs and file-like objects are not supported. If you want to pass in a path object, pandas accepts any `os.PathLike`. Alternatively, pandas accepts an open `pandas.HDFStore` object.

- `key` [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

- `mode` [‘r’, ‘r+’, ‘a’], default ‘r’] Mode to use when opening the file. Ignored if `path_or_buf` is a `pandas.HDFStore`. Default is ‘r’.

- `errors` [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

- `where` [list, optional] A list of Term (or convertible) objects.

- `start` [int, optional] Row number to start selection.

- `stop` [int, optional] Row number to stop selection.

- `columns` [list, optional] A list of columns names to return.

- `iterator` [bool, optional] Return an iterator object.

- `chunksize` [int, optional] Number of rows to include in an iteration when using an iterator.

- `**kwargs` Additional keyword arguments passed to HDFStore.

**Returns**

- `item` [object] The selected object. Return type depends on the object stored.

**See also:**

- `DataFrame.to_hdf` Write a HDF file from a DataFrame.

- `HDFStore` Low-level access to HDF files.
Examples

```python
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

**pandas.HDFStore.put**

HDFStore.put(key, value, format=None, index=True, append=False, complevel=None, min_itemsize=None, nan_rep=None, data_columns=None, encoding=None, errors='strict', track_times=True, dropna=False)

Store object in HDFStore.

**Parameters**

- **key** [str]
- **value** [{Series, DataFrame}]
- **format** ['fixed(f)|table(t)', default is 'fixed'] Format to use when storing object in HDFStore. Value can be one of:
  - 'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- **append** [bool, default False] This will force Table format, append the input data to the existing.
- **data_columns** [list of columns or True, default None] List of columns to create as data columns, or True to use all columns. See here.
- **encoding** [str, default None] Provide an encoding for strings.
- **track_times** [bool, default True] Parameter is propagated to ‘create_table’ method of ‘PyTables’. If set to False it enables to have the same h5 files (same hashes) independent on creation time.

  New in version 1.1.0.

**pandas.HDFStore.append**

HDFStore.append(key, value, format=None, axes=None, index=True, append=True, complevel=None, columns=None, min_itemsize=None, nan_rep=None, chunks=None, expectedrows=None, dropna=None, data_columns=None, encoding=None, errors='strict')

Append to Table in file. Node must already exist and be Table format.

**Parameters**

- **key** [str]
- **value** [{Series, DataFrame}]
- **format** ['table' is the default] Format to use when storing object in HDFStore. Value can be one of:
  - 'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- **append** [bool, default True] Append the input data to the existing.
**Notes**

Does *not* check if data being appended overlaps with existing data in the table, so be careful

**pandas.HDFStore.get**

```python
def HDFStore.get(key)
    Retrieve pandas object stored in file.
    Parameters
    key [str]
    Returns
    object Same type as object stored in file.
```

**pandas.HDFStore.select**

```python
def HDFStore.select(key, where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, auto_close=False)
    Retrieve pandas object stored in file, optionally based on where criteria.
    Warning: Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype
data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.
    See: https://docs.python.org/3/library/pickle.html for more.
    Parameters
    key [str] Object being retrieved from file.
    where [list or None] List of Term (or convertible) objects, optional.
    start [int or None] Row number to start selection.
    stop [int, default None] Row number to stop selection.
    columns [list or None] A list of columns that if not None, will limit the return columns.
    iterator [bool or False] Returns an iterator.
```
chunksize [int or None] Number or rows to include in iteration, return an iterator.

auto_close [bool or False] Should automatically close the store when finished.

Returns

object Retrieved object from file.

pandas.HDFStore.info

HDFStore.info()

Print detailed information on the store.

Returns

str

pandas.HDFStore.keys

HDFStore.keys(include='pandas')

Return a list of keys corresponding to objects stored in HDFStore.

Parameters

include [str, default 'pandas'] When kind equals ‘pandas’ return pandas objects. When kind equals ‘native’ return native HDF5 Table objects.

New in version 1.1.0.

Returns

list List of ABSOLUTE path-names (e.g. have the leading ‘/’).

Raises

raises ValueError if kind has an illegal value

pandas.HDFStore.groups

HDFStore.groups()

Return a list of all the top-level nodes.

Each node returned is not a pandas storage object.

Returns

list List of objects.

pandas.HDFStore.walk

HDFStore.walk(where='/')

Walk the pytables group hierarchy for pandas objects.

This generator will yield the group path, subgroups and pandas object names for each group.

Any non-pandas PyTables objects that are not a group will be ignored.

The where group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.

Parameters
where [str, default ‘/’] Group where to start walking.

Yields

path [str] Full path to a group (without trailing ‘/’).
groups [list] Names (strings) of the groups contained in path.
leaves [list] Names (strings) of the pandas objects contained in path.

Warning: One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

3.1.10 Feather

read_feather(path[, columns, use_threads, ...]) Load a feather-format object from the file path.

DataFrame.to_feather(path, **kwargs) Write a DataFrame to the binary Feather format.

pandas.read_feather

pandas.read_feather(path, columns=None, use_threads=True, storage_options=None)
Load a feather-format object from the file path.

Parameters

path [str, path object, or file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a binary read() function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.feather.
columns [sequence, default None] If not provided, all columns are read.
use_threads [bool, default True] Whether to parallelize reading using multiple threads.
storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns
type of object stored in file
pandas.DataFrame.to_feather

DataFrame.to_feather(path, **kwargs)

Write a DataFrame to the binary Feather format.

Parameters

path [str, path object, file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a binary write() function. If a string or a path, it will be used as Root Directory path when writing a partitioned dataset.

**kwargs : Additional keywords passed to pyarrow.feather.write_feather(). Starting with pyarrow 0.17, this includes the compression, compression_level, chunksize and version keywords.

New in version 1.1.0.

Notes

This function writes the dataframe as a feather file. Requires a default index. For saving the DataFrame with your custom index use a method that supports custom indices e.g. to_parquet.

3.1.11 Parquet

read_parquet(path[, engine, columns, ...])  
Load a parquet object from the file path, returning a DataFrame.

DataFrame.to_parquet([path, engine, ...])  
Write a DataFrame to the binary parquet format.

pandas.read_parquet

pandas.read_parquet(path, engine='auto', columns=None, storage_options=None, use_nullable_dtypes=False, **kwargs)

Load a parquet object from the file path, returning a DataFrame.

Parameters

path [str, path object or file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a binary read() function. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.parquet. A file URL can also be a path to a directory that contains multiple partitioned parquet files. Both pyarrow and fastparquet support paths to directories as well as file URLs. A directory path could be: file://localhost/path/to/tables or s3://bucket/partition_dir.

engine [{'auto', 'pyarrow', 'fastparquet'}, default ‘auto’] Parquet library to use. If ‘auto’, then the option io.parquet.engine is used. The default io.parquet.engine behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

columns [list, default=None] If not None, only these columns will be read from the file.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”), and
`pandas.DataFrame.to_parquet`  

This function writes the dataframe as a parquet file. You can choose different parquet backends, and have the option of compression. See the user guide for more details.

**Parameters**

- `path` [str, path object, file-like object, or None, default None] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `write()` function. If `None`, the result is returned as bytes. If a string or path, it will be used as Root Directory path when writing a partitioned dataset.  
  Changed in version 1.2.0.  

- `engine` [{'auto', 'pyarrow', 'fastparquet'}, default 'auto'] Parquet library to use. If `auto`, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try `pyarrow`, falling back to `fastparquet` if `pyarrow` is unavailable.

- `compression` [{'snappy', 'gzip', 'brotli', None}, default 'snappy'] Name of the compression to use. Use None for no compression.

- `index` [bool, default None] If True, include the dataframe’s index(es) in the file output. If False, they will not be written to the file. If None, similar to True the dataframe’s index(es) will be saved. However, instead of being saved as values, the RangeIndex will be stored as a range in the metadata so it doesn’t require much space and is faster. Other indexes will be included as columns in the file output.

- `partition_cols` [list, optional, default None] Column names by which to partition the dataset. Columns are partitioned in the order they are given. Must be None if path is not a string.

- `storage_options` [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.  
  New in version 1.2.0.
**kwargs Additional arguments passed to the parquet library. See pandas io for more details.

Returns

bytes if no path argument is provided else None

See also:

read_parquet Read a parquet file.
DataFrame.to_csv Write a csv file.
DataFrame.to_sql Write to a sql table.
DataFrame.to_hdf Write to hdf.

Notes

This function requires either the fastparquet or pyarrow library.

Examples

```python
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip',
...   compression='gzip')
>>> pd.read_parquet('df.parquet.gzip')
  col1  col2
0    1    3
1    2    4
```

If you want to get a buffer to the parquet content you can use a io.BytesIO object, as long as you don’t use partition_cols, which creates multiple files.

```python
>>> import io
>>> f = io.BytesIO()
>>> df.to_parquet(f)
>>> f.seek(0)
0
>>> content = f.read()
```

3.1.12 ORC

read_orc(path[, columns]) Load an ORC object from the file path, returning a DataFrame.
pandas.read_orc

pandas.read_orc(path, columns=None, **kwargs)

Load an ORC object from the file path, returning a DataFrame.

New in version 1.0.0.

Parameters

- **path** [str, path object, or file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a binary read() function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.orc.
- **columns** [list, default None] If not None, only these columns will be read from the file.
- **kwargs** Any additional kwargs are passed to pyarrow.

Returns

- DataFrame

Notes

Before using this function you should read the user guide about ORC and install optional dependencies.

3.1.13 SAS

pandas.read_sas

pandas.read_sas(filepath_or_buffer, format=None, index=None, encoding=None, chunksize=None, iterator=False)

Read SAS files stored as either XPORT or SAS7BDAT format files.

Parameters

- **filepath_or_buffer** [str, path object, or file-like object] String, path object (implementing os.PathLike[str]), or file-like object implementing a binary read() function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.sas.
- **format** [str {'xport', 'sas7bdat'} or None] If None, file format is inferred from file extension. If ‘xport’ or ‘sas7bdat’, uses the corresponding format.
- **index** [identifier of index column, defaults to None] Identifier of column that should be used as index of the DataFrame.
- **encoding** [str, default is None] Encoding for text data. If None, text data are stored as raw bytes.
- **chunksize** [int] Read file chunksize lines at a time, returns iterator.

    Changed in version 1.2: TextFileReader is a context manager.

- **iterator** [bool, defaults to False] If True, returns an iterator for reading the file incrementally.
Changed in version 1.2: `TextFileReader` is a context manager.

**Returns**

- DataFrame if `iterator=False` and `chunksize=None`, else SAS7BDATReader or XportReader

### 3.1.14 SPSS

```python
pandas.read_spss(path[, usecols, convert_categoricals])
```

Load an SPSS file from the file path, returning a DataFrame.

**Parameters**

- `path` [str or Path] File path.
- `usecols` [list-like, optional] Return a subset of the columns. If None, return all columns.
- `convert_categoricals` [bool, default is True] Convert categorical columns into pd.Categorical.

**Returns**

- DataFrame

### 3.1.15 SQL

```python
pandas.read_sql_table(table_name, con[, schema, ...])

pandas.read_sql_query(sql, con[, index_col, ...])

pandas.read_sql(sql, con[, index_col, ...])

DataFrame.to_sql(name, con[, schema, ...])
```

Read SQL database table into a DataFrame.

**Parameters**

- `table_name` [str] Name of SQL table in database.
- `con` [SQLAlchemy connectable or str] A database URI could be provided as str. SQLite DBAPI connection mode not supported.
schema [str, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.

parse_dates [list or dict, default None]

• List of column names to parse as dates.

• Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.

• Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default None] List of column names to select from SQL table.

chunksize [int, default None] If specified, returns an iterator where chunksize is the number of rows to include in each chunk.

Returns

Dataframe or Iterator[Dataframe] A SQL table is returned as two-dimensional data structure with labeled axes.

See also:

read_sql_query Read SQL query into a DataFrame.

read_sql Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information will be converted to UTC.

Examples

```python
>>> pd.read_sql_table('table_name', 'postgres:///db_name')
```

pandas.read_sql_query

pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None, dtype=None)

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an index_col parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

sql [str SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.
con  [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name': 'value'}.

parse_dates [list or dict, default: None]

• List of column names to parse as dates.

• Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.

• Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

chunksize [int, default None] If specified, return an iterator where chunksize is the number of rows to include in each chunk.

dtype [Type name or dict of columns] Data type for data or columns. E.g. np.float64 or {'a': np.float64, 'b': np.int32, 'c': 'Int64'}.

New in version 1.3.0.

Returns

DataFrame or Iterator[DataFrame]

See also:

read_sql_table Read SQL database table into a DataFrame.

read_sql Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information parsed via the parse_dates parameter will be converted to UTC.

pandas.read_sql

pandas.read_sql(sql, con=con, index_col=index_col, coerce_float=coerce_float, params=params, parse_dates=parse_dates, columns=columns, chunksize=chunksize)

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around read_sql_table and read_sql_query (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to read_sql_query, while a database table name will be routed to read_sql_table. Note that the delegated function might have more specific notes about their functionality not listed here.

Parameters
sql  [str or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table
name.

con  [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possi-
bable to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported. The user is responsible for engine disposal and connection closure for the
SQLAlchemy connectable; str connections are closed automatically. See here.

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric ob-
jects (like decimal.Decimal) to floating point, useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute
method. The syntax used to pass parameters is database driver dependent. Check your
database driver documentation for which of the five syntax styles, described in PEP 249’s
paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' :
'value'}.

parse_dates [list or dict, default: None]
  • List of column names to parse as dates.
  • Dict of {column_name: format string} where format string is strftime compat-
ible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing
integer timestamps.
  • Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword
arguments of pandas.to_datetime() Especially useful with databases without na-
tive Datetime support, such as SQLite.

columns [list, default: None] List of column names to select from SQL table (only used when
reading a table).

chunksize [int, default None] If specified, return an iterator where chunksize is the number of
rows to include in each chunk.

Returns

DataFrame or Iterator[DataFrame]

See also:

read_sql_table Read SQL database table into a DataFrame.
read_sql_query Read SQL query into a DataFrame.

Examples

Read data from SQL via either a SQL query or a SQL tablename. When using a SQLite database only SQL
queries are accepted, providing only the SQL tablename will result in an error.

```python
>>> from sqlite3 import connect
>>> conn = connect(':memory:)
>>> df = pd.DataFrame(data=[[0, '10/11/12'], [1, '12/11/10']],
... columns=['int_column', 'date_column'])
>>> df.to_sql('test_data', conn)
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data', conn)
    int_column  date_column
   0       0  10/11/12
   1       1  12/11/10

>>> pd.read_sql('test_data', 'postgres:///db_name')

Apply date parsing to columns through the `parse_dates` argument

```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
               ... conn,
               ... parse_dates=['date_column'])
    int_column  date_column
   0       0  2012-10-11
   1       1  2010-12-11

The `parse_dates` argument calls `pd.to_datetime` on the provided columns. Custom argument values for applying `pd.to_datetime` on a column are specified via a dictionary format:

1. Ignore errors while parsing the values of "date_column"
```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
               ... conn,
               ... parse_dates={'date_column': {'errors': 'ignore'}})
    int_column  date_column
   0       0  2012-10-11
   1       1  2010-12-11

2. Apply a dayfirst date parsing order on the values of "date_column"
```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
               ... conn,
               ... parse_dates={'date_column': {'dayfirst': True}})
    int_column  date_column
   0       0  2012-11-10
   1       1  2010-11-12

3. Apply custom formatting when date parsing the values of "date_column"
```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
               ... conn,
               ... parse_dates={'date_column': {'format': '%d/%m/%y'}})
    int_column  date_column
   0       0  2012-11-10
   1       1  2010-11-12
```

3.1. Input/output
DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

**Parameters**

- **name** [str] Name of SQL table.
- **con** [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See here.
- **schema** [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
- **if_exists** [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
- **index** [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.
- **index_label** [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **chunksize** [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.
- **dtype** [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.
- **method** [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:
  - None: Uses standard SQL INSERT clause (one per row).
  - 'multi': Pass multiple values in a single INSERT clause.
  - callable with signature (pd_table, conn, keys, data_iter).

Details and a sample callable implementation can be found in the section insert method.

**Returns**

None or int Number of rows affected by to_sql. None is returned if the callable passed into method does not return the number of rows.

The number of returned rows affected is the sum of the rowcount attribute of sqlite3.Cursor or SQLAlchemy connectable which may not reflect the exact number of written rows as stipulated in the sqlite3 or SQLAlchemy.

New in version 1.4.0.

**Raises**
ValueError  When the table already exists and if_exists is ‘fail’ (the default).

See also:

read_sql  Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as Timestamp with timezone type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

References

[1],[2]

Examples

Create an in-memory SQLite database.

>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)

Create a table from scratch with 3 rows.

>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3

>>> df.to_sql('users', con=engine)
3

An sqlalchemy.engine.Connection can also be passed to con:

>>> with engine.begin() as connection:
...    df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
...    df1.to_sql('users', con=connection, if_exists='append')
2

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.
Overwrite the table with just \texttt{df2}.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace',
...            index_label='id')
2
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the \texttt{dtype} (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({'A': [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0

>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...           dtype={'A': Integer()})
3
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

### 3.1.16 Google BigQuery

\texttt{read_gbq(query[, project_id, index_col, ...])}Load data from Google BigQuery.

\texttt{pandas.read_gbq}

\texttt{pandas.read_gbq(query, project_id=None, index_col=None, col_order=None, reauth=False, auth_local_webserver=False, dialect=None, location=None, configuration=None, credentials=None, use_bqstorage_api=None, max_results=None, progress_bar_type=None)}

Load data from Google BigQuery.

This function requires the \texttt{pandas-gbq} package.

See the \texttt{How to authenticate with Google BigQuery} guide for authentication instructions.

**Parameters**

- \texttt{query} [str] SQL-Like Query to return data values.
- \texttt{project_id} [str, optional] Google BigQuery Account project ID. Optional when available from the environment.
- \texttt{index_col} [str, optional] Name of result column to use for index in results DataFrame.
- \texttt{col_order} [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.
**reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

**auth_local_webserver** [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.

*New in version 0.2.0 of pandas-gbq.*

**dialect** [str, default 'legacy'] Note: The default value is changing to 'standard' in a future version.

SQL syntax dialect to use. Value can be one of:

'legacy' Use BigQuery’s legacy SQL dialect. For more information see BigQuery Legacy SQL Reference.

'standard' Use BigQuery’s standard SQL, which is compliant with the SQL 2011 standard. For more information see BigQuery Standard SQL Reference.

**location** [str, optional] Location where the query job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of any datasets used in the query.

*New in version 0.5.0 of pandas-gbq.*

**configuration** [dict, optional] Query config parameters for job processing. For example:

```
    configuration = {'query': {'useQueryCache': False}}
```

For more information see BigQuery REST API Reference.

**credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.

*New in version 0.8.0 of pandas-gbq.*

**use_bqstorage_api** [bool, default False] Use the BigQuery Storage API to download query results quickly, but at an increased cost. To use this API, first enable it in the Cloud Console. You must also have the bigquery.readsessions.create permission on the project you are billing queries to.

This feature requires version 0.10.0 or later of the pandas-gbq package. It also requires the google-cloud-bigquery-storage and fastavro packages.

*New in version 0.25.0.*

**max_results** [int, optional] If set, limit the maximum number of rows to fetch from the query results.

*New in version 0.12.0 of pandas-gbq.*

*New in version 1.1.0.*

**progress_bar_type** [Optional, str] If set, use the tqdm library to display a progress bar while the data downloads. Install the tqdm package to use this feature.

Possible values of progress_bar_type include:

- **None** No progress bar.
- **'tqdm'** Use the tqdm.tqdm() function to print a progress bar to sys.stderr.
- **'tqdm_notebook'** Use the tqdm.tqdm_notebook() function to display a progress bar as a Jupyter notebook widget.
'tqdm_gui' Use the `tqdm.tqdm_gui()` function to display a progress bar as a graphical dialog box.

Note that this feature requires version 0.12.0 or later of the pandas-gbq package. And it requires the tqdm package. Slightly different than pandas-gbq, here the default is `None`.

New in version 1.0.0.

Returns

- df: DataFrame DataFrame representing results of query.

See also:

- `pandas_gbq.read_gbq` This function in the pandas-gbq library.
- `DataFrame.to_gbq` Write a DataFrame to Google BigQuery.

3.1.17 STATA

<table>
<thead>
<tr>
<th>pandas.read_stata</th>
<th>Read Stata file into DataFrame.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_stata(filepath_or_buffer[, ...])</code></td>
<td>Export DataFrame object to Stata dta format.</td>
</tr>
<tr>
<td><code>DataFrame.to_stata(path[, convert_dates, ...])</code></td>
<td></td>
</tr>
</tbody>
</table>

**pandas.read_stata**

```
pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False, compression='infer', storage_options=None)
```

Read Stata file into DataFrame.

**Parameters**

- **filepath_or_buffer** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.dta`.
  
  If you want to pass in a path object, pandas accepts any os.PathLike.

  By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via builtin `open` function) or `StringIO`.

- **convert_dates** [bool, default True] Convert date variables to DataFrame time values.

- **convert_categoricals** [bool, default True] Read value labels and convert columns to Categorical/Factor variables.

- **index_col** [str, optional] Column to set as index.

- **convert_missing** [bool, default False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by Stata MissingValue objects.

- **preserve_dtypes** [bool, default True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

- **columns** [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.
**order_categoricals** [bool, default True] Flag indicating whether converted categorical data are ordered.

**chunksize** [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

**iterator** [bool, default False] Return StataReader object.

**compression** [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘%s’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: `compression={‘method’: ‘zstd’, ‘dict_data’: my_compression_dict}`.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

**Returns**

DataFrame or StataReader

**See also:**

io stata StataReader Low-level reader for Stata data files.

**Dataframe.to_stata** Export Stata data files.

**Notes**

Categorical variables read through an iterator may not have the same categories and dtype. This occurs when a variable stored in a DTA file is associated to an incomplete set of value labels that only label a strict subset of the values.

**Examples**

Creating a dummy stata for this example >>> df = pd.DataFrame(‘animal’: [‘falcon’, ‘parrot’, ‘falcon’, ... ‘parrot’], ‘speed’: [350, 18, 361, 15]) # doctest: +SKIP >>> df.to_stata(‘animals.dta’) # doctest: +SKIP

Read a Stata dta file:

```python
>>> df = pd.read_stata(‘animals.dta’)
```

Read a Stata dta file in 10,000 line chunks: >>> values = np.random.randint(0, 10, size=(20_000, 1), dtype=“uint8”) # doctest: +SKIP >>> df = pd.DataFrame(values, columns=[“i”]) # doctest: +SKIP >>> df.to_stata(‘filename.dta’) # doctest: +SKIP

```python
>>> itr = pd.read_stata(‘filename.dta’, chunksize=10000)
```

```python
>>> for chunk in itr:
...     # Operate on a single chunk, e.g., chunk.mean()
...     pass
```
**DataFrame.to_stata**

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

**Parameters**

- **path** [str, path object, or buffer] String, path object (implementing os.PathLike[str]), or file-like object implementing a binary write() function.
  
  Changed in version 1.0.0.
  
  Previously this was “fname”

- **convert_dates** [dict] Dictionary mapping columns containing datetme types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises NotImplemented error if a datetime column has timezone information.

- **write_index** [bool] Write the index to Stata dataset.

- **byteorder** [str] Can be “>”, “<”, “little”, or “big”. default is sys.byteorder.

- **time_stamp** [datetime] A datetime to use as file creation date. Default is the current time.

- **data_label** [str, optional] A label for the data set. Must be 80 characters or smaller.

- **variable_labels** [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

- **version** [{114, 117, 118, 119, None}, default 114] Version to use in the output dta file. Set to None to let pandas decide between 118 or 119 formats depending on the number of columns in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata 15 and later. Version 114 limits string variables to 244 characters or fewer while versions 117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119 support Unicode characters, and version 119 supports more than 32,767 variables.

  Version 119 should usually only be used when the number of variables exceeds the capacity of dta format 118. Exporting smaller datasets in format 119 may have unintended consequences, and, as of November 2020, Stata SE cannot read version 119 files.

  Changed in version 1.0.0: Added support for formats 118 and 119.

- **convert_strl** [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

- **compression** [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={’method’: ‘gzip’, ‘compresslevel’: 1, ‘mtime’: 1}.
New in version 1.1.0.

Changed in version 1.4.0: Zstandard support.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**value_labels** [dict of dicts] Dictionary containing columns as keys and dictionaries of column value to labels as values. Labels for a single variable must be 32,000 characters or smaller.

New in version 1.4.0.

**Raises**

**NotImplementedError**
- If datetimes contain timezone information
- Column dtype is not representable in Stata

**ValueError**
- Columns listed in convert_dates are neither datetime64[ns] or datetime.datetime
- Column listed in convert_dates is not in DataFrame
- Categorical label contains more than 32,000 characters

**See also:**

*read_stata* Import Stata data files.

*io.stata.StataWriter* Low-level writer for Stata data files.

*io.stata.StataWriter117* Low-level writer for version 117 files.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',
... 'parrot'],
... 'speed': [350, 18, 361, 15]})
>>> df.to_stata('animals.dta')
```

<table>

3.1. Input/output
pandas.io.stata.StataReader.data_label

**property** StataReader.data_label
Return data label of Stata file.

pandas.io.stata.StataReader.value_labels

StataReader.value_labels()
Return a dict, associating each variable name a dict, associating each value its corresponding label.

**Returns**
dict

pandas.io.stata.StataReader.variable_labels

StataReader.variable_labels()
Return variable labels as a dict, associating each variable name with corresponding label.

**Returns**
dict

pandas.io.stata.StataWriter.write_file

StataWriter.write_file()
Export DataFrame object to Stata dta format.

### 3.2 General functions

#### 3.2.1 Data manipulations

pandas.melt

pandas.melt(frame, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.

var_name [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.

value_name [scalar, default ‘value’] Name to use for the ‘value’ column.

col_level [int or str, optional] If columns are a MultiIndex then use this level to melt.

ignore_index [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

DataFrame Unpivoted DataFrame.

See also:

DataFrame.melt Identical method.

pivot_table Create a spreadsheet-style pivot table as a DataFrame.

DataFrame.pivot Return reshaped DataFrame organized by given index / column values.

DataFrame.explode Explode a DataFrame from list-like columns to long format.

Notes

Reference the user guide for more examples.
### Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'}, 'B': {0: 1, 1: 3, 2: 5}, 'C': {0: 2, 1: 4, 2: 6}})

>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6

>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a      B    1
1  b      B    3
2  c      B    5

>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a      B    1
1  b      B    3
2  c      B    5
3  a      C    2
4  b      C    4
5  c      C    6

The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B'], var_name='myVarname', value_name='myValname')
   myVarname  myValname
0      a      B    1
1      b      B    3
2      c      B    5
3      a      C    2
4      b      C    4
5      c      C    6
```

Original index values can be kept around:

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
   A variable  value
0  a      B    1
1  b      B    3
2  c      B    5
0  a      C    2
1  b      C    4
2  c      C    6
```

If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]

>>> df
   A  B  C  D  E  F
0  a  1  2  D  E  F
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.1

(continued from previous page)

<table>
<thead>
<tr>
<th>1</th>
<th>b</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>c</td>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>

```python
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A   variable  value
 0   a  B     1
 1   b  B     3
 2   c  B     5
```

```python
>>> pd.melt(df, id_vars=['A', 'D'], value_vars=['B', 'E'])
   (A, D)   variable_0 variable_1  value
 0   a     B     E      1
 1   b     B     E      3
 2   c     B     E      5
```

**pandas.pivot**

`pandas.pivot(data, index=None, columns=None, values=None)`

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified `index` / `columns` to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the [User Guide](#) for more on reshaping.

**Parameters**

- **data** [DataFrame]:

- **index** [str or object or a list of str, optional]: Column to use to make new frame’s index. If None, uses existing index.
  Changed in version 1.1.0: Also accept list of index names.

- **columns** [str or object or a list of str]: Column to use to make new frame’s columns.
  Changed in version 1.1.0: Also accept list of columns names.

- **values** [str, object or a list of the previous, optional]: Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

**Returns**

- **DataFrame**: Returns reshaped DataFrame.

**Raises**

- **ValueError**: When there are any `index`, `columns` combinations with multiple values. Then use `DataFrame.pivot_table` when you need to aggregate.

**See also**:

- **DataFrame.pivot_table**: Generalization of pivot that can handle duplicate values for one index/column pair.
- **DataFrame.unstack**: Pivot based on the index values instead of a column.
- **wide_to_long**: Wide panel to long format. Less flexible but more user-friendly than melt.
Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods. Reference the user guide for more examples.

Examples

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', ...
...      'two'],
...                      ...
...      'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                      ...
...      'baz': [1, 2, 3, 4, 5, 6],
...                      ...
...      'zoo': ['x', 'y', 'z', 'q', 'w', 't']})

>>> df
foo  bar  baz  zoo
0    one  A    1    x
1    one  B    2    y
2    one  C    3    z
3    two  A    4    q
4    two  B    5    w
5    two  C    6    t

>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A  B  C
foo
  one 1  2  3
  two 4  5  6

>>> df.pivot(index='foo', columns='bar')['baz']
bar  A  B  C
foo
  one 1  2  3
  two 4  5  6

>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
bar  baz  zoo
foo
  one 1  2  3  x  y  z
  two 4  5  6  q  w  t

You could also assign a list of column names or a list of index names.

```python
>>> df = pd.DataFrame({
...                        ...
...      "lev1": [1, 1, 2, 2, 2],
...                        ...
...      "lev2": [1, 1, 2, 1, 1, 2],
...                        ...
...      "lev3": [1, 2, 1, 2, 1, 2],
...                        ...
...      "lev4": [1, 2, 3, 4, 5, 6],
...                        ...
...      "values": [0, 1, 2, 3, 4, 5]})

>>> df
lev1  lev2  lev3  lev4  values
0    1      1      1      1      0
```
(continues on next page)
1 1 1 2 2 1
2 1 2 1 3 2
3 2 1 2 4 3
4 2 1 1 5 4
5 2 2 2 6 5

```python
>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")
lev2 1 2
lev3 1 2 1 2
lev1
1 0.0 1.0 2.0 NaN
2 4.0 3.0 NaN 5.0
```

```python
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"], values="values")
lev3 1 2
lev1 lev2
1 1 0.0 1.0
2 2.0 NaN
2 1 4.0 3.0
2 NaN 5.0
```

A ValueError is raised if there are any duplicates.

```python
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                     "bar": ['A', 'A', 'B', 'C'],
...                     "baz": [1, 2, 3, 4]})
```

```python
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

**pandas.pivot_table**

**pandas.pivot_table** (*data*, *values=None*, *index=None*, *columns=None*, *aggfunc='mean'*, *fill_value=None*, *margins=False*, *dropna=True*, *margins_name='All'*, *observed=False*, *sort=True*)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

**Parameters**

- **data** [DataFrame]
values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

margins [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna [bool, default True] Do not include columns whose entries are all NaN.

margins_name [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

    Changed in version 0.25.0.

sort [bool, default True] Specifies if the result should be sorted.

    New in version 1.3.0.

Returns

Dataframe An Excel style pivot table.

See also:

Dataframe.pivot Pivot without aggregation that can handle non-numeric data.

Dataframe.melt Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

wide_to_long Wide panel to long format. Less flexible but more user-friendly than melt.

Notes

Reference the user guide for more examples.
## Examples

```python
>>> df = pd.DataFrame({'A': ['foo', 'foo', 'foo', 'foo', 'foo', ...
  'bar', 'bar', 'bar', 'bar'],
  'B': ['one', 'one', 'one', 'two', 'two', ...
  'one', 'one', 'two', 'two'],
  'C': ['small', 'large', 'large', 'small', 'small', ...
  'small', 'large', 'small', 'small', 'large'],
  'D': [1, 2, 2, 3, 3, 4, 5, 6, 7],
  'E': [2, 4, 5, 5, 6, 6, 8, 9, 9]})

>>> df
   A  B   C  D  E
0  foo one  small  1  2
1  foo one  large  2  4
2  foo one  large  2  5
3  foo two  small  3  5
4  foo two  small  3  6
5  bar one  large  4  6
6  bar one  small  5  8
7  bar two  small  6  9
8  bar two  large  7  9
```

This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum)

>>> table
   C   large  small
   A  B
bar one  4.0  5.0
  two  7.0  6.0
foo one  4.0  1.0
  two NaN  6.0
```

We can also fill missing values using the `fill_value` parameter.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum, fill_value=0)

>>> table
   C  large  small
   A  B
bar one  4  5
  two  7  6
foo one  4  1
  two  0  6
```

The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                        aggfunc={'D': np.mean,
                                 'E': np.mean})

>>> table
```

(continues on next page)
We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                        ...     aggfunc={'D': np.mean,
                        ...             'E': [min, max, np.mean]})
>>> table

<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td>5.5000</td>
<td>7.5000</td>
</tr>
<tr>
<td></td>
<td>5.5000</td>
<td>8.5000</td>
</tr>
<tr>
<td>small</td>
<td>2.0000</td>
<td>4.5000</td>
</tr>
<tr>
<td>foo</td>
<td>2.3333</td>
<td>4.3333</td>
</tr>
</tbody>
</table>
```

**pandas.crosstab**

The `pandas.crosstab` function computes a simple cross tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

### Parameters

- **index** [array-like, Series, or list of arrays/Series] Values to group by in the rows.
- **columns** [array-like, Series, or list of arrays/Series] Values to group by in the columns.
- **values** [array-like, optional] Array of values to aggregate according to the factors. Requires `aggfunc` be specified.
- **rownames** [sequence, default None] If passed, must match number of row arrays passed.
- **colnames** [sequence, default None] If passed, must match number of column arrays passed.
- **aggfunc** [function, optional] If specified, requires `values` be specified as well.
- **margins** [bool, default False] Add row/column margins (subtotals).
- **margins_name** [str, default ‘All’] Name of the row/column that will contain the totals when margins is True.
- **dropna** [bool, default True] Do not include columns whose entries are all NaN.
- **normalize** [bool, {‘all’, ‘index’, ‘columns’}, or {0,1}, default False] Normalize by dividing all values by the sum of values.
  - If passed ‘all’ or True, will normalize over all values.
  - If passed ‘index’ will normalize over each row.
  - If passed ‘columns’ will normalize over each column.
• If margins is True, will also normalize margin values.

Returns

DataFrame Cross tabulation of the data.

See also:

DataFrame.pivot Reshape data based on column values.
pivot_table Create a pivot table as a DataFrame.

Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have all of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren’t overlapping indexes an empty DataFrame will be returned.

Reference the user guide for more examples.

Examples

```python
da = np.array(['foo', 'foo', 'foo', 'foo', 'bar', 'bar',
               'bar', 'bar', 'foo', 'foo', 'foo'], dtype=object)
db = np.array(['one', 'one', 'one', 'two', 'one', 'one',
               'two', 'two', 'one', 'two', 'one'], dtype=object)
dc = np.array(['dull', 'dull', 'shiny', 'dull', 'dull', 'shiny',
               'shiny', 'dull', 'shiny', 'shiny', 'shiny'],
               dtype=object)

dpd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
```

```
   b  one  two
  c   dull  shiny  dull  shiny
  a
  bar    1    2    1    0
  foo    2    2    1    2
```

Here ‘c’ and ‘f’ are not represented in the data and will not be shown in the output because dropna is True by default. Set dropna=False to preserve categories with no data.

```python
da = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
db = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])

dpd.crosstab(a, b, dropna=False)
```

```
col  d  e  f
row
a    1  0  0
b    0  1  0
c    0  0  0
```
Bin values into discrete intervals.

Use `cut` when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

**Parameters**

- `x` [array-like] The input array to be binned. Must be 1-dimensional.
- `bins` [int, sequence of scalars, or IntervalIndex] The criteria to bin by.
  - int : Defines the number of equal-width bins in the range of `x`. The range of `x` is extended by .1% on each side to include the minimum and maximum values of `x`.
  - sequence of scalars : Defines the bin edges allowing for non-uniform width. No extension of the range of `x` is done.
  - IntervalIndex : Defines the exact bins to be used. Note that IntervalIndex for `bins` must be non-overlapping.
- `right` [bool, default True] Indicates whether `bins` includes the rightmost edge or not. If `right` == True (the default), then the `bins` [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when `bins` is an IntervalIndex.
- `labels` [array or False, default None] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when `bins` is an IntervalIndex. If True, raises an error. When `ordered=False`, labels must be provided.
- `retbins` [bool, default False] Whether to return the bins or not. Useful when `bins` is provided as a scalar.
- `precision` [int, default 3] The precision at which to store and display the bins labels.
- `include_lowest` [bool, default False] Whether the first interval should be left-inclusive or not.
- `duplicates` [{default ‘raise’, ‘drop’}, optional] If bin edges are not unique, raise `ValueError` or drop non-unique.
- `ordered` [bool, default True] Whether the labels are ordered or not. Applies to returned types Categorical and Series (with Categorical dtype). If True, the resulting categorical will be ordered. If False, the resulting categorical will be unordered (labels must be provided).
  
**New in version 1.1.0.**

**Returns**

- `out` [Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of `x`. The type depends on the value of `labels`.
  - None (default) : returns a Series for Series x or a Categorical for all other inputs. The values stored within are Interval dtype.
  - sequence of scalars : returns a Series for Series x or a Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
  - False : returns an ndarray of integers.
bins [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when retbins=True. For scalar or sequence bins, this is an ndarray with the computed bins. If set duplicates=drop, bins will drop non-unique bin. For an IntervalIndex bins, this is equal to bins.

See also:

qcut Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

Categorical Array type for storing data that come from a fixed set of values.

Series One-dimensional array with axis labels (including time series).

IntervalIndex Immutable Index implementing an ordered, sliceable set.

Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or Categorical object.

Reference the user guide for more examples.

Examples

Discretize into three equal-sized bins.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
...
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [(0.994, 3.0] < (3.0, 5.0] ...
```

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
...
([(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [(0.994, 3.0] < (3.0, 5.0] ...
array([0.994, 3. , 5. , 7. ]))
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical’s categories are labels and is ordered.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, labels=['bad', 'medium', 'good'])
...
3, labels=['bad', 'medium', 'good'])
['bad', 'good', 'medium', 'medium', 'good', 'bad']
Categories (3, object): ['bad' < 'medium' < 'good']
```

ordered=False will result in unordered categories when labels are passed. This parameter can be used to allow non-unique labels:

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, 
            labels=['B', 'A', 'B'], ordered=False)
['B', 'B', 'A', 'A', 'B', 'B']
Categories (2, object): ['A', 'B']
```

labels=False implies you just want the bins back.
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])

Passing a Series as an input returns a Series with categorical dtype:

```python
cut = pd.cut(s, 3)...
dtype: category
Categories (3, interval[float64, right]): [(1.992, 4.667] < (4.667, ...]
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```python
cut = pd.cut(s, [0, 2, 4, 6, 10], labels=False, retbins=True, right=False,...
dtype: float64, array([ 0, 2, 4, 6, 10]))
```

Use `drop` optional when bins is not unique

```python
cut = pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True, right=False,...
dtype: float64, array([ 0, 2, 4, 6, 10]))
```

Passing an IntervalIndex for `bins` results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```python
bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
cut = pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0.0, 1.0], NaN, (2.0, 3.0], (4.0, 5.0]]
```

Categories (3, interval[int64, right]): [(0, 1] < (2, 3] < (4, 5]]
pandas.qcut

**pandas.qcut** *(x, q, labels=None, retbins=False, precision=3, duplicates='raise')*

Quantile-based discretization function.

Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

**Parameters**

- **x** [1d ndarray or Series] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1] for quartiles.
- **q** [int or list-like of float] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1] for quartiles.
- **labels** [array or False, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins. If True, raises an error.
- **retbins** [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.
- **precision** [int, optional] The precision at which to store and display the bins labels.
- **duplicates** [{default 'raise', 'drop'}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

**Returns**

- **out** [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.
- **bins** [ndarray of floats] Returned only if retbins is True.

**Notes**

Out of bounds values will be NA in the resulting Categorical object

**Examples**

```python
>>> pd.qcut(range(5), 4
... ...
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64, right]): [-0.001 < 1.0 < 2.0 ...]
```

```python
>>> pd.qcut(range(5), 3, labels=['good', 'medium', 'bad'])
...
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```python
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

pandas.merge

```python
pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)
```

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

**Warning:** If both key columns contain rows where the key is a null value, those rows will be matched against each other. This is different from usual SQL join behaviour and can lead to unexpected results.

**Parameters**

- **left** [DataFrame]
- **right** [DataFrame or named Series] Object to merge with.
- **how** [{‘left’, ‘right’, ‘outer’, ‘inner’, ‘cross’}, default ‘inner’] Type of merge to be performed.
  - left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
  - right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
  - outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
  - inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
  - cross: creates the cartesian product from both frames, preserves the order of the left keys.

  New in version 1.2.0.

- **on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

- **left_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

- **right_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

- **left_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

- **right_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

- **sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).
suffixes [list-like, default is ("_x", "_y")) A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called "_merge" with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of "left_only" for observations whose merge key only appears in the left DataFrame, "right_only" for observations whose merge key only appears in the right DataFrame, and "both" if the observation's merge key is found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

merge_ordered Merge with optional filling/interpolation.

merge_asof Merge on nearest keys.

DataFrame.join Similar method using indices.

Notes

Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```python
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
                       'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
                       'value': [5, 6, 7, 8]})
>>> df1
lkey  value
0   foo    1
1   bar    2
2   baz    3
3   foo    5
>>> df2
rkey  value
0   foo    5
```
Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
lkey  value_x rkey  value_y
0 foo  1 foo   5
1 foo  1 foo   8
2 foo  5 foo   5
3 foo  5 foo   8
4 bar  2 bar   6
5 baz  3 baz   7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
            suffixes=('_left', '_right'))
lkey  value_left rkey  value_right
0 foo  1 foo      5
1 foo  1 foo      8
2 foo  5 foo      5
3 foo  5 foo      8
4 bar  2 bar      6
5 baz  3 baz      7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
  ... Value Error: columns overlap but no suffix specified:
     Index([['value'], dtype='object'])
```

```python
>>> df1 = pd.DataFrame({'a': ['foo', 'bar'], 'b': [1, 2]})
>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})
>>> df1
   a  b
0  foo  1
1  bar  2
>>> df2
   a  c
0  foo  3
1  baz  4
>>> df1.merge(df2, how='inner', on='a')
a  b  c
0  foo  1  3
```
```
>>> df1.merge(df2, how='left', on='a')
   a  b  c
0 foo 1 3.0
1 bar 2 NaN
```

```
>>> df1 = pd.DataFrame({'left': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'right': [7, 8]})
>>> df1
    left
0   foo
1   bar
>>> df2
    right
0    7
1    8
```

```
>>> df1.merge(df2, how='cross')
   left  right
0   foo     7
1   foo     8
2   bar     7
3   bar     8
```

**pandas.merge_ordered**

`pandas.merge_ordered(left, right, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('_x', '_y'), how='outer')`

Performs a merge for ordered data with optional filling/interpolation.

Designed for ordered data like time series data. Optionally perform group-wise merge (see examples).

**Parameters**

- `left` [DataFrame]:
- `right` [DataFrame]:
- `on` [label or list]: Field names to join on. Must be found in both DataFrames.
- `left_on` [label or list, or array-like]: Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns.
- `right_on` [label or list, or array-like]: Field names to join on in right DataFrame or vector/list of vectors per left_on docs.
- `left_by` [column name or list of column names]: Group left DataFrame by group columns and merge piece by piece with right DataFrame.
- `right_by` [column name or list of column names]: Group right DataFrame by group columns and merge piece by piece with left DataFrame.
- `fill_method` [None, 'ffill', default None]: Interpolation method for data.
- `suffixes` [list-like, default is ("_x", "_y")]: A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in `left` and `right` respectively. Pass a value of `None` instead of a string to indicate that the column name
from left or right should be left as-is, with no suffix. At least one of the values must not be None.

Changed in version 0.25.0.

how [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘outer’]

• left: use only keys from left frame (SQL: left outer join)
• right: use only keys from right frame (SQL: right outer join)
• outer: use union of keys from both frames (SQL: full outer join)
• inner: use intersection of keys from both frames (SQL: inner join).

Returns

DataFrame The merged DataFrame output type will the be same as ‘left’, if it is a subclass of DataFrame.

See also:

merge Merge with a database-style join.
merge_asof Merge on nearest keys.

Examples

```python
>>> df1 = pd.DataFrame({
...     "key": ["a", "c", "e", "a", "c", "e"],
...     "lvalue": [1, 2, 3, 1, 2, 3],
...     "group": ["a", "a", "a", "b", "b", "b"]
... })
>>> df1
   key  lvalue group
0   a     1    a
1   c     2    a
2   e     3    a
3   a     1    b
4   c     2    b
5   e     3    b
```

```python
>>> df2 = pd.DataFrame({"key": ["b", "c", "d"], "rvalue": [1, 2, 3]})
>>> df2
   key  rvalue
0   b      1
1   c      2
2   d      3
```

```python
>>> merge_ordered(df1, df2, fill_method="ffill", left_by="group")
   key  lvalue group  rvalue
0   a     1    a  NaN
1   b     1    a  1.0
2   c     2    a  2.0
3   d     2    a  3.0
```

pandas.merge_asof

pandas.merge_asof( left, right, on=None, left_on=None, right_on=None, left_index=False, right_index=False, by=None, left_by=None, right_by=None, suffixes=('x', '_y'), tolerance=None, allow_exact_matches=True, direction='backward')

Perform a merge by key distance.

This is similar to a left-join except that we match on nearest key rather than equal keys. Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

Parameters

- **left** [DataFrame or named Series]
- **right** [DataFrame or named Series]
- **on** [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.
- **left_on** [label] Field name to join on in left DataFrame.
- **right_on** [label] Field name to join on in right DataFrame.
- **left_index** [bool] Use the index of the left DataFrame as the join key.
- **right_index** [bool] Use the index of the right DataFrame as the join key.
- **by** [column name or list of column names] Match on these columns before performing merge operation.
- **left_by** [column name] Field names to match on in the left DataFrame.
- **right_by** [column name] Field names to match on in the right DataFrame.
- **suffixes** [2-length sequence (tuple, list, . . .)] Suffix to apply to overlapping column names in the left and right side, respectively.

3.2. General functions 1133
tolerance  [int or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.

allow_exact_matches  [bool, default True]

- If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
- If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than).

direction  ['backward' (default), 'forward', or 'nearest'] Whether to search for prior, subsequent, or closest matches.

Returns

merged  [DataFrame]

See also:

merge  Merge with a database-style join.
merge_ordered  Merge with optional filling/interpolation.

Examples

```python
>>> left = pd.DataFrame({"a": [1, 5, 10], "left_val": ["a", "b", "c"]})

>>> left
          a  left_val
0     1    a
1     5    b
2    10    c

>>> right = pd.DataFrame({"a": [1, 2, 3, 6, 7], "right_val": [1, 2, 3, 6, 7]})

>>> right
          a   right_val
0     1      1
1     2      2
2     3      3
3     6      6
4     7      7

>>> pd.merge_asof(left, right, on="a")
          a  left_val right_val
0     1    a      1
1     5    b      3
2    10    c      7
```

```python
>>> pd.merge_asof(left, right, on="a", allow_exact_matches=False)
          a  left_val right_val
0     1    a      NaN
1     5    b      3.0
2    10    c      7.0
```

```python
>>> pd.merge_asof(left, right, on="a", direction="forward")
          a  left_val right_val
(continues on next page)
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

0  1  a  1.0
1  5  b  6.0
2 10  c  NaN

```
>>> pd.merge_asof(left, right, on="a", direction="nearest")
   a  left_val  right_val
0  1       a       1
1  5       b       6
2 10      c       NaN
```

We can use indexed DataFrames as well.

```
>>> left = pd.DataFrame({'left_val': ['a', 'b', 'c'], index=[1, 5, 10])
>>> left
     left_val
1       a
5       b
10      c

>>> right = pd.DataFrame({'right_val': [1, 2, 3, 6, 7], index=[1, 2, 3, 6, 7])
>>> right
     right_val
1        1
2        2
3        3
6        6
7        7

>>> pd.merge_asof(left, right, left_index=True, right_index=True)
     left_val  right_val
1       a       1
5       b       3
10      c       7
```

Here is a real-world times-series example

```
>>> quotes = pd.DataFrame(
...     {
...         "time": [
...             pd.Timestamp("2016-05-25 13:30:00.023"),
...             pd.Timestamp("2016-05-25 13:30:00.023"),
...             pd.Timestamp("2016-05-25 13:30:00.030"),
...             pd.Timestamp("2016-05-25 13:30:00.041"),
...             pd.Timestamp("2016-05-25 13:30:00.048"),
...             pd.Timestamp("2016-05-25 13:30:00.049"),
...             pd.Timestamp("2016-05-25 13:30:00.072"),
...             pd.Timestamp("2016-05-25 13:30:00.075")
...         ],
...         "ticker": [
...             "GOOG",
...             "MSFT",
...             "MSFT",
...             "MSFT",
...             "MSFT",
...             "MSFT",
...             "MSFT",
...             "MSFT"
...         ]
...     }
... )
```
By default we are taking the asof of the quotes

```python
>>> pd.merge_asof(trades, quotes, on="time", by="ticker")
```

<table>
<thead>
<tr>
<th>time</th>
<th>ticker</th>
<th>price</th>
<th>quantity</th>
<th>bid</th>
<th>ask</th>
</tr>
</thead>

<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

1136 Chapter 3. API reference
We only asof within 2ms between the quote time and the trade time

```python
>>> pd.merge_asof(
...     trades, quotes, on="time", by="ticker", tolerance=pd.Timedelta("2ms")
... )
```

<table>
<thead>
<tr>
<th>time</th>
<th>ticker</th>
<th>price</th>
<th>quantity</th>
<th>bid</th>
<th>ask</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-05-25 13:30:00.023</td>
<td>MSFT</td>
<td>51.95</td>
<td>75</td>
<td>51.95</td>
<td>51.96</td>
</tr>
<tr>
<td>2016-05-25 13:30:00.038</td>

</tbody>
</table>

**pandas.concat**

```python
pandas.concat(objs, axis=0, join='outer', ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, sort=False, copy=True)
```

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

**Parameters**

- **objs** [a sequence or mapping of Series or DataFrame objects] If a mapping is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- **axis** [{0/'index', 1/'columns'}, default 0] The axis to concatenate along.

- **join** [{‘inner’, ‘outer’}, default ‘outer’] How to handle indexes on other axis (or axes).

- **ignore_index** [bool, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **keys** [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level.
levels [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

names [list, default None] Names for the levels in the resulting hierarchical index.

verify_integrity [bool, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

sort [bool, default False] Sort non-concatenation axis if it is not already aligned when join is 'outer'. This has no effect when join='inner', which already preserves the order of the non-concatenation axis.

Changed in version 1.0.0: Changed to not sort by default.

copy [bool, default True] If False, do not copy data unnecessarily.

Returns

object, type of objs When concatenating all Series along the index (axis=0), a Series is returned. When objs contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (axis=1), a DataFrame is returned.

See also:

Series.append Concatenate Series.

DataFrame.append Concatenate DataFrames.

DataFrame.join Join DataFrames using indexes.

DataFrame.merge Merge DataFrames by indexes or columns.

Notes

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found here.

Examples

Combine two Series.

```python
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0   a
1   b
0   c
1   d
dtype: object
```

Clear the existing index and reset it in the result by setting the ignore_index option to True.

```python
>>> pd.concat([s1, s2], ignore_index=True)
0   a
1   b
2   c
3   d
dtype: object
```
Add a hierarchical index at the outermost level of the data with the keys option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1    0    a
     1    b
s2    0    c
     1    d
dtype: object
```

Label the index keys you create with the names option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'],
             names=['Series name', 'Row ID'])
Series name   Row ID
s1            0    a
             1    b
s2            0    c
             1    d
dtype: object
```

Combine two DataFrame objects with identical columns.

```python
>>> df1 = pd.DataFrame([['a', 1], ['b', 2]],
                      columns=['letter', 'number'])
>>> df1
   letter  number
0      a      1
1      b      2

>>> df2 = pd.DataFrame([['c', 3], ['d', 4]],
                      columns=['letter', 'number'])
>>> df2
   letter  number
0      c      3
1      d      4

>>> pd.concat([df1, df2])
   letter  number
0      a      1
1      b      2
0      c      3
1      d      4
```

Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```python
>>> df3 = pd.DataFrame([['c', 3, 'cat'], ['d', 4, 'dog']],
                      columns=['letter', 'number', 'animal'])
>>> df3
   letter  number  animal
0      c      3  cat
1      d      4  dog

>>> pd.concat([df1, df3], sort=False)
   letter  number  animal
0      a      1  NaN
1      b      2  NaN
```

(continues on next page)
Combine DataFrame objects with overlapping columns and return only those that are shared by passing `inner` to the `join` keyword argument.

```python
>>> pd.concat([df1, df3], join="inner")
     letter number
0       a   1
1       b   2
0       c   3
1       d   4
```

Combine DataFrame objects horizontally along the `x` axis by passing in `axis=1`.

```python
>>> df4 = pd.DataFrame([["bird", 'polly'], ['monkey', 'george']],
        columns=['animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
     letter number animal name
0       a   1   bird   polly
1       b   2  monkey   george
```

Prevent the result from including duplicate index values with the `verify_integrity` option.

```python
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df6 = pd.DataFrame([2], index=['a'])
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
  ... ValueError: Indexes have overlapping values: ['a']
```

### pandas.get_dummies

**pandas.get_dummies**(*data*, *prefix=None, prefix_sep='__', *dummy_na=False, columns=None, sparse=False, drop_first=False, dtype=None*)

Convert categorical variable into dummy/indicator variables.

**Parameters**

- **data** [array-like, Series, or DataFrame] Data of which to get dummy indicators.
- **prefix** [str, list of str, or dict of str, default None] String to append DataFrame column names. Pass a list with length equal to the number of columns when calling `get_dummies` on a DataFrame. Alternatively, `prefix` can be a dictionary mapping column names to prefixes.
- **prefix_sep** [str, default '_'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with `prefix`.
- **dummy_na** [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.
columns [list-like, default None] Column names in the DataFrame to be encoded. If columns is None then all the columns with object or category dtype will be converted.

sparse [bool, default False] Whether the dummy-encoded columns should be backed by a SparseArray (True) or a regular NumPy array (False).

drop_first [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.

dtype [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

Returns

DataFrame Dummy-coded data.

See also:

Series.str.get_dummies Convert Series to dummy codes.

Notes

Reference the user guide for more examples.

Examples

```python
>>> s = pd.Series(list('abca'))

>>> pd.get_dummies(s)
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0

>>> s1 = ['a', 'b', np.nan]

>>> pd.get_dummies(s1)
   a  b
0  1  0
1  0  1
2  0  0

>>> pd.get_dummies(s1, dummy_na=True)
   a  b  NaN
0  1  0  0
1  0  1  0
2  0  0  1

>>> df = pd.DataFrame({
    'A': ['a', 'b', 'a'],
    'B': ['b', 'a', 'c'],
    ...
    'C': [1, 2, 3]})
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

```python
>>> pd.get_dummies(df, prefix=['col1', 'col2'])
   C  col1_a  col1_b  col2_a  col2_b  col2_c
0  1      1      0      0      1      0
1  2      0      1      1      0      0
2  3      1      0      0      0      1

>>> pd.get_dummies(pd.Series(list('abcaa')))
     a  b  c
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0

>>> pd.get_dummies(pd.Series(list('abc')), dtype=float)
     a  b  c
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

### pandas.factorize

**pandas.factorize(values, sort=False, na_sentinel=-1, size_hint=None)**

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

**Parameters**

- **values** [sequence] A 1-D sequence. Sequences that aren’t pandas objects are coerced to ndarrays before factorization.
- **sort** [bool, default False] Sort `uniques` and shuffle `codes` to maintain the relationship.
- **na_sentinel** [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.
  
  Changed in version 1.1.2.
- **size_hint** [int, optional] Hint to the hashtable sizer.

**Returns**

- **codes** [ndarray] An integer ndarray that’s an indexer into `uniques`. `uniques.take(codes)` will have the same values as `values`. 
uniques [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in values, uniques will not contain an entry for it.

See also:
cut Discretize continuous-valued array.
unique Find the unique value in an array.

Notes
Reference the user guide for more examples.

Examples
These examples all show factorize as a top-level method like pd.factorize(values). The results are identical for methods like Series.factorize().

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```
With sort=True, the uniques will be sorted, and codes will be shuffled so that the relationship is the maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in codes with na_sentinel (-1 by default). Note that missing values are never included in uniques.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```
Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of uniques will differ. For Categoricals, a Categorical is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
```
(continues on next page)
Notice that 'b' is in uniques.categories, despite not being present in cat.values.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting na_sentinel=None.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([1., 2.])
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])
```

**pandas.unique**

pandas.unique(values)

Return unique values based on a hash table.

Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than numpy.unique for long enough sequences. Includes NA values.

**Parameters**

- **values** [1d array-like]

**Returns**

- **numpy.ndarray or ExtensionArray** The return can be:
  - Index : when the input is an Index
  - Categorical : when the input is a Categorical dtype
  - ndarray : when the input is a Series/ndarray

Return numpy.ndarray or ExtensionArray.

**See also:**

- **Index.unique** Return unique values from an Index.
**Series.unique**  Return unique values of Series object.

**Examples**

```python
>>> pd.unique(pd.Series([2, 1, 3, 3]))
array([2, 1, 3])

>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])

>>> pd.unique(pd.Series([pd.Timestamp("20160101"), pd.Timestamp("20160101")]))
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

... pd.Timestamp("20160101", tz="US/Eastern"),
... ])
...)
...)
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

>>> pd.unique(pd.Index([pd.Timestamp("20160101", tz="US/Eastern"), pd.Timestamp("20160101", tz="US/Eastern"),
... pd.Timestamp("20160101", tz="US/Eastern"),
... ])
...)
DateTimeIndex(['2016-01-01 00:00:00-05:00'],
dtype='datetime64[ns, US/Eastern]',
freq=None)

>>> pd.unique(list("baabc"))
array(['b', 'a', 'c'], dtype=object)

An unordered Categorical will return categories in the order of appearance.

>>> pd.unique(pd.Series(pd.Categorical(list("baabc"))))
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> pd.unique(pd.Series(pd.Categorical(list("baabc"), categories=list("abc"))))
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

An ordered Categorical preserves the category ordering.
pandas: powerful Python data analysis toolkit, Release 1.4.1

```python
>>> pd.unique(...
...    pd.Series(...
...        pd.Categorical(list("baabc"), categories=list("abc"), ordered=True)
...    )
...)
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

An array of tuples

```python
>>> pd.unique([("a", "b"), ("b", "a"), ("a", "c"), ("b", "a")])
array([('a', 'a'), ('b', 'b'), ('a', 'c')], dtype=object)
```

### pandas.wide_to_long

`pandas.wide_to_long` is a function that unpivots a DataFrame from wide to long format. It's less flexible but more user-friendly than `melt`. With stubnames ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2,..., B-suffix1, B-suffix2,... You specify what you want to call this suffix in the resulting long format with `j` (for example `j='year'`). Each row of these wide variables are assumed to be uniquely identified by `i` (can be a single column name or a list of column names). All remaining variables in the data frame are left intact.

#### Parameters

- **df** [DataFrame] The wide-format DataFrame.
- **stubnames** [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.
- **i** [str or list-like] Column(s) to use as id variable(s).
- **j** [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.
- **sep** [str, default ""] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2,... you can strip the hyphen by specifying `sep='-'`.
- **suffix** [str, default '\d+'] A regular expression capturing the wanted suffixes. '\d+' captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class '\D+'. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,... and you have an unrelated column A-rating, you can ignore the last one by specifying `suffix='(!?one|two)'`. When all suffixes are numeric, they are cast to int64/float64.

#### Returns

- **DataFrame** A DataFrame that contains each stub name as a variable, with new index (`i`, `j`).

#### See also

- `melt` Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
**pivot** Create a spreadsheet-style pivot table as a DataFrame.

*DataFrame.pivot* Pivot without aggregation that can handle non-numeric data.

*DataFrame.pivot_table* Generalization of pivot that can handle duplicate values for one index/column pair.

*DataFrame.unstack* Pivot based on the index values instead of a column.

**Notes**

All extra variables are left untouched. This simply uses *pandas.melt* under the hood, but is hard-coded to “do the right thing” in a typical case.

**Examples**

```python
>>> np.random.seed(123)
>>> df = pd.DataFrame({"A1970": {0 : "a", 1 : "b", 2 : "c"},
... "A1980": {0 : "d", 1 : "e", 2 : "f"},
... "B1970": {0 : 2.5, 1 : 1.2, 2 : .7},
... "B1980": {0 : 3.2, 1 : 1.3, 2 : .1},
... "X" : dict(zip(range(3), np.random.randn(3)))
... })
>>> df["id"] = df.index
>>> df
0   a      d  2.5     3.2  -1.085631
1   b      e  1.2     1.3    0.997345
2   c      f  0.7     0.1    0.282978

>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
   X  A  B
id year
0  1970   a  2.5
1  1970  0.997345  1.2
2  1970  0.282978  0.7
0  1980  -1.085631  3.2
1  1980  0.997345  1.3
2  1980  0.282978  0.1
```

With multiple id columns

```python
>>> df = pd.DataFrame({
... 'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
... 'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
... 'ht1': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
... 'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   famid  birth  ht1  ht2
0     1      1  2.8    3.4
1     1      2  2.9    3.8
2     1      3  2.2    2.9
3     2      1  2.0    3.2
```

(continues on next page)
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')

Going from long back to wide just takes some creative use of unstack

>>> w = l.unstack()

>>> w.columns = w.columns.map('{0[0]}{0[1]}'.format)

Less wieldy column names are also handled

>>> np.random.seed(0)

>>> df = pd.DataFrame({'A(weekly)-2010': np.random.rand(3),
                     'A(weekly)-2011': np.random.rand(3),
                     'B(weekly)-2010': np.random.rand(3),
                     'B(weekly)-2011': np.random.rand(3),
                     })
... 'X': np.random.randint(3, size=3))

>>> df['id'] = df.index
>>> df
A(weekly)-2010  A(weekly)-2011  B(weekly)-2010  B(weekly)-2011  X  id
0  0.548814      0.544883      0.437587      0.383442  0  0
1  0.715189      0.423655      0.891773      0.791725  1  1
2  0.602763      0.645894      0.963663      0.528895  1  2

>>> pd.wide_to_long(df, ['A(weekly)', 'B(weekly)'], i='id',
... j='year', sep='-')
... X  A(weekly)  B(weekly)
id  year
0  2010  0  0.548814  0.437587
1  2010  1  0.715189  0.891773
2  2010  1  0.602763  0.963663
0  2011  0  0.544883  0.383442
1  2011  1  0.423655  0.791725
2  2011  1  0.645894  0.528895

If we have many columns, we could also use a regex to find our stubnames and pass that list on to wide_to_long

>>> stubnames = sorted(
... set([match[0] for match in df.columns.str.findall(r'[A-B]([-.*\d])').values if match != []])
... )
>>> list(stubnames)
['A(weekly)', 'B(weekly)']

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

>>> df = pd.DataFrame({
... 'famid': [1, 1, 1, 2, 2, 3, 3, 3],
... 'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
... 'ht_one': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
... 'ht_two': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
famid  birth  ht_one  ht_two
0   1   1   2.8   3.4
1   1   2   2.9   3.8
2   1   3   2.2   2.9
3   2   1   2.0   3.2
4   2   2   1.8   2.8
5   2   3   1.9   2.4
6   3   1   2.2   3.3
7   3   2   2.3   3.4
8   3   3   2.1   2.9

>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',
... sep='-', suffix=r'\w+')
>>> l
(continues on next page)
3.2.2 Top-level missing data

<table>
<thead>
<tr>
<th></th>
<th>Description</th>

pandas.isna

pandas.isna(obj)

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

- **obj** [scalar or array-like] Object to check for null or missing values.

Returns

- **bool** or **array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

- **notna** Boolean inverse of pandas.isna.
- **Series.isna** Detect missing values in a Series.
- **DataFrame.isna** Detect missing values in a DataFrame.
**Index.isna** Detect missing values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False
```

```python
>>> pd.isna(pd.NA)
True
```

```python
>>> pd.isna(np.nan)
True
```

Ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
                             '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
       0  1  2
0  ant  bee  cat
1  dog  None  fly
>>> pd.isna(df)
       0  1  2
0  False False False
1  False  True False
>>> pd.isna(df[1])
0  False
1  True
Name: 1, dtype: bool
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

pandas.isnull

pandas.isnull(obj)
Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

- **obj** [scalar or array-like] Object to check for null or missing values.

Returns

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

- **notna** Boolean inverse of pandas.isna.
- **Series.isna** Detect missing values in a Series.
- **DataFrame.isna** Detect missing values in a DataFrame.
- **Index.isna** Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False
```

```python
>>> pd.isna(pd.NA)
True
```

```python
>>> pd.isna(np.nan)
True
```

Ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
```

```python
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
```

```python
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None,
                             ... '2017-07-08'])
```

```python
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
```

(continues on next page)
>>> pd.isna(index)
array([False, False, True, False])

For Series and DataFrame, the same type is returned, containing booleans.

>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
  0    1  2
0 ant  bee cat
1 dog  None fly
>>> pd.isna(df)
  0  1  2
0 False False False
1 False True False

>>> pd.isna(df[1])
0    False
1    True
Name: 1, dtype: bool

pandas.notna

pandas\:\:notna(obj)

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

- **obj** [array-like or object value] Object to check for not null or non-missing values.

Returns

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

- **isna** Boolean inverse of pandas.notna.
- **Series.notna** Detect valid values in a Series.
- **DataFrame.notna** Detect valid values in a DataFrame.
- **Index.notna** Detect valid values in an Index.
Examples

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.notna('dog')
True
```

```python
>>> pd.notna(pd.NA)
False
```

```python
>>> pd.notna(np.nan)
False
```

Ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
                           '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True, True, False, True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([[ant, bee, cat], [dog, None, fly]])
>>> df
   0  1  2
0 ant bee cat
1 dog None fly
>>> pd.notna(df)
   0  1  2
0 True True True
1 True False True
```

```python
>>> pd.notna(df[1])
0    True
1    False
Name: 1, dtype: bool
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

pandas.notnull

pandas.notnull(obj)

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

obj [array-like or object value] Object to check for not null or non-missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

isna Boolean inverse of pandas.notna.
Series.notna Detect valid values in a Series.
DataFrame.notna Detect valid values in a DataFrame.
Index.notna Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

>>> pd.notna('dog')
True

>>> pd.notna(pd.NA)
False

>>> pd.notna(np.nan)
False

ndarrays result in an ndarray of booleans.

>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])

>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])

>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])

For indexes, an ndarray of booleans is returned.

>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
   '2017-07-08'])

>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', 'None', 'fly']])
>>> df
   0   1   2
0  ant  bee  cat
1   dog None  fly
>>> pd.notna(df)
   0   1   2
0  True True True
1  True False True
```
• ‘integer’ or ‘signed’: smallest signed int dtype (min.: np.int8)
• ‘unsigned’: smallest unsigned int dtype (min.: np.uint8)
• ‘float’: smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the ‘errors’ input.

In addition, downcasting will only occur if the size of the resulting data’s dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

Returns
ret Numeric if parsing succeeded. Return type depends on input. Series if Series, otherwise ndarray.

See also:
DataFrame.astype Cast argument to a specified dtype.
to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
numpy.ndarray.astype Cast a numpy array to a specified type.
DataFrame.convert_dtypes Convert dtypes.

Examples
Take separate series and convert to numeric, coercing when told to

```python
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0     1
1     2
2    -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', -3])
>>> pd.to_numeric(s, errors='ignore')
0       apple
1     1.0
2       2
3      -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
```

(continues on next page)
Downcasting of nullable integer and floating dtypes is supported:

```python
>>> s = pd.Series([1, 2, 3], dtype="Int64")
>>> pd.to_numeric(s, downcast="integer")
0 1
1 2
2 3
dtype: Int8
>>> s = pd.Series([1.0, 2.1, 3.0], dtype="Float64")
>>> pd.to_numeric(s, downcast="float")
0 1.0
1 2.1

**pandas.to_datetime**

```python
pandas.to_datetime(arg, errors='raise', dayfirst=False, yearfirst=False, utc=None, format=None, exact=True, unit=None, infer_datetime_format=False, origin='unix', cache=True)
```

Convert argument to datetime.

This function converts a scalar, array-like, Series or DataFrame/dict-like to a pandas datetime object.

**Parameters**

- **arg** [int, float, str, datetime, list, tuple, 1-d array, Series, DataFrame/dict-like] The object to convert to a datetime. If a DataFrame is provided, the method expects minimally the following columns: "year", "month", "day".
- **errors** [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]
  - If 'raise', then invalid parsing will raise an exception.
  - If 'coerce', then invalid parsing will be set as NaT.
• If 'ignore', then invalid parsing will return the input.

dayfirst [bool, default False] Specify a date parse order if arg is str or is list-like. If True, parses dates with the day first, e.g. "10/11/12" is parsed as 2012-11-10.

**Warning:** dayfirst=True is not strict, but will prefer to parse with day first. If a delimited date string cannot be parsed in accordance with the given dayfirst option, e.g. to_datetime(['31-12-2021']), then a warning will be shown.

yearfirst [bool, default False] Specify a date parse order if arg is str or is list-like.

• If True parses dates with the year first, e.g. "10/11/12" is parsed as 2010-11-12.

• If both dayfirst and yearfirst are True, yearfirst is preceded (same as dateutil).

**Warning:** yearfirst=True is not strict, but will prefer to parse with year first.

utc [bool, default None] Control timezone-related parsing, localization and conversion.

• If True, the function always returns a timezone-aware UTC-localized Timestamp, Series or DatetimeIndex. To do this, timezone-naive inputs are localized as UTC, while timezone-aware inputs are converted to UTC.

• If False (default), inputs will not be coerced to UTC. Timezone-naive inputs will remain naive, while timezone-aware ones will keep their time offsets. Limitations exist for mixed offsets (typically, daylight savings), see Examples section for details.

See also: pandas general documentation about timezone conversion and localization.

format [str, default None] The strftime to parse time, e.g. "%d/%m/%Y". Note that "%f" will parse all the way up to nanoseconds. See strftime documentation for more information on choices.

exact [bool, default True] Control how format is used:

• If True, require an exact format match.

• If False, allow the format to match anywhere in the target string.

unit [str, default 'ns'] The unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit='ms' and origin='unix' (the default), this would calculate the number of milliseconds to the unix epoch start.

infer_datetime_format [bool, default False] If True and no format is given, attempt to infer the format of the datetime strings based on the first non-NaN element, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

origin [scalar, default 'unix'] Define the reference date. The numeric values would be parsed as number of units (defined by unit) since this reference date.

• If 'unix' (or POSIX) time; origin is set to 1970-01-01.

• If 'julian', unit must be 'D', and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.

• If Timestamp convertible, origin is set to Timestamp identified by origin.
cache [bool, default True] If True, use a cache of unique, converted dates to apply the date-time conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets. The cache is only used when there are at least 50 values. The presence of out-of-bounds values will render the cache unusable and may slow down parsing.

Changed in version 0.25.0: changed default value from False to True.

Returns

- `datetime` If parsing succeeded. Return type depends on input (types in parenthesis correspond to fallback in case of unsuccessful timezone or out-of-range timestamp parsing):
  - scalar: `Timestamp` (or `datetime.datetime`)
  - array-like: `DatetimeIndex` (or `Series` with `object` dtype containing `datetime.datetime`)
  - `Series` of `datetime64` dtype (or `Series` of `object` dtype containing `datetime.datetime`)
  - `DataFrame`: `Series` of `datetime64` dtype (or `Series` of `object` dtype containing `datetime.datetime`)

Raises

- `ParserError` When parsing a date from string fails.
- `ValueError` When another datetime conversion error happens. For example when one of ‘year’, ‘month’, day’ columns is missing in a `DataFrame`, or when a Timezone-aware `datetime.datetime` is found in an array-like of mixed time offsets, and `utc=False`.

See also:

- `DataFrame.astype` Cast argument to a specified dtype.
- `to_timedelta` Convert argument to timedelta.
- `convert_dtypes` Convert dtypes.

Notes

Many input types are supported, and lead to different output types:

- **scalars** can be int, float, str, `datetime` object (from stdlib `datetime` module or `numpy`). They are converted to `Timestamp` when possible, otherwise they are converted to `datetime.datetime`. None/NaN/null scalars are converted to NaT.

- **array-like** can contain int, float, str, `datetime` objects. They are converted to `DatetimeIndex` when possible, otherwise they are converted to `Index` with `object` dtype, containing `datetime.datetime`. None/NaN/null entries are converted to NaT in both cases.

- **`Series`** are converted to `Series` with `datetime64` dtype when possible, otherwise they are converted to `Series` with `object` dtype, containing `datetime.datetime`. None/NaN/null entries are converted to NaT in both cases.

- **`DataFrame/dict-like`** are converted to `Series` with `datetime64` dtype. For each row a datetime is created from assembling the various dataframe columns. Column keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same.
The following causes are responsible for `datetime.datetime` objects being returned (possibly inside an `Index` or a `Series` with `object` dtype) instead of a proper pandas designated type (`Timestamp`, `DatetimeIndex` or `Series` with `datetime64` dtype):

- when any input element is before `Timestamp.min` or after `Timestamp.max`, see timestamp limitations.
- when `utc=False` (default) and the input is an array-like or `Series` containing mixed naive/aware datetime, or aware with mixed time offsets. Note that this happens in the (quite frequent) situation when the timezone has a daylight savings policy. In that case you may wish to use `utc=True`.

Examples

Handling various input formats

Assembling a datetime from multiple columns of a `DataFrame`. The keys can be common abbreviations like `['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']` or plurals of the same

```python
>>> df = pd.DataFrame({'year': [2015, 2016],
                     'month': [2, 3],
                     'day': [4, 5]})
>>> pd.to_datetime(df)
0  2015-02-04
1  2016-03-05
dtype: datetime64[ns]
```

Passing `infer_datetime_format=True` can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```python
>>> s.head()
0  3/11/2000
1  3/12/2000
2  3/13/2000
3  3/11/2000
4  3/12/2000
dtype: object
```

```python
>>> %timeit pd.to_datetime(s, infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
```

```python
>>> %timeit pd.to_datetime(s, infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```python
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
```

```python
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

**Warning:** For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.
Using a non-unix epoch origin

```python
>>> pd.to_datetime([1, 2, 3], unit='D',
... origin=pd.Timestamp('1960-01-01'))
DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'],
                 dtype='datetime64[ns]', freq=None)
```

Non-convertible date/times

If a date does not meet the timestamp limitations, passing `errors='ignore'` will return the original input instead of raising any exception.

Passing `errors='coerce'` will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```python
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)

>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Timezones and time offsets

The default behaviour (utc=False) is as follows:

- Timezone-naive inputs are converted to timezone-naive `DatetimeIndex`:

```python
>>> pd.to_datetime(['2018-10-26 12:00', '2018-10-26 13:00:15'])
DatetimeIndex(['2018-10-26 12:00:00', '2018-10-26 13:00:15'],
               dtype='datetime64[ns]', freq=None)
```

- Timezone-aware inputs with constant time offset are converted to timezone-aware `DatetimeIndex`:

```python
>>> pd.to_datetime(['2018-10-26 12:00 -0500', '2018-10-26 13:00 -0500'])
DatetimeIndex(['2018-10-26 12:00:00-05:00', '2018-10-26 13:00:00-05:00'],
               dtype='datetime64[ns, pytz.FixedOffset(-300)]', freq=None)
```

- However, timezone-aware inputs with mixed time offsets (for example issued from a timezone with daylight savings, such as Europe/Paris) are not successfully converted to a `DatetimeIndex`. Instead a simple `Index` containing `datetime.datetime` objects is returned:

```python
>>> pd.to_datetime(['2020-10-25 02:00 +0200', '2020-10-25 04:00 +0100'])
Index([2020-10-25 02:00:00+02:00, 2020-10-25 04:00:00+01:00],
     dtype='object')
```

- A mix of timezone-aware and timezone-naive inputs is converted to a timezone-aware `DatetimeIndex` if the offsets of the timezone-aware are constant:

```python
>>> from datetime import datetime
>>> pd.to_datetime(['2020-01-01 01:00 -01:00', datetime(2020, 1, 1, 3, 0)])
DatetimeIndex(['2020-01-01 01:00:00-01:00', '2020-01-01 02:00:00-01:00'],
               dtype='datetime64[ns, pytz.FixedOffset(-60)]', freq=None)
```

- Finally, mixing timezone-aware strings and `datetime.datetime` always raises an error, even if the elements all have the same time offset.
Setting utc=True solves most of the above issues:

- Timezone-naive inputs are *localized* as UTC

```python
>>> pd.to_datetime(['2018-10-26 12:00', '2018-10-26 13:00'], utc=True)
DatetimeIndex(['2018-10-26 12:00:00+00:00', '2018-10-26 13:00:00+00:00'],
       dtype='datetime64[ns, UTC]', freq=None)
```

- Timezone-aware inputs are *converted* to UTC (the output represents the exact same datetime, but viewed from the UTC time offset +00:00).

```python
>>> pd.to_datetime(['2018-10-26 12:00 -0530', '2018-10-26 12:00 -0500'],
       utc=True)
DatetimeIndex(['2018-10-26 17:30:00+00:00', '2018-10-26 17:00:00+00:00'],
       dtype='datetime64[ns, UTC]', freq=None)
```

- Inputs can contain both naive and aware, string or datetime, the above rules still apply

```python
>>> pd.to_datetime(['2018-10-26 12:00', '2018-10-26 12:00 -0530',
       ...               datetime(2020, 1, 1, 18),
       ...               datetime(2020, 1, 1, 18,
       ...               tzinfo=timezone(-timedelta(hours=1))),
       ...               utc=True)
DatetimeIndex(['2018-10-26 12:00:00+00:00', '2018-10-26 17:30:00+00:00',
       '2029-01-01 18:00:00+00:00', '2029-01-01 19:00:00+00:00'],
       dtype='datetime64[ns, UTC]', freq=None)
```

### pandas.to_timedelta

`pandas.to_timedelta(arg, unit=None, errors='raise')`

Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

**Parameters**

- **arg** [str, timedelta, list-like or Series] The data to be converted to timedelta.

Deprecated since version 1.2: Strings with units ‘M’, ‘Y’ and ‘y’ do not represent unambiguous timedelta values and will be removed in a future version.
unit [str, optional] Denotes the unit of the arg for numeric arg. Defaults to "ns".

Possible values:

- ‘W’
- ‘D’ / ‘days’ / ‘day’
- ‘hours’ / ‘hour’ / ‘hr’ / ‘h’
- ‘m’ / ‘minute’ / ‘min’ / ‘minutes’ / ‘T’
- ‘S’ / ‘seconds’ / ‘sec’ / ‘second’
- ‘ms’ / ‘milliseconds’ / ‘millisecond’ / ‘milli’ / ‘millis’ / ‘L’
- ‘us’ / ‘microseconds’ / ‘microsecond’ / ‘micro’ / ‘micros’ / ‘U’
- ‘ns’ / ‘nanoseconds’ / ‘nano’ / ‘nanos’ / ‘nanosecond’ / ‘N’

Changed in version 1.1.0: Must not be specified when arg context strings and errors= "raise”.

errors [\{'ignore', 'raise', 'coerce'}, default 'raise']

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaT.
- If ‘ignore’, then invalid parsing will return the input.

Returns

timedelta If parsing succeeded. Return type depends on input:

- list-like: TimedeltaIndex of timedelta64 dtype
- Series: Series of timedelta64 dtype
- scalar: Timedelta

See also:

DataFrame.astype Cast argument to a specified dtype.
to_datetime Convert argument to datetime.
convert_dtypes Convert dtypes.

Notes

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds for string inputs.
Examples

Parsing a single string to a Timedelta:

```python
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015500')
```

Parsing a list or array of strings:

```python
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the `unit` keyword argument:

```python
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
'0 days 00:00:03', '0 days 00:00:04'],
dtype='timedelta64[ns]', freq=None)
```

```python
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
dtype='timedelta64[ns]', freq=None)
```

pandas.date_range

```python
pandas.date_range(start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=NoDefault.no_default, inclusive=None, **kwargs)
```

Return a fixed frequency DatetimeIndex.

Returns the range of equally spaced time points (where the difference between any two adjacent points is specified by the given frequency) such that they all satisfy \( \text{start} \leq x \leq \text{end} \), where the first one and the last one are, resp., the first and last time points in that range that fall on the boundary of \( \text{freq} \) (if given as a frequency string) or that are valid for \( \text{freq} \) (if given as a \text{pandas.tseries.offsets.DateOffset}). (If exactly one of \( \text{start} \), \( \text{end} \), or \( \text{freq} \) is not specified, this missing parameter can be computed given \text{periods}, the number of timesteps in the range. See the note below.)

Parameters

- **start** [str or datetime-like, optional] Left bound for generating dates.
- **end** [str or datetime-like, optional] Right bound for generating dates.
- **periods** [int, optional] Number of periods to generate.
- **freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See here for a list of frequency aliases.
- **tz** [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong_Kong’. By default, the resulting DatetimeIndex is timezone-naive.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **name** [str, default None] Name of the resulting DatetimeIndex.
closed  [{None, ‘left’, ‘right’}, optional] Make the interval closed with respect to the given
frequency to the ‘left’, ‘right’, or both sides (None, the default).

Deprecated since version 1.4.0: Argument closed has been deprecated to standardize
boundary inputs. Use inclusive instead, to set each bound as closed or open.

inclusive  [{“both”, “neither”, “left”, “right”}, default “both”] Include boundaries; Whether
to set each bound as closed or open.

New in version 1.4.0.

**kwargs For compatibility. Has no effect on the result.

Returns

rng  [DatetimeIndex]

See also:

DatetimeIndex  An immutable container for datetimes.
timedelta_range  Return a fixed frequency TimedeltaIndex.
period_range  Return a fixed frequency PeriodIndex.
interval_range  Return a fixed frequency IntervalIndex.

Notes

Of the four parameters start, end, periods, and freq, exactly three must be specified. If freq is omitted, the
resulting DatetimeIndex will have periods linearly spaced elements between start and end (closed on both
sides).

To learn more about the frequency strings, please see this link.

Examples

Specifying the values

The next four examples generate the same DatetimeIndex, but vary the combination of start, end and periods.

Specify start and end, with the default daily frequency.

```python
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
               dtype='datetime64[ns]', freq='D')
```

Specify start and periods, the number of periods (days).

```python
>>> pd.date_range(start='1/1/2018', periods=8)
               dtype='datetime64[ns]', freq='D')
```

Specify end and periods, the number of periods (days).
pandas: powerful Python data analysis toolkit, Release 1.4.1

```python
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
              '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
               dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
               '2018-04-27 00:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Other Parameters

Changed the `freq` (frequency) to `'M'` (month end frequency).

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
               '2018-05-31'],
               dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
               '2019-01-31'],
               dtype='datetime64[ns]', freq='3M')
```

`freq` can also be specified as an Offset object.

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
               '2019-01-31'],
               dtype='datetime64[ns]', freq='3M')
```

Specify `tz` to set the timezone.

```python
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
               '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
               '2018-01-05 00:00:00+09:00'],
               dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

`inclusive` controls whether to include `start` and `end` that are on the boundary. The default, “both”, includes boundary points on either end.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', inclusive='both')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
               dtype='datetime64[ns]', freq='D')
```

Use `inclusive='left'` to exclude `end` if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', inclusive='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
               dtype='datetime64[ns]', freq='D')
```

3.2. General functions

1167
Use `inclusive='right'` to exclude `start` if it falls on the boundary, and similarly `inclusive='neither'` will exclude both `start` and `end`.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', inclusive='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
dtype='datetime64[ns]', freq='D')
```

**pandas.bdate_range**

`pandas.bdate_range` returns a fixed frequency DatetimeIndex, with business day as the default frequency.

**Parameters**

- **start** [str or datetime-like, default None] Left bound for generating dates.
- **end** [str or datetime-like, default None] Right bound for generating dates.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, default ‘B’ (business daily)] Frequency strings can have multiples, e.g. ‘5H’.
- **tz** [str or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **name** [str, default None] Name of the resulting DatetimeIndex.
- **weekmask** [str or None, default None] Weekmask of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed. The default value None is equivalent to ‘Mon Tue Wed Thu Fri’.
- **holidays** [list-like or None, default None] Dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed.
- **closed** [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).
  
  Deprecated since version 1.4.0: Argument `closed` has been deprecated to standardize boundary inputs. Use `inclusive` instead, to set each bound as closed or open.
- **inclusive** [[“both”, “neither”, “left”, “right”], default “both”] Include boundaries; Whether to set each bound as closed or open.
  
  New in version 1.4.0.

**kwargs** For compatibility. Has no effect on the result.

**Returns**

DatetimeIndex
**Notes**

Of the four parameters: `start`, `end`, `periods`, and `freq`, exactly three must be specified. Specifying `freq` is a requirement for `bdate_range`. Use `date_range` if specifying `freq` is not desired.

To learn more about the frequency strings, please see this link.

**Examples**

Note how the two weekend days are skipped in the result.

```
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
dtype='datetime64[ns]', freq='B')
```

**pandas.period_range**

`pandas.period_range(start=None, end=None, periods=None, freq=None, name=None)`

Return a fixed frequency PeriodIndex.

The day (calendar) is the default frequency.

**Parameters**

- `start` [str or period-like, default None] Left bound for generating periods.
- `end` [str or period-like, default None] Right bound for generating periods.
- `periods` [int, default None] Number of periods to generate.
- `freq` [str or DateOffset, optional] Frequency alias. By default the freq is taken from `start` or `end` if those are Period objects. Otherwise, the default is "D" for daily frequency.
- `name` [str, default None] Name of the resulting PeriodIndex.

**Returns**

PeriodIndex

**Notes**

Of the three parameters: `start`, `end`, and `periods`, exactly two must be specified.

To learn more about the frequency strings, please see this link.

**Examples**

```
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
dtype='period[M]')
```

If `start` or `end` are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the `period_range` constructor.
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
                      end=pd.Period('2017Q2', freq='Q'), freq='M'))
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
dtype='period[M]')

pandas.timedelta_range

pandas.timedelta_range(start=None, end=None, periods=None, freq=None, name=None, closed=None)

Return a fixed frequency TimedeltaIndex, with day as the default frequency.

Parameters

- **start** [str or timedelta-like, default None] Left bound for generating tdedeltas.
- **end** [str or timedelta-like, default None] Right bound for generating tdedeltas.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’.
- **name** [str, default None] Name of the resulting TimedeltaIndex.
- **closed** [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).

Returns

- TimedeltaIndex

Notes

Of the four parameters start, end, periods, and freq, exactly three must be specified. If freq is omitted, the resulting TimedeltaIndex will have periods linearly spaced elements between start and end (closed on both sides).

To learn more about the frequency strings, please see this link.

Examples

>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
dtype='timedelta64[ns]', freq='D')

The closed parameter specifies which endpoint is included. The default behavior is to include both endpoints.

>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
dtype='timedelta64[ns]', freq='D')

The freq parameter specifies the frequency of the TimedeltaIndex. Only fixed frequencies can be passed, non-fixed frequencies such as ‘M’ (month end) will raise.

>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                '1 days 18:00:00', '2 days 00:00:00'],
dtype='timedelta64[ns]', freq='6H')
Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00', '5 days 00:00:00'],
dtype='timedelta64[ns]', freq=None)
```

**pandas.infer_freq**

`pandas.infer_freq(index, warn=True)`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

**Parameters**

- `index` [DatetimeIndex or TimedeltaIndex] If passed a Series will use the values of the series (NOT THE INDEX).
- `warn` [bool, default True]

**Returns**

- `str` or `None` None if no discernible frequency.

**Raises**

- `TypeError` If the index is not datetime-like.
- `ValueError` If there are fewer than three values.

**Examples**

```python
>>> idx = pd.date_range(start='2020/12/01', end='2020/12/30', periods=30)
>>> pd.infer_freq(idx)
'D'
```

### 3.2.5 Top-level dealing with Interval data

**interval_range**([start, end, periods, freq, ...]) Return a fixed frequency IntervalIndex.

**pandas.interval_range**

`pandas.interval_range(start=None, end=None, periods=None, freq=None, name=None, closed='right')` Return a fixed frequency IntervalIndex.

**Parameters**

- `start` [numeric or datetime-like, default None] Left bound for generating intervals.
- `end` [numeric or datetime-like, default None] Right bound for generating intervals.
- `periods` [int, default None] Number of periods to generate.
- `freq` [numeric, str, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or ‘5H’ for datetime-like. Default is 1 for numeric and ‘D’ for datetime-like.
name  [str, default None] Name of the resulting IntervalIndex.
closed  [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

IntervalIndex

See also:

IntervalIndex  An Index of intervals that are all closed on the same side.

Notes

Of the four parameters start, end, periods, and freq, exactly three must be specified. If freq is omitted, the resulting IntervalIndex will have periods linearly spaced elements between start and end, inclusively.

To learn more about datetime-like frequency strings, please see this link.

Examples

Numeric start and end is supported.

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
            dtype='interval[int64, right]')
```

Additionally, datetime-like input is also supported.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
                   end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
             (2017-01-03, 2017-01-04]],
            dtype='interval[datetime64[ns], right]')
```

The freq parameter specifies the frequency between the left and right endpoints of the individual intervals within the IntervalIndex. For numeric start and end, the frequency must also be numeric.

```python
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
            dtype='interval[float64, right]')
```

Similarly, for datetime-like start and end, the frequency must be convertible to a DateOffset.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
                   periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
             (2017-03-01, 2017-04-01]],
            dtype='interval[datetime64[ns], right]')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```python
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
            dtype='interval[float64, right]')
```
The closed parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```python
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]],
              dtype='interval[int64, both]')
```

### 3.2.6 Top-level evaluation

```python
pandas.eval
```

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: `+`, `-`, `*`, `/`, `**`, `%`, `//` (python engine only) along with the following boolean operations: `|` (or), `&` (and), and `~` (not). Additionally, the 'pandas' parser allows the use of `and`, `or`, and `not` with the same semantics as the corresponding bitwise operators. `Series` and `DataFrame` objects are supported and behave as they would with plain ol’ Python evaluation.

#### Parameters

- **expr** [str] The expression to evaluate. This string cannot contain any Python statements, only Python expressions.
- **parser** [{‘pandas’, ‘python’}, default ‘pandas’] The parser to use to construct the syntax tree from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the enhancing performance documentation for more details.
- **engine** [{‘python’, ‘numexpr’}, default ‘numexpr’] The engine used to evaluate the expression. Supported engines are
  - None : tries to use numexpr, falls back to python
  - 'numexpr': This default engine evaluates pandas objects using numexpr for large speed ups in complex expressions with large frames.
  - 'python': Performs operations as if you had eval’d in top level python. This engine is generally not that useful.
- **truediv** [bool, optional] Whether to use true division, like in Python >= 3.
- **local_dict** [dict or None, optional] A dictionary of local variables, taken from locals() by default.
- **global_dict** [dict or None, optional] A dictionary of global variables, taken from globals() by default.
- **resolvers** [list of dict-like or None, optional] A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to
use for variable lookup. For example, this is used in the `query()` method to inject the DataFrame.index and DataFrame.columns variables that refer to their respective DataFrame instance attributes.

**level** [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will **not** need to change this parameter.

**target** [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then target must support item assignment with string keys, and if a copy is being returned, it must also support .copy().

**inplace** [bool, default False] If target is provided, and the expression mutates target, whether to modify target inplace. Otherwise, return a copy of target with the mutation.

**Returns**

```
ndarray, numeric scalar, DataFrame, Series, or None
```

The completion value of evaluating the given code or None if inplace=True.

**Raises**

**ValueError** There are many instances where such an error can be raised:

- **target=None**, but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:
  
  ```
a = b + 1 a + 2
  ```

  Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of \( a + 2 \).
- **inplace=True**, but the expression is missing item assignment.
- Item assignment is provided, but the target does not support string item assignment.
- Item assignment is provided and inplace=False, but the target does not support the .copy() method

**See also:**

*DataFrame.query* Evaluates a boolean expression to query the columns of a frame.

*DataFrame.eval* Evaluate a string describing operations on DataFrame columns.

**Notes**

The dtype of any objects involved in an arithmetic % operation are recursively cast to `float64`.

See the *enhancing performance* documentation for more details.
Examples

```python
>>> df = pd.DataFrame({'animal': ['dog', 'pig'], 'age': [10, 20]})
>>> df
animal  age
0  dog   10
1  pig   20

We can add a new column using `pd.eval`:

```python
>>> pd.eval("double_age = df.age * 2", target=df)
animal  age  double_age
0  dog   10       20
1  pig   20       40
```

3.2.7 Hashing

```python
util.hash_array(vals[, encoding, hash_key, ...]) Given a 1d array, return an array of deterministic integers.
util.hash_pandas_object(obj[, index, ...]) Return a data hash of the Index/Series/DataFrame.
```

**pandas.util.hash_array**

Given a 1d array, return an array of deterministic integers.

**Parameters**

- `vals` [ndarray or ExtensionArray]
- `encoding` [str, default ‘utf8’] Encoding for data & key when strings.
- `hash_key` [str, default _default_hash_key] Hash_key for string key to encode.
- `categorize` [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

**Returns**

`ndarray[np.uint64, ndim=1]` Hashed values, same length as the vals.

**pandas.util.hash_pandas_object**

Return a data hash of the Index/Series/DataFrame.

**Parameters**

- `obj` [Index, Series, or DataFrame]
- `index` [bool, default True] Include the index in the hash (if Series/DataFrame).
- `encoding` [str, default ‘utf8’] Encoding for data & key when strings.
- `hash_key` [str, default _default_hash_key] Hash_key for string key to encode.
categorize [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

Returns

Series of uint64, same length as the object

### 3.2.8 Testing

<table>
<thead>
<tr>
<th>test([extra_args])</th>
<th>Run the pandas test suite using pytest.</th>
</tr>
</thead>
</table>

**pandas.test**

```python
def pandas.test(extra_args=None)
    """Run the pandas test suite using pytest."""
```

### 3.3 Series

#### 3.3.1 Constructor

```python
Series([data, index, dtype, name, copy, ...]) One-dimensional ndarray with axis labels (including time series).
```

**pandas.Series**

```python
class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fastpath=False)
    One-dimensional ndarray with axis labels (including time series).
```

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *, **) align values based on their associated index values— they need not be the same length. The result index will be the sorted union of the two indexes.

**Parameters**

- **data** [array-like, Iterable, dict, or scalar value] Contains data stored in Series. If data is a dict, argument order is maintained.
- **index** [array-like or Index (1d)] Values must be hashable and have the same length as data. Non-unique index values are allowed. Will default to RangelIndex (0, 1, 2, …, n) if not provided. If data is dict-like and index is None, then the keys in the data are used as the index. If the index is not None, the resulting Series is reindexed with the index values.
- **dtype** [str, numpy.dtype, or ExtensionDtype, optional] Data type for the output Series. If not specified, this will be inferred from data. See the user guide for more usages.
- **name** [str, optional] The name to give to the Series.
- **copy** [bool, default False] Copy input data. Only affects Series or 1d ndarray input. See examples.
Examples

Constructing Series from a dictionary with an Index specified

```python
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['a', 'b', 'c'])
>>> ser
a 1  
b 2  
c 3  
dtype: int64
```

The keys of the dictionary match with the Index values, hence the Index values have no effect.

```python
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['x', 'y', 'z'])
>>> ser
x NaN  
y NaN  
z NaN  
dtype: float64
```

Note that the Index is first build with the keys from the dictionary. After this the Series is reindexed with the given Index values, hence we get all NaN as a result.

Constructing Series from a list with `copy=False`.

```python
>>> r = [1, 2]
>>> ser = pd.Series(r, copy=False)
>>> ser
0 999  
1 2  
dtype: int64
```

Due to input data type the Series has a copy of the original data even though `copy=False`, so the data is unchanged.

Constructing Series from a 1d ndarray with `copy=False`.

```python
>>> r = np.array([1, 2])
>>> ser = pd.Series(r, copy=False)
>>> ser
0 999  
1 2  
dtype: int64
```

Due to input data type the Series has a view on the original data, so the data is changed as well.
### Attributes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>T</code></td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td><code>array</code></td>

<tr>
<td><code>is_monotonic_decreasing</code></td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
<tr>
<td><code>is_monotonic_increasing</code></td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td><code>is_unique</code></td>
<td>Return boolean if values in the object are unique.</td>
</tr>
<tr>
<td><code>loc</code></td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>Return the name of the Series.</td>
</tr>
<tr>
<td><code>nbytes</code></td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td><code>ndim</code></td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td><code>shape</code></td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td><code>size</code></td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td><code>values</code></td>
<td>Return Series as ndarray or ndarray-like depending on the dtype.</td>
</tr>
</tbody>
</table>

#### pandas.Series.T

**property Series.T**

Return the transpose, which is by definition self.

#### pandas.Series.array

**property Series.array**

The ExtensionArray of the data backing this Series or Index.

**Returns**

- **ExtensionArray** An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.
  .array differs .values which may require converting the data to a different form.
See also:

* **Index.to_numpy**: Similar method that always returns a NumPy array.
* **Series.to_numpy**: Similar method that always returns a NumPy array.

**Notes**

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes, `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

**Examples**

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned.

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

**pandas.Series.at**

* **property** `Series.at`

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

* **KeyError** If ‘label’ does not exist in DataFrame.

See also:
DataFrame.iat  Access a single value for a row/column pair by integer position.

DataFrame.loc  Access a group of rows and columns by label(s).

Series.at  Access a single value using a label.

## Examples

```python
def = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                   index=[4, 5, 6], columns=['A', 'B', 'C'])
def

A   B   C
--- --- ---
 4   0   2   3
 5   0   4   1
 6  10  20  30
```

Get value at specified row/column pair

```python
def.at[4, 'B']  # 2
```

Set value at specified row/column pair

```python
def.at[4, 'B'] = 10
def.at[4, 'B']  # 10
```

Get value within a Series

```python
def.loc[5].at['B']  # 4
```

### pandas.Series.attrs

**property** Series.attrs

Dictionary of global attributes of this dataset.

**Warning:** attrs is experimental and may change without warning.

**See also:**

DataFrame.flags  Global flags applying to this object.
**pandas.Series.axes**

**property** `Series.axes`

Return a list of the row axis labels.

**pandas.Series.dtype**

**property** `Series.dtype`

Return the dtype object of the underlying data.

**pandas.Series.dtypes**

**property** `Series.dtypes`

Return the dtype object of the underlying data.

**pandas.Series.flags**

**property** `Series.flags`

Get the properties associated with this pandas object.

The available flags are

- `Flags.allows_duplicate_labels`

See also:

- `Flags` Flags that apply to pandas objects.
- `DataFrame.attrs` Global metadata applying to this dataset.

**Notes**

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`.

**Examples**

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags
<Flags(allow_duplicates_labels=True)>
```

Flags can be get or set using .

```python
>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False
```

Or by slicing with a key
pandas.Series.hasnans

property Series.hasnans
  Return True if there are any NaNs.
  Enables various performance speedups.

pandas.Series.iat

property Series.iat
  Access a single value for a row/column pair by integer position.
  Similar to iloc, in that both provide integer-based lookups. Use iat if you only need to get or set a single value in a DataFrame or Series.

  Raises
    IndexError  When integer position is out of bounds.

  See also:
    DataFrame.at  Access a single value for a row/column label pair.
    DataFrame.loc  Access a group of rows and columns by label(s).
    DataFrame.iloc  Access a group of rows and columns by integer position(s).

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                     columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series
pandas.Series.iloc

property Series.iloc
Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:
- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at Selection by Position.

See also:

DataFrame.iat Fast integer location scalar accessor.

DataFrame.loc Purely label-location based indexer for selection by label.

Series.iloc Purely integer-location based indexing for selection by position.

Examples

```python
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
            {'a': 100, 'b': 200, 'c': 300, 'd': 400},
            {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
    a     b     c     d
0  1     2     3     4
1 100   200   300   400
2 1000  2000  3000  4000
```

Indexing just the rows

With a scalar integer.

```python
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
```

(continues on next page)
With a list of integers.

```python
>>> df.iloc[[0]]
a b c d
0 1 2 3 4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
a b c d
0 1 2 3 4
1 100 200 300 400
```

With a slice object.

```python
>>> df.iloc[:3]
a b c d
0 1 2 3 4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```python
>>> df.iloc[[True, False, True]]
a b c d
0 1 2 3 4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The x passed to the lambda is the DataFrame being sliced. This selects the rows whose index label even.

```python
>>> df.iloc[lambda x: x.index % 2 == 0]
a b c d
0 1 2 3 4
2 1000 2000 3000 4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

```python
>>> df.iloc[0, 1]
2
```

With lists of integers.
>>> df.iloc[[0, 2], [1, 3]]
   b  d
0  2  4
2 2000 4000

With *slice* objects.

>>> df.iloc[1:3, 0:3]
    a    b    c
1  100  200  300
2 1000 2000 3000

With a boolean array whose length matches the columns.

>>> df.iloc[:, [True, False, True, False]]
   a  c
0  1  3
1 100 300
2 1000 3000

With a callable function that expects the Series or DataFrame.

>>> df.iloc[:, lambda df: [0, 2]]
   a  c
0  1  3
1 100 300
2 1000 3000

**pandas.Series.index**

*Series.index*

The index (axis labels) of the Series.

**pandas.Series.is_monotonic**

*property Series.is_monotonic*

Return boolean if values in the object are monotonic_increasing.

Returns

bool

**pandas.Series.is_monotonic_decreasing**

*property Series.is_monotonic_decreasing*

Return boolean if values in the object are monotonic_decreasing.

Returns

bool
**pandas.Series.is_monotonic_increasing**

**property** Series.is_monotonic_increasing

Alias for is_monotonic.

**pandas.Series.is_unique**

**property** Series.is_unique

Return boolean if values in the object are unique.

**Returns**

bool

**pandas.Series.loc**

**property** Series.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
- An alignable Index. The Index of the returned selection will be the input.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at Selection by Label.

**Raises**

- **KeyError** If any items are not found.
- **IndexingError** If an indexed key is passed and its index is unalignable to the frame index.

See also:

- **DataFrame.at** Access a single value for a row/column label pair.
- **DataFrame.iloc** Access group of rows and columns by integer position(s).
- **DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- **Series.loc** Access group of values using labels.
Examples

Getting values

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
... index=['cobra', 'viper', 'sidewinder'],
... columns=['max_speed', 'shield'])
>>> df
max_speed  shield
cobra      1   2
viper      4   5
sidewinder 7   8

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
max_speed  4
shield     5
Name: viper, dtype: int64
```n
List of labels. Note using [[]] returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
max_speed  shield
viper      4   5
sidewinder 7   8
...
```

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc['cobra':'viper', 'max_speed']
cobra   1
viper   4
Name: max_speed, dtype: int64
```n
Boolean list with the same length as the row axis

```python
>>> df.loc[[False, True, False]]
sidewinder 7   8
```

Alignable boolean Series:

```python
>>> df.loc[pd.Series([False, True, False],
... index=['viper', 'sidewinder', 'cobra'])]
sidewinder 7   8
```

Index (same behavior as df.reindex)
>> df.loc[pd.Index(['cobra', 'viper'], name='foo')]
  max_speed  shield
  cobra      1   2
  viper      4   5

Conditional that returns a boolean Series

>> df.loc[df['shield'] > 6]
  max_speed  shield
  sidewinder 7   8

Conditional that returns a boolean Series with column labels specified

>> df.loc[df['shield'] > 6, ['max_speed']]
  max_speed
  sidewinder 7

Callable that returns a boolean Series

>> df.loc[lambda df: df['shield'] == 8]
  max_speed  shield
  sidewinder 7   8

**Setting values**

Set value for all items matching the list of labels

>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>> df
  max_speed  shield
  cobra      1   2
  viper      4   50
  sidewinder 7   50

Set value for an entire row

>> df.loc['cobra'] = 10
>> df
  max_speed  shield
  cobra    10   10
  viper    4   50
  sidewinder 7   50

Set value for an entire column

>> df.loc[:, 'max_speed'] = 30
>> df
  max_speed  shield
  cobra     30   10
  viper     30   50
  sidewinder 30   50

Set value for rows matching callable condition
Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
    7       1      2
    8       4      5
    9       7      8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
   max_speed  shield
    7       1      2
    8       4      5
    9       7      8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...             ('cobra', 'mark i'), ('cobra', 'mark ii'),
...             ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...             ('viper', 'mark ii'), ('viper', 'mark iii')
...             ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...            [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
   max_speed  shield
    cobra     mark i   12      2
           mark ii    0      4
   sidewinder  mark i  10     20
           mark ii    1      4
    viper  mark ii    7      1
           mark iii  16     36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
   max_speed  shield
   cobra     mark i   12      2
```

(continues on next page)
Single index tuple. Note this returns a Series.

```python
>>> df.loc[['cobra', 'mark ii']]
max_speed     0
shield        4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```python
>>> df.loc['cobra', 'mark i']
max_speed    12
shield       2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[]` returns a DataFrame.

```python
>>> df.loc[['cobra', 'mark ii']]
max_speed  shield
cobra mark ii 0 4
```

Single tuple for the index with a single label for the column

```python
>>> df.loc[['cobra', 'mark i'], 'shield']
2
```

Slice from index tuple to single label

```python
>>> df.loc[['cobra', 'mark i']:'viper']
max_speed shield
cobra mark i 12 2
mark ii 0 4
sidewinder mark i 10 20
mark ii 1 4
viper mark ii 7 1
mark iii 16 36
```

Slice from index tuple to index tuple

```python
>>> df.loc[['cobra', 'mark i']:'viper', 'mark ii']]
max_speed shield
cobra mark i 12 2
mark ii 0 4
sidewinder mark i 10 20
mark ii 1 4
viper mark ii 7 1
```

---

### Example Code

```python
# Example code for pandas data analysis
```
pandas.Series.name

**property** Series.name

Return the name of the Series.

The name of a Series becomes its index or column name if it is used to form a DataFrame. It is also used whenever displaying the Series using the interpreter.

**Returns**

- **label (hashable object)** The name of the Series, also the column name if part of a DataFrame.

**See also:**

- **Series.rename** Sets the Series name when given a scalar input.
- **Index.name** Corresponding Index property.

**Examples**

The Series name can be set initially when calling the constructor.

```python
>>> s = pd.Series([1, 2, 3], dtype=np.int64, name='Numbers')
>>> s
0    1
1    2
2    3
Name: Numbers, dtype: int64
>>> s.name = 'Integers'
>>> s
0    1
1    2
2    3
Name: Integers, dtype: int64
```

The name of a Series within a DataFrame is its column name.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4], [5, 6]],
                    columns=['Odd Numbers', 'Even Numbers'])
>>> df
   Odd Numbers  Even Numbers
0       1         2
1       3         4
2       5         6
>>> df['Even Numbers'].name
'Even Numbers'
```
**pandas.Series.nbytes**

*property* Series.nbytes  
Return the number of bytes in the underlying data.

**pandas.Series.ndim**

*property* Series.ndim  
Number of dimensions of the underlying data, by definition 1.

**pandas.Series.shape**

*property* Series.shape  
Return a tuple of the shape of the underlying data.

**pandas.Series.size**

*property* Series.size  
Return the number of elements in the underlying data.

**pandas.Series.values**

*property* Series.values  
Return Series as ndarray or ndarray-like depending on the dtype.

**Warning:** We recommend using Series.array or Series.to_numpy(), depending on whether you need a reference to the underlying data or a NumPy array.

**Returns**

numpy.ndarray or ndarray-like

**See also:**

*Series.array*  Reference to the underlying data.
*Series.to_numpy*  A NumPy array representing the underlying data.

**Examples**

```python
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])

>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```
```python
>>> pd.Series(list('aabc')).astype('category').values
['a', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Timezone aware datetime data is converted to UTC:

```python
>>> pd.Series(pd.date_range('20130101', periods=3, ...
tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
       '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>add()</code></td>
<td>Return Addition of series and other, element-wise (binary operator <code>add</code>).</td>
</tr>
<tr>
<td><code>add_prefix()</code></td>
<td>Prefix labels with string <code>prefix</code>.</td>
</tr>
<tr>
<td><code>add_suffix()</code></td>
<td>Suffix labels with string <code>suffix</code>.</td>
</tr>
<tr>
<td><code>agg()</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>aggregate()</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>align()</code></td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>all()</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>any()</code></td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td><code>append()</code></td>
<td>(DEPRECATED) Concatenate two or more Series.</td>
</tr>
<tr>
<td><code>apply()</code></td>
<td>Invoke function on values of Series.</td>
</tr>
<tr>
<td><code>argmax()</code></td>
<td>Return int position of the largest value in the Series.</td>
</tr>
<tr>
<td><code>argmin()</code></td>
<td>Return int position of the smallest value in the Series.</td>
</tr>
<tr>
<td><code>argsort()</code></td>
<td>Return the integer indices that would sort the Series values.</td>
</tr>
<tr>
<td><code>asfreq()</code></td>
<td>Convert time series to specified frequency.</td>
</tr>
<tr>
<td><code>asof()</code></td>
<td>Return the last row(s) without any NaNs before <code>where</code>.</td>
</tr>
<tr>
<td><code>astype()</code></td>
<td>Cast a pandas object to a specified dtype <code>dtype</code>.</td>
</tr>
<tr>
<td><code>at_time()</code></td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td><code>autocorr()</code></td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td><code>backfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>between()</code></td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
</tbody>
</table>

<tr>
<td><code>bfill</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>bool()</code></td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td><code>cat</code></td>
<td>alias of <code>pandas.core.arrays.categorical.CategoricalAccessor</code></td>
</tr>
<tr>
<td><code>clip</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>combine</code></td>
<td>Combine the Series with a Series or scalar according to <code>func</code>.</td>
</tr>
<tr>
<td><code>combine_first</code></td>
<td>Update null elements with value in the same location in 'other'.</td>
</tr>
<tr>
<td><code>compare</code></td>
<td>Compare to another Series and show the differences.</td>
</tr>
<tr>
<td><code>convert_dtypes</code></td>
<td>Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code>.</td>
</tr>
<tr>
<td><code>copy</code></td>
<td>Make a copy of this object's indices and data.</td>
</tr>
<tr>
<td><code>corr</code></td>
<td>Compute correlation with another Series, excluding missing values.</td>
</tr>
<tr>
<td><code>count</code></td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td><code>cov</code></td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td><code>cummax</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cummin</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumprod</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumsum</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>describe</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>diff</code></td>
<td>First discrete difference of element.</td>

</tr>
<tr>
<td><code>divide</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>divmod</code></td>
<td>Return Integer division and modulo of series and other, element-wise (binary operator <code>divmod</code>).</td>
</tr>
<tr>
<td><code>dot</code></td>
<td>Compute the dot product between the Series and the columns of other.</td>
</tr>
<tr>
<td><code>drop</code></td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td><code>drop_duplicates</code></td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td><code>droplevel</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>dropna</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>dt</code></td>
<td>alias of <code>pandas.core.indexes.accessors.CombinedDatetimelikeProperties</code></td>
</tr>
<tr>
<td><code>duplicated</code></td>
<td>Indicate duplicate Series values.</td>
</tr>
<tr>
<td><code>eq</code></td>
<td>Return Equal to of series and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
</tbody>
</table>

<tr>
<td><em>multiply</em> (other[, level, fill_value, axis])</td>
<td>Return Multiplication of series and other, element-wise (binary operator mul).</td>
</tr>
<tr>
<td><em>ne</em> (other[, level, fill_value, axis])</td>
<td>Return Not equal to of series and other, element-wise (binary operator ne).</td>
</tr>
<tr>
<td><em>nlargest</em> ([n, keep])</td>
<td>Return the largest n elements.</td>
</tr>
<tr>
<td><em>notna</em> ()</td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><em>notnull</em> ()</td>
<td>Series.notnull is an alias for Series.notna.</td>
</tr>
<tr>
<td><em>nsmallest</em> ([n, keep])</td>
<td>Return the smallest n elements.</td>
</tr>
<tr>
<td><em>nunique</em> ([dropna])</td>
<td>Return number of unique elements in the object.</td>
</tr>
<tr>
<td><em>pad</em> ([axis, inplace, limit, downcast])</td>
<td>Synonym for DataFrame.fillna() with method='ffill'.</td>
</tr>
<tr>
<td><em>pct_change</em> ([periods, fill_method, limit, freq])</td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><em>pipe</em> (func, *args, **kwargs)</td>
<td>Apply chainable functions that expect Series or DataFrames.</td>
</tr>
<tr>
<td><em>plot</em></td>
<td>alias of pandas.plotting._core.PlotAccessor</td>
</tr>
<tr>
<td><em>pop</em> (item)</td>
<td>Return item and drops from series.</td>
</tr>
<tr>
<td><em>pow</em> (other[, level, fill_value, axis])</td>
<td>Return Exponential power of series and other, element-wise (binary operator pow).</td>
</tr>
<tr>
<td><em>prod</em> ([axis, skipna, level, numeric_only, ...])</td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><em>product</em> ([axis, skipna, level, numeric_only, ...])</td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><em>quantile</em> ([q, interpolation])</td>
<td>Return value at the given quantile.</td>
</tr>
<tr>
<td><em>radd</em> (other[, level, fill_value, axis])</td>
<td>Return Addition of series and other, element-wise (binary operator radd).</td>
</tr>
<tr>
<td><em>rank</em> ([axis, method, numeric_only, ...])</td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td><em>ravel</em> ([order])</td>
<td>Return the flattened underlying data as an ndarray.</td>
</tr>
<tr>
<td><em>rdiv</em> (other[, level, fill_value, axis])</td>
<td>Return Floating division of series and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td><em>rdivmod</em> (other[, level, fill_value, axis])</td>
<td>Return Integer division and modulo of series and other, element-wise (binary operator rdivmod).</td>
</tr>

continues on next page
**pandas.Series.abs**

**Series.abs()**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns**

- abs Series/DataFrame containing the absolute value of each element.

**See also:**

- `numpy.absolute` Calculate the absolute value element-wise.

**Notes**

For complex inputs, \(1.2 + 1j\), the absolute value is \(\sqrt{a^2 + b^2}\).

**Examples**

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0   1.10
1   2.00
2   3.33
3   4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0   1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0   1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).
```python
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
```

```python
df
```

```python
da b c
0 4 10 100
1 5 20 50
2 6 30 -30
3 7 40 -50
```

```python
df.loc[(df.c - 43).abs().argsort()]
```

```python
da b c
1 5 20 50
0 4 10 100
2 6 30 -30
3 7 40 -50
```

**pandas.Series.add**

`Series.add(other, level=None, fill_value=None, axis=0)`

Return Addition of series and other, element-wise (binary operator add).

Equivalent to `series + other`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- **Series** The result of the operation.

**See also:**

*Series.radd* Reverse of the Addition operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64

>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e   NaN
dtype: float64
```

**pandas.Series.add_prefix**

Series.add_prefix(prefix)

Prefix labels with string `prefix`.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters**

- prefix [str] The string to add before each label.

**Returns**

Series or DataFrame New Series or DataFrame with updated labels.

**See also:**

Series.add_suffix Suffix row labels with string `suffix`.
DataFrame.add_suffix Suffix column labels with string `suffix`.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```
```python
>>> s.add_prefix('item_')
item_0  1
item_1  2
item_2  3
item_3  4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A   B
0  1   3
1  2   4
2  3   5
3  4   6
```

```python
>>> df.add_prefix('col_')
   col_A  col_B
0     1     3
1     2     4
2     3     5
3     4     6
```

### pandas.Series.add_suffix

**Series.add_suffix(suffix)**

Suffix labels with string `suffix`.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**

- `suffix` [str] The string to add after each label.

**Returns**

- Series or DataFrame New Series or DataFrame with updated labels.

**See also:**

- `Series.add_prefix` Prefix row labels with string `prefix`.
- `DataFrame.add_prefix` Prefix column labels with string `prefix`.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0  1
1  2
2  3
3  4
dtype: int64
```
>>> s.add_suffix('_item')
0_item 1
1_item 2
2_item 3
3_item 4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
  A  B
0 1  3
1 2  4
2 3  5
3 4  6

>>> df.add_suffix('_col')
  A_col  B_col
0  1  3
1  2  4
2  3  5
3  4  6

pandas.Series.agg

Series.agg(func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

   func  [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

   Accepted combinations are:
   • function
   • string function name
   • list of functions and/or function names, e.g. [np.sum, 'mean']
   • dict of axis labels -> functions, function names or list of such.

   axis  [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

   *args  Positional arguments to pass to func.

   **kwargs  Keyword arguments to pass to func.

Returns

   scalar, Series or DataFrame  The return can be:
   • scalar : when Series.agg is called with single function
   • Series : when DataFrame.agg is called with a single function
   • DataFrame : when DataFrame.agg is called with several functions
Return scalar, Series or DataFrame.
See also:

*Series.apply*  Invoke function on a Series.
*Series.transform*  Transform function producing a Series with like indexes.

**Notes**

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```python
def s = pd.Series([1, 2, 3, 4])
>>> s
0   1
1   2
2   3
3   4
dtype: int64

>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
min  1
max  4
dtype: int64
```

**pandas.Series.aggregate**

*Series.aggregate*(*func=None, axis=0, *args, **kwargs*)

Aggregate using one or more operations over the specified axis.

**Parameters**

*func*  [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

• function

• string function name

• list of functions and/or function names, e.g. `[np.sum, 'mean']`

• dict of axis labels -> functions, function names or list of such.

*axis*  [[0 or ‘index’]] Parameter needed for compatibility with DataFrame.

*args  Positional arguments to pass to *func.*
**kwargs  Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame  The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

Series.apply  Invoke function on a Series.

Series.transform  Transform function producing a Series with like indexes.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported.

See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0  1  
1  2  
2  3  
3  4  
dtype: int64

>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
min  1  
max  4  
dtype: int64
```
pandas.Series.align

Series.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

other [DataFrame or Series]

join [{'outer', 'inner', 'left', 'right'}, default ‘outer’]

axis [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).

level [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.

copy [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

• pad / ffill: propagate last valid observation forward to next valid.
• backfill / bfill: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or ‘index’}, default 0] Filling axis, method and limit.

broadcast_axis [{0 or ‘index’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(Series, type of other)] Aligned objects.

Examples

```python
>>> df = pd.DataFrame(
...   [[1, 2, 3, 4], [6, 7, 8, 9]], columns=["D", "B", "E", "A"], index=[1, 2])
... )
... )
... other = pd.DataFrame(
...   [[10, 20, 30, 40], [60, 70, 80, 90], [600, 700, 800, 900]],
... columns=["A", "B", "C", "D"],
... index=[2, 3, 4],
... )
... df
```
Align on columns:

```python
left, right = df.align(other, join="outer", axis=1)
```

```
left
A  B  C  D  E
1  4  2  NaN  1  3
2  9  7  NaN  6  8
```

```
right
A  B  C  D  E
2  10  20  30  40  NaN
3  60  70  80  90  NaN
4  600  700  800  900  NaN
```

We can also align on the index:

```python
left, right = df.align(other, join="outer", axis=0)
```

```
left
D  B  E  A
1  1.0  2.0  3.0  4.0
2  6.0  7.0  8.0  9.0
3  NaN  NaN  NaN  NaN
4  NaN  NaN  NaN  NaN
```

```
right
A  B  C  D  E
1  NaN  NaN  NaN  NaN  NaN
2  10.0  20.0  30.0  40.0  NaN
3  60.0  70.0  80.0  90.0  NaN
4  600.0  700.0  800.0  900.0  NaN
```

Finally, the default `axis=None` will align on both index and columns:

```python
left, right = df.align(other, join="outer", axis=None)
```

```
left
A  B  C  D  E
1  4.0  2.0  NaN  1.0  3.0
2  9.0  7.0  NaN  6.0  8.0
3  NaN  NaN  NaN  NaN  NaN
4  NaN  NaN  NaN  NaN  NaN
```

```
right
A  B  C  D  E
1  NaN  NaN  NaN  NaN  NaN
2  10.0  20.0  30.0  40.0  NaN
3  60.0  70.0  80.0  90.0  NaN
4  600.0  700.0  800.0  900.0  NaN
```
**pandas.Series.all**

`Series.all(axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

**Parameters**

- **axis** [0 or ‘index’, 1 or ‘columns’, None], default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
  - 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
  - None : reduce all axes, return a scalar.

- **bool_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

- **skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

- **kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- scalar or Series  If level is specified, then, Series is returned; otherwise, scalar is returned.

**See also:**

- **Series.all** Return True if all elements are True.
- **DataFrame.any** Return True if one (or more) elements are True.

**Examples**

**Series**

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([], dtype="float64").all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

**DataFrames**

Create a dataframe from a dictionary.
>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>> df
  col1 col2
0   True  True
1   True  False

Default behaviour checks if column-wise values all return True.

>> df.all()
dtype: bool

Specify axis='columns' to check if row-wise values all return True.

>> df.all(axis='columns')
dtype: bool

Or axis=None for whether every value is True.

>> df.all(axis=None)
False

pandas.Series.any

Series.any(axis=0, bool_only=None, skipna=True, level=None, **kwargs)
Return whether any element is True, potentially over an axis.
Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters
  axis [(0 or 'index', 1 or 'columns', None), default 0] Indicate which axis or axes should be reduced.
  • 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
  • 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
  • None : reduce all axes, return a scalar.
  bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.
  skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.
  level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
  **kwargs [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.
Returns

scalar or Series  If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

numpy.any  Numpy version of this method.
Series.any  Return whether any element is True.
Series.all  Return whether all elements are True.
DataFrame.any  Return whether any element is True over requested axis.
DataFrame.all  Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```python
>>> df = pd.DataFrame(
   {
      "A": [1, 2],
      "B": [0, 2],
      "C": [0, 0]
   }
)
>>> df
    A B C
0  1 0 0
1  2 2 0

>>> df.any()
A   True
B   True
C   False
dtype: bool

Aggregating over the columns.

```python
>>> df = pd.DataFrame(
   {
      "A": [True, False],
      "B": [1, 2]
   }
)
>>> df
    A B
0  True 1
1 False 2
```
```python
>>> df.any(axis='columns')
0    True
1    True
dtype: bool

>>> df = pd.DataFrame({'A': [True, False], 'B': [1, 0]})
>>> df
   A  B
0  True    1
1  False    0

>>> df.any(axis='columns')
0    True
1    False
dtype: bool

Aggregating over the entire DataFrame with axis=None.

>>> df.any(axis=None)
True

any for an empty DataFrame is an empty Series.

>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

**pandas.Series.append**

`Series.append(to_append, ignore_index=False, verify_integrity=False)`

Concatenate two or more Series.

Deprecated since version 1.4.0: Use `concat()` instead. For further details see `Deprecated DataFrame.append and Series.append`

**Parameters**

- `to_append` [Series or list/tuple of Series] Series to append with self.
- `ignore_index` [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
- `verify_integrity` [bool, default False] If True, raise Exception on creating index with duplicates.

**Returns**

- `Series` Concatenated Series.

**See also:**

- `concat` General function to concatenate DataFrame or Series objects.
Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

Examples

```python
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
 0   1
 1   2
 2   3
 0   4
 1   5
 2   6
dtype: int64

>>> s1.append(s3)
 0   1
 1   2
 2   3
 3   4
 4   5
 5   6
dtype: int64

With `ignore_index` set to True:

```python
code snippet
```

With `verify_integrity` set to True:

```python
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
  ... 
ValueError: Indexes have overlapping values: [0, 1, 2]
```
pandas.Series.apply

Series.apply(func, convert_dtype=True, args=(), **kwargs)

Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

**Parameters**

- **func** [function] Python function or NumPy ufunc to apply.
- **convert_dtype** [bool, default True] Try to find better dtype for elementwise function results. If False, leave as dtype=object. Note that the dtype is always preserved for some extension array dtypes, such as Categorical.
- **args** [tuple] Positional arguments passed to func after the series value.
- **kwargs** Additional keyword arguments passed to func.

**Returns**

- **Series or DataFrame** If func returns a Series object the result will be a DataFrame.

See also:

- Series.map For element-wise operations.
- Series.agg Only perform aggregating type operations.
- Series.transform Only perform transforming type operations.

**Notes**

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

**Examples**

Create a series with typical summer temperatures for each city.

```python
>>> s = pd.Series([20, 21, 12],
...                index=['London', 'New York', 'Helsinki'])
>>> s
London  20
New York  21
Helsinki  12
dtype: int64
```

Square the values by defining a function and passing it as an argument to apply().

```python
>>> def square(x):
...    return x ** 2
>>> s.apply(square)
London   400
New York  441
Helsinki  144
dtype: int64
```
Square the values by passing an anonymous function as an argument to apply().

```python
>>> s.apply(lambda x: x ** 2)
London  400
New York 441
Helsinki 144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```python
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value

>>> s.apply(subtract_custom_value, args=(5,))
London  15
New York 16
Helsinki 7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to apply.

```python
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x

>>> s.apply(add_custom_values, june=30, july=20, august=25)
London  95
New York 96
Helsinki 87
dtype: int64
```

Use a function from the Numpy library.

```python
>>> s.apply(np.log)
London  2.995732
New York 3.044522
Helsinki 2.484907
dtype: float64
```

---

**pandas.Series.argmax**

`Series.argmax(axis=None, skipna=True, *args, **kwargs)`

Return int position of the largest value in the Series.

If the maximum is achieved in multiple locations, the first row position is returned.

**Parameters**

- `axis` ([None]) Dummy argument for consistency with Series.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `*args`, `**kwargs` Additional arguments and keywords for compatibility with NumPy.
Returns

int  Row position of the maximum value.

See also:

Series.argmax  Return position of the maximum value.
Series.argmin  Return position of the minimum value.
numpy.ndarray.argmax  Equivalent method for numpy arrays.
Series.idxmax  Return index label of the maximum values.
Series.idxmin  Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0, 'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes 100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff 110.0
dtype: float64
```

```python
>>> s.argmax()
2
```

```python
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Series.argmin

Series.argmin(axis=None, skipna=True, *args, **kwargs)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

axis ([None]) Dummy argument for consistency with Series.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs  Additional arguments and keywords for compatibility with NumPy.

Returns

int  Row position of the minimum value.

See also:

Series.argmin  Return position of the minimum value.
Series.argmax  Return position of the maximum value.

numpy.ndarray.argmin  Equivalent method for numpy arrays.

Series.idxmax  Return index label of the maximum values.

Series.idxmin  Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                 'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes 100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff 110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Series.argsort

Series.argsort(axis=0, kind='quicksort', order=None)  Return the integer indices that would sort the Series values.

Override ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

Parameters

- **axis** [[0 or “index”]] Has no effect but is accepted for compatibility with numpy.
- **kind** [['mergesort', 'quicksort', 'heapsort', 'stable'], default ‘quicksort’] Choice of sorting algorithm. See numpy.sort() for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms.
- **order** [None] Has no effect but is accepted for compatibility with numpy.

Returns

- **Series[np.intp]** Positions of values within the sort order with -1 indicating nan values.

See also:

- **numpy.ndarray.argsort** Returns the indices that would sort this array.
### pandas.Series.asfreq

**Series.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)**

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this Series is a `PeriodIndex`, the new index is the result of transforming the original index with `PeriodIndex.asfreq` (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to `pd.date_range(start, end, freq=freq)` where `start` and `end` are, respectively, the first and last entries in the original index (see `pandas.date_range()`). The values corresponding to any timesteps in the new index which were not present in the original index will be null (`NaN`), unless a method for filling such unknowns is provided (see the `method` parameter below).

The `resample()` method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

**Parameters**

- **freq**  [DateOffset or str] Frequency DateOffset or string.
- **method**  [{‘backfill’/’bfill’, ‘pad’/’ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  - ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
  - ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.
- **how**  [{‘start’, ‘end’}, default end] For PeriodIndex only (see `PeriodIndex.asfreq`).
- **normalize**  [bool, default False] Whether to reset output index to midnight.
- **fill_value**  [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

**Returns**

- **Series**  Series object reindexed to the specified frequency.

**See also:**

- `reindex`  Conform DataFrame to new index with optional filling logic.

**Notes**

To learn more about the frequency strings, please see this link.

**Examples**

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df
   s
2000-01-01 00:00:00  0.0
```

(continues on next page)
Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
```

<table>
<thead>
<tr>
<th>Date</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 00:00:00</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:00:30</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:01:00</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:01:30</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:02:00</td>
<td>2.0</td>
</tr>
<tr>
<td>2000-01-01 00:02:30</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:03:00</td>
<td>3.0</td>
</tr>
</tbody>
</table>

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
```

<table>
<thead>
<tr>
<th>Date</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 00:00:00</td>
<td>0.0</td>
</tr>
<tr>
<td>2000-01-01 00:00:30</td>
<td>9.0</td>
</tr>
<tr>
<td>2000-01-01 00:01:00</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:01:30</td>
<td>9.0</td>
</tr>
<tr>
<td>2000-01-01 00:02:00</td>
<td>2.0</td>
</tr>
<tr>
<td>2000-01-01 00:02:30</td>
<td>9.0</td>
</tr>
<tr>
<td>2000-01-01 00:03:00</td>
<td>3.0</td>
</tr>
</tbody>
</table>

Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')
```

<table>
<thead>
<tr>
<th>Date</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 00:00:00</td>
<td>0.0</td>
</tr>
<tr>
<td>2000-01-01 00:00:30</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:01:00</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01 00:01:30</td>
<td>2.0</td>
</tr>
<tr>
<td>2000-01-01 00:02:00</td>
<td>2.0</td>
</tr>
<tr>
<td>2000-01-01 00:02:30</td>
<td>3.0</td>
</tr>
<tr>
<td>2000-01-01 00:03:00</td>
<td>3.0</td>
</tr>
</tbody>
</table>

***pandas.Series.asof***

**Series.asof(where, subset=None)**

Return the last row(s) without any NaNs before where.

The last row (for each element in where, if list) without any NaN is taken. In case of a DataFrame, the last row without NaN considering only the subset of columns (if not None).

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame.

**Parameters**

- **where** [date or array-like of dates] Date(s) before which the last row(s) are returned.
subset [str or array-like of str, default None] For DataFrame, if not None, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar: when self is a Series and where is a scalar
- Series: when self is a Series and where is an array-like, or when self is a DataFrame and where is a scalar
- DataFrame: when self is a DataFrame and where is an array-like

Return scalar, Series, or DataFrame.

See also:

merge_asof Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30  NaN
40    4.0
dtype: float64

>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.

```python
>>> s.asof([5, 20])
5     NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```python
>>> s.asof(30)
2.0
```

Take all columns into consideration
pandas: powerful Python data analysis toolkit, Release 1.4.1

```python
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
                    'b': [None, None, None, None, 500],
                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
                                              '2018-02-27 09:02:00',
                                              '2018-02-27 09:03:00',
                                              '2018-02-27 09:04:00',
                                              '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
                             '2018-02-27 09:04:30']))
   a    b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN

Take a single column into consideration

```python
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
                             '2018-02-27 09:04:30']),
           subset=['a'])
   a    b
2018-02-27 09:03:30 30.0 NaN
2018-02-27 09:04:30 40.0 NaN
```

pandas.Series.astype

```python
pd.Series.astype(dtype, copy=True, errors='raise')
```

Cast a pandas object to a specified dtype `dtype`.

**Parameters**

- `dtype` [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.
- `copy` [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).
- `errors` [‘raise’, ‘ignore’], default ‘raise’] Control raising of exceptions on invalid data for provided dtype.
  - `raise`: allow exceptions to be raised
  - `ignore`: suppress exceptions. On error return original object.

**Returns**

- `casted` [same type as caller]

See also:

- `to_datetime` Convert argument to datetime.
- `to_timedelta` Convert argument to timedelta.
- `to_numeric` Convert argument to a numeric type.
- `numpy.ndarray.astype` Cast a numpy array to a specified type.
Notes

Deprecated since version 1.3.0: Using astype to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use Series.dt.tz_localize() instead.

Examples

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
0 col1    int64
1 col2    int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
0 col1    int32
1 col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
0 col1    int32
1 col2    int64
dtype: object
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```python
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype([1, 2])
>>> cat_dtype
Categories (2, int64): [1, 2]
```

(continues on next page)
>>> ser.astype(cat_dtype)
0  1
1  2
dtype: category
Categories (2, int64): [2 < 1]

Note that using copy=False and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1
# note that s1[0] has changed too
0   10
1    2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0  2020-01-01
1  2020-01-02
2  2020-01-03
dtype: datetime64[ns]
```

### pandas.Series.at_time

`Series.at_time(time, asof=False, axis=None)`

Select values at particular time of day (e.g., 9:30AM).

**Parameters**

- `time` [datetime.time or str]
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0]

**Returns**

Series or DataFrame

**Raises**

- `TypeError` If the index is not a `DatetimeIndex`

**See also:**

- `between_time` Select values between particular times of the day.
- `first` Select initial periods of time series based on a date offset.
- `last` Select final periods of time series based on a date offset.
- `DatetimeIndex.indexer_at_time` Get just the index locations for values at particular time of the day.
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
```

```
>>> ts
       A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4
```

```
>>> ts.at_time('12:00')
       A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

`pandas.Series.autocorr`

`Series.autocorr(lag=1)`

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

**Parameters**

- `lag` [int, default 1] Number of lags to apply before performing autocorrelation.

**Returns**

- float The Pearson correlation between self and self.shift(lag).

**See also:**

- `Series.corr` Compute the correlation between two Series.
- `Series.shift` Shift index by desired number of periods.
- `DataFrame.corr` Compute pairwise correlation of columns.
- `DataFrame.corrwith` Compute pairwise correlation between rows or columns of two DataFrame objects.

**Notes**

If the Pearson correlation is not well defined return ‘NaN’.
Examples

```python
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr()
0.10355...
>>> s.autocorr(lag=2)
-0.99999...
```

If the Pearson correlation is not well defined, then ‘NaN’ is returned.

```python
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

#### pandas.Series.backfill

`Series.backfill(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with method='bfill'.

**Returns**

- `Series/DataFrame or None` Object with missing values filled or None if `inplace=True`.

#### pandas.Series.between

`Series.between(left, right, inclusive='both')`

Return boolean Series equivalent to `left <= series <= right`.

This function returns a boolean vector containing `True` wherever the corresponding Series element is between the boundary values `left` and `right`. NA values are treated as `False`.

**Parameters**

- `left` [scalar or list-like] Left boundary.
- `right` [scalar or list-like] Right boundary.
- `inclusive` [['both', 'neither', 'left', 'right']] Include boundaries. Whether to set each bound as closed or open.

**Returns**

- `Series` Series representing whether each element is between left and right (inclusive).

**See also:**

- `Series.gt` Greater than of series and other.
- `Series.lt` Less than of series and other.
Notes

This function is equivalent to `(left <= ser) & (ser <= right)`

Examples

```python
>>> s = pd.Series([2, 0, 4, 8, np.nan])

Boundary values are included by default:

```python
>>> s.between(1, 4)
0   True
1   False
2   True
3   False
4   False
dtype: bool
```

With `inclusive` set to "neither" boundary values are excluded:

```python
>>> s.between(1, 4, inclusive="neither")
0   True
1   False
2   False
3   False
4   False
dtype: bool
```

`left` and `right` can be any scalar value:

```python
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0   False
1   True
2   True
3   False
dtype: bool
```

**pandas.Series.between_time**

Series.between_time(start_time, end_time, include_start=NoDefault.no_default,
include_end=NoDefault.no_default, inclusive=None, axis=None)

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are not between the two times.

**Parameters**

- `start_time` [datetime.time or str] Initial time as a time filter limit.
- `end_time` [datetime.time or str] End time as a time filter limit.

3.3. Series
include_start [bool, default True] Whether the start time needs to be included in the result.

Deprecated since version 1.4.0: Arguments include_start and include_end have been deprecated to standardize boundary inputs. Use inclusive instead, to set each bound as closed or open.

include_end [bool, default True] Whether the end time needs to be included in the result.

Deprecated since version 1.4.0: Arguments include_start and include_end have been deprecated to standardize boundary inputs. Use inclusive instead, to set each bound as closed or open.

inclusive [“both”, “neither”, “left”, “right”), default “both”] Include boundaries; whether to set each bound as closed or open.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] Determine range time on index or columns value.

Returns
Series or DataFrame Data from the original object filtered to the specified dates range.

Raises
TypeError If the index is not a DatetimeIndex

See also:
at_time Select values at a particular time of the day.
first Select initial periods of time series based on a date offset.
last Select final periods of time series based on a date offset.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({"A": [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4

>>> ts.between_time('0:15', '0:45')
   A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3

You get the times that are not between two times by setting start_time later than end_time:

```
pandas.Series.bfill

Series.bfill\(axis=None, inplace=False, limit=None, downcast=None\)

Synonym for DataFrame.fillna() with method='bfill'.

Returns

Series/DataFrame or None  Object with missing values filled or None if inplace=True.

pandas.Series.bool

Series.bool()

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool  The value in the Series or DataFrame.

See also:

Series.astype  Change the data type of a Series, including to boolean.

DataFrame.astype  Change the data type of a DataFrame, including to boolean.

numpy.bool_  NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True

>>> pd.Series([False]).bool()
False

>>> pd.DataFrame({'col': [True]}).bool()
True

>>> pd.DataFrame({'col': [False]}).bool()
False
```
pandas.Series.cat

Series.cat()
Accessor object for categorical properties of the Series values.

Be aware that assigning to categories is an in-place operation, while all methods return new categorical data per default (but can be called with inplace=True).

Parameters

data [Series or CategoricalIndex]

Examples

```python
>>> s = pd.Series(list("abbccc")).astype("category")
>>> s
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a', 'b', 'c']

>>> s.cat.categories
Index(['a', 'b', 'c'], dtype='object')

>>> s.cat.rename_categories(list("cba"))
0  c
1  b
2  b
3  a
4  a
5  a
dtype: category
Categories (3, object): ['c', 'b', 'a']

>>> s.cat.reorder_categories(list("cba"))
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['c', 'b', 'a']

>>> s.cat.add_categories(["d", "e"])
0  a
1  b
2  b
... (continues on next page)
3  c
4  c
5  c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']

```python
>>> s.cat.remove_categories(['a', 'c'])
0  NaN
1  b
2  b
3  NaN
4  NaN
5  NaN
dtype: category
Categories (1, object): ['b']
```

```python
>>> s1 = s.cat.add_categories(['d', 'e'])
>>> s1.cat.remove_unused_categories()
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```python
>>> s.cat.set_categories(list('abcde'))
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']
```

```python
>>> s.cat.as_ordered()
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']
```

```python
>>> s.cat.as_unordered()
0  a
1  b
2  b
(continues on next page)
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

pandas.Series.clip

Series.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)
Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.

upper [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame or None Same type as calling object with the values outside the clip boundaries replaced or None if inplace=True.

See also:

Series.clip Trim values at input threshold in series.

DataFrame.clip Trim values at input threshold in dataframe.

numpy.clip Clip (limit) the values in an array.

Examples

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
  col_0  col_1
0    9   -2
1   -3   -7
2     0     6
3   -1     8
4    5   -5

Clips per column using lower and upper thresholds:
```
Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0   2.0
1  -4.0
2   NaN
3   6.0
4   3.0
dtype: float64
>>> df.clip(t, t + 4, axis=0)
col_0  col_1
0     6   2
1    -3  -4
2      0   3
3     6   8
4     5   3
```

Clips using specific lower threshold per column element, with missing values:

```python
>>> t = pd.Series([2, -4, np.nan, 6, 3])
>>> t
0   2.0
1  -4.0
2   NaN
3   6.0
4   3.0
dtype: float64
>>> df.clip(t, axis=0)
col_0  col_1
0     9   2
1    -3  -4
2      0   6
3     6   8
4     5   3
```
pandas.Series.combine

Series.combine(other, func, fill_value=None)

Combine the Series with a Series or scalar according to func.

Combine the Series and other using func to perform elementwise selection for combined Series. fill_value is assumed when value is missing at some index from one of the two objects being combined.

Parameters

other [Series or scalar] The value(s) to be combined with the Series.

func [function] Function that takes two scalars as inputs and returns an element.

fill_value [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

Returns

Series The result of combining the Series with the other object.

See also:

Series.combine_first Combine Series values, choosing the calling Series’ values first.

Examples

Consider 2 Datasets s1 and s2 containing highest clocked speeds of different birds.

```python
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon 330.0
eagle 160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon 345.0
eagle 200.0
duck 30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```python
>>> s1.combine(s2, max)
duck    NaN
eagle  200.0
falcon  345.0
dtype: float64
```

In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set fill_value=0, so the maximum value returned will be the value from some dataset.

```python
>>> s1.combine(s2, max, fill_value=0)
duck  30.0
eagle  200.0
```
pandas.Series.combine_first

Series.combine_first(other)
Update null elements with value in the same location in ‘other’.
Combine two Series objects by filling null values in one Series with non-null values from the other Series. Result index will be the union of the two indexes.

Parameters

other [Series] The value(s) to be used for filling null values.

Returns

Series The result of combining the provided Series with the other object.

See also:

Series.combine Perform element-wise operation on two Series using a given function.

Examples

```python
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4, 5])
>>> s1.combine_first(s2)
0  1.0
1  4.0
2  5.0
dtype: float64
```

Null values still persist if the location of that null value does not exist in other

```python
>>> s1 = pd.Series({'falcon': np.nan, 'eagle': 160.0})
>>> s2 = pd.Series({'eagle': 200.0, 'duck': 30.0})
>>> s1.combine_first(s2)
duck   30.0
eagle  160.0
falcon  NaN
dtype: float64
```
pandas.Series.compare

Series.compare(other, align_axis=1, keep_shape=False, keep_equal=False)

Compare to another Series and show the differences.

New in version 1.1.0.

Parameters

other [Series] Object to compare with.

align_axis [{0 or 'index', 1 or 'columns'}, default 1] Determine which axis to align the comparison on.

• 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.

• 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.

keep_shape [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

keep_equal [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

Series or DataFrame If axis is 0 or ‘index’ the result will be a Series. The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

If axis is 1 or ‘columns’ the result will be a DataFrame. It will have two columns namely ‘self’ and ‘other’.

See also:

DataFrame.compare Compare with another DataFrame and show differences.

Notes

Matching NaNs will not appear as a difference.

Examples

```python
>>> s1 = pd.Series(['a', 'b', 'c', 'd', 'e'])
>>> s2 = pd.Series(['a', 'a', 'c', 'b', 'e'])
```

Align the differences on columns

```python
>>> s1.compare(s2)
     self  other
    1     b     a
    3     d     b
```

Stack the differences on indices

```python
```
>>> s1.compare(s2, align_axis=0)
1  self  b
   other a
3  self  d
   other b
dtype: object

Keep all original rows

>>> s1.compare(s2, keep_shape=True)
     self other
0  NaN  NaN
1    b   a
2  NaN  NaN
3    d   b
4  NaN  NaN

Keep all original rows and also all original values

>>> s1.compare(s2, keep_shape=True, keep_equal=True)
     self other
0    a   a
1    b   a
2    c   c
3    d   b
4    e   e

```
pandas.Series.convert_dtypes
```

Series.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True,
                      convert_boolean=True, convert_floating=True)

Convert columns to best possible dtypes using dtypes supporting pd.NA.

New in version 1.0.0.

Parameters

- **infer_objects** [bool, default True] Whether object dtypes should be converted to the best possible types.
- **convert_string** [bool, default True] Whether object dtypes should be converted to StringDtype().
- **convert_integer** [bool, default True] Whether, if possible, conversion can be done to integer extension types.
- **convert_boolean** [bool, defaults True] Whether object dtypes should be converted to BooleanDtypes().
- **convert_floating** [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If convert_integer is also True, preference will be give to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

Returns
Series or DataFrame  Copy of input object with new dtype.

See also:

infer_objects  Infer dtypes of objects.

to_datetime  Convert argument to datetime.

to_timedelta  Convert argument to timedelta.

to_numeric  Convert argument to a numeric type.

Notes

By default, convert_dtypes will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support pd.NA. By using the options convert_string, convert_integer, convert_boolean and convert_boolean, it is possible to turn off individual conversions to StringDtype, the integer extension types, BooleanDtype or floating extension types, respectively.

For object-dtyped columns, if infer_objects is True, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to StringDtype, BooleanDtype or an appropriate integer or floating extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support pd.NA, the results of this method will change to support those new dtypes.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )
```

Start with a DataFrame with default dtypes.

```python
>>> df
   a   b       c   d   e   f
0  1   x   True 10.0  NaN
1  2  y  False   i  NaN 100.5
2  3  z   NaN  NaN 20.0 200.0
```
Convert the DataFrame to use best possible dtypes.

```python
>>> dfn = df.convert_dtypes()
>>> dfn
   a   b   c   d   e   f
0  1   x  True  10  <NA>
1  2   y False  <NA> 100.5
2  3  <NA>  <NA>  20  200.0
```

Start with a Series of strings and missing data represented by np.nan.

```python
>>> s = pd.Series(['a', 'b', np.nan])
>>> s
0    a
1    b
2  NaN
```

Obtain a Series with dtype `StringDtype`.

```python
>>> s.convert_dtypes()
   0   1
0   a  NaN
1   b  NaN
dtype: string
```
pandas.Series.copy

Series.copy(deep=True)

Make a copy of this object’s indices and data.

When deep=True (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When deep=False, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

deepp [bool, default True] Make a deep copy, including a copy of the data and the indices. With deep=False neither the indices nor the data are copied.

Returns

copy [Series or DataFrame] Object type matches caller.

Notes

When deep=True, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to copy.deepcopy in the Standard Library, which recursively copies object data (see examples below).

While Index objects are copied when deep=True, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```python
>>> s = pd.Series([1, 2], index=['a', 'b'])
>>> s
a 1
b 2
dtype: int64
```

```python
>>> s_copy = s.copy()
>>> s_copy
a 1
b 2
dtype: int64
```

Shallow copy versus default (deep) copy:

```python
>>> s = pd.Series([1, 2], index=['a', 'b'])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.
Deep copy has own copy of data and index.

```python
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s[0] = 3
>>> shallow[1] = 4
```

```python
>>> s
a 3
b 4
dtype: int64
```

```python
>>> shallow
a 3
b 4
dtype: int64
```

```python
>>> deep
a 1
b 2
dtype: int64
```

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0  [10, 2]
1  [3, 4]
dtype: object
```

```python
>>> deep
0  [10, 2]
1  [3, 4]
dtype: object
```
**pandas.Series.corr**

`Series.corr(other, method='pearson', min_periods=None)`

Compute correlation with `other` Series, excluding missing values.

**Parameters**

- `other` [Series] Series with which to compute the correlation.
- `method` [{'pearson', 'kendall', 'spearman'} or callable] Method used to compute correlation:
  - `pearson` : Standard correlation coefficient
  - `kendall` : Kendall Tau correlation coefficient
  - `spearman` : Spearman rank correlation
  - `callable` : Callable with input two 1d ndarrays and returning a float.

**Warning:** Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

- `min_periods` [int, optional] Minimum number of observations needed to have a valid result.

**Returns**

- `float` Correlation with other.

**See also:**

- `DataFrame.corr` Compute pairwise correlation between columns.
- `DataFrame.corrwith` Compute pairwise correlation with another DataFrame or Series.

**Examples**

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v

>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```
**pandas.Series.count**

*Series.count(level=None)*

Return number of non-NA/null observations in the Series.

**Parameters**

- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series.

**Returns**

- `int` or `Series (if level specified)` Number of non-null values in the Series.

**See also:**

*DataFrame.count* Count non-NA cells for each column or row.

**Examples**

```python
>>> s = pd.Series([0.0, 1.0, np.nan])
>>> s.count()
2
```

**pandas.Series.cov**

*Series.cov(other, min_periods=None, ddof=1)*

Compute covariance with Series, excluding missing values.

**Parameters**

- `other` [Series] Series with which to compute the covariance.
- `min_periods` [int, optional] Minimum number of observations needed to have a valid result.
- `ddof` [int, default 1] Delta degrees of freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

**Returns**

- `float` Covariance between Series and other normalized by N-1 (unbiased estimator).

**See also:**

*DataFrame.cov* Compute pairwise covariance of columns.
Examples

```python
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

**pandas.Series.cummax**

`Series.cummax(axis=None, skipna=True, *args, **kwargs)`

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

**Parameters**

- **axis**  
  [(0 or ‘index’, 1 or ‘columns’), default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

- **skipna**  
  [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- ***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- scalar or Series Return cumulative maximum of scalar or Series.

**See also:**

- `core.window.Expanding.max` Similar functionality but ignores NaN values.

- `Series.max` Return the maximum over Series axis.

- `Series.cummax` Return cumulative maximum over Series axis.

- `Series.cummin` Return cumulative minimum over Series axis.

- `Series.cumsum` Return cumulative sum over Series axis.

- `Series.cumprod` Return cumulative product over Series axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.
>>> s.cummax()
0  2.0
1  NaN
2  5.0
3  5.0
4  5.0
dtype: float64

To include NA values in the operation, use skipna=False

>>> s.cummax(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
... [3.0, np.nan],
... [1.0, 0.0]],
... columns=list('AB'))

>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

By default, iterates over rows and finds the maximum in each column. This is equivalent to axis=None or axis='index'.

>>> df.cummax()
   A  B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0

To iterate over columns and find the maximum in each row, use axis=1

>>> df.cummax(axis=1)
   A  B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
pandas.Series.cummin

Series.cummin(axis=None, skipna=True, *args, **kwargs)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

- **axis** ([0 or ‘index’, 1 or ‘columns’], default 0) The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** (bool, default True) Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **args**, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

- **scalar or Series** Return cumulative minimum of scalar or Series.

See also:

- core.window.Expanding.min  Similar functionality but ignores NaN values.
- Series.min  Return the minimum over Series axis.
- Series.cummax  Return cumulative maximum over Series axis.
- Series.cummin  Return cumulative minimum over Series axis.
- Series.cumsum  Return cumulative sum over Series axis.
- Series.cumprod  Return cumulative product over Series axis.

Examples

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0    2.0
1   NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use skipna=False
```python
>>> s.cummin(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummin()
   A   B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```python
>>> df.cummin(axis=1)
   A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

**pandas.Series.cumprod**

`Series.cumprod(axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

**Parameters**

- **axis** [0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- ***args**, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**
scalar or Series  Return cumulative product of scalar or Series.

See also:

core.window.Expanding.prod  Similar functionality but ignores NaN values.

Series.prod  Return the product over Series axis.

Series.cummax  Return cumulative maximum over Series axis.

Series.cummin  Return cumulative minimum over Series axis.

Series.cumsum  Return cumulative sum over Series axis.

Series.cumprod  Return cumulative product over Series axis.

Examples

Series

>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
    0  2.0
    1  NaN
    2  5.0
    3 -1.0
    4  0.0
dtype: float64

By default, NA values are ignored.

>>> s.cumprod()
     0  2.0
     1  NaN
     2 10.0
     3 -10.0
     4  -0.0
dtype: float64

To include NA values in the operation, use skipna=False

>>> s.cumprod(skipna=False)
     0  2.0
     1  NaN
     2  NaN
     3  NaN
     4  NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
(continues on next page)
By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumprod()
  A   B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```python
>>> df.cumprod(axis=1)
  A   B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

### pandas.Series.cumsum

`Series.cumsum(axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

- **Parameters**
  - `axis`: [{0 or `index`, 1 or `columns`}, default 0] The index or the name of the axis. 0 is equivalent to None or `index`.
  - `skipna`: [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
  - `*args`, `**kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

- **Returns**
  - scalar or Series Return cumulative sum of scalar or Series.

See also:

- `core.window.Expanding.sum` Similar functionality but ignores NaN values.
- `Series.sum` Return the sum over Series axis.
- `Series.cummax` Return cumulative maximum over Series axis.
- `Series.cummin` Return cumulative minimum over Series axis.
- `Series.cumsum` Return cumulative sum over Series axis.
- `Series.cumprod` Return cumulative product over Series axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0   2.0
1   NaN
2   5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0   2.0
1   NaN
2   7.0
3   6.0
4   6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumsum(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0 1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumsum()
   A  B
0  2.0 1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`
pandas.Series.describe

Series.describe(percentiles=None, include=None, exclude=None, datetime_is_numeric=False)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

• ‘all’ : All columns of the input will be included in the output.

• A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'

• None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for Series. Here are the options:

• A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(exclude=['O'])). To exclude pandas categorical columns, use 'category'

• None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.
DataFrame.max  Maximum of the values in the object.
DataFrame.min  Minimum of the values in the object.
DataFrame.mean  Mean of the values.
DataFrame.std  Standard deviation of the observations.
DataFrame.select_dtypes  Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the count and top results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count 4
unique 3
top a
tfreq 2
dtype: object
```
Describing a timestamp Series.

```python
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame(
...     {'categorical': pd.Categorical(['d', 'e', 'f']),
...      'numeric': [1, 2, 3],
...      'object': ['a', 'b', 'c']
...     })
```
Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
   numeric
count   3.0
mean    2.0
std     1.0
min     1.0
25%     1.5
50%     2.0
75%     2.5
max     3.0
Name: numeric, dtype: float64
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
   object
count   3
unique  3
top     a
top freq 1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
   categorical
count   3
unique  3
top     d
top freq 1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
   categorical object
count   3   3
unique  3   3
top     f   a
top freq 1   1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])
   categorical numeric
count   3   3
unique  3   3
top     f   a
top freq 1   1
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

count 3 3.0
unique 3 NaN
top f NaN
tfreq 1 NaN
mean NaN 2.0
std NaN 1.0
min NaN 1.0
25% NaN 1.5
50% NaN 2.0
75% NaN 2.5
max NaN 3.0

pandas.Series.diff

Series.diff(periods=1)
First discrete difference of element.
Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

Parameters
periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

Returns
Series First differences of the Series.

See also:

Series.pct_change Percent change over given number of periods.
Series.shift Shift index by desired number of periods with an optional time freq.
DataFrame.diff First discrete difference of object.

Notes
For boolean dtypes, this uses operator.xor() rather than operator.sub(). The result is calculated according to current dtpe in Series, however dtpe of the result is always float64.

Examples
Difference with previous row

```python
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0  NaN
1  0.0
2  1.0
3  1.0
4  2.0
5  3.0
dtype: float64
```
Difference with 3rd previous row

```python
>>> s.diff(periods=3)
0     NaN
1     NaN
2     NaN
3     2
4     4
5     6
dtype: float64
```

Difference with following row

```python
>>> s.diff(periods=-1)
0    0
1   -1
2   -1
3   -2
4   -3
5     NaN
dtype: float64
```

Overflow in input dtype

```python
>>> s = pd.Series([1, 0], dtype=np.uint8)
>>> s.diff()
0     NaN
1    255
dtype: float64
```

---

**pandas.Series.div**

`Series.div(other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator `truediv`).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]

- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.rtruediv` Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a 1.0
b inf
c inf
d 0.0
e NaN
dtype: float64
```

**pandas.Series.divide**

`Series.divide(other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator `truediv`).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- **Series** The result of the operation.

**See also:**

- `Series.rtruediv` Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
```
```plaintext
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
```
```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
```
```plaintext
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
```
```python
>>> a.divide(b, fill_value=0)
```
```plaintext
a    1.0
b    inf
c    inf
d    0.0
e   NaN
dtype: float64
```

pandas.Series.divmod

Series.divmod(other, level=None, fill_value=None, axis=0)

Return Integer division and modulo of series and other, element-wise (binary operator divmod).

Equivalent to divmod(series, other), but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

2-Tuple of Series The result of the operation.

See also:

Series.rdivmod Reverse of the Integer division and modulo operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
```

```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
```

```python
>>> a.divmod(b, fill_value=0)
(a  1.0
d  0.0
dtype: float64,
(a  0.0
d  0.0
dtype: float64)
```

### pandas.Series.dot

**Series.dot(other)**

Compute the dot product between the Series and the columns of other.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using `self @ other` in Python >= 3.5.

**Parameters**

other  [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

**Returns**

scalar, Series or numpy.ndarray  Return the dot product of the Series and other if other is a Series, the Series of the dot product of Series and each rows of other if other is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

**See also:**

Dataframe.dot  Compute the matrix product with the DataFrame.
**Series.mul** Multiplication of series and other, element-wise.

**Notes**

The Series and other has to share the same index if other is a Series or a DataFrame.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other
8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])
```

**pandas.Series.drop**

**Series.drop**(*labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise'*)

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

**Parameters**

- **labels** [single label or list-like] Index labels to drop.
- **axis** [0, default 0] Redundant for application on Series.
- **index** [single label or list-like] Redundant for application on Series, but ‘index’ can be used instead of ‘labels’.
- **columns** [single label or list-like] No change is made to the Series; use ‘index’ or ‘labels’ instead.
- **level** [int or level name, optional] For MultiIndex, level for which the labels will be removed.
- **inplace** [bool, default False] If True, do operation inplace and return None.
- **errors** [‘ignore’, ‘raise’], default ‘raise’ If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

- **Series or None** Series with specified index labels removed or None if inplace=True.

**Raises**
KeyError  If none of the labels are found in the index.

See also:

Series.reindex  Return only specified index labels of Series.
Series.dropna  Return series without null values.
Series.drop_duplicates  Return Series with duplicate values removed.
DataFrame.drop  Drop specified labels from rows or columns.

Examples

```python
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A 0
B 1
C 2
dtype: int64

Drop labels B en C

>>> s.drop(labels=['B', 'C'])
A 0
dtype: int64

Drop 2nd level label in MultiIndex Series

>>> midx = pd.MultiIndex(levels=[["lama", 'cow', 'falcon'],
...                         ['speed', 'weight', 'length']],
...                         codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                                [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
...                index=midx)
>>> s
lama speed 45.0
weight 200.0
length 1.2
cow speed 30.0
weight 250.0
length 1.5
falcon speed 320.0
weight 1.0
length 0.3
dtype: float64

>>> s.drop(labels='weight', level=1)
lama speed 45.0
length 1.2
cow speed 30.0
length 1.5
falcon speed 320.0
length 0.3
dtype: float64
```
pandas.Series.drop_duplicates

Series.drop_duplicates(keep='first', inplace=False)
Return Series with duplicate values removed.

Parameters

keep [{'first', 'last', False}, default 'first'] Method to handle dropping duplicates:

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

inplace [bool, default False] If True, performs operation inplace and returns None.

Returns

Series or None  Series with duplicates dropped or None if inplace=True.

See also:

Index.drop_duplicates  Equivalent method on Index.
Dataframe.drop_duplicates  Equivalent method on DataFrame.
Series.duplicated  Related method on Series, indicating duplicate Series values.

Examples

Generate a Series with duplicated entries.

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
                 name='animal')
```

```python
>>> s
0    lama
1     cow
2    lama
3   beetle
4    lama
5    hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’
keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```python
>>> s.drop_duplicates()
0    lama
1     cow
3   beetle
5  hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.
>>> s.drop_duplicates(keep='last')
1   cow
3  beetle
4   lama
5   hippo
Name: animal, dtype: object

The value False for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to True performs the operation inplace and returns None.

>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1   cow
3  beetle
5   hippo
Name: animal, dtype: object

pandas.Series.droplevel

Series.droplevel(level, axis=0)
Return Series/DataFrame with requested index / column level(s) removed.

Parameters

level [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the level(s) is removed:
• 0 or ‘index’: remove level(s) in column.
• 1 or ‘columns’: remove level(s) in row.

Returns

Series/DataFrame Series/DataFrame with requested index / column level(s) removed.

Examples

>>> df = pd.DataFrame(
...     [[1, 2, 3, 4],
...      [5, 6, 7, 8],
...      [9, 10, 11, 12]],
...    index=[0, 1, 2],
...    columns=[
...     'c', 'd',
...     'e', 'f'])

>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])

>>> df
level_1  c  d  e  f
level_2  a  b  c  d
(continues on next page)
pandas.Series.dropna

Series.dropna(axis=0, inplace=False, how=None)

Return a new Series with missing values removed.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters

- **axis** [0 or ‘index’], default 0] There is only one axis to drop values from.
- **inplace** [bool, default False] If True, do operation inplace and return None.

Returns

Series or None  Series with NA entries dropped from it or None if inplace=True.

See also:

- **Series.isna**  Indicate missing values.
- **Series.notna**  Indicate existing (non-missing) values.
- **Series.fillna**  Replace missing values.
- **DataFrame.dropna**  Drop rows or columns which contain NA values.
- **Index.dropna**  Drop missing indices.
Examples

```python
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0  1.0
1  2.0
2  NaN
dtype: float64

Drop NA values from a Series.
```
```
>>> ser.dropna()
0  1.0
1  2.0
dtype: float64
```
Keep the Series with valid entries in the same variable.
```
>>> ser.dropna(inplace=True)
```
```
>>> ser
0  1.0
1  2.0
```
Keep the Series with valid entries in the same variable.
```
Empty strings are not considered NA values. None is considered an NA value.
```
```
pandas.Series.dt

Series.dt()
Accessor object for datetimelike properties of the Series values.

Examples

```python
def seconds_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="s"))
def seconds_series
  0 2000-01-01 00:00:00
  1 2000-01-01 00:00:01
  2 2000-01-01 00:00:02
dtype: datetime64[ns]
>>> seconds_series.dt.second
  0 0
  1 1
  2 2
dtype: int64

>>> hours_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="h"))
def hours_series
  0 2000-01-01 00:00:00
  1 2000-01-01 01:00:00
  2 2000-01-01 02:00:00
dtype: datetime64[ns]
>>> hours_series.dt.hour
  0 0
  1 1
  2 2
dtype: int64

>>> quarters_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="q"))
def quarters_series
  0 2000-03-31
  1 2000-06-30
  2 2000-09-30
dtype: datetime64[ns]
>>> quarters_series.dt.quarter
  0 1
  1 2
  2 3
dtype: int64
```

Returns a Series indexed like the original Series. Raises TypeError if the Series does not contain datetimelike values.
pandas.Series.duplicated

Series.duplicated(keep='first')
Indicate duplicate Series values.

Duplicated values are indicated as True values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

Parameters

keep [{‘first’, ‘last’, False}, default ‘first’] Method to handle dropping duplicates:
• ‘first’ : Mark duplicates as True except for the first occurrence.
• ‘last’ : Mark duplicates as True except for the last occurrence.
• False : Mark all duplicates as True.

Returns

Series[bool] Series indicating whether each value has occurred in the preceding values.

See also:

Index.duplicated Equivalent method on pandas.Index.
Dataframe.duplicated Equivalent method on pandas.DataFrame.
Series.drop_duplicates Remove duplicate values from Series.

Examples

By default, for each set of duplicated values, the first occurrence is set on False and all others on True:

```python
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1     False
2      True
3     False
4      True
dtype: bool
```

which is equivalent to

```python
>>> animals.duplicated(keep='first')
0    False
1     False
2      True
3     False
4      True
dtype: bool
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> animals.duplicated(keep='last')
0      True
1     False
```

(continues on next page)
By setting keep on False, all duplicates are True:

```python
>>> animals.duplicated(keep=False)
0   True
1  False
2   True
3  False
4   True
dtype: bool
```

### pandas.Series.eq

**Series.eq**(other, level=None, fill_value=None, axis=0)

Return Equal to of series and other, element-wise (binary operator `eq`).

Equivalent to `series == other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- **Series** The result of the operation.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
```

```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
```
pandas.Series.equals

Series.equals(other)
Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the
same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal.
Corresponding columns must be of the same dtypes.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is
True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each
element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides an
easy interface to ignore inequality in dtypes, indexes and precision among others.

testing.assert_frame_equal Like assert_series_equal, but targets DataFrames.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Examples

>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
   1  2
0 10 20

DataFrames df and exactly_equal have the same types and values for their elements and column labels,
which will return True.
```python
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1   2
0  10  20

>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return True.

```python
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0  10.0  20.0

>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```python
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1   2
0  10.0  20.0

>>> df.equals(different_data_type)
False
```

**pandas.Series.ewm**

Series.ewm(com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None, method='single')

Provide exponentially weighted (EW) calculations.

Exactly one parameter: `com`, `span`, `halflife`, or `alpha` must be provided.

**Parameters**

- **com** [float, optional] Specify decay in terms of center of mass
  \[ \alpha = \frac{1}{1 + \text{com}}, \text{ for } \text{com} \geq 0. \]

- **span** [float, optional] Specify decay in terms of span
  \[ \alpha = \frac{2}{(\text{span} + 1)}, \text{ for } \text{span} \geq 1. \]

- **halflife** [float, str, timedelta, optional] Specify decay in terms of half-life
  \[ \alpha = 1 - \exp\left(-\ln(2)/\text{halflife}\right), \text{ for } \text{halflife} > 0. \]

  If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()`, and halflife value will not apply to the other functions.

  New in version 1.1.0.

- **alpha** [float, optional] Specify smoothing factor \(\alpha\) directly
  \[ 0 < \alpha \leq 1. \]
min_periods [int, default 0] Minimum number of observations in window required to have a value; otherwise, result is np.nan.

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

- When adjust=True (default), the EW function is calculated using weights \( w_i = (1 - \alpha)^i \). For example, the EW moving average of the series \([x_0, x_1, ..., x_t]\) would be:
  \[
  y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ... + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t}
  \]

- When adjust=False, the exponentially weighted function is calculated recursively:
  \[
  y_0 = x_0
  \]
  \[
  y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
  \]

ignore_na [bool, default False] Ignore missing values when calculating weights.

- When ignore_na=False (default), weights are based on absolute positions. For example, the weights of \( x_0 \) and \( x_2 \) used in calculating the final weighted average of \([x_0, None, x_2]\) are \((1 - \alpha)^2\) and 1 if adjust=True, and \((1 - \alpha)^2\) and \(\alpha\) if adjust=False.

- When ignore_na=True, weights are based on relative positions. For example, the weights of \( x_0 \) and \( x_2 \) used in calculating the final weighted average of \([x_0, None, x_2]\) are \(1 - \alpha\) and 1 if adjust=True, and \(1 - \alpha\) and \(\alpha\) if adjust=False.

axis [{0, 1}, default 0] If 0 or ‘index’, calculate across the rows.
If 1 or ‘columns’, calculate across the columns.

times [str, np.ndarray, Series, default None] New in version 1.1.0.

Only applicable to mean().

Times corresponding to the observations. Must be monotonically increasing and datetime64[ns] dtype.

If 1-D array like, a sequence with the same shape as the observations.

Deprecated since version 1.4.0: If str, the name of the column in the DataFrame representing the times.

method [str {'single', 'table'}, default ‘single’] New in version 1.4.0.

Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying engine='numba' in the method call.

Only applicable to mean()

Returns

ExponentialMovingWindow subclass

See also:

rolling Provides rolling window calculations.
expanding Provides expanding transformations.
Notes

See *Windowing Operations* for further usage details and examples.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

>>> df.ewm(alpha=2 / 3).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

adjust

>>> df.ewm(com=0.5, adjust=True).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

>>> df.ewm(com=0.5, adjust=False).mean()
   B
0  0.000000
1  0.666667
2  1.555556
3  1.555556
4  3.650794

ignore_na

>>> df.ewm(com=0.5, ignore_na=True).mean()
   B
0  0.000000
(continues on next page)
times

Exponentially weighted mean with weights calculated with a timedelta `halflife` relative to `times`.

```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()

B
0   0.000000
1   0.585786
2   1.523889
3   1.523889
4   3.233686
```

**pandas.Series.expanding**

Series `.expanding(min_periods=1, center=None, axis=0, method='single')`

Provide expanding window calculations.

**Parameters**

- `min_periods` [int, default 1] Minimum number of observations in window required to have a value; otherwise, result is `np.nan`.
- `center` [bool, default False] If False, set the window labels as the right edge of the window index.
  
  If True, set the window labels as the center of the window index.

  Deprecated since version 1.1.0.
- `axis` [int or str, default 0] If 0 or `index`, roll across the rows.
  
  If 1 or `columns`, roll across the columns.
- `method` [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

  This argument is only implemented when specifying `engine='numba'` in the method call.

  New in version 1.3.0.

**Returns**

- `Expanding subclass`
See also:

rolling  Provides rolling window calculations.

ewm  Provides exponential weighted functions.

Notes

See Windowing Operations for further usage details and examples.

Examples

```python
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
      B
0    0.0
1    1.0
2    2.0
3  NaN
4    4.0

min_periods

Expanding sum with 1 vs 3 observations needed to calculate a value.

```python
>>> df.expanding(1).sum()
      B
0    0.0
1    1.0
2    3.0
3    3.0
4    7.0
>>> df.expanding(3).sum()
      B
0   NaN
1   NaN
2    3.0
3    3.0
4    7.0
```

pandas.Series.explode

Series.explode(\texttt{ignore\_index=False})

Transform each element of a list-like to a row.

New in version 0.25.0.

Parameters

\texttt{ignore\_index}  [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.1.0.
Returns

Series  Exploded lists to rows; index will be duplicated for these rows.

See also:

Series.str.split  Split string values on specified separator.
Series.unstack  Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame.
DataFrame.melt  Unpivot a DataFrame from wide format to long format.
DataFrame.explode  Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of elements in the output will be non-deterministic when exploding sets.

Reference the user guide for more examples.

Examples

```python
>>> s = pd.Series([[1, 2, 3], 'foo', [], [3, 4]])
>>> s
0    [1, 2, 3]
1     foo
2      []
3    [3, 4]
dtype: object

>>> s.explode()
0   1
0   2
0   3
1   foo
2  NaN
3   3
3   4
dtype: object
```

pandas.Series.factorize

Series.factorize(sort=False, na_sentinel=-1)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. factorize is available as both a top-level function pandas.factorize(), and as a method Series.factorize() and Index.factorize().

Parameters

sort [bool, default False] Sort uniques and shuffle codes to maintain the relationship.
na_sentinel [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

Returns

codes [ndarray] An integer ndarray that’s an indexer into uniques. uniques.
take(codes) will have the same values as values.

uniques [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in values, uniques will not contain an entry for it.

See also:

cut Discretize continuous-valued array.
unique Find the unique value in an array.

Notes

Reference the user guide for more examples.

Examples

These examples all show factorize as a top-level method like pd.factorize(values). The results are identical for methods like Series.factorize().

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)  
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With sort=True, the uniques will be sorted, and codes will be shuffled so that the relationship is the maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)  
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in codes with na_sentinel (-1 by default). Note that missing values are never included in uniques.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0]...)  
```

(continues on next page)
Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in *uniques.categories*, despite not being present in *cat.values*.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(['a', 'c'], dtype=object)
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting *na_sentinel=None*.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([1., 2.])
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])
```

### pandas.Series.**ffill**

**Series.ffill**(axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='ffill'.

**Returns**

*Series/DataFrame or None*  Object with missing values filled or None if inplace=True.
pandas.Series.fillna

Series.fillna(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)
Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a
dict/Series/DataFrame of values specifying which value to use for each index (for a
Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not
be filled. This value cannot be a list.

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling
holes in reindexed Series pad / ffill: propagate last valid observation forward to next
valid backfill / bfill: use next valid observation to fill gap.

axis [{0 or 'index'}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views
on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive
NaN values to forward/backward fill. In other words, if there is a gap with more than
this number of consecutive NaNs, it will only be partially filled. If method is not
specified, this is the maximum number of entries along the entire axis where NaNs
will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or
the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64
to int64 if possible).

Returns

Series or None  Object with missing values filled or None if inplace=True.

See also:

interpolate Fill NaN values using interpolation.
reindex Conform object to new index.
asfreq Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
... [3, 4, np.nan, 1],
... [np.nan, np.nan, np.nan, np.nan],
... [np.nan, 3, np.nan, 4]],
... columns=list("ABCD"))
```

Replace all NaN elements with 0s.
We can also propagate non-null values forward or backward.

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

Only replace the first NaN element.

When filling using a DataFrame, replacement happens along the same column names and same indices

Note that column D is not affected since it is not present in df2.
pandas.Series.filter

Series.filter(items=None, like=None, regex=None, axis=None)
Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

- **items** [list-like] Keep labels from axis which are in items.
- **like** [str] Keep labels from axis for which “like in label == True”.
- **regex** [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns

same type as input object

See also:

*DataFrame.loc* Access a group of rows and columns by label(s) or a boolean array.

Notes

The items, like, and regex parameters are enforced to be mutually exclusive.

axis defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df = pd.DataFrame(np.array(((1, 2, 3), (4, 5, 6))),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])
>>> df
  one  two  three
mouse 1  2   3
rabbit 4  5   6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
  one  three
mouse 1  3
rabbit 4  6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
  one  three
mouse 1  3
rabbit 4  6
```
pandas.Series.first

Series.first(offset)
Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

offset [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a DatetimeIndex

See also:

last Select final periods of time series based on a date offset.
at_time Select values at a particular time of the day.
between_time Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
     A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
     A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.
pandas.Series.first_valid_index

Series.first_valid_index()
Return index for first non-NA value or None, if no non-NA value is found.

Returns
scalar [type of index]

Notes
If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.floordiv

Series.floordiv(other, level=None, fill_value=None, axis=0)
Return Integer division of series and other, element-wise (binary operator floordiv).

Equivalent to series // other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters
other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns
Series The result of the operation.

See also:
Series.rfloordiv Reverse of the Integer division operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
```
pandas: powerful Python data analysis toolkit, Release 1.4.1

(continued from previous page)

```python
e  NaN
dtype: float64
```  

```python
>>> a.floordiv(b, fill_value=0)
a  1.0
b  NaN
c  NaN
d  0.0
e  NaN
dtype: float64
```

### pandas.Series.ge

`Series.ge(other, level=None, fill_value=None, axis=0)`

Return Greater than or equal to of series and other, element-wise (binary operator `ge`).

Equivalent to `series >= other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]

- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- **Series** The result of the operation.

**Examples**

```python
>>> a = pd.Series([1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.ge(b, fill_value=0)
```  

(continues on next page)
```
ap = True
b = True
c = False
d = False
e = True
f = False
dtype: bool
```

**pandas.Series.get**

**Series.get(key, default=None)**

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

**Parameters**

- **key** [object]

**Returns**

- **value** [same type as items contained in object]

**Examples**

```python
>>> df = pd.DataFrame(
...     [
...         [24.3, 75.7, "high"],
...         [31, 87.8, "high"],
...         [22, 71.6, "medium"],
...         [35, 95, "medium"],
...     ],
...     columns=["temp_celsius", "temp_fahrenheit", "windspeed"],
...     index=pd.date_range(start="2014-02-12", end="2014-02-15", freq="D"),
... )
```

```plaintext
+-----------------+----------+----------+
<table>
<thead>
<tr>
<th>Date</th>
<th>temp_celsius</th>
<th>temp_fahrenheit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014-02-12</td>
<td>24.3</td>
<td>75.7</td>
</tr>
<tr>
<td>2014-02-13</td>
<td>31.0</td>
<td>87.8</td>
</tr>
<tr>
<td>2014-02-14</td>
<td>22.0</td>
<td>71.6</td>
</tr>
<tr>
<td>2014-02-15</td>
<td>35.0</td>
<td>95.0</td>
</tr>
</tbody>
</table>
```

```python
>>> df.get(["temp_celsius", "windspeed"])
temp_celsius  windspeed
2014-02-12  24.3  high
2014-02-13  31.0  high
2014-02-14  22.0  medium
2014-02-15  35.0  medium
```

If the key isn't found, the default value will be used.
pandas.Series.groupby

Series.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=NoDefault.no_default, observed=False, dropna=True)

Group Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If by is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see .align() method). If a list or ndarray of length equal to the selected axis is passed (see the groupby user guide), the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in self. Notice that a tuple is interpreted as a (single) key.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. as_index=False is effectively “SQL-style” grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling apply, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

Deprecated since version 1.1.0.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

dropna [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

New in version 1.1.0.

Returns

SeriesGroupBy Returns a groupby object that contains information about the groups.

See also:

resample Convenience method for frequency conversion and resampling of time series.
Notes

See the user guide for more detailed usage and examples, including splitting an object into groups, iterating through groups, selecting a group, aggregation, and more.

Examples

```python
>>> ser = pd.Series([390., 350., 30., 20.],
                  index=['Falcon', 'Falcon', 'Parrot', 'Parrot'], name='Max Speed')
>>> ser
Falcon 390.0
Falcon 350.0
Parrot 30.0
Parrot 20.0
Name: Max Speed, dtype: float64
>>> ser.groupby(["a", "b", "a", "b"]).mean()
   a  210.0
   b  185.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level=0).mean()
Falcon 370.0
Parrot 25.0
Name: Max Speed, dtype: float64
>>> ser.groupby(ser > 100).mean()
   Max Speed
False 25.0
True 370.0
Name: Max Speed, dtype: float64
```

Grouping by Indexes

We can groupby different levels of a hierarchical index using the level parameter:

```python
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
            ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> ser = pd.Series([390., 350., 30., 20.], index=index, name='Max Speed')
>>> ser
Animal   Type
Falcon Captive 390.0
         Wild 350.0
Parrot Captive 30.0
         Wild 20.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level=0).mean()
Animal
Falcon 370.0
Parrot 25.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level="Type").mean()
Type
Captive 210.0
```

(continues on next page)
We can also choose to include NA in group keys or not by defining `dropna` parameter, the default setting is True.

```python
>>> ser = pd.Series([1, 2, 3, 3], index=['a', 'a', 'b', np.nan])
>>> ser.groupby(level=0).sum()
     a  b
0   3   3
Name: Max Speed, dtype: int64

>>> ser.groupby(level=0, dropna=False).sum()
     a  b  NaN
0   3   3   3
Name: Max Speed, dtype: int64
```

```python
>>> arrays = ['Falcon', 'Falcon', 'Parrot', 'Parrot']
>>> ser = pd.Series([390., 350., 30., 20.], index=arrays, name='Max Speed')
>>> ser.groupby(['a', 'b', 'a', np.nan]).mean()
     a  b  NaN
0  210.0  350.0   20.0
Name: Max Speed, dtype: float64

>>> ser.groupby(['a', 'b', 'a', np.nan], dropna=False).mean()
     a  b  NaN
0  210.0  350.0  20.0
Name: Max Speed, dtype: float64
```

### pandas.Series.gt

**Series.gt**(other, level=None, fill_value=None, axis=0)

Return Greater than of series and other, element-wise (binary operator `gt`).

Equivalent to `series > other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- **Series** The result of the operation.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
e  1.0
dtype: float64

>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a  0.0
b  1.0
c  2.0
d  NaN
f  1.0
dtype: float64

>>> a.gt(b, fill_value=0)
a  True
b  False
c  False
d  False
e  True
f  False
dtype: bool
```

**pandas.Series.head**

Series.head(n=5)

Return the first \( n \) rows.

This function returns the first \( n \) rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of \( n \), this function returns all rows except the last \( n \) rows, equivalent to `df[:-n]`.

**Parameters**

- **n** [int, default 5] Number of rows to select.

**Returns**

- **same type as caller** The first \( n \) rows of the caller object.

**See also:**

- **DataFrame.tail** Returns the last \( n \) rows.
Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
'      'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1       bee
2    falcon
3      lion
4    monkey
5    parrot
6      shark
7    whale
8    zebra

Viewing the first 5 lines

```python
>>> df.head()
   animal
0  alligator
1       bee
2    falcon
3      lion
4    monkey

Viewing the first n lines (three in this case)

```python
>>> df.head(3)
   animal
0  alligator
1       bee
2    falcon

For negative values of n

```python
>>> df.head(-3)
   animal
0  alligator
1       bee
2    falcon
3      lion
4    monkey
5    parrot
```
pandas.Series.hist

```
Series.hist(by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None,
figsize=None, bins=10, backend=None, legend=False, **kwargs)
```

Draw histogram of the input series using matplotlib.

**Parameters**

- `by` [object, optional] If passed, then used to form histograms for separate groups.
- `ax` [matplotlib axis object] If not passed, uses gca().
- `grid` [bool, default True] Whether to show axis grid lines.
- `xlabelsize` [int, default None] If specified changes the x-axis label size.
- `xrot` [float, default None] Rotation of x axis labels.
- `ylabelsize` [int, default None] If specified changes the y-axis label size.
- `yrot` [float, default None] Rotation of y axis labels.
- `figsize` [tuple, default None] Figure size in inches by default.
- `bins` [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- `backend` [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.
  
  New in version 1.0.0.
- `legend` [bool, default False] Whether to show the legend.
  
  New in version 1.1.0.

**kwargs To be passed to the actual plotting function.

**Returns**

- `matplotlib.AxesSubplot` A histogram plot.

**See also:**

- `matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

pandas.Series.idxmax

```
Series.idxmax(axis=0, skipna=True, *args, **kwargs)
```

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

**Parameters**

- `axis` [int, default 0] For compatibility with DataFrame.idxmax. Redundant for application on Series.
- `skipna` [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.
*args, **kwargs Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the maximum value.

Raises

ValueError If the Series is empty.

See also:

numpy.argmax Return indices of the maximum values along the given axis.

DataFrame.idxmax Return index of first occurrence of maximum over requested axis.

Series.idxmin Return index label of the first occurrence of minimum of values.

Notes

This method is the Series version of ndarray.argmax. This method returns the label of the maximum, while ndarray.argmax returns the position. To get the position, use series.values.argmax().

Examples

```python
>>> s = pd.Series(data=[1, None, 4, 3, 4],
             index=['A', 'B', 'C', 'D', 'E'])
>>> s
A 1.0
B NaN
C 4.0
D 3.0
E 4.0
dtype: float64

>>> s.idxmax()
'C'

If skipna is False and there is an NA value in the data, the function returns nan.

>>> s.idxmax(skipna=False)
nan
```

pandas.Series.idxmin

Series.idxmin(axis=0, skipna=True, *args, **kwargs)

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

Parameters

axis [int, default 0] For compatibility with DataFrame.idxmin. Redundant for application on Series.
**skipna** [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

**Index** Label of the minimum value.

**Raises**

**ValueError** If the Series is empty.

**See also:**

*numpy.argmin* Return indices of the minimum values along the given axis.

*DataFrame.idxmin* Return index of first occurrence of minimum over requested axis.

*Series.idxmax* Return index **label** of the first occurrence of maximum of values.

**Notes**

This method is the Series version of *ndarray.argmin*. This method returns the label of the minimum, while *ndarray.argmin* returns the position. To get the position, use *series.values.argmin()*.

**Examples**

```python
>>> s = pd.Series(data=[1, None, 4, 1],
                 index=['A', 'B', 'C', 'D'])
>>> s
A  1.0
B  NaN
C  4.0
D  1.0
dtype: float64

>>> s.idxmin()
'A'
```

If *skipna* is False and there is an NA value in the data, the function returns *nan*.

```python
>>> s.idxmin(skipna=False)
nan
```
**pandas.Series.infer_objects**

Series.infer_objects()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

**Returns**

converted [same type as input object]

**See also:**

to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.

**Examples**

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
0  1
1  2
2  3

>>> df.dtypes
A   object
dtype: object

>>> df.infer_objects().dtypes
A   int64
dtype: object
```

**pandas.Series.info**

Series.info(verbos=None, buf=None, max_cols=None, memory_usage=None, show_counts=True)

Print a concise summary of a Series.

This method prints information about a Series including the index dtype, non-null values and memory usage.

New in version 1.4.0.

**Parameters**

data [Series] Series to print information about.

verbose [bool, optional] Whether to print the full summary. By default, the setting in pandas.options.display.max_info_columns is followed.
buf [writable buffer, defaults to sys.stdout] Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.

memory_usage [bool, str, optional] Specifies whether total memory usage of the Series elements (including the index) should be displayed. By default, this follows the pandas.options.display.memory_usage setting.

True always show memory usage. False never shows memory usage. A value of ‘deep’ is equivalent to “True with deep introspection”. Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

show_counts [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than pandas.options.display.max_info_rows and pandas.options.display.max_info_columns. A value of True always shows the counts, and False never shows the counts.

Returns

None This method prints a summary of a Series and returns None.

See also:

Series.describe Generate descriptive statistics of Series.

Series.memory_usage Memory usage of Series.

Examples

>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> s = pd.Series(text_values, index=int_values)
>>> s.info()
<class 'pandas.core.series.Series'>
Int64Index: 5 entries, 1 to 5
Series name: None
Non-Null Count  Dtype
------------- ----
5 non-null   object
dtypes: object(1)
memory usage: 80.0+ bytes

Prints a summary excluding information about its values:

>>> s.info(verbose=False)
<class 'pandas.core.series.Series'>
Int64Index: 5 entries, 1 to 5
dtypes: object(1)
memory usage: 80.0+ bytes

Pipe output of Series.info to buffer instead of sys.stdout, get buffer content and writes to a text file:
The `memory_usage` parameter allows deep introspection mode, specially useful for big Series and fine-tune memory optimization:

```python
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> s = pd.Series(np.random.choice(['a', 'b', 'c'], 10 ** 6))
>>> s.info()
<class 'pandas.core.series.Series'>
RangeIndex: 1000000 entries, 0 to 999999
Series name: None
Non-Null Count   Dtype
             1000000 non-null object
dtypes: object(1)
memory usage: 7.6+ MB

>>> s.info(memory_usage='deep')
<class 'pandas.core.series.Series'>
RangeIndex: 1000000 entries, 0 to 999999
Series name: None
Non-Null Count   Dtype
             1000000 non-null object
dtypes: object(1)
memory usage: 55.3 MB
```

**pandas.Series.interpolate**

The `Series.interpolate` method fills NaN values using an interpolation method.

**Parameters**

- **method** [str, default ‘linear’] Interpolation technique to use. One of:
  - ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
  - ‘index’, ‘values’: use the actual numerical values of the index.
  - ‘pad’: Fill in NaNs using existing values.
pandas: powerful Python data analysis toolkit, Release 1.4.1

- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).

- ‘from_derivatives’: Refers to scipy.interpolate.BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{‘forward’, ‘backward’, ‘both’}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:
- If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
- If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:
- If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
- else the default is ‘forward’
