Anguilla  11300
Iceland  337000
dtype: int64
```

The $n$ smallest elements where $n=3$. Default keep value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)
Montserrat  5200
Nauru  11300
Tuvalu  11300
dtype: int64
```
The $n$ smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')
Montserrat  5200
Anguilla  11300
Tuvalu  11300
dtype: int64
```

The $n$ smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest(3, keep='all')
Montserrat  5200
Nauru  11300
Tuvalu  11300
Anguilla  11300
dtype: int64
```

**pandas.Series.nunique**

`Series.nunique(dropna=True)`

Return number of unique elements in the object.

Excludes NA values by default.

**Parameters**

- `dropna` [bool, default True] Don’t include NaN in the count.

**Returns**

- `int`

**See also:**

- `DataFrame.nunique` Method `nunique` for DataFrame.
- `Series.count` Count non-NA/null observations in the Series.

**Examples**

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```
pandas.Series.pad

Series.pad(axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='ffill'.

Returns

Series/DataFrame or None  Object with missing values filled or None if inplace=True.

pandas.Series.pct_change

Series.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

- **periods** [int, default 1] Periods to shift for forming percent change.
- **fill_method** [str, default 'pad'] How to handle NAs before computing percent changes.
- **limit** [int, default None] The number of consecutive NAs to fill before stopping.
- **freq** [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).

**kwargs Additional keyword arguments are passed into DataFrame.shift or Series.shift.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

Series.diff  Compute the difference of two elements in a Series.
DataFrame.diff  Compute the difference of two elements in a DataFrame.
Series.shift  Shift the index by some number of periods.
DataFrame.shift  Shift the index by some number of periods.

Examples

Series

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64
```
See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351],
...     index=['GOOG', 'APPL'])
>>> df
   2016  2015  2014
GOOG  1769950 1500923 1371819
APPL  30586265 40912316 41403351

>>> df.pct_change(axis='columns', periods=-1)
   2016  2015     2014
GOOG  0.179241 0.094112   NaN
APPL -0.252395 -0.011860   NaN

pandas.Series.pipe

Series.pipe(func, *args, **kwargs)

Apply chainable functions that expect Series or DataFrames.

Parameters

    func [function] Function to apply to the Series/DataFrame. args and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Series/DataFrame.

    args [iterable, optional] Positional arguments passed into func.

    kwargs [mapping, optional] A dictionary of keyword arguments passed into func.

Returns

    object [the return type of func.]

See also:

    DataFrame.apply Apply a function along input axis of DataFrame.
    DataFrame.applymap Apply a function elementwise on a whole DataFrame.
    Series.map Apply a mapping correspondence on a Series.

Notes

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

>>> func(g(h(df), arg1=a), arg2=b, arg3=c)

You can write

>>> (df.pipe(h)
...  .pipe(g, arg1=a)

(continues on next page)
If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose \( f \) takes its data as \( \arg2 \):

```python
gdf = df.pipe(h)
...  .pipe(g, arg1=a)
...  .pipe((func, 'arg2'), arg1=a, arg3=c)
```

### pandas.Series.plot

`Series.plot(*args, **kwargs)`

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

**Parameters**

- `data` [Series or DataFrame] The object for which the method is called.
- `x` [label or position, default None] Only used if data is a DataFrame.
- `y` [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.
- `kind` [str] The kind of plot to produce:
  - ‘line’: line plot (default)
  - ‘bar’: vertical bar plot
  - ‘barh’: horizontal bar plot
  - ‘hist’: histogram
  - ‘box’: boxplot
  - ‘kde’: Kernel Density Estimation plot
  - ‘density’: same as ‘kde’
  - ‘area’: area plot
  - ‘pie’: pie plot
  - ‘scatter’: scatter plot (DataFrame only)
  - ‘hexbin’: hexbin plot (DataFrame only)
- `ax` [matplotlib axes object, default None] An axes of the current figure.
- `subplots` [bool, default False] Make separate subplots for each column.
- `sharex` [bool, default True if ax is None else False] In case `subplots=True`, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and `sharex=True` will alter all x axis labels for all axis in a figure.
- `sharey` [bool, default False] In case `subplots=True`, share y axis and set some y axis labels to invisible.
layout [tuple, optional] (rows, columns) for the layout of subplots.

figsize [a tuple (width, height) in inches] Size of a figure object.

use_index [bool, default True] Use index as ticks for x axis.

title [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and subplots is True, print each item in the list above the corresponding subplot.

grid [bool, default None (matlab style default)] Axis grid lines.

legend [bool or {'reverse'}] Place legend on axis subplots.

style [list or dict] The matplotlib line style per column.

logx [bool or 'sym', default False] Use log scaling or symlog scaling on x axis. .. version-changed:: 0.25.0

logy [bool or 'sym' default False] Use log scaling or symlog scaling on y axis. .. version-changed:: 0.25.0

loglog [bool or 'sym', default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

xticks [sequence] Values to use for the xticks.

yticks [sequence] Values to use for the yticks.

xlim [2-tuple/list] Set the x limits of the current axes.

ylim [2-tuple/list] Set the y limits of the current axes.

xlabel [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel, or the x-column name for planar plots.

    New in version 1.1.0.

    Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel, or the y-column name for planar plots.

    New in version 1.1.0.

    Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

fontsize [int, default None] Font size for xticks and yticks.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

colorbar [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

yerr [DataFrame, Series, array-like, dict and str] See Plotting with Error Bars for detail.

xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.
stacked [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

sort_columns [bool, default False] Sort column names to determine plot ordering.

secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

include_bool [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

**kwargs Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

• See matplotlib documentation online for more on this subject
• If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.Series.pop

Series.pop(item)

Return item and drops from series. Raise KeyError if not found.

Parameters

item [label] Index of the element that needs to be removed.

Returns

Value that is popped from series.

Examples

```python
>>> ser = pd.Series([1,2,3])

>>> ser.pop(0)
1
```

```text
>>> ser
1 2
2 3
dtype: int64
```
pandas.Series.pow

Series.pow(other, level=None, fill_value=None, axis=0)

Return Exponential power of series and other, element-wise (binary operator pow).

Equivalent to series ** other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other  [Series or scalar value]

fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level  [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series  The result of the operation.

See also:

Series.rpow  Reverse of the Exponential power operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
>>> a.pow(b, fill_value=0)
           a         b
a   1.000000  1.000000
b   1.000000 NaN          
c   1.000000  1.000000
d   NaN        NaN
```

pandas.Series.prod

Series.prod(axis=None, skipna=True, level=None, numeric_only=None, min_count=0, **kwargs)
Return the product of the values over the requested axis.

Parameters

- axis [(index (0))] Axis for the function to be applied on.
- skipna [bool, default True] Exclude NA/null values when computing the result.
- level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**kwargs Additional keyword arguments to be passed to the function.

Returns
scalar or Series (if level specified)

See also:

- Series.sum Return the sum.
- Series.min Return the minimum.
- Series.max Return the maximum.
- Series.idxmin Return the index of the minimum.
- Series.idxmax Return the index of the maximum.
- DataFrame.sum Return the sum over the requested axis.
- DataFrame.min Return the minimum over the requested axis.
- DataFrame.max Return the maximum over the requested axis.
- DataFrame.idxmin Return the index of the minimum over the requested axis.
- DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the min_count parameter

```
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.
pandas.Series.product

Series.product(axis=None, skipna=True, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values over the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**kwargs Additional keyword arguments to be passed to the function.

Returns

 scalar or Series (if level specified)

See also:

Series.sum Return the sum.
Series.min Return the minimum.
Series.max Return the maximum.
Series.idxmin Return the index of the minimum.
Series.idxmax Return the index of the maximum.
DataFrame.sum Return the sum over the requested axis.
DataFrame.min Return the minimum over the requested axis.
DataFrame.max Return the maximum over the requested axis.
DataFrame.idxmin Return the index of the minimum over the requested axis.
DataFrame.idxmax Return the index of the maximum over the requested axis.
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

### pandas.Series.quantile

`Series.quantile(q=0.5, interpolation='linear')`

Return value at the given quantile.

**Parameters**

- **q** [float or array-like, default 0.5 (50% quantile)] The quantile(s) to compute, which can lie in range: 0 <= q <= 1.
- **interpolation** [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:
  - linear: i + (j - i) * fraction, where fraction is the fractional part of the index surrounded by i and j.
  - lower: i.
  - higher: j.
  - nearest: i or j whichever is nearest.
  - midpoint: (i + j) / 2.

**Returns**

- float or Series If q is an array, a Series will be returned where the index is q and the values are the quantiles, otherwise a float will be returned.

**See also:**

- `core.window.Rolling.quantile` Calculate the rolling quantile.
- `numpy.percentile` Returns the q-th percentile(s) of the array elements.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25 1.75
0.50 2.50
0.75 3.25
dtype: float64
```

pandas.Series.radd

Series.radd(other, level=None, fill_value=None, axis=0)

Return Addition of series and other, element-wise (binary operator radd).

Equivalent to other + series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.add Element-wise Addition, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
```
```python
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

**pandas.Series.rank**

`Series.rank(axis=0, method='average', numeric_only=NoDefault.no_default, na_option='keep', ascending=True, pct=False)`

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

**Parameters**

- `axis` [(0 or ‘index’, 1 or ‘columns’), default 0] Index to direct ranking.
- `method` [‘average’, ‘min’, ‘max’, ‘first’, ‘dense’], default ‘average’] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups.
- `numeric_only` [bool, optional] For DataFrame objects, rank only numeric columns if set to True.
- `na_option` [‘keep’, ‘top’, ‘bottom’], default ‘keep’] How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign lowest rank to NaN values
  - bottom: assign highest rank to NaN values
- `ascending` [bool, default True] Whether or not the elements should be ranked in ascending order.
- `pct` [bool, default False] Whether or not to display the returned rankings in percentile form.

**Returns**

- same type as caller Return a Series or DataFrame with data ranks as values.

**See also:**

- `core.groupby.GroupBy.rank` Rank of values within each group.
Examples

```python
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog', 'spider', 'snake'], 'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
   Animal  Number_legs
0      cat         4.0
1  penguin       2.0
2      dog         4.0
3   spider         8.0
4     snake        NaN

The following example shows how the method behaves with the above parameters:

• default_rank: this is the default behaviour obtained without using any parameter.

• max_rank: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)

• NA_bottom: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.

• pct_rank: when setting `pct = True`, the ranking is expressed as percentile rank.
```
```python
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
```
```python
>>> df
   Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0      cat         4.0          2.5        3.0      2.5      0.625
1  penguin       2.0          1.0        1.0      1.0      0.250
2      dog         4.0          2.5        3.0      2.5      0.625
3   spider         8.0          4.0        4.0      4.0      1.000
4     snake        NaN          NaN        NaN      5.0      NaN
```

pandas.Series.ravel

Series.ravel(order='C')

Return the flattened underlying data as an ndarray.

Returns

numpy.ndarray or ndarray-like Flattened data of the Series.

See also:

numpy.ndarray.ravel Return a flattened array.
pandas.Series.rdiv

Series.rdiv(other, level=None, fill_value=None, axis=0)
Return Floating division of series and other, element-wise (binary operator rtruediv).
Equivalent to other / series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters
other  [Series or scalar value]
fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level  [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns
Series  The result of the operation.

See also:
Series.truediv  Element-wise Floating division, see Python documentation for more details.

Examples
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a     1.0
b     1.0
c     1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a     1.0
b    NaN
d     1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a     1.0
b     inf
c     inf
d     0.0
e    NaN
dtype: float64
pandas.Series.rdivmod

Series.rdivmod(other, level=None, fill_value=None, axis=0)

Return integer division and modulo of series and other, element-wise (binary operator \texttt{rdivmod}). Equivalent to \texttt{other divmod series}, but with support to substitute a \texttt{fill_value} for missing data in either one of the inputs.

**Parameters**

- \texttt{other} [Series or scalar value]
- \texttt{fill_value} [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- \texttt{level} [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

2-Tuple of Series The result of the operation.

**See also:**

\texttt{Series.divmod} Element-wise integer division and modulo, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64

>>> a.divmod(b, fill_value=0)
(a 1.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64,
a 0.0
b NaN
c NaN
d 0.0
)```

(continues on next page)
pandas.Series.reindex

Series.reindex(*args, **kwargs)

Conform Series to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **index** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.
- **method** [[None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’]] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: Propagate last valid observation forward to next valid.
  - backfill / bfill: Use next valid observation to fill gap.
  - nearest: Use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.
- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
- **limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.
  
  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

Series with changed index.

**See also:**

- **DataFrame.set_index** Set row labels.
- **DataFrame.reset_index** Remove row labels or move them to new columns.
- **DataFrame.reindex_like** Change to same indices as other DataFrame.
Examples

DataFrame.reindex supports two calling conventions

• (index=index_labels, columns=column_labels, ...)

• (labels, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                   index=index)
>>> df
   http_status  response_time
Firefox       200          0.04
Chrome        200          0.02
Safari        404          0.07
IE10          404          0.08
Konqueror     301          1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10', 'Chrome']
>>> df.reindex(new_index)
   http_status  response_time
Safari       404.0          0.07
Iceweasel    NaN            NaN
Comodo Dragon NaN            NaN
IE10         404.0          0.08
Chrome       200.0          0.02
```

We can fill in the missing values by passing a value to the keyword fill_value. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
   http_status  response_time
Safari       404        0.07
Iceweasel    0         0.00
Comodo Dragon 0         0.00
IE10         404        0.08
Chrome       200        0.02
```

```python
>>> df.reindex(new_index, fill_value='missing')
   http_status  response_time
Safari       404        0.07
Iceweasel    missing   missing
Comodo Dragon missing   missing
IE10         404        0.08
Chrome       200        0.02
```
We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
  http_status  user_agent
Firefox          200   NaN
  Chrome          200   NaN
Safari           404   NaN
  IE10            404   NaN
Konqueror        301   NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex([['http_status', 'user_agent'], axis="columns")
  http_status  user_agent
Firefox          200   NaN
  Chrome          200   NaN
Safari           404   NaN
  IE10            404   NaN
Konqueror        301   NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({'prices': [100, 101, np.nan, 100, 89, 88]},
                    index=date_index)
>>> df2
   prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03  NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
   prices
2009-12-29  NaN
2009-12-30  NaN
2009-12-31  NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03  NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07  NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to
the method keyword.

```python
>>> df2.reindex(date_index2, method='bfill')
prices
2009-12-29   100.0
2009-12-30   100.0
2009-12-31   100.0
2010-01-01   100.0
2010-01-02   101.0
2010-01-03   NaN
2010-01-04   100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the user guide for more.

**pandas.Series.reindex_like**

Series.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.

- **method** [{None, ‘backfill’/‘bfill’, ‘pad’/‘ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap.

- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.

- **limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.
  
  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,
array, Series, and must be the same size as the index and its dtype must exactly match
the index’s type.

Returns

Series or DataFrame  Same type as caller, but with changed indices on each axis.

See also:

DataFrame.set_index  Set row labels.
DataFrame.reset_index  Remove row labels or move them to new columns.
DataFrame.reindex  Change to new indices or expand indices.

Notes

Same as calling .reindex(index=other.index, columns=other.columns,...).

Examples

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
    ...  [31, 87.8, 'high'],
    ...  [22, 71.6, 'medium'],
    ...  [35, 95, 'medium']],
    ...  columns=['temp_celsius', 'temp_fahrenheit',
    ...    'windspeed'],
    ...  index=pd.date_range(start='2014-02-12',
    ...    end='2014-02-15', freq='D'))

>>> df2
    temp_celsius  temp_fahrenheit  windspeed
2014-02-12   28.0            80.0       low
2014-02-13   30.0            86.0       low
2014-02-15   35.1            95.0       medium

>>> df2 = pd.DataFrame([[28, 'low'],
    ...  [30, 'low'],
    ...  [35.1, 'medium']],
    ...  columns=['temp_celsius', 'windspeed'],
    ...  index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
    ... '2014-02-15']))

>>> df2
    temp_celsius  windspeed
2014-02-12   28.0      low
2014-02-13   30.0      low
2014-02-15   35.1    medium

>>> df2.reindex_like(df1)
    temp_celsius  temp_fahrenheit  windspeed
2014-02-12   28.0            NaN      low
```

(continues on next page)
pandas.Series.rename

Series.rename(index=None, *, axis=None, copy=True, inplace=False, level=None, errors='ignore')

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

Alternatively, change Series.name with a scalar value.

See the user guide for more.

Parameters

axis [{0 or “index”}] Unused. Accepted for compatibility with DataFrame method only.

index [scalar, hashable sequence, dict-like or function, optional] Functions or dict-like are transformations to apply to the index. Scalar or hashable sequence-like will alter the Series.name attribute.

**kwargs Additional keyword arguments passed to the function. Only the “inplace” keyword is used.

Returns

Series or None Series with index labels or name altered or None if inplace=True.

See also:

DataFrames rename Corresponding DataFrame method.

Series.rename_axis Set the name of the axis.

Examples

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0 1
1 2
2 3
dtype: int64
>>> s.rename("my_name")  # scalar, changes Series.name
0 1
1 2
2 3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2)  # function, changes labels
0 1
1 2
4 3
dtype: int64
```
pandas.Series.rename_axis

Series.rename_axis(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)

Set the name of the axis for the index or columns.

Parameters

- mapper [scalar, list-like, optional] Value to set the axis name attribute.
- index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis’ values. Note that the columns parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.
  
  Use either mapper and axis to specify the axis to target with mapper, or index and/or columns.

- axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to rename.
- copy [bool, default True] Also copy underlying data.
- inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if inplace=True.

See also:

Series.rename Alter Series index labels or name.
DataFrame.rename Alter DataFrame index labels or name.
Index.rename Set new names on index.

Notes

DataFrame.rename_axis supports two calling conventions

- (index=index_mapper, columns=columns_mapper, …)
- (mapper, axis={‘index’, ‘columns’}, …)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter copy is ignored.

The second calling convention will modify the names of the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis labels.

We highly recommend using keyword arguments to clarify your intent.
Examples

Series

```python
>>> s = pd.Series(['dog', 'cat', 'monkey'])
>>> s
0    dog
1    cat
2  monkey
dtype: object
>>> s.rename_axis("animal")
animal
0    dog
1    cat
2  monkey
dtype: object
```

Dataframe

```python
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                     "num_arms": [0, 0, 2],
...                     ["dog", "cat", "monkey"]})
>>> df
num_legs num_arms
dog     4      0
cat     4      0
monkey  2      2
>>> df = df.rename_axis("animal")
>>> df
num_legs num_arms
animal
dog     4      0
cat     4      0
monkey  2      2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs num_legs num_arms
animal
dog     4      0
cat     4      0
monkey  2      2
```

MultiIndex

```python
>>> df.index = pd.MultiIndex.from_product([['mammal'], ['dog', 'cat', 'monkey']], names=['type', 'name'])
>>> df
limbs num_legs num_arms
type name
mammal dog     4      0
        cat     4      0
        monkey  2      2
```
```python
>>> df.rename_axis(index={'type': 'class'})
<table>
<thead>
<tr>
<th>limbs</th>
<th>num_legs</th>
<th>num_arms</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>name</td>
<td></td>
</tr>
<tr>
<td>mammal</td>
<td>dog</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>cat</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>monkey</td>
<td>2</td>
</tr>
</tbody>
</table>
```

```python
>>> df.rename_axis(columns=str.upper)
<table>
<thead>
<tr>
<th>LIMBS</th>
<th>num_legs</th>
<th>num_arms</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>name</td>
<td></td>
</tr>
<tr>
<td>mammal</td>
<td>dog</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>cat</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>monkey</td>
<td>2</td>
</tr>
</tbody>
</table>
```

**pandas.Series.reorder_levels**

`Series.reorder_levels(order)`

Rearrange index levels using input order.

May not drop or duplicate levels.

**Parameters**

- `order` [list of int representing new level order] Reference level by number or key.

**Returns**

- type of caller (new object)

**pandas.Series.repeat**

`Series.repeat(repeats, axis=None)`

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

**Parameters**

- `repeats` [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.

- `axis` [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

- `Series` Newly created Series with repeated elements.

**See also:**

- `Index.repeat` Equivalent function for Index.

- `numpy.repeat` Similar method for `numpy.ndarray`.  

3.3. Series
Examples

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0 a
1 b
2 c
dtype: object
>>> s.repeat(2)
0 a
0 a
1 b
1 b
2 c
2 c
dtype: object
>>> s.repeat([1, 2, 3])
0 a
1 b
1 b
2 c
2 c
2 c
dtype: object
```

**pandas.Series.replace**

`Series.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method=None)`

Replace values given in `to_replace` with `value`.

Values of the Series are replaced with other values dynamically.

This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

**Parameters**

- **to_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
  - numeric, str or regex:
    - numeric: numeric values equal to `to_replace` will be replaced with `value`
    - str: string exactly matching `to_replace` will be replaced with `value`
    - regex: regexes matching `to_replace` will be replaced with `value`
  - list of str, regex, or numeric:
    - First, if `to_replace` and `value` are both lists, they **must** be the same length.
    - Second, if `regex=True` then all of the strings in both lists will be interpreted as regexes otherwise they will match directly. This doesn’t matter much for `value` since there are only a few possible substitution regexes you can use.
    - str, regex and numeric rules apply as above.
dict:

- Dicts can be used to specify different replacement values for different existing values. For example, `{ 'a': 'b', 'y': 'z'}` replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the value parameter should be None.

- For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{ 'a': 1, 'b': 'z'}` looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in value. The value parameter should not be None in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.

- For a DataFrame nested dictionaries, e.g., `{ 'a': { 'b': np.nan}}`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The value parameter should be None to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) cannot be regular expressions.

None:

- This means that the regex argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If value is also None then this must be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching to_replace with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, performs operation inplace and returns None.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as to_replace, default False] Whether to interpret to_replace and/or value as regular expressions. If this is True then to_replace must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case to_replace must be None.

method [{‘pad’, ‘ffill’, ‘bfill’, None}] The method to use when for replacement, when to_replace is a scalar, list or tuple and value is None.

Changed in version 0.23.0: Added to DataFrame.

Returns

Series Object after replacement.

Raises

AssertionError

- If regex is not a bool and to_replace is not None.

TypeError

- If to_replace is not a scalar, array-like, dict, or None
- If to_replace is a dict and value is not a list, dict, ndarray, or Series
- If to_replace is None and regex is not compilable into a regular expression or is a list, dict, ndarray, or Series.
• When replacing multiple bool or datetime64 objects and the arguments to `to_replace` does not match the type of the value being replaced

`ValueError`

• If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

See also:

- `Series.fillna` Fill NA values.
- `Series.where` Replace values based on boolean condition.
- `Series.str.replace` Simple string replacement.

Notes

• Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When dict is used as the `to_replace` value, it is like key(s) in the dict are the `to_replace` part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s.replace(1, 5)
0    5
1    2
2    3
3    4
4    5
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
                    'B': [5, 6, 7, 8, 9],
                    'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
     A  B  C
0    5  5  a
1    1  6  b
2    2  7  c
3    3  8  d
4    4  9  e
```
List-like `to_replace`

```python
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```python
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```python
>>> s.replace([1, 2], method='bfill')
0  3  
1  3  
2  3  
3  4  
4  5  
dtype: int64
```

dict-like `to_replace`

```python
>>> df.replace({0: 10, 1: 100})
   A  B  C
0 10  5  a
1 100  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4 400  9  e
```

Regular expression `to_replace`
```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new  abc
1   foo  new
2  bait  xyz
```

```python
>>> df.replace({r'^ba.$': 'new'}, {'A': 'new'}, regex=True)
   A  B
0  new  abc
1   foo  bar
2  bait  xyz
```

```python
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new  abc
1   foo  new
2  bait  xyz
```

```python
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new  abc
1   xyz  new
2  bait  xyz
```

```
Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:
```
```
```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```
```
When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):
```
```
```python
>>> s.replace({'a': None})
0    10
1   None
2   None
3    b
4   None
dtype: object
```
```
When `value` is not explicitly passed and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default ‘pad’) to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case.
On the other hand, if `None` is explicitly passed for `value`, it will be respected:

```python
>>> s.replace('a', None)
0   10
1   None
2   None
3    b
4   None
dtype: object
```

Changed in version 1.4.0: Previously the explicit `None` was silently ignored.

### pandas.Series.resample

`Series.resample` function allows for frequency conversion and resampling of time series. The object must have a datetime-like index (`DatetimeIndex`, `PeriodIndex`, or `TimedeltaIndex`), or the caller must pass the label of a datetime-like series/index to the `on/level` keyword parameter.

**Parameters**

- **rule** `[DateOffset, Timedelta or str]` The offset string or object representing target conversion.
- **axis** `{0 or 'index', 1 or 'columns'}, default 0]` Which axis to use for up- or down-sampling. For `Series` this will default to 0, i.e. along the rows. Must be `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`.
- **label** `{‘right’, ‘left’}, default None]` Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.
- **convention** `{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For `PeriodIndex` only, controls whether to use the start or end of `rule`.
- **kind** `{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a `DateTimeIndex` or ‘period’ to convert it to a `PeriodIndex`. By default the input representation is retained.
- **loffset** `[timedelta, default None] Adjust the resampled time labels.
Andrews plots

Andrews [1] depicted a method for visualising multivariate data. The idea is to map a multivariate dataset onto a univariate function and then plot the dataset in one dimension.

For each point in the original dataset, a curve is created in the new space. The curves are parameterised by some parameter $\phi$, which is usually a subset of attribute or sample space.

The Andrews plot is constructed as follows:

1. Define a parameter $\phi$.
2. For each point $x_i$ in the original dataset, construct a curve $y_i(\phi) = \sum_{j=1}^{p} a_{ij} \sin((j-1)\phi)$.
3. Plot the curves in the new space.

The curves corresponding to the same point in the original dataset are connected, forming a closed curve.

### Debt-Rate Andrews Plots

Debt rate Andrews plots are a specific type of Andrews plot that are used to visualize the relationship between different countries' debt rates.

### Code Example

```python
import pandas as pd
import matplotlib.pyplot as plt

# Sample data
data = pd.DataFrame({'Country': ['US', 'Japan', 'China', 'Germany'], 'DebtRate': [1.2, 0.9, 1.5, 1.6]})

# Function to convert to Andrews plot
def to_andrews(data):
    phi = 2 * np.pi / len(data)
    x = np.arange(len(data))
    y = np.zeros(len(data))
    for i in range(len(data.columns) - 1):
        y += data.columns[i] * np.sin((i - 1) * phi * x)
    return x, y

# Plot the Andrews plot
x, y = to_andrews(data)
plt.plot(x, y, label='Debt Rate')
plt.xlabel('Parameter $\phi$')
plt.ylabel('Value')
plt.title('Debt Rate Andrews Plot')
plt.legend()
plt.show()
```

### Notes

- The parameter $\phi$ is a subset of the attribute or sample space.
- The curves corresponding to the same point in the original dataset are connected, forming a closed curve.
- Andrews plots are useful for visualising multivariate data in a univariate space.

See the [user guide](https://pandas.pydata.org/pandas-docs/stable/user_guide/visualization.html) for more.
Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
0   0
1   1
2   2
3   3
4   4
5   5
6   6
7   7
8   8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
```

(continues on next page)
Upsample the series into 30 second bins and fill the NaN values using the `pad` method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 0
2000-01-01 00:01:00 1
2000-01-01 00:01:30 1
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the `bfill` method.

```python
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 1
2000-01-01 00:01:00 1
2000-01-01 00:01:30 2
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Pass a custom function via `apply`

```python
>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
... >>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00 8
2000-01-01 00:03:00 17
2000-01-01 00:06:00 26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of `rule`.

Resample a year by quarter using `start` `convention`. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01', freq='A', periods=2))
>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1 1.0
2012Q2 NaN
2012Q3 NaN
2012Q4 NaN
2013Q1 2.0
```

(continues on next page)
Resample quarters by month using `end` convention. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
               freq='Q',
               periods=4))
>>> q
2018Q1 1
2018Q2 2
2018Q3 3
2018Q4 4
Freq: Q-DEC, dtype: int64
```

```python
>>> q.resample('M', convention='end').asfreq()
2018-03 1.0
2018-04 NaN
2018-05 NaN
2018-06 2.0
2018-07 NaN
2018-08 NaN
2018-09 3.0
2018-10 NaN
2018-11 NaN
2018-12 4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
       'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
                                      periods=8,
                                      freq='W')
>>> df
     price  volume week_starting
0     10     50 2018-01-07
1     11     60 2018-01-14
2     9     40 2018-01-21
3    13     100 2018-01-28
4    14     50 2018-02-04
5    18     100 2018-02-11
6    17     40 2018-02-18
7    19     50 2018-02-25
```

```python
>>> df.resample('M', on='week_starting').mean()
     price  volume
week_starting
2018-01-31  10.75  62.5
2018-02-28  17.00  60.0
```
For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
...      'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(
...    d2,
...    index=pd.MultiIndex.from_product([days, ['morning', 'afternoon']])
...)
```  
```shell
>>> df2
     price  volume
2000-01-01 morning    10     50
     afternoon    11     60
2000-01-02 morning     9     40
     afternoon    13    100
2000-01-03 morning    14     50
     afternoon    18    100
2000-01-04 morning    17     40
     afternoon    19     50
```  
```python
>>> df2.resample('D', level=0).sum()
     price  volume
2000-01-01      21    110
2000-01-02      22    140
2000-01-03      32    150
2000-01-04      36    90
```  
If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00     0
2000-10-01 23:37:00     3
2000-10-01 23:44:00     6
2000-10-01 23:51:00     9
2000-10-01 23:58:00    12
2000-10-02 00:05:00    15
2000-10-02 00:12:00    18
2000-10-02 00:19:00    21
2000-10-02 00:26:00    24
Freq: 7T, dtype: int64
```  
```shell
>>> ts.resample('17min').sum()
2000-10-01 23:14:00     0
2000-10-01 23:31:00     9
2000-10-01 23:48:00    21
2000-10-02 00:05:00    54
2000-10-02 00:22:00    24
Freq: 17T, dtype: int64
```
If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```
>>> ts.resample('17min', origin='2000-01-01').sum()
2000-10-01 23:24:00    3
2000-10-01 23:41:00    15
2000-10-01 23:58:00    45
2000-10-02 00:15:00    45
Freq: 17T, dtype: int64
```

If you want to take the largest Timestamp as the end of the bins:

```
>>> ts.resample('17min', origin='end').sum()
2000-10-01 23:38:00    3
2000-10-01 23:55:00    15
2000-10-02 00:12:00    45
2000-10-02 00:29:00    45
Freq: 17T, dtype: int64
```

In contrast with the start_day, you can use end_day to take the ceiling midnight of the largest Timestamp as the end of the bins and drop the bins not containing data:

```
>>> ts.resample('17min', origin='end_day').sum()
2000-10-01 23:35:00    0
2000-10-01 23:52:00    18
2000-10-02 00:09:00    27
2000-10-02 00:26:00    63
Freq: 17T, dtype: int64
```

To replace the use of the deprecated base argument, you can now use offset, in this example it is equivalent to have base=2:

```
>>> ts.resample('17min', origin='epoch').sum()
2000-10-01 23:18:00    0
2000-10-01 23:35:00    18
2000-10-01 23:52:00    27
2000-10-02 00:09:00    39
2000-10-02 00:26:00    24
Freq: 17T, dtype: int64
```

If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

If you want to take the largest Timestamp as the end of the bins:
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00   0
2000-10-01 23:33:00   9
2000-10-01 23:50:00  36
2000-10-02 00:07:00  39
2000-10-02 00:24:00  24
Freq: 17T, dtype: int64

To replace the use of the deprecated loffset argument:

>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
2000-10-01 23:33:00   0
2000-10-01 23:50:00   9
2000-10-02 00:07:00  21
2000-10-02 00:24:00  54
2000-10-02 00:41:00  24
Freq: 17T, dtype: int64

**pandas.Series.reset_index**

`Series.reset_index(level=None, drop=False, name=NoDefault.no_default, inplace=False)`

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

**Parameters**

- `level` [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.

- `drop` [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.

- `name` [object, optional] The name to use for the column containing the original Series values. Uses `self.name` by default. This argument is ignored when `drop` is True.

**Returns**

Series or DataFrame or None When `drop` is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When `drop` is True, a Series is returned. In either case, if `inplace=True`, no value is returned.

**See also:**

*DataFrame.reset_index* Analogous function for DataFrame.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4], name='foo',
                index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))
```

Generate a DataFrame with default index.

```python
>>> s.reset_index()
   idx  foo
0   a   1
1   b   2
2   c   3
3   d   4
```

To specify the name of the new column use `name`.

```python
>>> s.reset_index(name='values')
   idx  values
0   a     1
1   b     2
2   c     3
3   d     4
```

To generate a new Series with the default set `drop` to True.

```python
>>> s.reset_index(drop=True)
  0  1
  1  2
  2  3
  3  4
Name: foo, dtype: int64
```

To update the Series in place, without generating a new one set `inplace` to True. Note that it also requires `drop=True`.

```python
>>> s.reset_index(inplace=True, drop=True)
```

```python
>>> s
  0  1
  1  2
  2  3
  3  4
Name: foo, dtype: int64
```

The `level` parameter is interesting for Series with a multi-level index.

```python
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
            np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(range(4), name='foo',
                 index=pd.MultiIndex.from_arrays(arrays,
                 names=['a', 'b']))
```

To remove a specific level from the Index, use `level`.
```python
>>> s2.reset_index(level='a')
   a  foo
   b
   one  bar  0
   two  bar  1
   one  baz  2
   two  baz  3
```

If **level** is not set, all levels are removed from the Index.

```python
>>> s2.reset_index()
   a  b  foo
   0  bar  one  0
   1  bar  two  1
   2  baz  one  2
   3  baz  two  3
```

---

**pandas.Series.rfloordiv**

*Series.rfloordiv*(other, level=None, fill_value=None, axis=0)

Return Integer division of series and other, element-wise (binary operator \textit{rfloordiv}).

Equivalent to \texttt{other \div series}, but with support to substitute a \texttt{fill_value} for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

*Series* The result of the operation.

**See also:**

*Series.floordiv* Element-wise Integer division, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
```
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])

>>> a.floordiv(b, fill_value=0)

a 1.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64

**pandas.Series.rmod**

Series.rmod(other, level=None, fill_value=None, axis=0)

Return Modulo of series and other, element-wise (binary operator rmod).

Equivalent to other % series, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]

- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

Series The result of the operation.

**See also:**

Series.mod Element-wise Modulo, see Python documentation for more details.

**Examples**

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])

>>> a

a 1.0
b 1.0
c 1.0
d NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

>>> b
a   1.0
b   NaN
d   1.0
e   NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a   0.0
b   NaN
c   NaN
d   0.0
e   NaN
dtype: float64

pandas.Series.rmul

Series.rmul(other, level=None, fill_value=None, axis=0)

Return Multiplication of series and other, element-wise (binary operator rmul).

Equivalent to other * series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.mul Element-wise Multiplication, see Python documentation for more details.

Examples

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a   1.0
b   1.0
c   1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
(continues on next page)
pandas.Series.rolling

Series.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None, method='single')

Provide rolling window calculations.

Parameters

- **window** [int, offset, or BaseIndexer subclass] Size of the moving window.
  If an integer, the fixed number of observations used for each window.
  If an offset, the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. To learn more about the offsets & frequency strings, please see this link.
  If a BaseIndexer subclass, the window boundaries based on the defined get_window_bounds method. Additional rolling keyword arguments, namely min_periods, center, and closed will be passed to get_window_bounds.

- **min_periods** [int, default None] Minimum number of observations in window required to have a value; otherwise, result is np.nan.
  For a window that is specified by an offset, min_periods will default to 1.
  For a window that is specified by an integer, min_periods will default to the size of the window.

- **center** [bool, default False] If False, set the window labels as the right edge of the window index.
  If True, set the window labels as the center of the window index.

- **win_type** [str, default None] If None, all points are evenly weighted.
  If a string, it must be a valid scipy.signal window function.
  Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature.

- **on** [str, optional] For a DataFrame, a column label or Index level on which to calculate the rolling window, rather than the DataFrame’s index.
Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

**axis** [int or str, default 0] If 0 or 'index', roll across the rows.

  If 1 or 'columns', roll across the columns.

**closed** [str, default None] If 'right', the first point in the window is excluded from calculations.

  If 'left', the last point in the window is excluded from calculations.

  If 'both', the no points in the window are excluded from calculations.

  If 'neither', the first and last points in the window are excluded from calculations.

  Default None ('right').

  Changed in version 1.2.0: The closed parameter with fixed windows is now supported.

**method** [str {'single', 'table'}, default 'single'] New in version 1.3.0.

  Execute the rolling operation per single column or row ('single') or over the entire object ('table').

  This argument is only implemented when specifying engine='numba' in the method call.

**Returns**

  Window subclass if a win_type is passed

  Rolling subclass if win_type is not passed

**See also:**

expanding Provides expanding transformations.

ewm Provides exponential weighted functions.

**Notes**

See Windowing Operations for further usage details and examples.

**Examples**

```python
>>> df = pd.DataFrame({\'B\': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

window

Rolling sum with a window length of 2 observations.
Rolling sum with a window span of 2 seconds.

```
>>> df_time = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                         index=[pd.Timestamp('20130101 09:00:00'),
                                pd.Timestamp('20130101 09:00:02'),
                                pd.Timestamp('20130101 09:00:03'),
                                pd.Timestamp('20130101 09:00:05'),
                                pd.Timestamp('20130101 09:00:06')])
```

```
>>> df_time
B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

```
>>> df_time.rolling('2s').sum()  
```

```
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

Rolling sum with forward looking windows with 2 observations.

```
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)  
>>> df.rolling(window=indexer, min_periods=1).sum()  
```

```
B
0 1.0
1 3.0
2 2.0
3 4.0
4 4.0
```

**min_periods**

Rolling sum with a window length of 2 observations, but only needs a minimum of 1 observation to calculate a value.

```
>>> df.rolling(2, min_periods=1).sum()  
```

```
B
0 0.0
1 1.0
```

(continues on next page)
center

Rolling sum with the result assigned to the center of the window index.

```python
>>> df.rolling(3, min_periods=1, center=True).sum()
   B
0  1.0
1  3.0
2  3.0
3  6.0
4  4.0
```

```python
>>> df.rolling(3, min_periods=1, center=False).sum()
   B
0  0.0
1  1.0
2  3.0
3  3.0
4  6.0
```

**win_type**

Rolling sum with a window length of 2, using the Scipy 'gaussian' window type. `std` is required in the aggregation function.

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
   B
0   NaN
1  0.986207
2  2.958621
3   NaN
4   NaN
```

**pandas.Series.round**

```python
Series.round(decimals=0, *args, **kwargs)
```

Round each value in a Series to the given number of decimals.

**Parameters**

- **decimals** [int, default 0] Number of decimal places to round to. If decimals is negative, it specifies the number of positions to the left of the decimal point.
- ***args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **Series** Rounded values of the Series.

**See also**
numpy.around  Round values of an np.array.

DataFrames.round  Round values of a DataFrame.

Examples

```python
>>> s = pd.Series([0.1, 1.3, 2.7])
>>> s.round()
0   0.0
1   1.0
2   3.0
dtype: float64
```

pandas.Series.pow

Series.pow(other, level=None, fill_value=None, axis=0)

Return Exponential power of series and other, element-wise (binary operator rpow).

Equivalent to other ** series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other  [Series or scalar value]

fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level  [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series  The result of the operation.

See also:

Series.pow  Element-wise Exponential power, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a   1.0
b   1.0
c   1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a   1.0
b   NaN
```
```python
d  1.0
e  NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a  1.0
b  1.0
c  1.0
d  0.0
e  NaN
dtype: float64
```

**pandas.Series.rsub**

```
Series.rsub(other, level=None, fill_value=None, axis=0)
Return Subtraction of series and other, element-wise (binary operator rsub).
Equivalent to other - series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

  - *other* [Series or scalar value]
  - *fill_value* [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
  - *level* [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

  - *Series* The result of the operation.

See also:

  - *Series.sub* Element-wise Subtraction, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
```
"
pandas.Series.rtruediv

Series.rtruediv(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator rtruediv).

Equivalent to other / series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.truediv Element-wise Floating division, see Python documentation for more details.

Examples

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN

dtype: float64
pandas.Series.sample

Series.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None, ignore_index=False)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

Parameters

- **n** [int, optional] Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.

- **frac** [float, optional] Fraction of axis items to return. Cannot be used with n.

- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.

- **weights** [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

- **random_state** [int, array-like, BitGenerator, np.random.RandomState, np.random.Generator, optional] If int, array-like, or BitGenerator, seed for random number generator. If np.random.RandomState or np.random.Generator, use as given.

    Changed in version 1.1.0: array-like and BitGenerator object now passed to np.random.RandomState() as seed

    Changed in version 1.4.0: np.random.Generator objects now accepted

- **axis** [0 or ‘index’, 1 or ‘columns’, None], default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

- **ignore_index** [bool, default False] If True, the resulting index will be labeled 0, 1, …, n - 1.

    New in version 1.3.0.

Returns

- **Series or DataFrame** A new object of same type as caller containing n items randomly sampled from the caller object.
See also:

DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.

SeriesGroupBy.sample Generates random samples from each group of a Series object.

numpy.random.choice Generates a random sample from a given 1-D numpy array.

Notes

If frac > 1, replacement should be set to True.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                     'num_wings': [2, 0, 0, 0],
...                     'num_specimen_seen': [10, 2, 1, 8],
...                     index=['falcon', 'dog', 'spider', 'fish'])
>>> df
    num_legs num_wings num_specimen_seen
falcon     2       2           10
  dog       4       0            2
  spider    8       0            1
  fish      0       0            8
```

Extract 3 random elements from the Series df['num_legs']: Note that we use random_state to ensure the reproducibility of the examples.

```python
>>> df['num_legs'].sample(n=3, random_state=1)
    name
fish      0
spider   8
falcon   2
```

A random 50% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
    num_legs num_wings num_specimen_seen
  dog      4       0           2
  fish     0       0           8
```

An upsample sample of the DataFrame with replacement: Note that replace parameter has to be True for frac parameter > 1.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
    num_legs num_wings num_specimen_seen
  dog      4       0           2
  fish     0       0           8
  falcon   2       2           10
  falcon   2       2           10
  fish     0       0           8
  dog      4       0           2
  fish     0       0           8
  dog      4       0           2
```
Using a DataFrame column as weights. Rows with larger value in the `num_specimen_seen` column are more likely to be sampled.

```python
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
    num_legs num_wings num_specimen_seen
  falcon    2         2             10
    fish     0         0              8
```

**pandas.Series.searchsorted**

**Series.searchsorted** (*value, side='left', sorter=None*)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series `self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

**Note:** The Series must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

**Parameters**

- **value** [array-like or scalar] Values to insert into `self`.
- **side** [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or `N` (where `N` is the length of `self`).
- **sorter** [1-D array-like, optional] Optional array of integer indices that sort `self` into ascending order. They are typically the result of `np.argsort`.

**Returns**

- **int or array of int** A scalar or array of insertion points with the same shape as `value`.

**See also:**

- `sort_values` Sort by the values along either axis.
- `numpy.searchsorted` Similar method from NumPy.

**Notes**

Binary search is used to find the required insertion points.
Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0 1
1 2
2 3
dtype: int64
```

```python
>>> ser.searchsorted(4)
3
```

```python
>>> ser.searchsorted([0, 4])
array([0, 3])
```

```python
>>> ser.searchsorted([1, 3], side='left')
array([0, 2])
```

```python
>>> ser.searchsorted([1, 3], side='right')
array([1, 3])
```

```python
```  
```python
>>> ser
0 2000-03-11
1 2000-03-12
2 2000-03-13
dtype: datetime64[ns]
```

```python
>>> ser.searchsorted('3/14/2000')
3
```

```python
>>> ser = pd.Categorical(['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True)
```  
```python
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']
```

```python
>>> ser.searchsorted('bread')
1
```

```python
>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```python
>>> ser = pd.Series([2, 1, 3])
```  
```python
>>> ser
0 2
1 1
```
pandas.Series.sem

Series.sem(axis=None, skipna=True, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

- axis \[\{index (0)\}\]
- skipna \[bool, default True\] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- level \[int or level name, default None\] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- ddof \[int, default 1\] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- numeric_only \[bool, default None\] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

- scalar or Series (if level specified)

pandas.Series.set_axis

Series.set_axis(labels, axis=0, inplace=False)

Assign desired index to given axis.

Indexes for row labels can be changed by assigning a list-like or Index.

Parameters

- labels \[list-like, Index\] The values for the new index.
- axis \[\{0 or ‘index’\}, default 0\] The axis to update. The value 0 identifies the rows.
- inplace \[bool, default False\] Whether to return a new Series instance.

Returns

- renamed \[Series or None\] An object of type Series or None if inplace=True.

See also:

- Series.rename_axis Alter the name of the index.
Examples

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64

>>> s.set_axis(['a', 'b', 'c'], axis=0)
a    1
b    2
c    3
dtype: int64
```

**pandas.Series.set_flags**

`Series.set_flags(*, copy=False, allows_duplicate_labels=None)`

Return a new object with updated flags.

**Parameters**

- `allows_duplicate_labels` [bool, optional] Whether the returned object allows duplicate labels.

**Returns**

- `Series` or `DataFrame` The same type as the caller.

**See also:**

- `DataFrame.attrs` Global metadata applying to this dataset.
- `DataFrame.flags` Global flags applying to this object.

**Notes**

This method returns a new object that’s a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`.
Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags.allows_duplicate_labels
True
>>> df2 = df.set_flags(allows_duplicate_labels=False)
>>> df2.flags.allows_duplicate_labels
False
```

**pandas.Series.shift**

`Series.shift(periods=1, freq=None, axis=0, fill_value=None)`

Shift index by desired number of periods with an optional time `freq`.

When `freq` is not passed, shift the index without realigning the data. If `freq` is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the `freq`. `freq` can be inferred when specified as “infer” as long as either freq or inferred_freq attribute is set in the index.

**Parameters**

- `periods` [int] Number of periods to shift. Can be positive or negative.
- `freq` [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If `freq` is specified then the index values are shifted but the data is not realigned. That is, use `freq` if you would like to extend the index when shifting and preserve the original data. If `freq` is specified as “infer” then it will be inferred from the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.
- `axis` [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.
- `fill_value` [object, optional] The scalar value to use for newly introduced missing values. The default depends on the dtype of `self`. For numeric data, `np.nan` is used. For date-time, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

**Returns**

- `Series` Copy of input object, shifted.

**See also:**

- `Index.shift` Shift values of Index.
- `DatetimeIndex.shift` Shift values of DatetimeIndex.
- `PeriodIndex.shift` Shift values of PeriodIndex.
- `tshift` Shift the time index, using the index’s frequency if available.
Examples

```python
>>> df = pd.DataFrame({"Col1": [10, 20, 15, 30, 45],
... "Col2": [13, 23, 18, 33, 48],
... "Col3": [17, 27, 22, 37, 52]},
... index=pd.date_range("2020-01-01", "2020-01-05"))
>>> df
                   Col1  Col2  Col3
2020-01-01       10     13    17
2020-01-02       20     23    27
2020-01-03       15     18    22
2020-01-04       30     33    37
2020-01-05       45     48    52
```

```python
>>> df.shift(periods=3)
                   Col1  Col2  Col3
2020-01-01      NaN   NaN    NaN
2020-01-02      NaN   NaN    NaN

```

(continues on next page)
**pandas.Series.skew**

Series.skew(*axis=NoDefault.no_default, skipna=True, level=None, numeric_only=None, **kwargs*)

Return unbiased skew over requested axis. Normalized by N-1.

**Parameters**

- *axis* ([index (0)]) Axis for the function to be applied on.
- *skipna* [bool, default True] Exclude NA/null values when computing the result.
- *level* [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- *numeric_only* [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

scalar or Series (if level specified)

**pandas.Series.slice_shift**

Series.slice_shift(*periods=1, axis=0*)

Equivalent to shift without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: slice_shift is deprecated, use DataFrame/Series.shift instead.

**Parameters**

- *periods* [int] Number of periods to move, can be positive or negative.

**Returns**

shifted [same type as caller]

**Notes**

While the slice_shift is faster than shift, you may pay for it later during alignment.
pandas.Series.sort_index

Series.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)

Sort Series by index labels.

Returns a new Series sorted by label if inplace argument is False, otherwise updates the original series and returns None.

Parameters

- **axis** [int, default 0] Axis to direct sorting. This can only be 0 for Series.
- **level** [int, optional] If not None, sort on values in specified index level(s).
- **ascending** [bool or list-like of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** [{‘first’, ‘last’}, default ‘last’] If ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end. Not implemented for MultiIndex.
- **sort_remaining** [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
  
  New in version 1.0.0.
- **key** [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.
  
  New in version 1.1.0.

Returns

- **Series or None** The original Series sorted by the labels or None if inplace=True.

See also:

- **DataFrame.sort_index** Sort DataFrame by the index.
- **DataFrame.sort_values** Sort DataFrame by the value.
- **Series.sort_values** Sort Series by the value.
Examples

```python
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1    c
2    b
3    a
4    d
dtype: object
```

Sort Descending

```python
>>> s.sort_index(ascending=False)
4    d
3    a
2    b
1    c
dtype: object
```

Sort Inplace

```python
>>> s.sort_index(inplace=True)
>>> s
1    c
2    b
3    a
4    d
```

By default NaNs are put at the end, but use `na_position` to place them at the beginning

```python
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
NaN    d
1.0    c
2.0    b
3.0    a
dtype: object
```

Specify index level to sort

```python
>>> arrays = np.array([['qux', 'qux', 'foo', 'foo',
...                     'baz', 'baz', 'bar', 'bar'],
...                     np.array([['two', 'one', 'two', 'one',
...                               'two', 'one', 'two', 'one']])])
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
>>> s.sort_index(level=1)
bar  one  8
baz  one  6
foo  one  4
qux  one  2
bar  two  7
baz  two  5
foo  two  3
```
Does not sort by remaining levels when sorting by levels

```python
>>> s.sort_index(level=1, sort_remaining=False)
qux one  2
foo one  4
baz one  6
bar one  8
qux two  1
foo two  3
baz two  5
bar two  7
dtype: int64
```

Apply a key function before sorting

```python
>>> s = pd.Series([1, 2, 3, 4], index=['A', 'b', 'C', 'd'])
>>> s.sort_index(key=lambda x: x.str.lower())
A    1
b    2
C    3
d    4
dtype: int64
```

### pandas.Series.sort_values

`Series.sort_values(axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False, key=None)`

Sort by the values.

Sort a Series in ascending or descending order by some criterion.

**Parameters**

- `axis` [{0 or ‘index’}, default 0] Axis to direct sorting. The value ‘index’ is accepted for compatibility with DataFrame.sort_values.
- `ascending` [bool or list of bools, default True] If True, sort values in ascending order, otherwise descending.
- `inplace` [bool, default False] If True, perform operation in-place.
- `kind` [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms.
- `na_position` [{‘first’ or ‘last’}, default ‘last’] Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.
- `ignore_index` [bool, default False] If True, the resulting axis will be labeled 0, 1, …, n - 1.

New in version 1.0.0.
key [callable, optional] If not None, apply the key function to the series values before sorting. This is similar to the key argument in the builtin \texttt{sorted()} function, with the notable difference that this \texttt{key} function should be \textit{vectorized}. It should expect a \texttt{Series} and return an array-like.

New in version 1.1.0.

Returns

Series or None Series ordered by values or None if \texttt{inplace=True}.

See also:

\texttt{Series.sort_index} Sort by the Series indices.

\texttt{DataFrame.sort_values} Sort DataFrame by the values along either axis.

\texttt{DataFrame.sort_index} Sort DataFrame by indices.

Examples

```python
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0    NaN
1     1.0
2     3.0
3    10.0
4     5.0
dtype: float64
```

Sort values ascending order (default behaviour)

```python
>>> s.sort_values(ascending=True)
1     1.0
2     3.0
4     5.0
3    10.0
0    NaN
dtype: float64
```

Sort values descending order

```python
>>> s.sort_values(ascending=False)
3   10.0
4     5.0
2     3.0
1     1.0
0    NaN
dtype: float64
```

Sort values inplace

```python
>>> s.sort_values(ascending=False, inplace=True)
>>> s
3   10.0
4     5.0
```

(continues on next page)
Sort values putting NAs first

```python
>>> s.sort_values(na_position='first')
0   NaN
1  1.0
2  3.0
4  5.0
3 10.0
dtype: float64
```

Sort a series of strings

```python
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0    z
1    b
2    d
3    a
4    c
dtype: object

>>> s.sort_values()
3    a
1    b
4    c
2    d
0    z
dtype: object
```

Sort using a key function. Your key function will be given the Series of values and should return an array-like.

```python
>>> s = pd.Series(['a', 'B', 'c', 'D', 'e'])
>>> s.sort_values()
1    B
3    D
0    a
2    c
4    e
dtype: object

>>> s.sort_values(key=lambda x: x.str.lower())
0    a
1    B
2    c
3    D
4    e
dtype: object
```
NumPy ufuncs work well here. For example, we can sort by the $\sin$ of the value

```python
>>> s = pd.Series([-4, -2, 0, 2, 4])
>>> s.sort_values(key=np.sin)
  1   -2
  4    4
  2    0
  0   -4
  3    2
dtype: int64
```

More complicated user-defined functions can be used, as long as they expect a Series and return an array-like

```python
>>> s.sort_values(key=lambda x: (np.tan(x.cumsum())))
  0   -4
  3    2
  4    4
  1   -2
  2    0
dtype: int64
```

**pandas.Series.sparse**

Series.sparse()  
Accessor for SparseSparse from other sparse matrix data types.

**pandas.Series.squeeze**

Series.squeeze(axis=None)  
Squeeze 1 dimensional axis objects into scalars.  
Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.  
This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call squeeze to ensure you have a Series.

**Parameters**

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

**Returns**

DataFrame, Series, or scalar  The projection after squeezing axis or all the axes.

**See also:**

Series.iloc  Integer-location based indexing for selecting scalars.

DataFrame.iloc  Integer-location based indexing for selecting Series.

Series.to_frame  Inverse of DataFrame.squeeze for a single-column DataFrame.
Examples

```python
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```python
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0 2
dtype: int64
```  

```python
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```python
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1 3
2 5
3 7
dtype: int64
```  

```python
>>> odd_primes.squeeze()
1 3
2 5
3 7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0 1  2
1 3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
>>> df_a = df['a']
>>> df_a
   a
0 1
1 3
```

So the columns can be squeezed down, resulting in a Series:

```python
>>> df_a.squeeze('columns')
0 1
1 3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:
Squeezing the rows produces a single scalar Series:

```python
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a.squeeze('rows')
a  1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```python
>>> df_0a.squeeze()
1
```

### pandas.Series.std

`Series.std(axis=None, skipna=True, level=None, ddof=1, numeric_only=None, **kwargs)`

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- **axis** [{index (0)}]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- scalar or Series (if level specified)

**Notes**

To have the same behaviour as `numpy.std`, use `ddof=0` (instead of the default `ddof=1`)
Examples

```python
>>> df = pd.DataFrame({'person_id': [0, 1, 2, 3],
                      'age': [21, 25, 62, 43],
                      'height': [1.61, 1.87, 1.49, 2.01]}
                      ).set_index('person_id')
>>> df
          age   height
person_id
0      21.0  1.61
1      25.0  1.87
2      62.0  1.49
3      43.0  2.01
```

The standard deviation of the columns can be found as follows:

```python
>>> df.std()
age    18.786076
height 0.237417
```

Alternatively, `ddof=0` can be set to normalize by N instead of N-1:

```python
>>> df.std(ddof=0)
age    16.269219
height 0.205609
```

pandas.Series.str

Series.str()

Vectorized string functions for Series and Index.

NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

Examples

```python
>>> s = pd.Series(['A_Str_Series'])
>>> s
0     A_Str_Series
dtype: object

>>> s.str.split('_')
0     [A, Str, Series]  
dtype: object

>>> s.str.replace('_', '')
0     AStrSeries       
dtype: object
```
**pandas.Series.sub**

`Series.sub(other, level=None, fill_value=None, axis=0)`

Return Subtraction of series and other, element-wise (binary operator `sub`). Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**
- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**
- **Series** The result of the operation.

**See also:**
- **Series.rsub** Reverse of the Subtraction operator, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a  0.0
b  1.0
c  1.0
d -1.0
e  NaN
dtype: float64
```
pandas.Series.subtract

Series.subtract(other, level=None, fill_value=None, axis=0)

Return Subtraction of series and other, element-wise (binary operator sub).
Equivalent to series - other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rsub Reverse of the Subtraction operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a  0.0
b  1.0
c  1.0
d -1.0
e  NaN
dtype: float64
```
**pandas.Series.sum**

`Series.sum(axis=None, skipna=True, level=None, numeric_only=None, min_count=0, **kwargs)`  
Return the sum of the values over the requested axis.

This is equivalent to the method `numpy.sum`.

**Parameters**

- **axis** [(index (0))] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

scalar or Series (if level specified)

See also:

- **Series.sum** Return the sum.
- **Series.min** Return the minimum.
- **Series.max** Return the maximum.
- **Series.idxmin** Return the index of the minimum.
- **Series.idxmax** Return the index of the maximum.
- **DataFrame.sum** Return the sum over the requested axis.
- **DataFrame.min** Return the minimum over the requested axis.
- **DataFrame.max** Return the maximum over the requested axis.
- **DataFrame.idxmin** Return the index of the minimum over the requested axis.
- **DataFrame.idxmax** Return the index of the maximum over the requested axis.

**Examples**

```python
globals()['idx'] = pd.MultiIndex.from_arrays([  
    ...  
    ['warm', 'warm', 'cold', 'cold'],  
    ...  
    ['dog', 'falcon', 'fish', 'spider']],  
    ...  
    names=['blooded', 'animal'])

s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
```

(continues on next page)
spider 8
Name: legs, dtype: int64

```python
>>> s.sum()
14
```

By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([], dtype="float64").sum()  # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```python
>>> pd.Series([], dtype="float64").sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

**pandas.Series.swapaxes**

Series.swapaxes(axis1, axis2, copy=True)

Interchange axes and swap values axes appropriately.

**Returns**

- `y` [same as input]

**pandas.Series.swaplevel**

Series.swaplevel(i=-2, j=-1, copy=True)

Swap levels i and j in a MultiIndex.

Default is to swap the two innermost levels of the index.

**Parameters**

- `i, j` [int or str] Levels of the indices to be swapped. Can pass level name as string.
- `copy` [bool, default True] Whether to copy underlying data.

**Returns**

- `Series` Series with levels swapped in MultiIndex.
Examples

```python
>>> s = pd.Series(
...     ["A", "B", "A", "C"],
...     index=[
...         ["Final exam", "Final exam", "Coursework", "Coursework"],
...         ["History", "Geography", "History", "Geography"],
...         ["January", "February", "March", "April"],
...     ],
... )
>>> s
Final exam History January A
Geography February B
Coursework History March A
Geography April C
dtype: object
```

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for i and j, we swap the last and second to last indices.

```python
>>> s.swaplevel()
Final exam January History A
February Geography B
Coursework March History A
April Geography C
dtype: object
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.

```python
>>> s.swaplevel(0)
January History Final exam A
February Geography Final exam B
March History Coursework A
April Geography Coursework C
dtype: object
```

We can also define explicitly which indices we want to swap by supplying values for both i and j. Here, we for example swap the first and second indices.

```python
>>> s.swaplevel(0, 1)
History Final exam January A
Geography Final exam February B
History Coursework March A
Geography Coursework April C
dtype: object
```
Series.tail($n=5$)
Return the last $n$ rows.
This function returns last $n$ rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.
For negative values of $n$, this function returns all rows except the first $n$ rows, equivalent to $df[n:]$.

Parameters
- $n$ [int, default 5] Number of rows to select.

Returns
- type of caller The last $n$ rows of the caller object.

See also:
- DataFrame.head The first $n$ rows of the caller object.

Examples

```python
def = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
'...','monkey', 'parrot', 'shark', 'whale', 'zebra']})
def
animal
0 alligator  
1 bee       
2 falcon    
3 lion      
4 monkey    
5 parrot    
6 shark     
7 whale     
8 zebra
```

Viewing the last 5 lines

```python
def.tail()
animal
4 monkey
5 parrot
6 shark
7 whale
8 zebra
```

Viewing the last $n$ lines (three in this case)

```python
def.tail(3)
animal
6 shark
7 whale
8 zebra
```
For negative values of \( n \)

```python
>>> df.tail(-3)
   animal
3   lion
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

### pandas.Series.take

**Series.take(indices, axis=0, is_copy=None, **kwargs)**

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- **indices** [array-like] An array of ints indicating which positions to take.
- **axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements.
  - 0 means that we are selecting rows,
  - 1 means that we are selecting columns.
- **is_copy** [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, take always returns a copy, and the keyword is therefore deprecated.
  - Deprecated since version 1.0.0.
- **kwargs** For compatibility with numpy.take(). Has no effect on the output.

**Returns**

- **taken** [same type as caller] An array-like containing the elements taken from the object.

**See also:**

- **DataFrame.loc** Select a subset of a DataFrame by labels.
- **DataFrame.iloc** Select a subset of a DataFrame by positions.
- **numpy.take** Take elements from an array along an axis.

**Examples**

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
                     ('parrot', 'bird', 24.0),
                     ('lion', 'mammal', 80.5),
                     ('monkey', 'mammal', np.nan)],
                    columns=['name', 'class', 'max_speed'],
                    index=[0, 2, 3, 1])
>>> df
   name  class max_speed
0  falcon   bird   389.0
```
Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
   name     class max_speed
0  falcon     bird      389.0
1   monkey   mammal       NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
>>> df.take([1, 2], axis=1)
   name class max_speed
    0  bird    389.0
    2  bird     24.0
    3 mammal    80.5
   1 mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
   name     class max_speed
1   monkey   mammal       NaN
3    lion   mammal      80.5
```

### pandas.Series.to_clipboard

**Series.to_clipboard** *(excel=True, sep=None, **kwargs)*

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
  - False, write a string representation of the object to the clipboard.
- **sep** [str, default ':\t'] Field delimiter.
- **kwargs** These parameters will be passed to DataFrame.to_csv.

**See also:**

- **DataFrame.to_csv** Write a DataFrame to a comma-separated values (csv) file.
- **read_clipboard** Read text from clipboard and pass to read_csv.
Notes

Requirements for your platform.

- Linux: xclip, or xsel (with PyQt4 modules)
- Windows: none
- macOS: none

Examples

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```python
>>> df.to_clipboard(sep=',
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

**pandas.Series.to_csv**

Series.to_csv(path_or_buf=None, sep=',', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, mode='w', encoding=None, compression='infer', quoting=None, quotechar='', line_terminator=None, chunksize=None, date_format=None, doublequote=True, escapechar=None, decimal='.', errors='strict', storage_options=None)

Write object to a comma-separated values (csv) file.

**Parameters**

- **path_or_buf** [str, path object, file-like object, or None, default None] String, path object (implementing os.PathLike[str]), or file-like object implementing a write() function. If None, the result is returned as a string. If a non-binary file object is passed, it should be opened with `newline='\n'`, disabling universal newlines. If a binary file object is passed, `mode` might need to contain a ‘b’.

  Changed in version 1.2.0: Support for binary file objects was introduced.

- **sep** [str, default ‘,’] String of length 1. Field delimiter for the output file.

- **na_rep** [str, default ‘’] Missing data representation.

- **float_format** [str, default None] Format string for floating point numbers.

- **columns** [sequence, optional] Columns to write.
header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use index_label=False for easier importing in R.

mode [str] Python write mode, default ‘w’.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’. encoding is not supported if path_or_buf is a non-binary file object.

compression [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘%s’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={‘method’: ‘gzip’, ‘compresslevel’: 1, ‘mtime’: 1}.

Changed in version 1.0.0: May now be a dict with key ‘method’ as compression mode and other entries as additional compression options if compression mode is ‘zip’.

Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes ‘gzip’, ‘bz2’, ‘zstd’, and ‘zip’.

Changed in version 1.2.0: Compression is supported for binary file objects.

Changed in version 1.2.0: Previous versions forwarded dict entries for ‘gzip’ to gzip.open instead of gzip.GzipFile which prevented setting mtime.

quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a float_format then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

quotechar [str, default ‘”’] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to os.linesep, which depends on the OS in which this method is called (‘\n’ for linux, ‘\r\n’ for Windows, i.e.).

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of quotechar inside a field.

escapechar [str, default None] String of length 1. Character used to escape sep and quotechar when appropriate.

decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

New in version 1.1.0.
**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urlib` as header options. For other URLs (e.g. starting with “s3://” and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urlib` for more details.

New in version 1.2.0.

**Returns**

None or str If `path_or_buf` is None, returns the resulting csv format as a string. Otherwise returns `None`.

**See also:**

`read_csv` Load a CSV file into a DataFrame.

`to_excel` Write DataFrame to an Excel file.

**Examples**

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...   'mask': ['red', 'purple'],
...   'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff
```

Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
...   archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...   compression=compression_opts)
```

To write a csv file to a new folder or nested folder you will first need to create it using either Pathlib or os:

```python
>>> from pathlib import Path
>>> filepath = Path('folder/subfolder/out.csv')
>>> filepath.parent.mkdir(parents=True, exist_ok=True)
>>> df.to_csv(filepath)
```

```python
>>> import os
>>> os.makedirs('folder/subfolder', exist_ok=True)
>>> df.to_csv('folder/subfolder/out.csv')
```
pandas-Series.to_dict

Series.to_dict(into=<class 'dict'>)
Convert Series to {label -> value} dict or dict-like object.

Parameters

into [class, default dict] The collections.abc.Mapping subclass to use as the return object.
Can be the actual class or an empty instance of the mapping type you want. If you
want a collections.defaultdict, you must pass it initialized.

Returns

collections.abc.Mapping Key-value representation of Series.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
cpypd.Series.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

pandas.Series.to_excel

Series.to_excel(excel_writer, sheet_name=’Sheet1’, na_rep=‘’, float_format=None, columns=None,
header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None,
merge_cells=True, encoding=None, inf_rep=‘inf’, verbose=True, freeze_panes=None,
storage_options=None)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to
multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet
in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is
necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists
will result in the contents of the existing file being erased.

Parameters

excel_writer [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
sheet_name [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
na_rep [str, default ‘’] Missing data representation.
float_format [str, optional] Format string for floating point numbers. For example
float_format="%.2f" will format 0.123 to 0.12.
columns [sequence or list of str, optional] Columns to write.
header [bool or list of str, default True] Write out the column names. If a list of string is
given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not
 specified, and header and index are True, then the index names are used. A sequence
 should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

groupname [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this

Deprecation since version 1.2.0: As the xlwt package is no longer maintained, the xlwt
engine will be removed in a future version of pandas.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt,
other writers support unicode natively.

inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for
 infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row
 and rightmost column that is to be frozen.

storage_options [dict, optional] Extra options that make sense for a particular storage
 connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-
 value pairs are forwarded to urllib as header options. For other URLs (e.g. starting
 with "s3://", and "gs://") the key-value pairs are forwarded to fsspec. Please see
 fsspec and urllib for more details.

New in version 1.2.0.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole work-
book.
Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
index=['row 1', 'row 2'],
columns=['col 1', 'col 2'])

>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
    sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()

>>> with pd.ExcelWriter('output.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet_name_1')
    df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx',
    mode='a') as writer:
    df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

**pandas.Series.to_frame**

Series.to_frame(name=NoDefault.no_default)

Convert Series to DataFrame.

Parameters

- **name** [object, optional] The passed name should substitute for the series name (if it has one).

Returns

- **DataFrame** DataFrame representation of Series.
Examples

```python
>>> s = pd.Series(["a", "b", "c"],
                   name="vals")
>>> s.to_frame()
    vals
   0   a
   1   b
   2   c
```

**pandas.Series.to_hdf**

`Series.to_hdf(path_or_buf, key, mode='a', complevel=None, complib=None, append=False,
               format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None,
               data_columns=None, errors='strict', encoding='UTF-8')`

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.

**Warning:** One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

For more information see the *user guide*.

**Parameters**

- **path_or_buf** [str or pandas.HDFStore] File path or HDFStore object.
- **key** [str] Identifier for the group in the store.
- **mode** ["'a', 'w', 'r+'"], default 'a'] Mode to open file:
  - 'w': write, a new file is created (an existing file with the same name would be deleted).
  - 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
  - 'r+': similar to 'a', but the file must already exist.
- **complevel** [[0-9], default None] Specifies a compression level for data. A value of 0 or None disables compression.
- **complib** ["'zlib', 'lzo', 'bzip2', 'blosc'"] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.
- **append** [bool, default False] For Table formats, append the input data to the existing.
- **format** ["'fixed', 'table', None"], default 'fixed'] Possible values:
• ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
• If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”.

events [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

encoding [str, default “UTF-8”]
min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via data columns. Applicable only to format='table'.

See also:

read_hdf Read from HDF file.
DataFrame.to_parquet Write a DataFrame to the binary parquet format.
DataFrame.to_sql Write to a SQL table.
DataFrame.to_feather Write out feather-format for DataFrames.
DataFrame.to_csv Write out to a csv file.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A  B
a 1 4
b 2 5
c 3 6

>>> pd.read_hdf('data.h5', 's')
0 1
1 2
2 3
3 4
dtype: int64
```
pandas.Series.to_json

Series.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10,
force_ascii=True, date_unit='ms', default_handler=None, lines=False,
compression='infer', indent=None, storage_options=None)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str, path object, file-like object, or None, default None] String, path object
( Implementing os.PathLike[str]), or file-like object implementing a write() function.
If None, the result is returned as a string.

orient [str] Indication of expected JSON string format.

• Series:
  – default is ‘index’
  – allowed values are: {‘split’, ‘records’, ‘index’, ‘table’}.

• DataFrame:
  – default is ‘columns’
  – allowed values are: {‘split’, ‘records’, ‘index’, ‘columns’, ‘values’, ‘table’}.

• The format of the JSON string:
  – ‘split’: dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
  – ‘records’ : list like [[{column -> value}, ..., {column -> value}]
  – ‘index’: dict like {index -> {column -> value}}
  – ‘columns’: dict like {column -> {index -> value}}
  – ‘values’: just the values array
  – ‘table’: dict like {'schema': {schema}, 'data': {data}}

Describing the data, where data component is like orient='records'.

date_format [[None, ‘epoch’, ‘iso’]] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line-delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list-like.
compression [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path_or_buf’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: `compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}`. Changed in version 1.4.0: Zstandard support.

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.

Notes

The behavior of indent=0 varies from the stdlib, which does not indent the output but does insert newlines. Currently, indent=0 and the default indent=None are equivalent in pandas, though this may change in a future release.

orient='table' contains a ‘pandas_version’ field under ‘schema’. This stores the version of pandas used in the latest revision of the schema.

Examples

```python
>>> import json
>>> df = pd.DataFrame(
...     [["a", "b"], ["c", "d"]],
...     index=["row 1", "row 2"],
...     columns=["col 1", "col 2"],
... )
```
Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding:

```python
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    {
        "col 1": "a",
        "col 2": "b"
    },
    {
        "col 1": "c",
        "col 2": "d"
    }
]
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
        "col 1": "a",
        "col 2": "b"
    },
    "row 2": {
        "col 1": "c",
        "col 2": "d"
    }
}
```
Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "col 1": {
        "row 1": "a",
        "row 2": "c"
    },
    "col 2": {
        "row 1": "b",
        "row 2": "d"
    }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    ["a", "b"],
    ["c", "d"],
]
```

Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
                "type": "string"
            },
            {
                "name": "col 1",
                "type": "string"
            },
            {
                "name": "col 2",
                "type": "string"
            }
        ]
    }
}
```
pandas.Series.to_latex

Series.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None)

Render object to a LaTeX tabular, longtable, or nested table.

Requires \usepackage{booktabs}. The output can be copy/pasted into a main LaTeX document or read from an external file with \input{table.tex}.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space [int, optional] The minimum width of each column.

header [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

na_rep [str, default ‘NaN’] Missing data representation.
formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example float_format="%.2f" and float_format="{:0.2f}".format will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in LaTeX table format e.g. ‘rcfl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to column_format. The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str or tuple, optional] Tuple (full_caption, short_caption), which results in \caption[short_caption]{full_caption}; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

label [str, optional] The LaTeX label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

New in version 1.0.0.

position [str, optional] The LaTeX positional argument for tables, to be placed after \begin{} in the output.

New in version 1.2.0.

Returns
str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

**Styler.to_latex** Render a DataFrame to LaTeX with conditional formatting.

**DataFrame.to_string** Render a DataFrame to a console-friendly tabular output.

**DataFrame.to_html** Render a DataFrame as an HTML table.

**Examples**

```python
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
...    mask=['red', 'purple'],
...    weapon=['sai', 'bo staff']))

>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

**pandas.Series.to_list**

Series.to_list() Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns list

See also:

**numpy.ndarray.tolist** Return the array as an a.ndim-levels deep nested list of Python scalars.

**pandas.Series.to_markdown**

Series.to_markdown(buf=None, mode='wt', index=True, storage_options=None, **kwargs) Print Series in Markdown-friendly format.

New in version 1.0.0.

Parameters

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **mode** [str, optional] Mode in which file is opened, “wt” by default.
index [bool, optional, default True] Add index (row) labels.

   New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

   New in version 1.2.0.

**kwargs These parameters will be passed to tabulate.

Returns

str Series in Markdown-friendly format.

Notes

Requires the tabulate package.

Examples

```python
>>> s = pd.Series(['elk', 'pig', 'dog', 'quetzal'], name='animal')
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
</tr>
<tr>
<td>1</td>
<td>pig</td>
</tr>
<tr>
<td>2</td>
<td>dog</td>
</tr>
<tr>
<td>3</td>
<td>quetzal</td>
</tr>
</tbody>
</table>
```

Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt='grid'))
+---+----------+
|   | animal   |
+----+----------+
| 0  | elk      |
+----+----------+
| 1  | pig      |
+----+----------+
| 2  | dog      |
+----+----------+
| 3  | quetzal  |
```

3.3. Series
Series.to_numpy

A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.
na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the type of the array.

New in version 1.0.0.

**kwargs Additional keywords passed through to the to_numpy method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.
Index.array Get the actual data stored within.
DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in self will be equal in the returned array; likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, Series.array should be used instead.

This table lays out the different dtypes and default return types of to_numpy() for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>
Examples

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the `dtype` to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct tz.

```python
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz='CET'))
>>> ser.to_numpy(dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype='datetime64[ns]')
```

**pandas.Series.to_period**

Series.to_period(freq=None, copy=True)

Convert Series from DatetimeIndex to PeriodIndex.

Parameters

- **freq** [str, default None] Frequency associated with the PeriodIndex.
- **copy** [bool, default True] Whether or not to return a copy.

Returns

Series Series with index converted to PeriodIndex.

**pandas.Series.to_pickle**

Series.to_pickle(path, compression='infer', protocol=5, storage_options=None)

Pickle (serialize) object to file.

Parameters

- **path** [str] File path where the pickled object will be stored.
- **compression** [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for faster compression.
and to create a reproducible gzip archive: `compression={"method": 'gzip',
'compresslevel': 1, 'mtime': 1}.

**protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

- `read_pickle` Load pickled pandas object (or any object) from file.
- `DataFrame.to_hdf` Write DataFrame to an HDF5 file.
- `DataFrame.to_sql` Write DataFrame to a SQL database.
- `DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

### Examples

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0  0   5
1  1   6
2  2   7
3  3   8
4  4   9
>>> original_df.to_pickle("./dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0  0   5
1  1   6
2  2   7
3  3   8
4  4   9
```
pandas.Series.to_sql

Series.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [str] Name of SQL table.
con [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection close for the SQLAlchemy connectable. See here.
schema [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
if_exists [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
index [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.
index_label [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
chunksize [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.
dtype [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.
method [{None, ‘multi’, callable}, optional] Controls the SQL insertion clause used:
  - None: Uses standard SQL INSERT clause (one per row).
  - ‘multi’: Pass multiple values in a single INSERT clause.
  - callable with signature (pd_table, conn, keys, data_iter).

Returns

None or int Number of rows affected by to_sql. None is returned if the callable passed into method does not return the number of rows.

The number of returned rows affected is the sum of the rowcount attribute of sqlite3.Cursor or SQLAlchemy connectable which may not reflect the exact number of written rows as stipulated in the sqlite3 or SQLAlchemy.
New in version 1.4.0.

**Raises**

*ValueError* When the table already exists and `if_exists` is ‘fail’ (the default).

**See also:**

*read_sql* Read a DataFrame from a table.

**Notes**

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

**References**

[1], [2]

**Examples**

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name': ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```python
>>> df.to_sql('users', con=engine)
3
```

```sql
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An SQLAlchemy engine.Connection can also be passed to `con`:

```python
>>> with engine.begin() as connection:
...     df1 = pd.DataFrame({'name': ['User 4', 'User 5']})
...     df1.to_sql('users', con=connection, if_exists='append')
2
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.
Overwrite the table with just df2.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace',
...             index_label='id')
2
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({'A': [1, None, 2]})
>>> df
  A
0  1.0
1  NaN
2  2.0
>>> from sqlalchemy.types import Integer

>>> df.to_sql('integers', con=engine, index=False,
...          dtype={'A': Integer()})
3
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

**pandas.Series.to_string**

`Series.to_string(buf=None, na_rep='NaN', float_format=None, header=True, index=True, length=False, dtype=False, name=False, max_rows=None, min_rows=None)`

Render a string representation of the Series.

**Parameters**

- `buf` [StringIO-like, optional] Buffer to write to.
- `na_rep` [str, optional] String representation of NaN to use, default 'NaN'.
- `float_format` [one-parameter function, optional] Formatter function to apply to columns’ elements if they are floats, default None.
- `header` [bool, default True] Add the Series header (index name).
- `index` [bool, optional] Add index (row) labels, default True.
- `length` [bool, default False] Add the Series length.
**dtype** [bool, default False] Add the Series dtype.

**name** [bool, default False] Add the Series name if not None.

**max_rows** [int, optional] Maximum number of rows to show before truncating. If None, show all.

**min_rows** [int, optional] The number of rows to display in a truncated repr (when number of rows is above max_rows).

**Returns**

str or None String representation of Series if buf=None, otherwise None.

**pandas.Series.to_timestamp**

Series.to_timestamp(freq=None, how=’start’, copy=True)

Cast to DatetimeIndex of Timestamps, at beginning of period.

**Parameters**

freq [str, default frequency of PeriodIndex] Desired frequency.

how [‘s’, ‘e’, ‘start’, ‘end’] Convention for converting period to timestamp; start of period vs. end.

copy [bool, default True] Whether or not to return a copy.

**Returns**

Series with DatetimeIndex

**pandas.Series.to_xarray**

Series.to_xarray()

Return an xarray object from the pandas object.

**Returns**

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

**See also:**

*DataFrame.to_hdf* Write DataFrame to an HDF5 file.

*DataFrame.to_parquet* Write a DataFrame to the binary parquet format.

**Notes**

See the xarray docs
Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                     ('parrot', 'bird', 24.0, 2),
...                     ('lion', 'mammal', 80.5, 4),
...                     ('monkey', 'mammal', np.nan, 4)],
...                    columns=['name', 'class', 'max_speed',
...                             'num_legs'])
>>> df
name    class    max_speed    num_legs
0  falcon   bird        389.0       2
1  parrot   bird         24.0       2
2  lion    mammal       80.5        4
3  monkey  mammal      NaN         4

>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:
  * index (index) int64 0 1 2 3
Data variables:
  name (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed (index) float64 389.0 24.0 80.5 nan
  num_legs (index) int64 2 2 4 4

>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389., 24., 80.5, nan])
Coordinates:
  * index (index) int64 0 1 2 3

>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                           '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                                'animal': ['falcon', 'parrot',
...                                          'falcon', 'parrot'],
...                                'speed': [350, 18, 361, 15]})
>>> df_multiindex
  date  animal  speed
2018-01-01  falcon   350
        parrot    18
2018-01-02  falcon   361
        parrot    15

>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
  animal (animal) int64 0 1
  date (date)      int64 0 1
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

(continued from previous page)

<table>
<thead>
<tr>
<th>date (date)</th>
<th>datetime64[ns]</th>
<th>2018-01-01</th>
<th>2018-01-02</th>
</tr>
</thead>
<tbody>
<tr>
<td>animal (animal)</td>
<td>object</td>
<td>'falcon'</td>
<td>'parrot'</td>
</tr>
</tbody>
</table>

Data variables:

| speed (date, animal) | int64 | 350 | 18 | 361 | 15 |

pandas.Series.tolist

Series.tolist()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Series.transform

Series.transform(func, axis=0, *args, **kwargs)

Call func on self producing a Series with the same axis shape as self.

Parameters

func [function, str, list-like or dict-like] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to Series.apply. If func is both list-like and dict-like, dict-like behavior takes precedence.

Accepted combinations are:

- function
- string function name
- list-like of functions and/or function names, e.g. [np.exp, 'sqrt']
- dict-like of axis labels -> functions, function names or list-like of such.

axis [[0 or 'index']] Parameter needed for compatibility with DataFrame.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

Series A Series that must have the same length as self.

Raises

ValueError [If the returned Series has a different length than self.]

See also:

Series.agg Only perform aggregating type operations.
Series.apply  Invoke function on a Series.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

Examples

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0  0
1  1
2  2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
        sqrt    exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

You can call transform on a GroupBy object:

```python
>>> df = pd.DataFrame(
...     "Date": [
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120],
... )
>>> df
   Date  Data
0 2015-05-08     5
1 2015-05-07     8
2 2015-05-06     6
3 2015-05-05     1
4 2015-05-08    50
5 2015-05-07   100
```

(continues on next page)
6 2015-05-06  60

6  2    n    4

**pandas.Series.transpose**

Series.transpose(*args, **kwargs)

Return the transpose, which is by definition self.

Returns

c%(klass)s
**pandas.Series.truediv**

Series.truediv(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator truediv).
Equivalent to series / other, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

Series The result of the operation.

**See also:**

Series.rtruediv Reverse of the Floating division operator, see Python documentation for more details.

**Examples**

```python
g = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
g
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
g = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
g
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
g.divide(b, fill_value=0)
a 1.0
b inf
c inf
d 0.0
e NaN
dtype: float64```

3.3. Series
**pandas.Series.truncate**

Series.truncate(before=None, after=None, axis=None, copy=True)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True.] Return a copy of the truncated section.

**Returns**

type of caller  The truncated Series or DataFrame.

**See also:**

- **DataFrame.loc** Select a subset of a DataFrame by label.
- **DataFrame.iloc** Select a subset of a DataFrame by position.

**Notes**

If the index being truncated contains only datetime values, before and after may be specified as strings instead of Timestamps.

**Examples**

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
                      ...                     'B': ['f', 'g', 'h', 'i', 'j'],
                      ...                     'C': ['k', 'l', 'm', 'n', 'o']},
                      index=[1, 2, 3, 4, 5])
>>> df
     A  B  C
 0  a  f  k
 1  b  g  l
 2  c  h  m
 3  d  i  n
 4  e  j  o
```

```python
>>> df.truncate(before=2, after=4)
     A  B  C
 0  b  g  l
 1  c  h  m
 2  d  i  n
```

The columns of a DataFrame can be truncated.
```python
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
  1  a  f
  2  b  g
  3  c  h
  4  d  i
  5  e  j
```

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
  2  b
  3  c
  4  d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
         A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```python
>>> df.truncate(before=pd.Timestamp('2016-01-05'), ... after=pd.Timestamp('2016-01-10')).tail()
         A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a DatetimeIndex containing only dates, we can specify before and after as strings. They will be coerced to Timestamps before truncation.

```python
>>> df.truncate(before='2016-01-05', '2016-01-10').tail()
         A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```python
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
         A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

(continues on next page)

3.3. Series 1431
pandas.Series.tshift

Series.tshift(periods=1, freq=None, axis=0)
Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use shift instead.

Parameters
- **periods** [int] Number of periods to move, can be positive or negative.
- **freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] Corresponds to the axis that contains the Index.

Returns
- **shifted** [Series/DataFrame]

Notes
If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

pandas.Series.tz_convert

Series.tz_convert(tz, axis=0, level=None, copy=True)
Convert tz-aware axis to target time zone.

Parameters
- **tz** [str or tzinfo object]
- **axis** [the axis to convert]
- **level** [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.
- **copy** [bool, default True] Also make a copy of the underlying data.

Returns
- **{klass}** Object with time zone converted axis.

Raises
- **TypeError** If the axis is tz-naive.
Series.tz_localize

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use Series.dt.tz_localize().

Parameters

- **tz** [str or tzinfo] (the axis to localize)
- **axis** [the axis to localize] (int, str, default None) If axis ia a MultiIndex, localize a specific level. Otherwise must be None.
- **level** [int, str, default None] Also make a copy of the underlying data.
- **copy** [bool, default True] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer falls dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- **nonexistent** [str, default ‘raise’] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Series or DataFrame Same type as the input.

Raises

- **TypeError** If the TimeSeries is tz-aware and tz is not None.
Examples

Localize local times:

```python
>>> s = pd.Series([1],
                 index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.Series(range(7),
                 index=pd.DatetimeIndex(['2018-10-28 01:30:00',
                                         '2018-10-28 02:00:00',
                                         '2018-10-28 02:30:00',
                                         '2018-10-28 02:00:00',
                                         '2018-10-28 02:30:00',
                                         '2018-10-28 03:00:00',
                                         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly:

```python
>>> s = pd.Series(range(3),
                 index=pd.DatetimeIndex(['2018-10-28 01:20:00',
                                         '2018-10-28 02:36:00',
                                         '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
```

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or ‘shift_forward’ or ‘shift_backward’.

```python
>>> s = pd.Series(range(2),
                 index=pd.DatetimeIndex(['2015-03-29 02:30:00',
                                         '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
```
pandas.Series.unique

Series.unique()

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray  The unique values returned as a NumPy array. See Notes.

See also:

unique  Top-level unique method for any 1-d array-like object.

Index.unique  Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...            for _ in range(3)]).unique()
<DatetimeArray>
[2016-01-01 00:00:00-05:00]
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An `Categorical` will return categories in the order of appearance and with the same dtype.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                      ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

### pandas.Series.unstack

**Series.unstack**(level=-1, fill_value=None)

Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.

**Parameters**

- **level** [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.
- **fill_value** [scalar value, default None] Value to use when replacing NaN values.

**Returns**

- **DataFrame** Unstacked Series.

**Notes**

Reference *the user guide* for more examples.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4],
...                index=pd.MultiIndex.from_product([['one', 'two'],
...                                                  ['a', 'b']]))
>>> s
one   a  1
    b  2
two  a  3
    b  4
dtype: int64

>>> s.unstack(level=-1)
   b  a
one  2  1
two  4  3
```
pandas.Series.update

Series.update(other)

Modify Series in place using values from passed Series.

Uses non-NA values from passed Series to make updates. Aligns on index.

Parameters

other [Series, or object coercible into Series]

Examples

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0   4
1   5
2   6
dtype: int64
```

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0   d
1   b
2   e
dtype: object
```

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0   4
1   5
2   6
dtype: int64
```

If other contains NaNs the corresponding values are not updated in the original Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0   4
1   2
2   6
dtype: int64
```
other can also be a non-Series object type that is coercible into a Series

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update([4, np.nan, 6])
>>> s
0    4
1    2
2    6
dtype: int64
```

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update({1: 9})
>>> s
0    1
1    9
2    3
dtype: int64
```

**pandas.Series.value_counts**

Series.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

**Parameters**

- **normalize** [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.
- **bins** [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.
- **dropna** [bool, default True] Don’t include counts of NaN.

**Returns**

Series

**See also:**

- **Series.count** Number of non-NA elements in a Series.
- **DataFrame.count** Number of non-NA elements in a DataFrame.
- **DataFrame.value_counts** Equivalent method on DataFrames.
Examples

>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0  2
1.0  1
2.0  1
4.0  1
dtype: int64

With `normalize` set to `True`, returns the relative frequency by dividing all values by the sum of values.

>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0  0.4
1.0  0.2
2.0  0.2
4.0  0.2
dtype: float64

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

>>> s.value_counts(bins=3)
(0.996, 2.0]  2
(2.0, 3.0]   2
(3.0, 4.0]   1
dtype: int64

**dropna**

With `dropna` set to `False` we can also see NaN index values.

>>> s.value_counts(dropna=False)
3.0  2
1.0  1
2.0  1
4.0  1
NaN  1
dtype: int64

**pandas.Series.var**

`Series.var(axis=None, skipna=True, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument.

**Parameters**

- **axis** ([index (0)])
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddf [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddf, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
scalar or Series (if level specified)

Examples

```
>>> df = pd.DataFrame({
    'person_id': [0, 1, 2, 3],
    'age': [21, 25, 62, 43],
    'height': [1.61, 1.87, 1.49, 2.01]
}).set_index('person_id')

>>> df
   age  height
person_id
0   21  1.61
1   25  1.87
2   62  1.49
3   43  2.01

>>> df.var()
age   352.916667
height  0.056367

Alternatively, ddf=0 can be set to normalize by N instead of N-1:

```
>>> df.var(ddof=0)
age   264.687500
height  0.042275
```

pandas.Series.view

Series.view(dtype=None)
Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

Parameters

dtype [data type] Data type object or one of their string representations.

Returns

Series A new Series object as a view of the same data in memory.

See also:
**numpy.ndarray.view**  Equivalent numpy function to create a new view of the same data in memory.

**Notes**

Series are instantiated with `dtype=float64` by default. While `numpy.ndarray.view()` will return a view with the same data type as the original array, `Series.view()` (without specified dtype) will try using `float64` and may fail if the original data type size in bytes is not the same.

**Examples**

```python
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0   -2
1   -1
2    0
3    1
4    2
dtype: int8
```

The 8 bit signed integer representation of -1 is `0b11111111`, but the same bytes represent 255 if read as an 8 bit unsigned integer:

```python
>>> us = s.view('uint8')
>>> us
0   254
1   255
2    0
3    1
4    2
dtype: uint8
```

The views share the same underlying values:

```python
>>> us[0] = 128
>>> s
0  -128
1   -1
2    0
3    1
4    2
dtype: int8
```
pandas.Series.where

Series.where(cond, other=NoDefault.no_default, inplace=False, axis=None, level=None, errors=NoDefault.no_default, try_cast=NoDefault.no_default)

Replace values where the condition is False.

Parameters

- **cond** [bool Series/DataFrame, array-like, or callable] Where cond is True, keep the original value. Where False, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **other** [scalar, Series/DataFrame, or callable] Entries where cond is False are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **inplace** [bool, default False] Whether to perform the operation in place on the data.

- **axis** [int, default None] Alignment axis if needed.

- **level** [int, default None] Alignment level if needed.

- **errors** [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.
  - ‘raise’: allow exceptions to be raised.
  - ‘ignore’: suppress exceptions. On error return original object.

- **try_cast** [bool, default None] Try to cast the result back to the input type (if possible).
  Deprecation since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if inplace=True.

See also:

*DataFrame.mask()* Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is True the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for *DataFrame.where()* differs from *numpy.where()* Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the where documentation in *indexing*. 

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0   NaN
1   1.0
2   2.0
3   3.0
4   4.0
dtype: float64
>>> s.mask(s > 0)
0   0.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
>>> s.where(s > 1, 10)
0   10
1   10
2    2
3    3
4    4
dtype: int64
>>> s.mask(s > 1, 10)
0   0
1   1
2   10
3   10
4   10
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  1  2
2  2  3
3  3  4
4  4  5
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3 -6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
(continues on next page)
```
```python
>>> df.where(m, -df) == df.mask(~m, -df)
```

## pandas.Series.xs

`Series.xs(key, axis=0, level=None, drop_level=True)`

Return cross-section from the Series/DataFrame.

This method takes a `key` argument to select data at a particular level of a MultiIndex.

**Parameters**

- **key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to retrieve cross-section on.
- **level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- **drop_level** [bool, default True] If False, returns object with same levels as self.

**Returns**

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

**See also:**

- `DataFrame.loc` Access a group of rows and columns by label(s) or a boolean array.
- `DataFrame.iloc` Purely integer-location based indexing for selection by position.

**Notes**

- `xs` can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of `xs` functionality, see [MultiIndex Slicers](#).
Examples

```python
>>> d = {
'num_legs': [4, 4, 2, 2],
'num_wings': [0, 0, 2, 2],
'class': ['mammal', 'mammal', 'mammal', 'bird'],
'animal': ['cat', 'dog', 'bat', 'penguin'],
'locomotion': ['walks', 'walks', 'flies', 'walks']
}  
```  
```python
def = pd.DataFrame(data=d)
def = df.set_index(['class', 'animal', 'locomotion'])
def
```
```
<table>
<thead>
<tr>
<th>class</th>
<th>animal</th>
<th>locomotion</th>
</tr>
</thead>
<tbody>
<tr>
<td>mammal</td>
<td>cat</td>
<td>walks</td>
</tr>
<tr>
<td></td>
<td>dog</td>
<td>walks</td>
</tr>
<tr>
<td></td>
<td>bat</td>
<td>flies</td>
</tr>
<tr>
<td>bird</td>
<td>penguin</td>
<td>walks</td>
</tr>
</tbody>
</table>
```

Get values at specified index

```python
>>> df.xs('mammal')
```
```
<table>
<thead>
<tr>
<th>animal</th>
<th>locomotion</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>walks</td>
</tr>
<tr>
<td>dog</td>
<td>walks</td>
</tr>
<tr>
<td>bat</td>
<td>flies</td>
</tr>
</tbody>
</table>
```

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
```
```
<table>
<thead>
<tr>
<th>locomotion</th>
</tr>
</thead>
<tbody>
<tr>
<td>walks</td>
</tr>
</tbody>
</table>
```

Get values at specified index and level

```python
>>> df.xs('cat', level=1)
```
```
<table>
<thead>
<tr>
<th>class</th>
<th>locomotion</th>
</tr>
</thead>
<tbody>
<tr>
<td>mammal</td>
<td>walks</td>
</tr>
</tbody>
</table>
```

Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'),
... level=[0, 'locomotion'])
```
```
<table>
<thead>
<tr>
<th>animal</th>
<th>num_legs</th>
<th>num_wings</th>
</tr>
</thead>
<tbody>
<tr>
<td>penguin</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>
```

Get values at specified column and axis

```python
>>> df.xs('num_wings', axis=1)
```
```markdown
(continues on next page)
```
3.3.2 Attributes

Axes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.index</td>
<td>The index (axis labels) of the Series.</td>
</tr>
<tr>
<td>Series.array</td>
<td>The ExtensionArray of the data backing this Series or Index.</td>
</tr>
<tr>
<td>Series.values</td>
<td>Return Series as ndarray or ndarray-like depending on the dtype.</td>
</tr>
<tr>
<td>Series.dtype</td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td>Series.shape</td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td>Series.nbytes</td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td>Series.ndim</td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td>Series.size</td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td>Series.T</td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td>Series.memory_usage(index, deep)</td>
<td>Return the memory usage of the Series.</td>
</tr>
<tr>
<td>Series.empty</td>
<td>Indicator whether Series/DataFrame is empty.</td>
</tr>
<tr>
<td>Series.dtypes</td>
<td>Return the dtypes object of the underlying data.</td>
</tr>
<tr>
<td>Series.name</td>
<td>Return the name of the Series.</td>
</tr>
<tr>
<td>Series.flags</td>
<td>Get the properties associated with this pandas object.</td>
</tr>
<tr>
<td>Series.set_flags(*[, copy, ...])</td>
<td>Return a new object with updated flags.</td>
</tr>
</tbody>
</table>

pandas.Series.empty

**property Series.empty**

Indicator whether Series/DataFrame is empty.

True if Series/DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

**Returns**

*bool* If Series/DataFrame is empty, return True, if not return False.

**See also:**

*Series.dropna* Return series without null values.

*DataFrame.dropna* Return DataFrame with labels on given axis omitted where (all or any) data are missing.
Notes

If Series/DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A': []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A': [np.nan]})
>>> df
   A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

```python
>>> ser_empty = pd.Series({'A': []})
>>> ser_empty
A []
dtype: object
>>> ser_empty.empty
False
>>> ser_empty = pd.Series()
>>> ser_empty.empty
True
```
## 3.3.3 Conversion

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.astype(dtype[, copy, errors])</code></td>
<td>Cast a pandas object to a specified dtype <code>dtype</code>.</td>
</tr>
<tr>
<td><code>Series.convert_dtypes([infer_objects, ...])</code></td>
<td>Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code>.</td>
</tr>
<tr>
<td><code>Series.infer_objects()</code></td>
<td>Attempt to infer better dtypes for object columns.</td>
</tr>
<tr>
<td><code>Series.copy([deep])</code></td>
<td>Make a copy of this object’s indices and data.</td>
</tr>
<tr>
<td><code>Series.bool()</code></td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td><code>Series.to_numpy([dtype, copy, na_value])</code></td>
<td>A NumPy ndarray representing the values in this Series or Index.</td>
</tr>
<tr>
<td><code>Series.to_period([freq, copy])</code></td>
<td>Convert Series from DatetimeIndex to PeriodIndex.</td>
</tr>
<tr>
<td><code>Series.to_timestamp([freq, how, copy])</code></td>
<td>Cast to DatetimeIndex of Timestamps, at <em>beginning</em> of period.</td>
</tr>
<tr>
<td><code>Series.to_list()</code></td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td><code>Series.__array__(dtype)</code></td>
<td>Return the values as a NumPy array.</td>
</tr>
</tbody>
</table>

### pandas.Series.__array__

Returns the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

**Parameters**

- `dtype` [str or numpy.dtype, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

**Returns**

- `numpy.ndarray` The values in the series converted to a `numpy.ndarray` with the specified `dtype`.

**See also:**

- `array` Create a new array from data.
- `Series.array` Zero-copy view to the array backing the Series.
- `Series.to_numpy` Series method for similar behavior.

### Examples

```python
generate_code_snippet()```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```python
generate_code_snippet()```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```python
generate_code_snippet()```
3.3.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.get</code></td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>
<tr>
<td><code>Series.at</code></td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td><code>Series.iat</code></td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td><code>Series.loc</code></td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td><code>Series.iloc</code></td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td><code>Series.__iter__</code></td>
<td>Return an iterator of the values.</td>
</tr>
<tr>
<td><code>Series.items</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.iteritems</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.keys</code></td>
<td>Return alias for index.</td>
</tr>
<tr>
<td><code>Series.pop</code></td>
<td>Return item and drops from series.</td>
</tr>
<tr>
<td><code>Series.item</code></td>
<td>Return the first element of the underlying data as a Python scalar.</td>
</tr>
<tr>
<td><code>Series.xs</code></td>
<td>Return cross-section from the Series/DataFrame.</td>
</tr>
</tbody>
</table>

**pandas.Series.__iter__**

Series.__iter__()  

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

iterator

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the indexing documentation.
### 3.3.5 Binary operator functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.add()</code></td>
<td>Return Addition of series and other, element-wise (binary operator <code>add</code>).</td>
</tr>
<tr>
<td><code>Series.sub()</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).</td>
</tr>
<tr>
<td><code>Series.mul()</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator <code>mul</code>).</td>
</tr>
<tr>
<td><code>Series.div()</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>Series.truediv()</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>Series.floordiv()</code></td>
<td>Return Integer division of series and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>Series.mod()</code></td>
<td>Return Modulo of series and other, element-wise (binary operator <code>mod</code>).</td>
</tr>
<tr>
<td><code>Series.pow()</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator <code>pow</code>).</td>
</tr>
<tr>
<td><code>Series.radd()</code></td>
<td>Return Addition of series and other, element-wise (binary operator <code>radd</code>).</td>
</tr>
<tr>
<td><code>Series.rsub()</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator <code>rsub</code>).</td>
</tr>
<tr>
<td><code>Series.rmul()</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator <code>rmul</code>).</td>
</tr>
<tr>
<td><code>Series.rdiv()</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>Series.rtruediv()</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>Series.rfloordiv()</code></td>
<td>Return Integer division of series and other, element-wise (binary operator <code>rfloordiv</code>).</td>
</tr>
<tr>
<td><code>Series.rmod()</code></td>
<td>Return Modulo of series and other, element-wise (binary operator <code>rmod</code>).</td>
</tr>
<tr>
<td><code>Series.rpow()</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator <code>rpow</code>).</td>
</tr>
<tr>
<td><code>Series.combine()</code></td>
<td>Combine the Series with a Series or scalar according to <code>func</code>.</td>
</tr>
<tr>
<td><code>Series.combine_first()</code></td>
<td>Update null elements with value in the same location in 'other'.</td>
</tr>
<tr>
<td><code>Series.round()</code></td>
<td>Round each value in a Series to the given number of decimals.</td>
</tr>
<tr>
<td><code>Series.lt()</code></td>
<td>Return Less than of series and other, element-wise (binary operator <code>lt</code>).</td>
</tr>
<tr>
<td><code>Series.gt()</code></td>
<td>Return Greater than of series and other, element-wise (binary operator <code>gt</code>).</td>
</tr>
<tr>
<td><code>Series.le()</code></td>
<td>Return Less than or equal to of series and other, element-wise (binary operator <code>le</code>).</td>
</tr>
<tr>
<td><code>Series.ge()</code></td>
<td>Return Greater than or equal to of series and other, element-wise (binary operator <code>ge</code>).</td>
</tr>
<tr>
<td><code>Series.ne()</code></td>
<td>Return Not equal to of series and other, element-wise (binary operator <code>ne</code>).</td>
</tr>
<tr>
<td><code>Series.eq()</code></td>
<td>Return Equal to of series and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>Series.product()</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.dot()</code></td>
<td>Compute the dot product between the Series and the columns of other.</td>
</tr>
</tbody>
</table>
### 3.3.6 Function application, GroupBy & window

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.apply(func[, convert_dtype, args])</code></td>
<td>Invoke function on values of Series.</td>
</tr>
<tr>
<td><code>Series.agg([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>Series.aggregate([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>Series.transform(func[, axis])</code></td>
<td>Call func on self producing a Series with the same axis shape as self.</td>
</tr>
<tr>
<td><code>Series.map(arg[, na_action])</code></td>
<td>Map values of Series according to an input mapping or function.</td>
</tr>
<tr>
<td><code>Series.groupby(by, axis, level, as_index, ...)</code></td>
<td>Group Series using a mapper or by a Series of columns.</td>
</tr>
<tr>
<td><code>Series.rolling(window[, min_periods, ...])</code></td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td><code>Series.expanding([min_periods, center, ...])</code></td>
<td>Provide expanding window calculations.</td>
</tr>
<tr>
<td><code>Series.ewm([com, span, halflife, alpha, ...])</code></td>
<td>Provide exponentially weighted (EW) calculations.</td>
</tr>
<tr>
<td><code>Series.pipe(func, *args, **kwargs)</code></td>
<td>Apply chainable functions that expect Series or DataFrames.</td>
</tr>
</tbody>
</table>

### 3.3.7 Computations / descriptive stats

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>Series.all([axis, bool_only, skipna, level])</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>Series.any([axis, bool_only, skipna, level])</code></td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td><code>Series.autocorr([lag])</code></td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td><code>Series.between(left, right[, inclusive])</code></td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td><code>Series.clip([lower, upper, axis, inplace])</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>Series.corr(other[, method, min_periods])</code></td>
<td>Compute correlation with other Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.count([level])</code></td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td><code>Series.cov(other[, min_periods, ddof])</code></td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.cummax([axis, skipna])</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cummin([axis, skipna])</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumprod([axis, skipna])</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumsum([axis, skipna])</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.describe([percentiles, include, ...])</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>Series.diff([periods])</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>Series.factorize([sort, na_sentinel])</code></td>
<td>Encode the object as an enumerated type or categorical variable.</td>
</tr>
<tr>
<td><code>Series.kurt([axis, skipna, level, numeric_only])</code></td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
</tbody>
</table>
### Table 2 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Series.mad</strong>([axis, skipna, level])</td>
<td>Return the mean absolute deviation of the values over the requested axis.</td>
</tr>
<tr>
<td><strong>Series.max</strong>([axis, skipna, level, numeric_only])</td>
<td>Return the maximum of the values over the requested axis.</td>
</tr>
<tr>
<td><strong>Series.mean</strong>([axis, skipna, level, numeric_only])</td>
<td>Return the mean of the values over the requested axis.</td>
</tr>
<tr>
<td><strong>Series.median</strong>([axis, skipna, level])</td>
<td>Return the median of the values over the requested axis.</td>
</tr>
<tr>
<td><strong>Series.min</strong>([axis, skipna, level, numeric_only])</td>
<td>Return the minimum of the values over the requested axis.</td>
</tr>
<tr>
<td><strong>Series.mode</strong>([dropna])</td>
<td>Return the mode(s) of the Series.</td>
</tr>
<tr>
<td><strong>Series.nlargest</strong>([n, keep])</td>
<td>Return the largest n elements.</td>
</tr>
<tr>
<td><strong>Series.nsmallest</strong>([n, keep])</td>
<td>Return the smallest n elements.</td>
</tr>
<tr>
<td><strong>Series.pct_change</strong>([periods, fill_method, ...])</td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><strong>Series.prod</strong>([axis, skipna, level, ...])</td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><strong>Series.quantile</strong>([q, interpolation])</td>
<td>Return value at the given quantile.</td>
</tr>
<tr>
<td><strong>Series.rank</strong>([axis, method, numeric_only, ...])</td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td><strong>Series.sem</strong>([axis, skipna, level, ddof, ...])</td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td><strong>Series.skew</strong>([axis, skipna, level, numeric_only])</td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td><strong>Series.std</strong>([axis, skipna, level, ddof, ...])</td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td><strong>Series.sum</strong>([axis, skipna, level, ...])</td>
<td>Return the sum of the values over the requested axis.</td>
</tr>
<tr>
<td><strong>Series.var</strong>([axis, skipna, level, ddof, ...])</td>
<td>Return unbiased variance over requested axis.</td>
</tr>
<tr>
<td><strong>Series.kurtosis</strong>([axis, skipna, level, ...])</td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td><strong>Series.unique</strong>()</td>
<td>Return unique values of Series object.</td>
</tr>
<tr>
<td><strong>Series.nunique</strong>([dropna])</td>
<td>Return number of unique elements in the object.</td>
</tr>
<tr>
<td><strong>Series.is_unique</strong></td>
<td>Return boolean if values in the object are unique.</td>
</tr>
<tr>
<td><strong>Series.is_monotonic</strong></td>
<td>Return boolean if values in the object are monotonic_increasing.</td>
</tr>
<tr>
<td><strong>Series.is_monotonic_increasing</strong></td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td><strong>Series.is_monotonic_decreasing</strong></td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
<tr>
<td><strong>Series.value_counts</strong>([normalize, sort, ...])</td>
<td>Return a Series containing counts of unique values.</td>
</tr>
</tbody>
</table>
### 3.3.8 Reindexing / selection / label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.align</code>&lt;br&gt;(other[, join, axis, level, ...])</td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>Series.drop</code>&lt;br&gt;([labels, axis, index, columns, ...])</td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td><code>Series.drop_level</code>&lt;br&gt;(level[, axis])</td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>Series.drop_duplicates</code>&lt;br&gt;([keep, inplace])</td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td><code>Series.duplicated</code>&lt;br&gt;([keep])</td>
<td>Indicate duplicate Series values.</td>
</tr>
<tr>
<td><code>Series.equals</code>&lt;br&gt;(other)</td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>Series.first</code>&lt;br&gt;(offset)</td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.head</code>&lt;br&gt;([n])</td>
<td>Return the first $n$ rows.</td>
</tr>
<tr>
<td><code>Series.idxmax</code>&lt;br&gt;([axis, skipna])</td>
<td>Return the row label of the maximum value.</td>
</tr>
<tr>
<td><code>Series.idxmin</code>&lt;br&gt;([axis, skipna])</td>
<td>Return the row label of the minimum value.</td>
</tr>
<tr>
<td><code>Series.isin</code>&lt;br&gt;(values)</td>
<td>Whether elements in Series are contained in values.</td>
</tr>
<tr>
<td><code>Series.last</code>&lt;br&gt;(offset)</td>
<td>Select final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.reindex</code>&lt;br&gt;(*args, **kwargs)</td>
<td>Conform Series to new index with optional filling logic.</td>
</tr>
<tr>
<td><code>Series.reindex_like</code>&lt;br&gt;(other[, method, copy, ...])</td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td><code>Series.rename</code>&lt;br&gt;([index, axis, copy, inplace, ...])</td>
<td>Alter Series index labels or name.</td>
</tr>
<tr>
<td><code>Series.rename_axis</code>&lt;br&gt;([mapper, index, columns, ...])</td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
<tr>
<td><code>Series.reset_index</code>&lt;br&gt;([level, drop, name, inplace])</td>
<td>Generate a new DataFrame or Series with the index reset.</td>
</tr>
<tr>
<td><code>Series.sample</code>&lt;br&gt;([n, frac, replace, weights, ...])</td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td><code>Series.set_axis</code>&lt;br&gt;(labels[, axis, inplace])</td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td><code>Series.take</code>&lt;br&gt;(indices[, axis, is_copy])</td>
<td>Return the elements in the given positional indices along an axis.</td>
</tr>
<tr>
<td><code>Series.tail</code>&lt;br&gt;([n])</td>
<td>Return the last $n$ rows.</td>
</tr>
<tr>
<td><code>Series.truncate</code>&lt;br&gt;([before, after, axis, copy])</td>
<td>Truncate a Series or DataFrame before and after some index value.</td>
</tr>
<tr>
<td><code>Series.where</code>&lt;br&gt;(cond[, other, inplace, axis, ...])</td>
<td>Replace values where the condition is False.</td>
</tr>
<tr>
<td><code>Series.mask</code>&lt;br&gt;(cond[, other, inplace, axis, ...])</td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td><code>Series.add_prefix</code>&lt;br&gt;(prefix)</td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td><code>Series.add_suffix</code>&lt;br&gt;(suffix)</td>
<td>Suffix labels with string suffix.</td>
</tr>
<tr>
<td><code>Series.filter</code>&lt;br&gt;([items, like, regex, axis])</td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
</tbody>
</table>
3.3.9 Missing data handling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.backfill</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>Series.bfill</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>Series.dropna</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>Series.ffill</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>Series.fillna</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>Series.interpolate</code></td>
<td>Fill NaN values using an interpolation method.</td>
</tr>
<tr>
<td><code>Series.isna</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>Series.isnull</code></td>
<td>Series.isnull is an alias for Series.isna.</td>
</tr>
<tr>
<td><code>Series.notna</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>Series.notnull</code></td>
<td>Series.notnull is an alias for Series.notna.</td>
</tr>
<tr>
<td><code>Series.pad</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>Series.replace</code></td>
<td>Replace values given in <code>to_replace</code> with <code>value</code>.</td>
</tr>
</tbody>
</table>

3.3.10 Reshaping, sorting

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.argsort</code></td>
<td>Return the integer indices that would sort the Series values.</td>
</tr>
<tr>
<td><code>Series.argmin</code></td>
<td>Return int position of the smallest value in the Series.</td>
</tr>
<tr>
<td><code>Series.argmax</code></td>
<td>Return int position of the largest value in the Series.</td>
</tr>
<tr>
<td><code>Series.reorder_levels</code></td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><code>Series.sort_values</code></td>
<td>Sort the values.</td>
</tr>
<tr>
<td><code>Series.sort_index</code></td>
<td>Sort Series by index labels.</td>
</tr>
<tr>
<td><code>Series.swaplevel</code></td>
<td>Swap levels i and j in a <code>MultiIndex</code>.</td>
</tr>
<tr>
<td><code>Series.unstack</code></td>
<td>Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.</td>
</tr>
<tr>
<td><code>Series.explode</code></td>
<td>Transform each element of a list-like to a row.</td>
</tr>
<tr>
<td><code>Series.searchsorted</code></td>
<td>Find indices where elements should be inserted to maintain order.</td>
</tr>
<tr>
<td><code>Series.ravel</code></td>
<td>Return the flattened underlying data as an ndarray.</td>
</tr>
<tr>
<td><code>Series.repeat</code></td>
<td>Repeat elements of a Series.</td>
</tr>
<tr>
<td><code>Series.squeeze</code></td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
</tr>
<tr>
<td><code>Series.view</code></td>
<td>Create a new view of the Series.</td>
</tr>
</tbody>
</table>

3.3.11 Combining / comparing / joining / merging

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.append</code></td>
<td>(DEPRECATED) Concatenate two or more Series.</td>
</tr>
<tr>
<td><code>Series.compare</code></td>
<td>Compare to another Series and show the differences.</td>
</tr>
<tr>
<td><code>Series.update</code></td>
<td>Modify Series in place using values from passed Series.</td>
</tr>
</tbody>
</table>
3.3.12 Time Series-related

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.asfreq(freq[, method, how, ...])</code></td>
<td>Convert time series to specified frequency.</td>
</tr>
<tr>
<td><code>Series.asof(where[, subset])</code></td>
<td>Return the last row(s) without any NaNs before <code>where</code>.</td>
</tr>
<tr>
<td><code>Series.shift([periods, freq, axis, fill_value])</code></td>
<td>Shift index by desired number of periods with an optional time <code>freq</code>.</td>
</tr>
<tr>
<td><code>Series.first_valid_index()</code></td>
<td>Return index for first non-NA value or None, if no non-NA value is found.</td>
</tr>
<tr>
<td><code>Series.last_valid_index()</code></td>
<td>Return index for last non-NA value or None, if no non-NA value is found.</td>
</tr>
<tr>
<td><code>Series.resample(rule[, axis, closed, label, ...])</code></td>
<td>Resample time-series data.</td>
</tr>
<tr>
<td><code>Series.tz_convert(tz[, axis, level, copy])</code></td>
<td>Convert tz-aware axis to target time zone.</td>
</tr>
<tr>
<td><code>Series.tz_localize(tz[, axis, level, copy, ...])</code></td>
<td>Localize tz-naive index of a Series or DataFrame to target time zone.</td>
</tr>
<tr>
<td><code>Series.at_time(time[, asof, axis])</code></td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td><code>Series.between_time(start_time, end_time[, ...])</code></td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>Series.tshift([periods, freq, axis])</code></td>
<td>(DEPRECATED) Shift the time index, using the index's frequency if available.</td>
</tr>
<tr>
<td><code>Series.slice_shift([periods, axis])</code></td>
<td>(DEPRECATED) Equivalent to <code>shift</code> without copying data.</td>
</tr>
</tbody>
</table>

3.3.13 Accessors

pandas provides dtype-specific methods under various accessors. These are separate namespaces within `Series` that only apply to specific data types.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Accessor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datetime, Timedelta, Period</td>
<td><code>dt</code></td>
</tr>
<tr>
<td>String</td>
<td><code>str</code></td>
</tr>
<tr>
<td>Categorical</td>
<td><code>cat</code></td>
</tr>
<tr>
<td>Sparse</td>
<td><code>sparse</code></td>
</tr>
</tbody>
</table>

Datetimelike properties

`Series.dt` can be used to access the values of the series as datetimelike and return several properties. These can be accessed like `Series.dt.<property>`. 
### Datetime properties

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.dt.date</code></td>
<td>Returns numpy array of <code>datetime.date</code> objects.</td>
</tr>
<tr>
<td><code>Series.dt.time</code></td>
<td>Returns numpy array of <code>datetime.time</code> objects.</td>
</tr>
<tr>
<td><code>Series.dt.timetz</code></td>
<td>Returns numpy array of <code>datetime.time</code> objects with timezone information.</td>
</tr>
<tr>
<td><code>Series.dt.year</code></td>
<td>The year of the datetime.</td>
</tr>
<tr>
<td><code>Series.dt.month</code></td>
<td>The month as January=1, December=12.</td>
</tr>
<tr>
<td><code>Series.dt.day</code></td>
<td>The day of the datetime.</td>
</tr>
<tr>
<td><code>Series.dt.hour</code></td>
<td>The hours of the datetime.</td>
</tr>
<tr>
<td><code>Series.dt.minute</code></td>
<td>The minutes of the datetime.</td>
</tr>
<tr>
<td><code>Series.dt.second</code></td>
<td>The seconds of the datetime.</td>
</tr>
<tr>
<td><code>Series.dt.microsecond</code></td>
<td>The microseconds of the datetime.</td>
</tr>
<tr>
<td><code>Series.dt.nanosecond</code></td>
<td>The nanoseconds of the datetime.</td>
</tr>
<tr>
<td><code>Series.dt.week</code></td>
<td>(DEPRECATED) The week ordinal of the year according to the ISO 8601 standard.</td>
</tr>
<tr>
<td><code>Series.dt.weekofyear</code></td>
<td>(DEPRECATED) The week ordinal of the year according to the ISO 8601 standard.</td>
</tr>
<tr>
<td><code>Series.dt.dayofweek</code></td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td><code>Series.dt.weekday</code></td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td><code>Series.dt.dayofyear</code></td>
<td>The ordinal day of the year.</td>
</tr>
<tr>
<td><code>Series.dt.day_of_year</code></td>
<td>The ordinal day of the year.</td>
</tr>
<tr>
<td><code>Series.dt.quarter</code></td>
<td>The quarter of the date.</td>
</tr>
<tr>
<td><code>Series.dt.is_month_start</code></td>
<td>Indicates whether the date is the first day of the month.</td>
</tr>
<tr>
<td><code>Series.dt.is_month_end</code></td>
<td>Indicates whether the date is the last day of the month.</td>
</tr>
<tr>
<td><code>Series.dt.is_quarter_start</code></td>
<td>Indicator for whether the date is the first day of a quarter.</td>
</tr>
<tr>
<td><code>Series.dt.is_quarter_end</code></td>
<td>Indicator for whether the date is the last day of a quarter.</td>
</tr>
<tr>
<td><code>Series.dt.is_year_start</code></td>
<td>Indicate whether the date is the first day of a year.</td>
</tr>
<tr>
<td><code>Series.dt.is_year_end</code></td>
<td>Indicate whether the date is the last day of the year.</td>
</tr>
<tr>
<td><code>Series.dt.is_leap_year</code></td>
<td>Boolean indicator if the date belongs to a leap year.</td>
</tr>
<tr>
<td><code>Series.dt.daysinmonth</code></td>
<td>The number of days in the month.</td>
</tr>
<tr>
<td><code>Series.dt.days_in_month</code></td>
<td>The number of days in the month.</td>
</tr>
<tr>
<td><code>Series.dt.tz</code></td>
<td>Return the timezone.</td>
</tr>
<tr>
<td><code>Series.dt.freq</code></td>
<td>Return the frequency object for this PeriodArray.</td>
</tr>
</tbody>
</table>

#### pandas.Series.dt.date

- **Series.dt.date**
  - Returns numpy array of `datetime.date` objects.
  - Namely, the date part of Timestamps without time and timezone information.
pandas.Series.dt.time

Series.dt.time
Returns numpy array of datetime.time objects.
The time part of the Timestamps.

pandas.Series.dt.timetz

Series.dt.timetz
Returns numpy array of datetime.time objects with timezone information.
The time part of the Timestamps.

pandas.Series.dt.year

Series.dt.year
The year of the datetime.

Examples

```python
>>> datetime_series = pd.Series(...
...    pd.date_range("2000-01-01", periods=3, freq="Y")
...)
>>> datetime_series
datetime_series
0 2000-12-31
1 2001-12-31
2 2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0 2000
1 2001
2 2002
dtype: int64
```

pandas.Series.dt.month

Series.dt.month
The month as January=1, December=12.
Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
datetime_series
0    2000-01-31
1    2000-02-29
2    2000-03-31
dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.month
datetime_series.dt.month
0    1
1    2
2    3
dtype: int64
```

**pandas.Series.dt.day**

Series.dt.day

The day of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
datetime_series
0    2000-01-01
1    2000-01-02
2    2000-01-03
```

```python
>>> datetime_series.dt.day
datetime_series.dt.day
0    1
1    2
2    3
```

**pandas.Series.dt.hour**

Series.dt.hour

The hours of the datetime.
Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 01:00:00
2   2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0    0
1    1
2    2
dtype: int64
```

### pandas.Series.dt.minute

**Series.dt.minute**

The minutes of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 00:01:00
2   2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0    0
1    1
2    2
dtype: int64
```

### pandas.Series.dt.second

**Series.dt.second**

The seconds of the datetime.
Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 00:00:01
2  2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0   0
1   1
2   2
dtype: int64
```

`pandas.Series.dt.microsecond`

Series.dt.microsecond

The microseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0  2000-01-01 00:00:00.000000
1  2000-01-01 00:00:00.000001
2  2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0   0
1   1
2   2
dtype: int64
```

`pandas.Series.dt.nanosecond`

Series.dt.nanosecond

The nanoseconds of the datetime.
Examples

```python
>>> datetime_series = pd.Series(
...   pd.date_range("2000-01-01", periods=3, freq="ns")
... )
```

```plaintext
>>> datetime_series
0 2000-01-01 00:00:00.000000000
1 2000-01-01 00:00:00.000000001
2 2000-01-01 00:00:00.000000002
```

```plaintext
dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.nanosecond
0 0
1 1
2 2
```

**pandas.Series.dt.week**

`Series.dt.week`  
The week ordinal of the year according to the ISO 8601 standard.  
Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please call `Series.dt.isocalendar()` and access the `week` column instead.

**pandas.Series.dt.weekofyear**

`Series.dt.weekofyear`  
The week ordinal of the year according to the ISO 8601 standard.  
Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please call `Series.dt.isocalendar()` and access the `week` column instead.

**pandas.Series.dt.dayofweek**

`Series.dt.dayofweek`  
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the `dt` accessor) or DatetimeIndex.

**Returns**

- **Series or Index** Containing integers indicating the day number.

**See also:**

- `Series.dt.dayofweek` Alias.
- `Series.dt.weekday` Alias.
- `Series.dt.day_name` Returns the name of the day of the week.
Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

`pandas.Series.dt.day_of_week`

Series.dt.day_of_week

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index  Containing integers indicating the day number.

See also:

Series.dt.dayofweek  Alias.
Series.dt.weekday  Alias.
Series.dt.day_name  Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```
**pandas.Series.dt.weekday**

Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

**Returns**

Series or Index Containing integers indicating the day number.

**See also:**

- Series.dt.dayofweek Alias.
- Series.dt.weekday Alias.
- Series.dt.day_name Returns the name of the day of the week.

**Examples**

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

**pandas.Series.dt.dayofyear**

Series.dt.dayofyear

The ordinal day of the year.

**pandas.Series.dt.day_of_year**

Series.dt.day_of_year

The ordinal day of the year.
pandas.Series.dt.quarter

Series.dt.quarter

The quarter of the date.

pandas.Series.dt.is_month_start

Series.dt.is_month_start

Indicates whether the date is the first day of the month.

Returns

Series or array  For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start  Return a boolean indicating whether the date is the first day of the month.
is_month_end  Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
dtype: datetime64[ns]
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0  False
1  False
2  True
dtype: bool

>>> s.dt.is_month_end
0  False
1  True
2  False
dtype: bool

>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```
pandas.Series.dt.is_month_end

Series.dt.is_month_end
Indicates whether the date is the last day of the month.

Returns

Series or array  For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start  Return a boolean indicating whether the date is the first day of the month.
is_month_end  Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0  False
1  False
2  True
dtype: bool
>>> s.dt.is_month_end
0  False
1  True
2  False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.Series.dt.is_quarter_start

Series.dt.is_quarter_start
Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start  [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter  Return the quarter of the date.
is_quarter_end  Similar property for indicating the quarter start.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range('2017-03-30',
... periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
... is_quarter_start=df.dates.dt.is_quarter_start)
  dates  quarter  is_quarter_start
  0 2017-03-30 1          False
  1 2017-03-31 1          False
  2 2017-04-01 2           True
  3 2017-04-02 2          False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx.is_quarter_start
array([False, False, True, False])
```

```python
pandas.Series.dt.is_quarter_end
```

Series.dt.is_quarter_end

Indicator for whether the date is the last day of a quarter.

Returns

- **is_quarter_end** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

- **quarter** Return the quarter of the date.
- **is_quarter_start** Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range('2017-03-30',
... periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
... is_quarter_end=df.dates.dt.is_quarter_end)
  dates  quarter  is_quarter_end
  0 2017-03-30 1          False
  1 2017-03-31 1           True
  2 2017-04-01 2          False
  3 2017-04-02 2          False
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
```

```python
datetime_index(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
               dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_end
array([False, True, False, False])
```

**pandas.Series.dt.is_year_start**

Series.dt.is_year_start

Indicate whether the date is the first day of a year.

**Returns**

- Series or DatetimeIndex: The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- is_year_end: Similar property indicating the last day of the year.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
```

```python
datetime_index(["2017-12-30", "2017-12-31", "2018-01-01"],
               dtype='datetime64[ns]')
```

```python
>>> dates.dt.is_year_start
0   False
1   False
2    True
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
```

```python
datetime_index(["2017-12-30", "2017-12-31", "2018-01-01"],
               dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_year_start
array([False, False, True])
```
pandas.Series.dt.is_year_end

Series.dt.is_year_end
Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_start Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_end
0   False
1   True
2   False
dtype: bool

>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
Date_range('2017-12-30', '2017-12-31', '2018-01-01', freq='D', closed='left', name=None, dtype='O', freq='D')

>>> idx.is_year_end
array([False,  True, False])
```

pandas.Series.dt.is_leap_year

Series.dt.is_leap_year
Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray Booleans indicating if dates belong to a leap year.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'], dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False])
```

```python
>>> dates_series = pd.Series(idx)
>>> dates_series
0  2012-12-31
1  2013-12-31
2  2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0   True
1  False
2  False
dtype: bool
```

**pandas.Series.dt.daysinmonth**

Series.dt.daysinmonth

The number of days in the month.

**pandas.Series.dt.days_in_month**

Series.dt.days_in_month

The number of days in the month.

**pandas.Series.dt.tz**

Series.dt.tz

Return the timezone.

Returns

`datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None` Returns None when
the array is tz-naive.
pandas.Series.dt.freq

Series.dt.freq

Datetime methods

</tbody>
</table>

pandas.Series.dt.isocalendar

Series.dt.isocalendar()  
Calculate year, week, and day according to the ISO 8601 standard.

New in version 1.1.0.

Returns  
DataFrame With columns year, week and day.

See also:

Timestamp.isocalendar Function return a 3-tuple containing ISO year, week number, and weekday for the given Timestamp object.
datetime.date.isocalendar Return a named tuple object with three components: year, week and weekday.

Examples

```python
>>> ser = pd.to_datetime(pd.Series(['2010-01-01', pd.NaT]))
>>> ser.dt.isocalendar()
    year  week  day
0  2009    53   5
1  <NA>   <NA> <NA>
>>> ser.dt.isocalendar().week
0  53
```

(continues on next page)
pandas.Series.dt.to_period

Series.dt.to_period(*args, **kwargs)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex Immutable ndarray holding ordinal values.
DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```python
>>> df = pd.DataFrame({'y': [1, 2, 3]},
                   index=pd.to_datetime(['2000-03-31 00:00:00',
                                         '2000-05-31 00:00:00',
                                         '2000-08-31 00:00:00']))
>>> df.index.to_period('M')
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]')
```

Infer the daily frequency

```python
>>> idx = pd.date_range('2017-01-01', periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]')
```
**pandas.Series.dt.to_pydatetime**

`Series.dt.to_pydatetime()`

Return the data as an array of `datetime.datetime` objects.

Timezone information is retained if present.

**Warning:** Python’s datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

**Returns**

- `numpy.ndarray` Object dtype array containing native Python datetime objects.

**See also:**

- `datetime.datetime` Standard library value for a datetime.

**Examples**

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0 2018-03-10
1 2018-03-11
dtype: datetime64[ns]

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)

pandas’ nanosecond precision is truncated to microseconds.

>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0 2018-03-10 00:00:00.000000000
1 2018-03-10 00:00:00.000000001

dtype: datetime64[ns]

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

**pandas.Series.dt.tz_localize**

`Series.dt.tz_localize(*args, **kwargs)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass `tz=None`.
Parameters

**tz**  [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

**ambiguous**  ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.

* `infer` will attempt to infer fall dst-transition hours based on order
* `bool-ndarray` where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
* `NaT` will return NaT where there are ambiguous times
* `raise` will raise an AmbiguousTimeError if there are ambiguous times.

**nonexistent**  ['shift_forward', 'shift_backward, 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

* `shift_forward` will shift the nonexistent time forward to the closest existing time
* `shift_backward` will shift the nonexistent time backward to the closest existing time
* `NaT` will return NaT where there are nonexistent times
* `timedelta` objects will shift nonexistent times by the timedelta
* `raise` will raise an NonExistentTimeError if there are nonexistent times.

Returns

**Same type as self**  Array/Index converted to the specified time zone.

Raises

**TypeError**  If the Datetime Array/Index is tz-aware and tz is not None.

See also:

* `DatetimeIndex.tz_convert`  Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
```

(continues on next page)
With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00', '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00']))
```

```python
0 2018-10-28 01:30:00+02:00
1 2018-10-28 02:00:00+02:00
2 2018-10-28 02:30:00+02:00
3 2018-10-28 02:00:00+01:00
4 2018-10-28 02:30:00+01:00
5 2018-10-28 03:00:00+01:00
6 2018-10-28 03:30:00+01:00
```

```python
dtype: datetime64[ns, CET]
```

```python
>>> s.dt.tz_localize('CET', ambiguous='infer')
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+01:00
2 2018-10-28 03:46:00+01:00
```

```python
dtype: datetime64[ns, CET]
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00']))
```

```python
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
```

```python
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `shift_forward` or `shift_backwards`.

```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
... '2015-03-29 03:30:00']))
```

```python
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
```

```python
dtype: datetime64[ns, Europe/Warsaw]
```
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

pandas.Series.dt.tz_convert

Series.dt.tz_convert(*args, **kwargs)

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

- tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A tz of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

- TypeError If Datetime Array/Index is tz-naive.

See also:

- DatetimeIndex.tz A timezone that has a variable offset from UTC.
- DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the tz parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
... freq='H', periods=3, tz='Europe/Berlin')

>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the tz=None, we can remove the timezone (after converting to UTC if necessary):
pandas.Series.dt.normalize

Series.dt.normalize(*args, **kwargs)
Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the
time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on Datetime Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will
have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.
cell Ceil the datetimes to the specified freq.
round Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                       periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
```
pandas.Series.dt.strftime

Series.dt.strftime(*args, **kwargs)
Convert to Index using specified date_format.
Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray[object] NumPy ndarray of formatted strings.

See also:
to_datetime Convert the given argument to datetime.
DatetimeIndex.normalize Return DatetimeIndex with times to midnight.
DatetimeIndex.round Round the DatetimeIndex to the specified freq.
DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
dtype='object')
```

pandas.Series.dt.round

Series.dt.round(*args, **kwargs)

Perform round operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  • ‘infer’ will attempt to infer fall dst-transition hours based on order
  • bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  • ‘NaT’ will return NaT where there are ambiguous times
  • ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  • ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Notes

If the timestamps have a timezone, rounding will take place relative to the local (“wall”) time and re-localized to the same timezone. When rounding near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

Examples

DatetimeIndex

>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00', '2018-01-01 12:00:00'],
dtype='datetime64[ns]', freq=None)

Series

>>> pd.Series(rng).dt.round("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

>>> rng_tz = pd.DatetimeIndex(['2021-10-31 03:30:00'], tz="Europe/Amsterdam")

>>> rng_tz.floor("2H", ambiguous=False)
DatetimeIndex(['2021-10-31 02:00:00+01:00'],
dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
>>> rng_tz.floor("2H", ambiguous=True)
DatetimeIndex(['2021-10-31 02:00:00+02:00'],
       dtype='datetime64[ns, Europe/Amsterdam]', freq=None)

pandas.Series.dt.floor

Series.dt.floor(*args, **kwargs)

Perform floor operation on the data to the specified freq.

**Parameters**

- **freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.
- **ambiguous** ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- **nonexistent** ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

- ValueError if the freq cannot be converted.

**Notes**

If the timestamps have a timezone, flooring will take place relative to the local (“wall”) time and re-localized to the same timezone. When flooring near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.
Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
                '2018-01-01 12:01:00'],
               dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
                '2018-01-01 12:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0  2018-01-01 11:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]
```

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

```python
>>> rng_tz = pd.DatetimeIndex(['2021-10-31 03:30:00'], tz="Europe/Amsterdam")
>>> rng_tz.floor("2H", ambiguous=False)
DatetimeIndex(['2021-10-31 02:00:00+01:00'],
               dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
>>> rng_tz.floor("2H", ambiguous=True)
DatetimeIndex(['2021-10-31 02:00:00+02:00'],
               dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```

pandas.Series.dt.ceil

Series.dt.ceil(*args, **kwargs)

Perform ceil operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
nonexistent  ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Notes

If the timestamps have a timezone, ceiling will take place relative to the local ("wall") time and re-localized to the same timezone. When ceiling near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

```python
>>> rng_tz = pd.DatetimeIndex(['2021-10-31 01:30:00'], tz="Europe/Amsterdam")
```
pandas.Series.dt.month_name

Series.dt.month_name(*args, **kwargs)

Return the month names of the Series or DatetimeIndex with specified locale.

Parameters

locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

Series or Index Series or Index of month names.

Examples

```python
>>> s = pd.Series(pd.date_range(start='2018-01', freq='M', periods=3))
>>> s
datetime64[ns]
0 2018-01-31
1 2018-02-28
2 2018-03-31
>>> s.dt.month_name()
0 January
1 February
2 March
dtype: object
```

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DateIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
          dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```
### pandas.Series.dt.day_name

**Series.dt.day_name(*args, **kwargs)**

Return the day names of the `Series` or `DatetimeIndex` with specified locale.

**Parameters**

- `locale` [str, optional] Locale determining the language in which to return the day name. Default is English locale.

**Returns**

`Series` or `Index` Series or Index of day names.

**Examples**

```python
>>> s = pd.Series(pd.date_range(start='2018-01-01', freq='D', periods=3))
>>> s
0  2018-01-01
1  2018-01-02
2  2018-01-03
dtype: datetime64[ns]
>>> s.dt.day_name()
0  Monday
1  Tuesday
2  Wednesday
dtype: object
```

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DateIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
          dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

### Period properties

<td>Return a Dataframe of the components of the Timedeltas.</td>
</tr>
</tbody>
</table>

pandas.Series.dt.days

Series.dt.days
    Number of days for each element.

pandas.Series.dt.seconds

Series.dt.seconds
    Number of seconds (>= 0 and less than 1 day) for each element.

pandas.Series.dt.microseconds

Series.dt.microseconds
    Number of microseconds (>= 0 and less than 1 second) for each element.
pandas.Series.dt.nanoseconds

Series.dt.nanoseconds
Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

pandas.Series.dt.components

Series.dt.components
Return a Dataframe of the components of the Timedeltas.

Returns
DataFrame

Examples

```python
g = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
g
dtype: timedelta64[ns]
>>> g.dt.components
                      days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0                   0.0       0.0       0.0       0.0              0.0           0.0           0.0
1                   0.0       0.0       0.0       1.0              0.0           0.0           0.0
2                   0.0       0.0       0.0       2.0              0.0           0.0           0.0
3                   0.0       0.0       0.0       3.0              0.0           0.0           0.0
4                   0.0       0.0       0.0       4.0              0.0           0.0           0.0
```

Timedelta methods

<table>
<thead>

</thead>
<tbody>
<tr>
<td>Series.dt.to_pytimedelta()</td>
<td>Return an array of native <code>datetime.timedelta</code> objects.</td>
</tr>
<tr>
<td>Series.dt.total_seconds(*args, **kwargs)</td>
<td>Return total duration of each element expressed in seconds.</td>
</tr>
</tbody>
</table>

pandas.Series.dt.to_pytimedelta

Series.dt.to_pytimedelta()
Return an array of native `datetime.timedelta` objects.

Python’s standard `datetime` library uses a different representation timedelta’s. This method converts a Series of pandas Timedeltas to `datetime.timedelta` format with the same length as the original Series.

Returns
numpy.ndarray Array of 1D containing data with `datetime.timedelta` type.

See also:

Chapter 3. API reference
**datetime.timedelta**  A duration expressing the difference between two date, time, or datetime.

**Examples**

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
0 0 days
1 1 days
2 2 days
3 3 days
4 4 days
dtype: timedelta64[ns]
```

```python
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(days=1),
datetime.timedelta(days=2), datetime.timedelta(days=3),
datetime.timedelta(days=4)], dtype=object)
```

**pandas.Series.dt.total_seconds**

`Series.dt.total_seconds(*args, **kwargs)`

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the `.dt` namespace.

**Returns**

- `seconds` [[ndarray, Float64Index, Series]] When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type `float64` whose index is the same as the original.

**See also:**

- `datetime.timedelta.total_seconds` Standard library version of this method.
- `TimedeltaIndex.components` Return a DataFrame with components of each Timedelta.

**Examples**

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0 0 days
1 1 days
2 2 days
3 3 days
4 4 days
dtype: timedelta64[ns]
```
>>> s.dt.total_seconds()
0    0.0
1   86400.0
2  172800.0
3  259200.0
4  345600.0
dtype: float64

TimedeltaIndex

>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
dtype='timedelta64[ns]', freq=None)

>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.0000000003, 345600.0],
dtype='float64')

String handling

Series.str can be used to access the values of the series as strings and apply several methods to it. These can be accessed like Series.str.<function/property>.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.str.capitalize()</td>
<td>Convert strings in the Series/Index to be capitalized.</td>

**pandas.Series.str.capitalize**

`Series.str.capitalize()`  
Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.

**Returns**

Series or Index of object

**See also:**

- `Series.str.lower` Converts all characters to lowercase.
- `Series.str.upper` Converts all characters to uppercase.
- `Series.str.title` Converts first character of each word to uppercase and remaining to lowercase.
- `Series.str.capitalize` Converts first character to uppercase and remaining to lowercase.
- `Series.str.swapcase` Converts uppercase to lowercase and lowercase to uppercase.
- `Series.str.casefold` Removes all case distinctions in the string.

**Examples**

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0   lower
1  CAPITALS
2   this is a sentence
3     SwApCaSe
dtype: object

>>> s.str.lower()
0   lower
1  capitals
2   this is a sentence
3     swapcase
dtype: object

>>> s.str.upper()
0   LOWER
1  CAPITALS
2   THIS IS A SENTENCE
3     SWAPCASE
dtype: object

>>> s.str.title()
0   Lower
1   Capitals
2  This Is A Sentence
```

(continues on next page)
pandas.Series.str.casefold

Series.str.casefold()

Convert strings in the Series/Index to be casefolded.
New in version 0.25.0.
Equivalent to str.casefold().

Returns
Series or Index of object

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0   lower
1  CAPITALS
2  this is a sentence
3   SwApCaSe
dtype: object

>>> s.str.lower()
0   lower
1     capitals
```

(continues on next page)
```python
>>> s.str.upper()
0 LOWER
1 CAPITALS
2 THIS IS A SENTENCE
3 SWAPCASE
dtype: object
```

```python
>>> s.str.title()
0 Lower
1 Capitals
2 This Is A Sentence
3 Swapcase
dtype: object
```

```python
>>> s.str.capitalize()
0 Lower
1 Capitals
2 This is a sentence
3 Swapcase
dtype: object
```

```python
>>> s.str.swapcase()
0 LOWER
1 capitals
2 THIS IS A SENTENCE
3 sWaPcAsE
dtype: object
```

### pandas.Series.str.cat

`Series.str.cat(others=None, sep=None, na_rep=None, join='left')`

Concatenate strings in the Series/Index with given separator.

If `others` is specified, this function concatenates the Series/Index and elements of `others` element-wise. If `others` is not passed, then all values in the Series/Index are concatenated into a single string with a given `sep`.

**Parameters**

- `others` [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if `join` is not None.

  If `others` is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

  If `others` is None, the method returns the concatenation of all strings in the calling Series/Index.
sep [str, default ‘’] The separator between the different elements/columns. By default the empty string ‘’ is used.

na_rep [str or None, default None] Representation that is inserted for all missing values:

- If na_rep is None, and others is None, missing values in the Series/Index are omitted from the result.
- If na_rep is None, and others is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

join [‘left’, ‘right’, ‘outer’, ‘inner’], default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in others (objects without an index need to match the length of the calling Series/Index). To disable alignment, use .values on any Series/Index/DataFrame in others.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of join from None to ‘left’.

Returns

str, Series or Index If others is None, str is returned, otherwise a Series/Index (same type as caller) of objects is returned.

See also:

split Split each string in the Series/Index.
join Join lists contained as elements in the Series/Index.

Examples

When not passing others, all values are concatenated into a single string:

```python
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using na_rep, they can be given a representation:

```python
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If others is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0   a,A
1   b,B
2  NaN
3   d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using na_rep

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-' )
0   a,A
1   b,B
2  -,C
```

(continues on next page)
If `sep` is not specified, the values are concatenated without separation.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0  aA
1  bB
2  -C
3  dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The `join`-keyword works as in other methods.

```python
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0  aa
1  b-
2  -c
3  dd
dtype: object

>>> s.str.cat(t, join='outer', na_rep='-')
0  aa
1  b-
2  -c
3  dd
4  -e
dtype: object

>>> s.str.cat(t, join='inner', na_rep='-')
0  aa
2  -c
3  dd
dtype: object

>>> s.str.cat(t, join='right', na_rep='-')
3  dd
0  aa
4  -e
2  -c
dtype: object
```

For more examples, see [here](#).
pandas.Series.str.center

Series.str.center(width, fillchar=')
Pad left and right side of strings in the Series/Index.
Equivalent to str.center().

Parameters

- **width** [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- **fillchar** [str] Additional character for filling, default is whitespace.

Returns

- **filled** [Series/Index of objects.]

pandas.Series.str.contains

Series.str.contains(pat, case=True, flags=0, na=None, regex=True)
Test if pattern or regex is contained within a string of a Series or Index.
Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

Parameters

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.
- **na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.
- **regex** [bool, default True] If True, assumes the pat is a regular expression. If False, treats the pat as a literal string.

Returns

- **Series or Index of boolean values** A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

See also:

- **match** Analogous, but stricter, relying on re.match instead of re.search.
- **Series.str.startswith** Test if the start of each string element matches a pattern.
- **Series.str.endswith** Same as startswith, but tests the end of string.

Examples

Returning a Series of booleans using only a literal pattern.

```python
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
Name: og, dtype: bool
```

(continues on next page)
Returning an Index of booleans using only a literal pattern.

```python
ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.nan])
ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using `case`.

```python
s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False
4    NaN
dtype: object
```

Specifying `na` to be `False` instead of `NaN` replaces `NaN` values with `False`. If Series or Index does not contain `NaN` values the resultant dtype will be `bool`, otherwise, an `object` dtype.

```python
s1.str.contains('og', na=False, regex=True)
0    False
1    True
2    False
3    False
4    False
dtype: bool
```

Returning ‘house’ or ‘dog’ when either expression occurs in a string.

```python
s1.str.contains('house|dog', regex=True)
0    False
1    True
2    True
3    False
4    NaN
dtype: object
```

Ignoring case sensitivity using `flags` with regex.

```python
import re
s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2    True
3    False
4    NaN
dtype: object
```

Returning any digit using regular expression.
```python
>>> s1.str.contains('\\d', regex=True)
0    False
1    False
2    False
3     True
4    NaN
dtype: object
```

Ensure pat is not a literal pattern when regex is set to True. Note in the following example one might expect only s2[1] and s2[3] to return True. However, '.0' as a regex matches any character followed by a 0.

```python
>>> s2 = pd.Series([40, '40.0', '41', '41.0', 35])
>>> s2.str.contains('.0', regex=True)
0    True
1    True
2    False
3     True
4    False
dtype: bool
```

### pandas.Series.str.count

Series.str.count(pat, flags=0)

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the `Series`.

**Parameters**

- **pat** [str] Valid regular expression.
- **flags** [int, default 0, meaning no flags] Flags for the `re` module. For a complete list, see here.
- **kwargs** For compatibility with other string methods. Not used.

**Returns**

Series or Index Same type as the calling object containing the integer counts.

**See also:**

- `re` Standard library module for regular expressions.
- `str.count` Standard library version, without regular expression support.

**Notes**

Some characters need to be escaped when passing in pat. eg. '\$' has a special meaning in regex and must be escaped when finding this literal character.
Examples

```python
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4  NaN
5    0.0
6    1.0
dtype: float64
```

Escape '§' to find the literal dollar sign.

```python
>>> s = pd.Series(['$', 'B', 'Aab§', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('§')
0    1
1    0
2    1
3    2
4    2
5    0
dtype: int64
```

This is also available on Index

```python
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

**pandas.Series.str.decode**

Series.str.decode(encoding, errors='strict')

Decodes character string in the Series/Index using indicated encoding.

Equivalent to str.decode() in python2 and bytes.decode() in python3.

**Parameters**

- **encoding** [str]
- **errors** [str, optional]

**Returns**

Series or Index
pandas.Series.str.encode

Series.str.encode(encoding, errors='strict')
    Encode character string in the Series/Index using indicated encoding.
    Equivalent to str.encode().

    Parameters
    encoding [str]
    errors [str, optional]

    Returns
    encoded [Series/Index of objects]

pandas.Series.str.endswith

Series.str.endswith(pat, na=None)
    Test if the end of each string element matches a pattern.
    Equivalent to str.endswith().

    Parameters
    pat [str] Character sequence. Regular expressions are not accepted.
    na [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

    Returns
    Series or Index of bool A Series of booleans indicating whether the given pattern matches the end of each string element.

    See also:
    str.endswith Python standard library string method.
    Series.str.startswith Same as endswith, but tests the start of string.
    Series.str.contains Tests if string element contains a pattern.

Examples

```python
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0   bat
1   bear
2   caT
3   NaN
dtype: object
```

```python
>>> s.str.endswith('t')
0   True
1   False
2   False
3   NaN
dtype: object
```
Specifying `na` to be `False` instead of `NaN`.

```python
>>> s.str.endswith('t', na=False)
0    True
1    False
2    False
3    False
dtype: bool
```

### pandas.Series.str.extract

**Series.str.extract(pat, flags=0, expand=True)**

Extract capture groups in the regex `pat` as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression `pat`.

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] Flags from the `re` module, e.g. `re.IGNORECASE`, that modify regular expression matching for things like case, spaces, etc. For more details, see `re`.
- **expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

**Returns**

- **DataFrame** or **Series** or **Index** A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression `pat` will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and `pat` has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

**See also:**
- `extractall` Returns all matches (not just the first match).

**Examples**

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```python
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'(\[ab\])(\d)')
   0 1
0  a 1
1  b 2
2  NaN NaN
```

A pattern may contain optional groups.

```python
>>> s.str.extract(r'(\[ab\])?(\d)')
   0 1
0  a 1
```
Named groups will become column names in the result.

```python
>>> s.str.extract(r'(\P<letter>[ab])(\P<digit>\d)\')
letter  digit
0 a  1
1 b  2
2 NaN NaN
```

A pattern with one group will return a DataFrame with one column if expand=True.

```python
>>> s.str.extract(r'([ab])(\d)', expand=True)
   0
0  1
1  2
2 NaN
```

A pattern with one group will return a Series if expand=False.

```python
>>> s.str.extract(r'([ab])(\d)', expand=False)
0 1
1 2
2 NaN
dtype: object
```

### pandas.Series.str.extractall

**Series.str.extractall**(pat, flags=0)

Extract capture groups in the regex pat as columns in DataFrame.

For each subject string in the Series, extract groups from all matches of regular expression pat. When each subject string in the Series has exactly one match, extractall(pat).xs(0, level='match') is the same as extract(pat).

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] A re module flag, for example re.IGNORECASE. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example re.IGNORECASE | re.MULTILINE.

**Returns**

- **DataFrame** A DataFrame with one row for each match, and one column for each group. Its rows have a MultiIndex with first levels that come from the subject Series. The last level is named ‘match’ and indexes the matches in each item of the Series. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used.

**See also:**

- **extract** Returns first match only (not all matches).
Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```python
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r\"[ab](\d)\")
match
    0
A  1
  1  2
B  1
```

Capture group names are used for column names of the result.

```python
>>> s.str.extractall(r\"[ab](?P<digit>\d)\")
match
digit
A  1
  1  2
B  1
```

A pattern with two groups will return a DataFrame with two columns.

```python
>>> s.str.extractall(r\"(?P<letter>[ab])(?P<digit>\d)\")
match
letter digit
A  a  1
  1  a  2
B  b  1
```

Optional groups that do not match are NaN in the result.

```python
>>> s.str.extractall(r\"(?P<letter>[ab])?(?P<digit>\d)\")
match
letter digit
A  a  1
  1  a  2
B  b  1
C  NaN  1
```

**pandas.Series.str.find**

`Series.str.find(sub, start=0, end=None)`

Return lowest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

**Parameters**

- `sub` [str] Substring being searched.
- `start` [int] Left edge index.
- `end` [int] Right edge index.
pandas: powerful Python data analysis toolkit, Release 1.4.3

Returns

Series or Index of int.

See also:

**rfind**  Return highest indexes in each strings.

**pandas.Series.str.findall**

Series.str.findall(*pat, flags=0*)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying *re.findall()* to all the elements in the Series/Index.

**Parameters**

- **pat**  [str] Pattern or regular expression.
- **flags**  [int, default 0] Flags from *re* module, e.g. *re.IGNORECASE* (default is 0, which means no flags).

**Returns**

Series/Index of lists of strings  All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

See also:

**count**  Count occurrences of pattern or regular expression in each string of the Series/Index.

**extractall**  For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.

**re.findall**  The equivalent *re* function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

**Examples**

```python
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])

The search for the pattern ‘Monkey’ returns one match:

```python
>>> s.str.findall('Monkey')
0    []
1  [Monkey]
2    []
dtype: object
```

On the other hand, the search for the pattern ‘MONKEY’ doesn’t return any match:

```python
>>> s.str.findall('MONKEY')
0    []
1    []
2    []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern ‘MONKEY’ ignoring the case:

```python
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0    []
1    []
2    []
dtype: object
```
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0   []
1   [Monkey]
2   []
dtype: object

When the pattern matches more than one string in the Series, all matches are returned:

>>> s.str.findall('on')
0   [on]
1   [on]
2   []
dtype: object

Regular expressions are supported too. For instance, the search for all the strings ending with the word ‘on’ is shown next:

>>> s.str.findall('on$')
0   [on]
1   []
2   []
dtype: object

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

>>> s.str.findall('b')
0   []
1   []
2   [b, b]
dtype: object

**pandas.Series.str.fullmatch**

Series.str.fullmatch(*pat, case=True, flags=0, na=None*)

Determine if each string entirely matches a regular expression.

New in version 1.1.0.

**Parameters**

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.
- **na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

**Returns**

Series/Index/array of boolean values

See also:

- **match** Similar, but also returns True when only a prefix of the string matches the regular expression.
- **extract** Extract matched groups.
pandas.Series.str.get

Series.str.get(i)
Extract element from each component at specified position.
Extract element from lists, tuples, or strings in each element in the Series/Index.

Parameters
  i [int] Position of element to extract.

Returns
  Series or Index

Examples

```python
>>> s = pd.Series(["String",
...                (1, 2, 3),
...                ["a", "b", "c"],
...                123,
...                -456,
...                {1: "Hello", "2": "World"}])
>>> s
0 String
1 (1, 2, 3)
2 [a, b, c]
3 123
4 -456
5 {1: 'Hello', '2': 'World'}
dtype: object

>>> s.str.get(1)
   0  t
   1  2
   2  b
   3  NaN
   4  NaN
   5  Hello
dtype: object

>>> s.str.get(-1)
   0  g
   1  3
   2  c
   3  NaN
   4  NaN
   5  None
dtype: object
```
**pandas.Series.str.index**

Series.str.index(sub, start=0, end=None)

Return lowest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as str.find except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard str.index.

**Parameters**

- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

**Returns**

Series or Index of object

See also:

- rindex Return highest indexes in each strings.

**pandas.Series.str.join**

Series.str.join(sep)

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to str.join().

**Parameters**

- sep [str] Delimiter to use between list entries.

**Returns**

Series/Index: object The list entries concatenated by intervening occurrences of the delimiter.

**Raises**

- AttributeError If the supplied Series contains neither strings nor lists.

See also:

- str.join Standard library version of this method.
- Series.str.split Split strings around given separator/delimiter.

**Notes**

If any of the list items is not a string object, the result of the join will be NaN.
Examples

Example with a list that contains non-string elements.

```python
>>> s = pd.Series([["lion", 'elephant', 'zebra'],
                   [1.1, 2.2, 3.3],
                   ['cat', np.nan, 'dog'],
                   ['cow', 4.5, 'goat'],
                   ['duck', ['swan', 'fish'], 'guppy']])
```

```python
>>> s
0    [lion, elephant, zebra]
1    [1.1, 2.2, 3.3]
2      [cat, nan, dog]
3     [cow, 4.5, goat]
4  [duck, [swan, fish], guppy]
dtype: object
```

Join all lists using a '. The lists containing object(s) of types other than str will produce a NaN.

```python
>>> s.str.join('-')
0    lion-elephant-zebra
1         NaN
2          NaN
3          NaN
4          NaN
dtype: object
```

**pandas.Series.str.len**

Series.str.len()

Compute the length of each element in the Series/Index.

The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

**Returns**

Series or Index of int A Series or Index of integer values indicating the length of each element in the Series or Index.

**See also:**

str.len Python built-in function returning the length of an object.

Series.size Returns the length of the Series.

**Examples**

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```python
>>> s = pd.Series(['dog',
                   '',
                   5,
                   {'foo' : 'bar'},
                   [2, 3, 5, 7],
                   ('one', 'two', 'three')])
```
```python
>>> s
0    dog
1  
2      5
3      {'foo': 'bar'}
4    [2, 3, 5, 7]
5    (one, two, three)
dtype: object
>>> s.str.len()
0   3.0
1   0.0
2   NaN
3   1.0
4   4.0
5   3.0
dtype: float64
```

**pandas.Series.str.ljust**

Series.str.ljust(*width, fillchar=‘ ‘*)

Pad right side of strings in the Series/Index.

Equivalent to `str.ljust()`.

**Parameters**

- `width` [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.
- `fillchar` [str] Additional character for filling, default is whitespace.

**Returns**

- `filled` [Series/Index of objects.]

**pandas.Series.str.lower**

Series.str.lower()

Convert strings in the Series/Index to lowercase.

Equivalent to `str.lower()`.

**Returns**

- Series or Index of object

See also:

- `Series.str.lower` Converts all characters to lowercase.
- `Series.str.upper` Converts all characters to uppercase.
- `Series.str.title` Converts first character of each word to uppercase and remaining to lowercase.
- `Series.str.capitalize` Converts first character to uppercase and remaining to lowercase.
- `Series.str.swapcase` Converts uppercase to lowercase and lowercase to uppercase.
- `Series.str.casefold` Removes all case distinctions in the string.
Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0     lower
1   CAPITALS
2   this is a sentence
3     SwApCaSe
dtype: object
```

```python
>>> s.str.lower()
0     lower
1   capitals
2   this is a sentence
3     swapcase
dtype: object
```

```python
>>> s.str.upper()
0      LOWER
1   CAPITALS
2 THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```python
>>> s.str.title()
0     Lower
1   Capitals
2  This Is A Sentence
3     Swapcase
dtype: object
```

```python
>>> s.str.capitalize()
0     Lower
1   Capitals
2  This is a sentence
3     Swapcase
dtype: object
```

```python
>>> s.str.swapcase()
0      LOWER
1   capitals
2 THIS IS A SENTENCE
3    sWaPcAsE
dtype: object
```
pandas.Series.str.lstrip

Series.str.lstrip(to_strip=None)
Remove leading characters.
Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to str.lstrip().

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:
Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0    1. Ant.
1    2. Bee!
2    3. Cat?
3     NaN
dtype: object

>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3     NaN
dtype: object

>>> s.str.lstrip('123. ')
0    Ant.
1    Bee!
2    Cat?
3     NaN
dtype: object

>>> s.str.rstrip(' .!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3     NaN
dtype: object
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> s.str.strip('123.! \n\t')
0   Ant
1   Bee
2   Cat
3   NaN
dtype: object
```

**pandas.Series.str.strip**

Series.str.strip(pat, axis=0, level=None, expand=False)

Remove whitespace characters from the start and end of each string in the Series/Index.

Parameters

- **pat** [str or list] A character sequence or regular expression that defines the characters to be removed.

Returns

Series/Index of objects.

**pandas.Series.str.match**

Series.str.match(pat, case=True, flags=0, na=None)

Determine if each string starts with a match of a regular expression.

Parameters

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.
- **na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

Returns

Series/Index/array of boolean values

See also:

- `fullmatch` - Stricter matching that requires the entire string to match.
- `contains` - Analogous, but less strict, relying on re.search instead of re.match.
- `extract` - Extract matched groups.

**pandas.Series.str.normalize**

Series.str.normalize(form)

Return the Unicode normal form for the strings in the Series/Index.

For more information on the forms, see the `unicodedata.normalize()`.

Parameters

Returns

normalized [Series/Index of objects]

**pandas.Series.str.pad**

Series.str.pad(width, side='left', fillchar=None)

Pad strings in the Series/Index up to width.

Parameters

- **width** [int] Minimum width of resulting string; additional characters will be filled with character defined in `fillchar`.
- **side** [{‘left’, ‘right’, ‘both’}, default ‘left’] Side from which to fill resulting string.
filchar  [str, default ‘ ‘] Additional character for filling, default is whitespace.

Returns

Series or Index of object  Returns Series or Index with minimum number of char in object.

See also:

Series.str.rjust  Fills the left side of strings with an arbitrary character. Equivalent to Series.str.
                      pad(side='left').
Series.str.ljust  Fills the right side of strings with an arbitrary character. Equivalent to Series.str.
                      pad(side='right').
Series.str.center  Fills both sides of strings with an arbitrary character. Equivalent to Series.str.
                      pad(side='both').
Series.str.zfill  Pad strings in the Series/Index by prepending '0' character. Equivalent to Series.str.
                      pad(side='left', fillchar='0').

Examples

```python
>>> s = pd.Series(['caribou', 'tiger'])
```

```plaintext
0  caribou
1  tiger
dtype: object
```

```python
>>> s.str.pad(width=10)
```

```plaintext
0  caribou
1  tiger
dtype: object
```

```python
>>> s.str.pad(width=10, side='right', fillchar='-')
```

```plaintext
0  caribou---
1  tiger-----
dtype: object
```

```python
>>> s.str.pad(width=10, side='both', fillchar='-')
```

```plaintext
0  -caribou--
1  --tiger---
dtype: object
```

pandas.Series.str.partition

Series.str.partition(sep=' ', expand=True)

Split the string at the first occurrence of sep.

This method splits the string at the first occurrence of sep, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters

sep  [str, default whitespace] String to split on.
expand  [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality.
               If False, return Series/Index.
Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

rpartition Split the string at the last occurrence of sep.
Series.str.split Split strings around given separators.
str.partition Standard library version.

Examples

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0   Linda van der Berg
1    George Pitt-Rivers
dtype: object

>>> s.str.partition()
     0   1   2
0  Linda    van der    Berg
1   George     Pitt      Rivers

To partition by the last space instead of the first one:

>>> s.str.rpartition()
     0   1   2
0  Linda  van der    Berg
1   George     Pitt-Rivers

To partition by something different than a space:

>>> s.str.partition('-')
     0   1   2
0  Linda van der Berg
1    George Pitt - Rivers

To return a Series containing tuples instead of a DataFrame:

>>> s.str.partition('-', expand=False)
    0          1          2
0  (Linda van der Berg, , )
1  (George Pitt, -, Rivers)
dtype: object

Also available on indices:

>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')

Which will create a MultiIndex:

>>> idx.str.partition()
MultiIndex([('X', '', '123'),
            ('Y', '', '999')],
          names=['X', 'Y'])
```

(continues on next page)
Or an index with tuples with `expand=False`:

```python
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

### pandas.Series.str.removeprefix

**Series.str.removeprefix(prefix)**

Remove a prefix from an object series. If the prefix is not present, the original string will be returned.

**Parameters**

- `prefix` [str] Remove the prefix of the string.

**Returns**

- `Series/Index: object` The Series or Index with given prefix removed.

**See also:**

- `Series.str.removesuffix` Remove a suffix from an object series.

**Examples**

```python
>>> s = pd.Series(['str_foo', 'str_bar', 'no_prefix'])
>>> s
0    str_foo
1    str_bar
2    no_prefix
dtype: object
>>> s.str.removeprefix("str_")
0       foo
1       bar
2    no_prefix
dtype: object
```

```python
>>> s = pd.Series(['foo_str', 'bar_str', 'no_suffix'])
>>> s
0    foo_str
1    bar_str
2    no_suffix
dtype: object
>>> s.str.removesuffix("_str")
0       foo
1       bar
2    no_suffix
dtype: object
```
**pandas.Series.str.removeprefix**

Series.str.removeprefix(suffix)

Remove a prefix from an object series. If the prefix is not present, the original string will be returned.

**Parameters**

- suffix [str] Remove the prefix of the string.

**Returns**

Series/Index: object The Series or Index with given prefix removed.

**See also:**

Series.str.removeprefix Remove a prefix from an object series.

**Examples**

```python
>>> s = pd.Series(["str_foo", "str_bar", "no_prefix"])
>>> s
0  str_foo
1  str_bar
2  no_prefix
dtype: object

>>> s.str.removeprefix("str_")
0  foo
1  bar
2  no_prefix
dtype: object
```

```python
>>> s = pd.Series(["foo_str", "bar_str", "no_suffix"])
>>> s
0  foo_str
1  bar_str
2  no_suffix
dtype: object

>>> s.str.removesuffix("_str")
0  foo
1  bar
2  no_suffix
dtype: object
```

**pandas.Series.str.repeat**

Series.str.repeat(repeats)

Duplicate each string in the Series or Index.

**Parameters**

- repeats [int or sequence of int] Same value for all (int) or different value per (sequence).

**Returns**

Series or Index of object Series or Index of repeated string objects specified by input parameter repeats.
Examples

```python
>>> s = pd.Series(['a', 'b', 'c'])
```

```python
0   a
1   b
2   c
dtype: object
```

Single int repeats string in Series

```python
>>> s.str.repeat(repeats=2)
```

```python
0   aa
1   bb
2   cc
dtype: object
```

Sequence of int repeats corresponding string in Series

```python
>>> s.str.repeat(repeats=[1, 2, 3])
```

```python
0   a
1   bb
2   ccc
dtype: object
```

**pandas.Series.str.replace**

Series.str.replace(pat, repl, n=-1, case=None, flags=0, regex=None)

Replace each occurrence of pattern/regex in the Series/Index.

Equivalent to str.replace() or re.sub(), depending on the regex value.

**Parameters**

- **pat** [str or compiled regex] String can be a character sequence or regular expression.
- **repl** [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See re.sub().
- **n** [int, default -1 (all)] Number of replacements to make from start.
- **case** [bool, default None] Determines if replace is case sensitive:
  - If True, case sensitive (the default if pat is a string)
  - Set to False for case insensitive
  - Cannot be set if pat is a compiled regex.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE. Cannot be set if pat is a compiled regex.
- **regex** [bool, default True] Determines if the passed-in pattern is a regular expression:
  - If True, assumes the passed-in pattern is a regular expression.
  - If False, treats the pattern as a literal string
  - Cannot be set to False if pat is a compiled regex or repl is a callable.
New in version 0.23.0.

Returns

**Series or Index of object** A copy of the object with all matching occurrences of *pat* replaced by *repl*.

Raises

**ValueError**

- if *regex* is False and *repl* is a callable or *pat* is a compiled regex
- if *pat* is a compiled regex and *case* or *flags* is set

Notes

When *pat* is a compiled regex, all flags should be included in the compiled regex. Use of *case*, *flags*, or *regex=False* with a compiled regex will raise an error.

Examples

When *pat* is a string and *regex* is True (the default), the given *pat* is compiled as a regex. When *repl* is a string, it replaces matching regex patterns as with re.sub(). NaN value(s) in the Series are left as is:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0  bao
1  baz
2  NaN
dtype: object
```

When *pat* is a string and *regex* is False, every *pat* is replaced with *repl* as with **str.replace()**:

```python
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0  bao
1  fuz
2  NaN
dtype: object
```

When *repl* is a callable, it is called on every *pat* using re.sub(). The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr, regex=True)
0  <re.Match object; span=(0, 1), match='f'>oo
1  <re.Match object; span=(0, 1), match='f'>uz
2  NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```python
>>> repl = lambda m: m.group(0)[::-1]
>>> ser = pd.Series(['foo 123', 'bar baz', np.nan])
>>> ser.str.replace(r'[a-z]+', repl, regex=True)
0  oof 123
```

(continues on next page)
Using regex groups (extract second group and swap case):

```python
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> ser = pd.Series(['One Two Three', 'Foo Bar Baz'])
```

```python
>>> ser.str.replace(pat, repl, regex=True)
0    tWO
1     bAR
dtype: object
```

Using a compiled regex with flags

```python
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex=regex_pat, 'bar', regex=True)
0     foo
1     bar
2     NaN
dtype: object
```

**pandas.Series.str.rfind**

Series.str.rfind(sub, start=0, end=None)

Return highest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

**Parameters**

- **sub** [str] Substring being searched.
- **start** [int] Left edge index.
- **end** [int] Right edge index.

**Returns**

Series or Index of int.

See also:

- `find` Return lowest indexes in each strings.
**pandas.Series.str.rindex**

Series.str.rindex(sub, start=0, end=None)

Return highest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as str.rfind except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard str.rindex.

**Parameters**

- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

**Returns**

Series or Index of object

See also:

index Return lowest indexes in each strings.

**pandas.Series.str.rjust**

Series.str.rjust(width, fillchar=' ')

Pad left side of strings in the Series/Index.

Equivalent to str.rjust().

**Parameters**

- width [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- fillchar [str] Additional character for filling, default is whitespace.

**Returns**

filled [Series/Index of objects.]

**pandas.Series.str.rpartition**

Series.str.rpartition(sep=' ', expand=True)

Split the string at the last occurrence of sep.

This method splits the string at the last occurrence of sep, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

**Parameters**

- sep [str, default whitespace] String to split on.
- expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

**Returns**

DataFrame/MultiIndex or Series/Index of objects

See also:
**partition** Split the string at the first occurrence of `sep`.

**Series.str.split** Split strings around given separators.

**str.partition** Standard library version.

### Examples

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
    dtype: object

>>> s.str.partition()
    0  1  2
   0 Linda  van der Berg
   1   George   Pitt-Rivers
```

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
    0  1  2
   0 Linda  van der Berg
   1   George   Pitt-Rivers
```

To partition by something different than a space:

```python
>>> s.str.partition('-')
    0  1  2
   0 Linda  van der Berg
   1   George   Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
    0  1  2
   0 (Linda van der Berg, , )
   1 (George Pitt, -, Rivers)
    dtype: object
```

Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
            ('Y', ' ', '999')])
```

Or an index with tuples with `expand=False`:
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')

pandas.Series.str.rstrip

Series.str.rstrip(to_strip=None)
Remove trailing characters.
Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to str.rstrip().

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!
2    3. Cat?
3       NaN
dtype: object

>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3       NaN
dtype: object

>>> s.str.lstrip('123. ')
0    Ant.
1    Bee!
2    Cat?
3       NaN
dtype: object

>>> s.str.rstrip('!? \n\t')
0    1. Ant
(continues on next page)```
pandas: powerful Python data analysis toolkit, Release 1.4.3

>>> s.str.strip('123.!? \n\t')
0   Ant
1    Bee
2     Cat
3    NaN
dtype: object

pandas.Series.str.slice

Series.str.slice(start=None, stop=None, step=None)

Slice substrings from each element in the Series or Index.

Parameters

- **start** [int, optional] Start position for slice operation.
- **stop** [int, optional] Stop position for slice operation.
- **step** [int, optional] Step size for slice operation.

Returns

Series or Index of object Series or Index from sliced substring from original string object.

See also:

- Series.str.slice_replace Replace a slice with a string.
- Series.str.get Return element at position. Equivalent to Series.str.slice(start=i, stop=i+1) with i being the position.

Examples

>>> s = pd.Series(["koala", "dog", "chameleon")

>>> s
0   koala
1     dog
2  chameleon
dtype: object

>>> s.str.slice(start=1)
0   oala
1    og
2   hameleon

dtype: object

>>> s.str.slice(start=-1)
0    a
1     g

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> s.str.slice(stop=2)
0  ko
1  do
2  ch
dtype: object

>>> s.str.slice(step=2)
0  kaa
1  dg
2  caeen
dtype: object

>>> s.str.slice(start=0, stop=5, step=3)
0  kl
1  d
2  cm
dtype: object
```

Equivalent behaviour to:

```python
>>> s.str[0:5:3]
0  kl
1  d
2  cm
dtype: object
```

### pandas.Series.str.slice_replace

`Series.str.slice_replace(start=None, stop=None, repl=None)`

Replace a positional slice of a string with another value.

**Parameters**

- **start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.

- **stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.

- **repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

**Returns**

- **Series or Index** Same type as the original object.

**See also:**

- `Series.str.slice` Just slicing without replacement.

---

3.3. Series  1523
Examples

```python
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0   a
1  ab 
2  abc
3  abdc
4  abcde
dtype: object
```

Specify just `start`, meaning replace `start` until the end of the string with `repl`.

```python
>>> s.str.slice_replace(1, repl='X')
0   aX
1  aX 
2  aX
3  aX
4  aX
dtype: object
```

Specify just `stop`, meaning the start of the string to `stop` is replaced with `repl`, and the rest of the string is included.

```python
>>> s.str.slice_replace(stop=2, repl='X')
0   X
1   Xc
2   Xdc
3   Xcde
4   Xcde
dtype: object
```

Specify `start` and `stop`, meaning the slice from `start` to `stop` is replaced with `repl`. Everything before or after `start` and `stop` is included as is.

```python
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0   aX
1   aX
2   aX
3   aXc
4   aXc
dtype: object
```

### pandas.Series.str.split

`Series.str.split(pat=None, n=-1, expand=False, *, regex=None)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string.

- **Parameters**
  - `pat` [str or compiled regex, optional] String or regular expression to split on. If not specified, split on whitespace.
n [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.

expand [bool, default False] Expand the split strings into separate columns.

- If True, return DataFrame/MultiIndex expanding dimensionality.
- If False, return Series/Index, containing lists of strings.

regex [bool, default None] Determines if the passed-in pattern is a regular expression:

- If True, assumes the passed-in pattern is a regular expression
- If False, treats the pattern as a literal string.
- If None and pat length is 1, treats pat as a literal string.
- If None and pat length is not 1, treats pat as a regular expression.
- Cannot be set to False if pat is a compiled regex

New in version 1.4.0.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless expand=True (see Notes).

Raises

ValueError

- if regex is False and pat is a compiled regex

See also:

Series.str.split Split strings around given separator/delimiter.
Series.str.rsplit Splits string around given separator/delimiter, starting from the right.
Series.str.join Join lists contained as elements in the Series/Index with passed delimiter.
str.split Standard library version for split.
str.rsplit Standard library version for rsplit.

Notes

The handling of the n keyword depends on the number of found splits:

- If found splits > n, make first n splits only
- If found splits <= n, make all splits
- If for a certain row the number of found splits < n, append None for padding up to n if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Use of regex=False with a pat as a compiled regex will raise an error.

Examples

```python
>>> s = pd.Series(
    ...     [               
    ...       "this is a regular sentence",
    ...       "https://docs.python.org/3/tutorial/index.html",
    ...       np.nan
    ...     ]
    ...
```
(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

(continued from previous page)

>>> s
0
this is a regular sentence
1
https://docs.python.org/3/tutorial/index.html
2
NaN
dtype: object
In the default setting, the string is split by whitespace.
>>> s.str.split()
0
[this, is, a, regular, sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2
NaN
dtype: object
Without the n parameter, the outputs of rsplit and split are identical.
>>> s.str.rsplit()
0
[this, is, a, regular, sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2
NaN
dtype: object
The n parameter can be used to limit the number of splits on the delimiter. The outputs of split and rsplit are
different.
>>> s.str.split(n=2)
0
[this, is, a regular sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2
NaN
dtype: object
>>> s.str.rsplit(n=2)
0
[this is a, regular, sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2
NaN
dtype: object
The pat parameter can be used to split by other characters.
>>> s.str.split(pat="/")
0
[this is a regular sentence]
1
[https:, , docs.python.org, 3, tutorial, index...
2
NaN
dtype: object
When using expand=True, the split elements will expand out into separate columns. If NaN is present, it is
propagated throughout the columns during the split.

Chapter 3. API reference


For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

\[
\begin{array}{cc}
0 & \text{this is a regular sentence} \\
1 & \text{https://docs.python.org/3/tutorial index.html} \\
2 & \text{NaN NaN}
\end{array}
\]

Remember to escape special characters when explicitly using regular expressions.

Regular expressions can be used to handle urls or file names. When \texttt{pat} is a string and \texttt{regex=None} (the default), the given \texttt{pat} is compiled as a regex only if \texttt{len(pat) \neq 1}.

\[
\begin{array}{c}
\text{foojpgbar.jpg} \\
\text{foojpgbar.jpg}
\end{array}
\]

When \texttt{regex=True}, \texttt{pat} is interpreted as a regex

\[
\begin{array}{c}
\text{foojpgbar} \\
\text{foojpgbar}
\end{array}
\]

A compiled regex can be passed as \texttt{pat}

\[
\begin{array}{c}
\text{foojpgbar} \\
\text{foojpgbar}
\end{array}
\]

When \texttt{regex=False}, \texttt{pat} is interpreted as the string itself

\[
\begin{array}{c}
\text{foojpgbar.jpg} \\
\text{foojpgbar.jpg}
\end{array}
\]
pandas.Series.str.rsplit

Series.str.rsplit(pat=None, n=-1, expand=False)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string.

Parameters

- **pat** [str or compiled regex, optional] String or regular expression to split on. If not specified, split on whitespace.
- **n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
- **expand** [bool, default False] Expand the split strings into separate columns.
  - If True, return DataFrame/MultiIndex expanding dimensionality.
  - If False, return Series/Index, containing lists of strings.
- **regex** [bool, default None] Determines if the passed-in pattern is a regular expression:
  - If True, assumes the passed-in pattern is a regular expression
  - If False, treats the pattern as a literal string.
  - If None and pat length is 1, treats pat as a literal string.
  - If None and pat length is not 1, treats pat as a regular expression.
  - Cannot be set to False if pat is a compiled regex

New in version 1.4.0.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless expand=True (see Notes).

Raises

- ValueError
  - if regex is False and pat is a compiled regex

See also:

- Series.str.split Split strings around given separator/delimiter.
- Series.str.rsplit Splits string around given separator/delimiter, starting from the right.
- Series.str.join Join lists contained as elements in the Series/Index with passed delimiter.
- str.split Standard library version for split.
- str.rsplit Standard library version for rsplit.

Notes

The handling of the n keyword depends on the number of found splits:

- If found splits > n, make first n splits only
- If found splits <= n, make all splits
- If for a certain row the number of found splits < n, append None for padding up to n if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Use of regex=False with a pat as a compiled regex will raise an error.
Examples

```python
>>> s = pd.Series(["this is a regular sentence", "https://docs.python.org/3/tutorial/index.html", np.nan])
>>> s
0 this is a regular sentence
1 https://docs.python.org/3/tutorial/index.html
2 NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```python
>>> s.str.split()
0 [this, is, a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

Without the `n` parameter, the outputs of `rsplit` and `split` are identical.

```python
>>> s.str.rsplit()
0 [this, is, a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

The `n` parameter can be used to limit the number of splits on the delimiter. The outputs of `split` and `rsplit` are different.

```python
>>> s.str.split(n=2)
0 [this, is, a regular sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

```python
>>> s.str.rsplit(n=2)
0 [this is a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

The `pat` parameter can be used to split by other characters.

```python
>>> s.str.split(pat="/")
0 [this is a regular sentence]
1 [https:, , docs.python.org, 3, tutorial, index...]
2 NaN
dtype: object
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

When using expand=True, the split elements will expand out into separate columns. If NaN is present, it is
propagated throughout the columns during the split.
>>> s.str.split(expand=True)
0
1
2

0
this
https://docs.python.org/3/tutorial/index.html
NaN

1
is
None
NaN

2
a
None
NaN

3
regular
None
NaN

4
sentence
None
NaN

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter
settings can be used.
>>> s.str.rsplit("/", n=1, expand=True)
0
1
0
this is a regular sentence
None
1 https://docs.python.org/3/tutorial index.html
2
NaN
NaN
Remember to escape special characters when explicitly using regular expressions.
>>> s = pd.Series(["foo and bar plus baz"])
>>> s.str.split(r"and|plus", expand=True)
0
1
2
0 foo bar baz
Regular expressions can be used to handle urls or file names. When pat is a string and regex=None (the default),
the given pat is compiled as a regex only if len(pat) != 1.
>>> s = pd.Series(['foojpgbar.jpg'])
>>> s.str.split(r".", expand=True)
0
1
0 foojpgbar jpg
>>> s.str.split(r"\.jpg", expand=True)
0 1
0 foojpgbar
When regex=True, pat is interpreted as a regex
>>> s.str.split(r"\.jpg", regex=True, expand=True)
0 1
0 foojpgbar
A compiled regex can be passed as pat
>>> import re
>>> s.str.split(re.compile(r"\.jpg"), expand=True)
0 1
0 foojpgbar
When regex=False, pat is interpreted as the string itself
>>> s.str.split(r"\.jpg", regex=False, expand=True)
0
0 foojpgbar.jpg

1530

Chapter 3. API reference


**pandas.Series.str.startswith**

Series.str.startswith(*pat*, *na=None*)

Test if the start of each string element matches a pattern.

Equivalent to str.startswith().

**Parameters**

- **pat** [str] Character sequence. Regular expressions are not accepted.
- **na** [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

**Returns**

Series or Index of bool A Series of booleans indicating whether the given pattern matches the start of each string element.

**See also:**

- str.startswith Python standard library string method.
- Series.str.endswith Same as startswith, but tests the end of string.
- Series.str.contains Tests if string element contains a pattern.

**Examples**

```python
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0  bat
1  Bear
2  cat
3   NaN
dtype: object

>>> s.str.startswith('b')
0   True
1   False
2   False
3   False
daetype: object
```

Specifying `na` to be `False` instead of `NaN`.

```python
>>> s.str.startswith('b', na=False)
0   False
1   False
2   False
3   False
daetype: bool
```
pandas.Series.str.strip

Series.str.strip(to_strip=None)
Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from
left and right sides. Equivalent to str.strip().

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All
 combinations of this set of characters will be stripped. If None then whitespaces are
 removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0    1. Ant.
1    2. Bee!
2    3. Cat?
3     NaN
dtype: object

>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3     NaN
dtype: object

>>> s.str.lstrip('123. ')
0       Ant.
1      Bee!
2      Cat?
3     NaN
dtype: object

>>> s.str.rstrip('.!? \n\t')
0       1. Ant
1       2. Bee
2       3. Cat
3      NaN
dtype: object
```
```python
>>> s.str.strip('123.!? \n\t')
0   Ant
1   Bee
2   Cat
3   NaN
dtype: object
```

## pandas.Series.str.swapcase

### pandas.Series.str.swapcase()

Convert strings in the Series/Index to be swapcased.

Equivalent to `str.swapcase()`.

**Returns**

Series or Index of object

**See also:**

- `Series.str.lower` Converts all characters to lowercase.
- `Series.str.upper` Converts all characters to uppercase.
- `Series.str.title` Converts first character of each word to uppercase and remaining to lowercase.
- `Series.str.capitalize` Converts first character to uppercase and remaining to lowercase.
- `Series.str.swapcase` Converts uppercase to lowercase and lowercase to uppercase.
- `Series.str.casefold` Removes all case distinctions in the string.

### Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0    lower
1  CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1  capitals
2  this is a sentence
3      swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```
pandas.Series.str.title

Series.str.title()

Convert strings in the Series/Index to titlecase.

Equivalent to str.title().

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1  CAPITALS
2  this is a sentence
3    SwApCaSe
dtype: object
```python
>>> s.str.lower()
0    lower
1  capitals
2  this is a sentence
3  swapcase
dtype: object

>>> s.str.upper()
0   LOWER
1   CAPITALS
2  THIS IS A SENTENCE
3   SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
1   Capitals
2 This Is A Sentence
3   Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1   Capitals
2 This is a sentence
3   Swapcase
dtype: object

>>> s.str.swapcase()
0   LOWER
1   capitals
2  THIS IS A SENTENCE
3 sWaPcAsE
dtype: object
```

**pandas.Series.str.translate**

Series.str.translate(table)

Map all characters in the string through the given mapping table.

Equivalent to standard str.translate().

**Parameters**

- `table` [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. str.maketrans() is a helper function for making translation tables.

**Returns**

Series or Index
pandas.Series.str.upper

Series.str.upper()

Convert strings in the Series/Index to uppercase.

Equivalent to str.upper().

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SWAPCaSe'])
>>> s
0  lower
1  CAPITALS
2  this is a sentence
3  SWAPCaSe
dtype: object

>>> s.str.lower()
0  lower
1  capitals
2  this is a sentence
3  swapcase
dtype: object

>>> s.str.upper()
0  LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  SWAPCASE
dtype: object

>>> s.str.title()
0  Lower
1  Capitals
2  This Is A Sentence
3  Swapcase
dtype: object

>>> s.str.capitalize()
0  Lower
1  Capitals
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

This is a sentence

```
>>> s.str.swapcase()
0    LOWER
1  capitals
2  THIS IS A SENTENCE
3     sWaPcAsE
dtype: object
```

**pandas.Series.str.wrap**

**Series.str.wrap(width, **kwargs)**

Wrap strings in Series/Index at specified line width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

**Parameters**

- `width` [int] Maximum line width.
- `expand_tabs` [bool, optional] If True, tab characters will be expanded to spaces (default: True).
- `replace_whitespace` [bool, optional] If True, each whitespace character (as defined by `string.whitespace`) remaining after tab expansion will be replaced by a single space (default: True).
- `drop_whitespace` [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).
- `break_long_words` [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).
- `break_on_hyphens` [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly inseparable words (default: True).

**Returns**

Series or Index

**Notes**

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R’s stringr library `str_wrap` function, use the arguments:

- `expand_tabs = False`
- `replace_whitespace = True`
- `drop_whitespace = True`
- `break_long_words = False`
- `break_on_hyphens = False`
Examples

```python
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0    line to be\nwrapped
1  another line\n    to be\nwrapped
dtype: object
```

**pandas.Series.str.zfill**

Series.str.zfill(width)

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length `width`. Strings in the Series/Index with length greater or equal to `width` are unchanged.

**Parameters**

- **width** [int] Minimum length of resulting string; strings with length less than `width` be prepended with ‘0’ characters.

**Returns**

Series/Index of objects.

**See also:**

- `Series.str.rjust` Fills the left side of strings with an arbitrary character.
- `Series.str.ljust` Fills the right side of strings with an arbitrary character.
- `Series.str.pad` Fills the specified sides of strings with an arbitrary character.
- `Series.str.center` Fills both sides of strings with an arbitrary character.

**Notes**

Differs from `str.zfill()` which has special handling for ‘+’/-’ in the string.

**Examples**

```python
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0   -1
1    1
2  1000
3   10
4  NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in '-1' is treated as a regular character and the zero is added to the left of it (str.zfill() would have moved it to the left). 1000 remains unchanged as it is longer than `width`.

```python
>>> s.str.zfill(3)
0   0-1
1   001
```
**pandas.Series.str.isalnum**

Series.str.isalnum()  
Check whether all characters in each string are alphanumeric.  
This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.  
**Returns**  
Series or Index of bool  
Series or Index of boolean values with the same length as the original Series/Index.  
**See also:**  
Series.str.isalpha Check whether all characters are alphabetic.  
Series.str.isnumeric Check whether all characters are numeric.  
Series.str.isalnum Check whether all characters are alphanumeric.  
Series.str.isdigit Check whether all characters are digits.  
Series.str.isdecimal Check whether all characters are decimal.  
Series.str.isspace Check whether all characters are whitespace.  
Series.str.islower Check whether all characters are lowercase.  
Series.str.isupper Check whether all characters are uppercase.  
Series.str.istitle Check whether all characters are titlecase.  

**Examples**

**Checks for Alphabetic and Numeric Characters**

```python  
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True  
(continues on next page)"
Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', ' ', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The `s3.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s3.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0   False
1   False
2   False
3   False
dtype: bool
```

(continues on next page)
Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
>>> s5.str.islower()
0    True
1    True
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

**pandas.Series.str.isalpha**

`Series.str.isalpha()`

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- **Series or Index of bool**: Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha`: Check whether all characters are alphabetic.
- `Series.str.isnumeric`: Check whether all characters are numeric.
- `Series.str.isalnum`: Check whether all characters are alphanumeric.
- `Series.str.isdigit`: Check whether all characters are digits.
- `Series.str.isdecimal`: Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ' '])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0  False
1  False
2  False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '13', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   True
2  False
```
The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

### Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	
'], '')
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

### Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0   True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2   True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by
whitespace characters.

```python
>>> s5.str.istitle()
0   False
1   True
2   False
3   False
dtype: bool
```

### pandas.Series.str.isdigit

**Series.str.isdigit()**

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

**Returns**

- **Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.

**Examples**

### Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'onen', '1', ''])

>>> s1.str.isalpha()
0   True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2   True
3   False
dtype: bool
```
>> s1.str.isalnum()
0   True
1   True
2   True
3   False
dtype: bool

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

>> s2 = pd.Series(['A B', '1.5', '3,000'])
>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

>> s3 = pd.Series(['23', '3', '', ''])
The s3.str.isdecimal method checks for characters used to form numbers in base 10.

>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like super-scripted and subscripted digits in unicode.

>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool

The s.str.isnumeric method is the same as s3.str.isdigit but also includes other characters that can represent quantities such as unicode fractions.

>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool

Checks for Whitespace
```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0   True
1   True
2  False
dtype: bool
```

**Checks for Character Case**

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

>>> s5.str.islower()
0   True
1  False
2  False
3  False
dtype: bool

>>> s5.str.isupper()
0  False
1  False
2   True
3  False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0  False
1   True
2  False
3  False
dtype: bool
```

**pandas.Series.str.isspace**

`Series.str.isspace()`

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

```
Series or Index of bool
```

See also:

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
Series.str.isdecimal  Check whether all characters are decimal.
Series.str.isspace  Check whether all characters are whitespace.
Series.str.islower  Check whether all characters are lowercase.
Series.str.isupper  Check whether all characters are uppercase.
Series.str.istitle  Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

0     True
1    False
2    False
3    False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
```
The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n ', ' '])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of
each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

### pandas.Series.str.islower

**Series.str.islower()**

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- Series or Index of bool

  Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.

**Examples**

**Checks for Alphabetic and Numeric Characters**

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0   False
1  False
2   True
3  False
dtype: bool
```
```python
>>> s1.str.isalnum()
0    True
1    True
2    True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The s.str.isnumeric method is the same as s3.str.isdigit but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace
```python
>>> s4 = pd.Series([' ', '	\n', ''])
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
>>> s5.str.islower()
0   True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2   True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1   True
2   False
3   False
dtype: bool
```

### pandas.Series.str.isupper

**Series.str.isupper()**

Check whether all characters in each string are uppercase.

This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- **Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
```
The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '	\n ', ''])
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0   True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2   True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of
each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

**pandas.Series.str.istitle**

Series.str.istitle()

Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method `str.istitle()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

**Examples**

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```python
>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool
```

```python
>>> s1.str.isnumeric()
0   False
1  False
2   True
3  False
dtype: bool
```
>>> s1.str.isalnum()
0    True
1    True
2    True
3    False
dtype: bool

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool

The s.str.isnumeric method is the same as s3.str.isdigit but also includes other characters that can represent quantities such as unicode fractions.

>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool

Checks for Whitespace
>>> s4 = pd.Series([',', '\n', '', ''])
>>> s4.str.isspace()
0    True
1    True
2    False

dtype: bool

Checks for Character Case

>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

>>> s5.str.islower()
0    True
1    False
2    False
3    False

dtype: bool

>>> s5.str.isupper()
0    False
1    False
2    True
3    False

dtype: bool

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

>>> s5.str.istitle()
0    False
1    True
2    False
3    False

dtype: bool

**pandas.Series.str.isnumeric**

Series.str.isnumeric()

Check whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

**Returns**

Series or Index of bool    Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

Series.str.isalpha    Check whether all characters are alphabetic.
Series.str.isnumeric    Check whether all characters are numeric.
Series.str.isalnum    Check whether all characters are alphanumeric.
Series.str.isdigit    Check whether all characters are digits.
Series.str.isdecimal  Check whether all characters are decimal.
Series.str.isspace  Check whether all characters are whitespace.
Series.str.islower  Check whether all characters are lowercase.
Series.str.isupper  Check whether all characters are uppercase.
Series.str.istitle  Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2   True
3   False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

>>> s3.str.isdecimal()
0   True
(continues on next page)
The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0   True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2   True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of
each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

**pandas.Series.str.isdecimal**

Series.str.isdecimal()  
Check whether all characters in each string are decimal.

This is equivalent to running the Python string method `str.isdecimal()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

**Returns**

Series or Index of bool  
Series or Index of boolean values with the same length as the original Series/Index.

**See also:**  
Series.str.isalpha  
Check whether all characters are alphabetic.  
Series.str.isnumeric  
Check whether all characters are numeric.  
Series.str.isalnum  
Check whether all characters are alphanumerical.  
Series.str.isdigit  
Check whether all characters are digits.  
Series.str.isdecimal  
Check whether all characters are decimal.  
Series.str.isspace  
Check whether all characters are whitespace.  
Series.str.islower  
Check whether all characters are lowercase.  
Series.str.isupper  
Check whether all characters are uppercase.  
Series.str.istitle  
Check whether all characters are titlecase.

**Examples**

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool

>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```
Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

**More Detailed Checks for Numeric Characters**

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The s.str.isnumeric method is the same as s3.str.isdigit but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

**Checks for Whitespace**
```python
>>> s4 = pd.Series([' ', '\t\r\n', ''])
>>> s4.str.isspace()
0   True
1   True
2  False
dtype: bool

Checks for Character Case

```nn```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```nn```python
```python
>>> s5.str.islower()
0   True
1  False
2  False
3  False
dtype: bool

```nn```python
```python
>>> s5.str.isupper()
0  False
1  False
2   True
3  False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0  False
1   True
2  False
3  False
dtype: bool
```

**pandas.Series.str.get_dummies**

`Series.str.get_dummies(sep='|')`

Return DataFrame of dummy/indicator variables for Series.

Each string in Series is split by sep and returned as a DataFrame of dummy/indicator variables.

**Parameters**

- `sep` [str, default “|”] String to split on.

**Returns**

- **DataFrame** Dummy variables corresponding to values of the Series.

**See also:**

- `get_dummies` Convert categorical variable into dummy/indicator variables.
Examples

```python
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
 a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```python
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
 a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```

Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.cat.categories</code></td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td><code>Series.cat.ordered</code></td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td><code>Series.cat.codes</code></td>
<td>Return Series of codes as well as the index.</td>
</tr>
</tbody>
</table>

**pandas.Series.cat.categories**

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

**Raises**

- `ValueError` If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories.

**See also:**

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.
pandas.Series.cat.ordered

Series.cat.ordered
Whether the categories have an ordered relationship.

pandas.Series.cat.codes

Series.cat.codes
Return Series of codes as well as the index.

pandas.Series.cat.rename_categories

Series.cat.rename_categories(*args, **kwargs)
Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
- callable: a callable that is called on all items in the old categories and whose return values comprise the new categories.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories  Remove the specified categories.
remove_unused_categories  Remove categories which are not used.
set_categories  Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

**pandas.Series.cat.reorder_categories**

Series.cat.reorder_categories(*args, **kwargs)

Reorder categories as specified in new_categories.

`new_categories` need to include all old categories and no new category items.

Parameters

- `new_categories` [Index-like] The categories in new order.
- `ordered` [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- `inplace` [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories. Deprecated since version 1.3.0.

Returns

- `cat` [Categorical or None] Categorical with removed categories or None if `inplace=True`.

Raises

- `ValueError` If the new categories do not contain all old category items or any new ones

See also:

- rename_categories  Rename categories.
- add_categories  Add new categories.
- remove_categories  Remove the specified categories.
- remove_unused_categories  Remove categories which are not used.
- set_categories  Set the categories to the specified ones.
pandas.Series.cat.add_categories

Series.cat.add_categories(*args, **kwargs)

Add new categories.

Parameters

   new_categories [category or list-like of category] The new categories to be included.

   inplace [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

   Deprecated since version 1.3.0.

Returns

   cat [Categorical or None] Categorical with new categories added or None if inplace=True.

Raises

ValueError If the new categories include old categories or do not validate as categories.

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(['c', 'b', 'c'])
>>> c
['c', 'b', 'c']
Categories (2, object): ['b', 'c']

>>> c.add_categories(['d', 'a'])
['c', 'b', 'c', 'd', 'a']
Categories (4, object): ['b', 'c', 'd', 'a']
```

pandas.Series.cat.remove_categories

Series.cat.remove_categories(*args, **kwargs)

Remove the specified categories.

Parameters

   removals [category or list of categories] The categories which should be removed.

   inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

   Deprecated since version 1.3.0.
Returns

cat [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError If the removals are not contained in the categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(['a', 'c', 'b', 'c', 'd'])
>>> c
[a, c, b, c, d]
Categories (4, object): ['a', 'b', 'c', 'd']

>>> c.remove_categories(['d', 'a'])
[NaN, c, b, c, NaN]
Categories (2, object): ['b', 'c']
```

pandas.Series.cat.remove_unused_categories

Series.cat.remove_unused_categories(*args, **kwargs)

Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Deprecated since version 1.2.0.

Returns

cat [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
set_categories Set the categories to the specified ones.
Examples

```python
>>> c = pd.Categorical(['a', 'c', 'b', 'c', 'd'])
>>> c
['a', 'c', 'b', 'c', 'd']
Categories (4, object): ['a', 'b', 'c', 'd']

>>> c[2] = 'a'
>>> c[4] = 'c'
>>> c
['a', 'c', 'a', 'c', 'c']
Categories (4, object): ['a', 'b', 'c', 'd']

>>> c.remove_unused_categories()
['a', 'c', 'a', 'c', 'c']
Categories (2, object): ['a', 'c']
```

**pandas.Series.cat.set_categories**

```python
def set_categories(*args, **kwargs):
    Set the categories to the specified new_categories.

    new_categories can include new categories (which will result in unused categories) or remove old categories
    (which results in values set to NaN). If rename==True, the categories will simple be renamed (less or more
    items than in old categories will result in values set to NaN or in unused categories respectively).

    This method can be used to perform more than one action of adding, removing, and reordering simultaneously
    and is therefore faster than performing the individual steps via the more specialised methods.

    On the other hand this methods does not do checks (e.g., whether the old categories are included in the new
categories on a reorder), which can result in surprising changes, for example when using special string dtypes,
which does not considers a S1 string equal to a single char python string.

    Parameters
    ----------
    new_categories : Index-like
        The categories in new order.
    ordered : bool, default False
        Whether or not the categorical is treated as a ordered categori-
        cal. If not given, do not change the ordered information.
    rename : bool, default False
        Whether or not the new_categories should be considered as a
        rename of the old categories or as reordered categories.
    inplace : bool, default False
        Whether or not to reorder the categories in-place or return a
        copy of this categorical with reordered categories.

    Returns
    -------
    Categorical with reordered categories or None if inplace.

    Raises
    -----
    ValueError
        If new_categories does not validate as categories

    See also:
    --------
    rename_categories Rename categories.
    reorder_categories Reorder categories.
```

3.3. Series
**add_categories** Add new categories.

**remove_categories** Remove the specified categories.

**remove_unused_categories** Remove categories which are not used.

### pandas.Series.cat.as_ordered

```python
Series.cat.as_ordered(*args, **kwargs)
```

Set the Categorical to be ordered.

**Parameters**

- **inplace** [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

**Returns**

- **Categorical or None** Ordered Categorical or None if inplace=True.

### pandas.Series.cat.as_unordered

```python
Series.cat.as_unordered(*args, **kwargs)
```

Set the Categorical to be unordered.

**Parameters**

- **inplace** [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

**Returns**

- **Categorical or None** Unordered Categorical or None if inplace=True.

### Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `Series.sparse` accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.sparse.npoints</code></td>
<td>The number of non- <code>fill_value</code> points.</td>
</tr>
<tr>
<td><code>Series.sparse.density</code></td>
<td>The percent of non- <code>fill_value</code> points, as decimal.</td>
</tr>
<tr>
<td><code>Series.sparse.fill_value</code></td>
<td>Elements in data that are <code>fill_value</code> are not stored.</td>
</tr>
<tr>
<td><code>Series.sparse.sp_values</code></td>
<td>An ndarray containing the non- <code>fill_value</code> values.</td>
</tr>
</tbody>
</table>

### pandas.Series.sparse.npoints

```python
Series.sparse.npoints
```

The number of non- `fill_value` points.
Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

pandas.Series.sparse.density

Series.sparse.density
The percent of non-fill_value points, as decimal.

Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

pandas.Series.sparse.fill_value

Series.sparse.fill_value
Elements in data that are fill_value are not stored.
For memory savings, this should be the most common value in the array.

pandas.Series.sparse.sp_values

Series.sparse.sp_values
An ndarray containing the non-fill_value values.

Examples

```python
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

<table>
<thead>
<tr>
<th><code>Series.sparse.from_coo</code></th>
<th>Create a Series with sparse values from a scipy.sparse.coo_matrix.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.sparse.to_coo</code></td>
<td>Create a scipy.sparse.coo_matrix from a Series with MultiIndex.</td>
</tr>
</tbody>
</table>
pandas.Series.sparse.from_coo

**classmethod** Series.sparse.from_coo(A, dense_index=False)

Create a Series with sparse values from a scipy.sparse.coo_matrix.

**Parameters**

A [scipy.sparse.coo_matrix]

dense_index [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

**Returns**

s [Series] A Series with sparse values.

**Examples**

```python
>>> from scipy import sparse

>>> A = sparse.coo_matrix(
...     ([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4)
... )
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

>>> A.todense()
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

>>> ss = pd.Series.sparse.from_coo(A)
>>> ss
0   2  1.0
3   2  2.0
1   0  3.0
dtype: Sparse[float64, nan]
```

pandas.Series.sparse.to_coo

Series.sparse.to_coo(row_levels=(0,), column_levels=(1,), sort_labels=False)

Create a scipy.sparse.coo_matrix from a Series with MultiIndex.

Use row_levels and column_levels to determine the row and column coordinates respectively. row_levels and column_levels are the names (labels) or numbers of the levels. {row_levels, column_levels} must be a partition of the MultiIndex level names (or numbers).

**Parameters**

row_levels [tuple/list]

column_levels [tuple/list]
sort_labels [bool, default False] Sort the row and column labels before forming the sparse matrix. When row_levels and/or column_levels refer to a single level, set to True for a faster execution.

Returns

y [scipy.sparse.coo_matrix]
rows [list (row labels)]
columns [list (column labels)]

Examples

```python
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples(
...     [(1, 2, "a", 0),
...      (1, 2, "a", 1),
...      (1, 1, "b", 0),
...      (1, 1, "b", 1),
...      (2, 1, "b", 0),
...      (2, 1, "b", 1)],
...     names=["A", "B", "C", "D"],
... )
>>> s
A  B  C  D
1  2  a  0  3.0
   1   NaN
1  1  b  0  1.0
   1   3.0
2  1  b  0   NaN
   1   NaN
dtype: float64

>>> ss = s.astype("Sparse")
>>> ss
A  B  C  D
1  2  a  0  3.0
   1   NaN
1  1  b  0  1.0
   1   3.0
2  1  b  0   NaN
   1   NaN
dtype: Sparse[float64, nan]

>>> A, rows, columns = ss.sparse.to_coo(
...     row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
... )
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>
>>> A.todense()
```

(continues on next page)
Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date is was recorded, the URL it was accessed from, etc.) should be stored in `Series.attrs`.

```
Flags(obj, *, allows_duplicate_labels) Flags that apply to pandas objects.
```

```
pandas.Flags
class pandas.Flags(obj, *, allows_duplicate_labels)
Flags that apply to pandas objects.

New in version 1.2.0.

Parameters

obj [Series or DataFrame] The object these flags are associated with.

allows_duplicate_labels [bool, default True] Whether to allow duplicate labels in this object. By default, duplicate labels are permitted. Setting this to False will cause an `errors.DuplicateLabelError` to be raised when index (or columns for DataFrame) is not unique, or any subsequent operation on introduces duplicates. See Disallowing Duplicate Labels for more.

Warning: This is an experimental feature. Currently, many methods fail to propagate the allows_duplicate_labels value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate allows_duplicate_labels.
```

Notes

Attributes can be set in two ways

```
>>> df = pd.DataFrame()
>>> df.flags
<Flags(allows_duplicate_labels=True)>
>>> df.flags.allows_duplicate_labels = False
>>> df.flags
<Flags(allows_duplicate_labels=False)>
```
>>> df.flags['allows_duplicate_labels'] = True
>>> df.flags
<Flags(allowed_duplicate_labels=True)>

Attributes

allows_duplicate_labels

Whether this object allows duplicate labels.

pandas.Flags.allows_duplicate_labels

property Flags.allows_duplicate_labels

Whether this object allows duplicate labels.

Setting allows_duplicate_labels=False ensures that the index (and columns of a DataFrame) are unique. Most methods that accept and return a Series or DataFrame will propagate the value of allows_duplicate_labels.

See Duplicate Labels for more.

See also:

DataFrame.attrs Set global metadata on this object.
DataFrame.set_flags Set global flags on this object.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2]}, index=['a', 'a'])
>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False
Traceback (most recent call last):
  ...  
pandas.errors.DuplicateLabelError: Index has duplicates.

    positions
    label    a  [0, 1]
```

Metadata

Series.attrs is a dictionary for storing global metadata for this Series.

Warning: Series.attrs is considered experimental and may change without warning.

Series.attrs

Dictionary of global attributes of this dataset.
3.3.14 Plotting

Series.plot is both a callable method and a namespace attribute for specific plotting methods of the form Series.plot.<kind>.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.plot([kind, ax, figsize, ....])</td>
<td>Series plotting accessor and method</td>
</tr>
<tr>
<td>Series.plot.area([x, y])</td>
<td>Draw a stacked area plot.</td>
</tr>
<tr>
<td>Series.plot.bar([x, y])</td>
<td>Vertical bar plot.</td>
</tr>
<tr>

<td>Make a horizontal bar plot.</td>
</tr>
<tr>
<td>Series.plot.box([by])</td>
<td>Make a box plot of the DataFrame columns.</td>
</tr>
<tr>
<td>Series.plot.density([bw_method, ind])</td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td>Series.plot.hist([by, bins])</td>
<td>Draw one histogram of the DataFrame's columns.</td>
</tr>
<tr>
<td>Series.plot.kde([bw_method, ind])</td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td>Series.plot.line([x, y])</td>
<td>Plot Series or DataFrame as lines.</td>
</tr>
<tr>
<td>Series.plot.pie(**kwargs)</td>
<td>Generate a pie plot.</td>
</tr>
</tbody>
</table>

**pandas.Series.plot.area**

Series.plot.area(x=None, y=None, **kwargs)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

**Parameters**

- **x** [label or position, optional] Coordinates for the X axis. By default uses the index.
- **y** [label or position, optional] Column to plot. By default uses all columns.
- **stacked** [bool, default True] Area plots are stacked by default. Set to False to create a un-stacked plot.
- ****kwargs Additional keyword arguments are documented in DataFrame.plot().

**Returns**

matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

**See also:**

DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

**Examples**

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame(
...     {'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01', freq='M'))
>>> ax = df.plot.area()
```
Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```
**pandas.Series.plot.bar**

Series.plot.bar(x=None, y=None, **kwargs)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs** Additional keyword arguments are documented in DataFrame.plot().

**Returns**

- matplotlib.axes.Axes or np.ndarray of them: An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

- DataFrame.plot.barh: Horizontal bar plot.
- DataFrame.plot: Make plots of a DataFrame.
- matplotlib.pyplot.bar: Make a bar plot with matplotlib.

**Examples**

Basic plot.

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({
    'speed': speed,
    'lifespan': lifespan
}, index=index)
>>> ax = df.plot.bar(rot=0)

Plot stacked bar charts for the DataFrame

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with subplots=True. In this case, a numpy.ndarray of matplotlib.axes.Axes are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
>>> axes = df.plot.bar(
    ...     rot=0, subplots=True, color={
    ...         "speed": "red",
    ...         "lifespan": "green"
    ...     }
    ... )
```
Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

### pandas.Series.plot.barh

**Series.plot.barh** *(x=None, y=None, **kwargs)*

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.

- A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {‘a’: ‘green’, ‘b’: ‘red’} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.bar Vertical bar plot.

DataFrame.plot Make plots of DataFrame using matplotlib.

matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
       'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed, ...
       'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column
```python
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

![Horizontal bar plot example](image)

Plot a column of the DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
           'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
                      'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
           'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
                      'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
pandas.Series.plot.box

Series.plot.box(by=None, **kwargs)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

**Parameters**

- by [str or sequence] Column in the DataFrame to group by.

  Changed in version 1.4.0: Previously, by is silently ignore and makes no groupings

- **kwargs Additional keywords are documented in DataFrame.plot().

**Returns**

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

**Examples**

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

You can also generate groupings if you specify the by parameter (which can take a column name, or a list or tuple of column names):

Changed in version 1.4.0.

```python
>>> age_list = [8, 10, 12, 14, 72, 74, 76, 78, 20, 25, 30, 35, 60, 85]
>>> df = pd.DataFrame({'gender': list('MMMMMMMMMMMMFFFF'), 'age': age_list})
>>> ax = df.plot.box(column='age', by='gender', figsize=(10, 8))
```
3.3. Series

pandas: powerful Python data analysis toolkit, Release 1.4.3
pandas.Series.plot.density

Series.plot.density(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
```

```python
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the ind parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:
3.3. Series
```python
>>> ax = df.plot.kde(bw_method=0.3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### pandas.Series.plot.hist

`Series.plot.hist(by=None, bins=10, **kwargs)`

Draw one histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame’s Series are in a similar scale.

**Parameters**

- `by` [str or sequence, optional] Column in the DataFrame to group by.

  Changed in version 1.4.0: Previously, `by` is silently ignore and makes no groupings

- `bins` [int, default 10] Number of histogram bins to be used.
**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

class:matplotlib.AxesSubplot Return a histogram plot.

See also:

- DataFrame.hist Draw histograms per DataFrame’s Series.
- Series.hist Draw a histogram with Series’ data.

Examples

When we roll a die 6000 times, we expect to get each value around 1000 times. But when we roll two dice and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

A grouped histogram can be generated by providing the parameter by (which can be a column name, or a list of column names):
pandas.Series.plot.kde

Series.plot.kde(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.
**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
```
Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame(
...     {'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6]})
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
3.3. Series
3.3. Series
pandas.Series.plot.line

Series.plot.line(x=None, y=None, **kwargs)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a9d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green','yellow'] each column’s line will be filled in green or yellow, alternatively. If there is only a
single column to be plotted, then only the first color from the color list will be used.

- **A dict of the form** `{column name: color}`, so that each column will be colored accordingly. For example, if your columns are called `a` and `b`, then passing `{‘a’: ‘green’, ‘b’: ‘red’}` will color lines for column `a` in green and lines for column `b` in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in `DataFrame.plot()`.  

Returns

- `matplotlib.axes.Axes` or `np.ndarray` of them
  
  An `ndarray` is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

- `matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

Examples

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
<AxesSubplot:ylabel='Density'>
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

The following example shows the populations for some animals over the years.
>>> df = pd.DataFrame({
...
'pig': [20, 18, 489, 675, 1776],
...
'horse': [4, 25, 281, 600, 1900]
...
>>> lines = df.plot.line()

An example with subplots, so an array of axes is returned.
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).
>>> axes = df.plot.line(
...
subplots=True, color={"pig": "pink", "horse": "#742802"}
... )
The following example shows the relationship between both populations.
>>> lines = df.plot.line(x='pig', y='horse')

3.3. Series

1617


3.3. Series
pandas.Series.plot.pie

Series.plot.pie(**kwargs)
Generate a pie plot.
A pie plot is a proportional representation of the numerical data in a column. This function wraps matplotlib.pyplot.pie() for the specified column. If no column reference is passed and subplots=True a pie plot is drawn for each numerical column independently.

Parameters

- y [int or label, optional] Label or position of the column to plot. If not provided, subplots=True argument must be passed.
- **kwargs Keyword arguments to pass on to DataFrame.plot().

Returns

- matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when subplots is True.

See also:

- Series.plot.pie Generate a pie plot for a Series.
- DataFrame.plot Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                   'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

Series.hist([by, ax, grid, xlabels, ...]) Draw histogram of the input series using matplotlib.
3.3.15 Serialization / IO / conversion

<table>
<thead>

3.4 DataFrame

3.4.1 Constructor

```python
def DataFrame(data=None, index=None, columns=None, dtype=None, copy=None):
    Two-dimensional, size-mutable, potentially heterogeneous tabular data.
```

pandas.DataFrame

class pandas.DataFrame(data=None, index=None, columns=None, dtype=None, copy=None)

Two-dimensional, size-mutable, potentially heterogeneous tabular data.

Data structure also contains labeled axes (rows and columns). Arithmetic operations align on both row and column labels. Can be thought of as a dict-like container for Series objects. The primary pandas data structure.

Parameters

- **data** [ndarray (structured or homogeneous), Iterable, dict, or DataFrame] Dict can contain Series, arrays, constants, dataclass or list-like objects. If data is a dict, column order follows insertion-order. If a dict contains Series which have an index defined, it is aligned by its index.

  Changed in version 0.25.0: If data is a list of dicts, column order follows insertion-order.

- **index** [Index or array-like] Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided.

- **columns** [Index or array-like] Column labels to use for resulting frame when data does not have them, defaulting to RangeIndex(0, 1, 2, ..., n). If data contains column labels, will perform column selection instead.

- **dtype** [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer.
copy [bool or None, default None] Copy data from inputs. For dict data, the default of None behaves like copy=True. For DataFrame or 2d ndarray input, the default of None behaves like copy=False.

Changed in version 1.3.0.

See also:
- DataFrame.from_records Constructor from tuples, also record arrays.
- DataFrame.from_dict From dicts of Series, arrays, or dicts.
- read_csv Read a comma-separated values (csv) file into DataFrame.
- read_table Read general delimited file into DataFrame.
- read_clipboard Read text from clipboard into DataFrame.

Examples

Constructing DataFrame from a dictionary.

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0    1    3
1    2    4
```

Notice that the inferred dtype is int64.

```python
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

To enforce a single dtype:

```python
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from a dictionary including Series:

```python
>>> d = {'col1': [0, 1, 2, 3], 'col2': pd.Series([2, 3], index=[2, 3])}
>>> pd.DataFrame(data=d, index=[0, 1, 2, 3])
   col1  col2
0    0    NaN
1    1    NaN
2    2    2.0
3    3    3.0
```

Constructing DataFrame from numpy ndarray:

```python
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
                     columns=['a', 'b', 'c'])
>>> df2
   a   b   c
0  1   2   3
1  4   5   6
2  7   8   9
```
Constructing DataFrame from a numpy ndarray that has labeled columns:

```python
>>> data = np.array([(1, 2, 3), (4, 5, 6), (7, 8, 9)],
                   dtype=[('a', 'i4'), ('b', 'i4'), ('c', 'i4')])
>>> df3 = pd.DataFrame(data, columns=['c', 'a'])
... 
>>> df3
  c  a
0 3 1
1 6 4
2 9 7
```

Constructing DataFrame from dataclass:

```python
>>> from dataclasses import make_dataclass
>>> Point = make_dataclass("Point", [('x', int), ('y', int)])
>>> pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
   x  y
0 0 0
1 0 3
2 2 3
```

Attributes

</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.4.3

**pandas.DataFrame.at**

**property DataFrame.at**

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

- **KeyError** If ‘label’ does not exist in DataFrame.

**See also:**

- `DataFrame.iat` Access a single value for a row/column pair by integer position.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `Series.at` Access a single value using a label.

**Examples**

```python
def df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                      index=[4, 5, 6], columns=['A', 'B', 'C'])
def
>>> df
    A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
Get value at specified row/column pair
```

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```
pandas.DataFrame.attrs

**property** DataFrame.attrs

Dictionary of global attributes of this dataset.

**Warning:** attrs is experimental and may change without warning.

See also:

*DataFrame.flags* Global flags applying to this object.

pandas.DataFrame.axes

**property** DataFrame.axes

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

**Examples**

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

pandas.DataFrame.columns

Dataframe.columns

The column labels of the DataFrame.

pandas.DataFrame.dtypes

**property** DataFrame.dtypes

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

**Returns**

* pandas.Series The data type of each column.
Examples

```python
>>> df = pd.DataFrame({'float': [1.0],
...                    'int': [1],
...                    'datetime': [pd.Timestamp('20180310')],
...                    'string': ['foo']})
>>> df.dtypes
float float64
int   int64
datetime datetime64[ns]
string object
dtype: object
```

**pandas.DataFrame.empty**

**property DataFrame.empty**

Indicator whether Series/DataFrame is empty.

True if Series/DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

**Returns**

```
bool If Series/DataFrame is empty, return True, if not return False.
```

**See also:**

*Series.dropna* Return series without null values.

*DataFrame.dropna* Return DataFrame with labels on given axis omitted where (all or any) data are missing.

**Notes**

If Series/DataFrame contains only NaNs, it is still not considered empty. See the example below.

**Examples**

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A': []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:
```python
>>> df = pd.DataFrame({'A': [np.nan]})
>>> df
   A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True

>>> ser_empty = pd.Series({'A': []})
>>> ser_empty
A []
dtype: object
>>> ser_empty.empty
False
>>> ser_empty = pd.Series()
>>> ser_empty.empty
True
```

**pandas.DataFrame.flags**

**property** `DataFrame.flags`

Get the properties associated with this pandas object.

The available flags are

- `Flags.allows_duplicate_labels`

**See also:**

`Flags` Flags that apply to pandas objects.

`DataFrame.attrs` Global metadata applying to this dataset.

**Notes**

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2]})
>>> df.flags
<Flags(allows_duplicate_labels=True)>
```

Flags can be get or set using .

```python
>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False
```

Or by slicing with a key

```python
>>> df.flags.allows_duplicate_labels
False
```
```python
>>> df.flags['allows_duplicate_labels']
False
>>> df.flags['allows_duplicate_labels'] = True
```

**pandas.DataFrame.iat**

**property DataFrame.iat**

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

** Raises **

* **IndexError** When integer position is out of bounds.

**See also:**

* `DataFrame.at` Access a single value for a row/column label pair.
* `DataFrame.loc` Access a group of rows and columns by label(s).
* `DataFrame.iloc` Access a group of rows and columns by integer position(s).

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```python
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```python
>>> df.loc[0].iat[1]
2
```
pandas.DataFrame.iloc

property DataFrame.iloc
Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:
   • An integer, e.g. 5.
   • A list or array of integers, e.g. [4, 3, 0].
   • A slice object with ints, e.g. 1:7.
   • A boolean array.
   • A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at Selection by Position.

See also:

DataFrame.iat  Fast integer location scalar accessor.
DataFrame.loc  Purely label-location based indexer for selection by label.
Series.iloc  Purely integer-location based indexing for selection by position.

Examples

```python
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
            {'a': 100, 'b': 200, 'c': 300, 'd': 400},
            {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
    a   b   c   d
0  1   2   3   4
1 100 200 300 400
2 1000 2000 3000 4000
```

Indexing just the rows

With a scalar integer.

```python
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
     a     b     c     d
0  1.0  2.0  3.0  4.0
```
With a list of integers.

```python
>>> df.iloc[[0]]
da b c d
0 1 2 3 4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```python
>>> df.iloc[[0, 1]]
da b c d
0 1 2 3 4
1 100 200 300 400
```

With a slice object.

```python
>>> df.iloc[:3]
da b c d
0 1 2 3 4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```python
>>> df.iloc[[True, False, True]]
da b c d
0 1 2 3 4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The x passed to the lambda is the DataFrame being sliced. This selects the rows whose index label even.

```python
>>> df.iloc[lambda x: x.index % 2 == 0]
da b c d
0 1 2 3 4
2 1000 2000 3000 4000
```

### Indexing both axes

You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

```python
>>> df.iloc[0, 1]
2
```

With lists of integers.

```python
>>> df.iloc[[0, 2], [1, 3]]
b d
0 2 4
2 2000 4000
```

With slice objects.
>>> df.iloc[1:3, 0:3]
   a   b   c
0  100  200  300
1 1000  2000 3000

With a boolean array whose length matches the columns.

>>> df.iloc[:, [True, False, True, False]]
   a  c
0   1  3
1  100 300
2 1000 3000

With a callable function that expects the Series or DataFrame.

>>> df.iloc[:, lambda df: [0, 2]]
   a  c
0   1  3
1  100 300
2 1000 3000

pandas.DataFrame.index

DataFrame.index

The index (row labels) of the DataFrame.

pandas.DataFrame.loc

property DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and never as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, both the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
- An alignable Index. The Index of the returned selection will be the input.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at Selection by Label.
Raises

- **KeyError** If any items are not found.
- **IndexingError** If an indexed key is passed and its index is unalignable to the frame index.

See also:

- **DataFrame.at** Access a single value for a row/column label pair.
- **DataFrame.iloc** Access group of rows and columns by integer position(s).
- **DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- **Series.loc** Access group of values using labels.

Examples

Getting values

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
cobra     1       2
viper     4       5
sidewinder 7       8
```

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
max_speed    4
shield      5
Name: viper, dtype: int64
```

List of labels. Note using `[]` returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
   max_speed  shield
viper     4       5
sidewinder 7       8
```

Single label for row and column

```python
>>> df.loc['cobra': 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc['cobra': 'viper', 'max_speed']
cobra    1
viper     4
Name: max_speed, dtype: int64
```
Boolean list with the same length as the row axis

```python
>>> df.loc[[False, False, True]]
       max_speed  shield
sidewinder    7       8
```

Alignable boolean Series:

```python
>>> df.loc[pd.Series([False, True, False],
                    index=['viper', 'sidewinder', 'cobra'])]
       max_speed  shield
sidewinder    7       8
```

Index (same behavior as `df.reindex`)

```python
>>> df.loc[pd.Index(["cobra", "viper"], name="foo")]
                      max_speed  shield
foo                   cobra    1       2
                   viper    4       5
```

Conditional that returns a boolean Series

```python
>>> df.loc[df['shield'] > 6]
       max_speed  shield
sidewinder    7       8
```

Conditional that returns a boolean Series with column labels specified

```python
>>> df.loc[df['shield'] > 6, ['max_speed']]
       max_speed
sidewinder    7
```

Callable that returns a boolean Series

```python
>>> df.loc[lambda df: df['shield'] == 8]
       max_speed  shield
sidewinder    7       8
```

Setting values

Set value for all items matching the list of labels

```python
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
                      max_speed  shield
cobra                   1       2
viper                   4       50
sidewinder              7       50
```

Set value for an entire row

```python
>>> df.loc['cobra'] = 10
>>> df
                      max_speed  shield
```

(continues on next page)
Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
          max_speed  shield
    cobra         30      10
    viper         30      50
   sidewinder     30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
          max_speed  shield
    cobra         30      10
    viper          0      0
   sidewinder     0      0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
          max_speed  shield
          7          1
          8          4
          9          7
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
          max_speed  shield
          7          1
          8          4
          9          7
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
           ('cobra', 'mark i'), ('cobra', 'mark ii'),
           ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
           ('viper', 'mark ii'), ('viper', 'mark iii')
           ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
```
... [1, 4], [7, 1], [16, 36]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)

```
max_speed shield
  cobra mark i  12  2
     mark ii  0  4
    sidewinder mark i  10  20
       mark ii  1  4
     viper mark ii  7  1
        mark iii 16  36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
max_speed shield
  mark i  12  2
  mark ii  0  4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed  0
shield  4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed  12
shield  2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
max_speed shield
  cobra mark ii  0  4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[['cobra', 'mark i'], 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[['cobra', 'mark i':'viper']]
max_speed shield
  cobra mark i  12  2
     mark ii  0  4
    sidewinder mark i  10  20
       mark ii  1  4
     viper mark ii  7  1
        mark iii 16  36
```
Slice from index tuple to index tuple

```python
>>> df.loc[('cobra', 'mark i'), ('viper', 'mark ii')]
            max_speed  shield
       cobra mark i       12       2
           mark ii       0       4
    sidewinder mark i       10      20
           mark ii        1       4
       viper mark ii        7       1
```

### pandas.DataFrame.ndim

**property** `DataFrame.ndim`

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

### pandas.DataFrame.shape

**property** `DataFrame.shape`

Return a tuple representing the dimensionality of the DataFrame.

**Examples**

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
                    'col3': [5, 6]})
>>> df.shape
(2, 3)
```
pandas.DataFrame.size

**property DataFrame.size**

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

**See also:**

*ndarray.size* Number of elements in the array.

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

pandas.DataFrame.style

**property DataFrame.style**

Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame.

**See also:**

*io.formats.style.Styler* Helps style a DataFrame or Series according to the data with HTML and CSS.

pandas.DataFrame.values

**property DataFrame.values**

Return a Numpy representation of the DataFrame.

**Warning:** We recommend using `DataFrame.to_numpy()` instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

**Returns**

*numpy.ndarray* The values of the DataFrame.

**See also:**

*DataFrame.to_numpy* Recommended alternative to this method.

*DataFrame.index* Retrieve the index labels.
DataFrame.columns Retrieving the column names.

Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes 
(even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if 
you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, 
dtype will be upcast to int32. By numpy.find_common_type() convention, mixing int64 and uint64 will 
result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```python
>>> df = pd.DataFrame({'age': [3, 29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
   age  height  weight
0    3    94      31
1   29   170     115
>>> df.dtypes
age    int64
height  int64
weight  int64
dtype: object
>>> df.values
array([[ 3, 94, 31],
       [29, 170, 115]])
```

A DataFrame with mixed type columns (e.g., str/object, int64, float32) results in an ndarray of the broadest 
type that accommodates these mixed types (e.g., object).

```python
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                     ('lion', 80.5, 1),
...                     ('monkey', np.nan, None),
...                     columns=['name', 'max_speed', 'rank'])
>>> df2.dtypes
name    object
max_speed  float64
rank       object
dtype: object
>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)
```
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>add(other[, axis, level, fill_value])</td>
<td>Get Addition of dataframe and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td>add_prefix(prefix)</td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td>add_suffix(suffix)</td>
<td>Suffix labels with string suffix.</td>
</tr>
<tr>
<td>agg([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>aggregate([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>align(other[, join, axis, level, copy, ...])</td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td>all([axis, bool_only, skipna, level])</td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td>any([axis, bool_only, skipna, level])</td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td>append(other[, ignore_index, ...])</td>
<td>(DEPRECATED) Append rows of other to the end of caller, returning a new object.</td>
</tr>
<tr>
<td>apply(func[, axis, raw, result_type, args])</td>
<td>Apply a function along an axis of the DataFrame.</td>
</tr>
<tr>
<td>applymap(func[, na_action])</td>
<td>Apply a function to a DataFrame elementwise.</td>
</tr>
<tr>
<td>asfreq(freq[, method, how, normalize, ...])</td>
<td>Convert time series to specified frequency.</td>
</tr>
<tr>
<td>asof(where[, subset])</td>
<td>Return the last row(s) without any NaNs before where.</td>
</tr>
<tr>
<td>assign(**kwargs)</td>
<td>Assign new columns to a DataFrame.</td>
</tr>
<tr>
<td>astype(dtype[, copy, errors])</td>
<td>Cast a pandas object to a specified dtype dtype.</td>
</tr>
<tr>
<td>at_time(time[, copy, errors])</td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td>backfill([axis, inplace, limit, downcast])</td>
<td>Synonym for DataFrame.fillna() with method='bfill'.</td>
</tr>
<tr>
<td>between_time(start_time, end_time[, ...])</td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td>bfill([axis, inplace, limit, downcast])</td>
<td>Synonym for DataFrame.fillna() with method='bfill'.</td>
</tr>
<tr>
<td>bool()</td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td>boxplot([column, by, ax, fontsize, rot, ...])</td>
<td>Make a box plot from DataFrame columns.</td>
</tr>
<tr>
<td>clip([lower, upper, axis, inplace])</td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td>combine(other, func[, fill_value, overwrite])</td>
<td>Perform column-wise combine with another DataFrame.</td>
</tr>
<tr>
<td>combine_first(other)</td>
<td>Update null elements with value in the same location in other.</td>
</tr>
<tr>
<td>compare(other[, align_axis, keep_shape, ...])</td>
<td>Compare to another DataFrame and show the differences.</td>
</tr>
<tr>
<td>convert_dtypes([infer_objects, ...])</td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
<tr>
<td>copy([deep])</td>
<td>Make a copy of this object's indices and data.</td>
</tr>
<tr>
<td>corr([method, min_periods])</td>
<td>Compute pairwise correlation of columns, excluding NA/null values.</td>
</tr>
<tr>
<td>corrwith(other[, axis, drop, method])</td>
<td>Compute pairwise correlation.</td>
</tr>
<tr>
<td>count([axis, level, numeric_only])</td>
<td>Count non-NA cells for each column or row.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>cov</code></td>
<td>Compute pairwise covariance of columns, excluding NA/null values.</td>
</tr>
<tr>
<td><code>cummax</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cummin</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumprod</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumsum</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>describe</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>diff</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>div</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>divide</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>dot</code></td>
<td>Compute the matrix multiplication between the DataFrame and other.</td>
</tr>
<tr>
<td><code>drop</code></td>
<td>Drop specified labels from rows or columns.</td>
</tr>
<tr>
<td><code>drop_duplicates</code></td>
<td>Return DataFrame with duplicate rows removed.</td>
</tr>
<tr>
<td><code>droplevel</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>dropna</code></td>
<td>Remove missing values.</td>
</tr>
<tr>
<td><code>duplicated</code></td>
<td>Return boolean Series denoting duplicate rows.</td>
</tr>
<tr>
<td><code>eq</code></td>
<td>Get Equal to of dataframe and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>equals</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>eval</code></td>
<td>Evaluate a string describing operations on DataFrame columns.</td>
</tr>
<tr>
<td><code>ewm</code></td>
<td>Provide exponentially weighted (EW) calculations.</td>
</tr>
<tr>
<td><code>expanding</code></td>
<td>Provide expanding window calculations.</td>
</tr>
<tr>
<td><code>explode</code></td>
<td>Transform each element of a list-like to a row, replicating index values.</td>
</tr>
<tr>
<td><code>ffill</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>fillna</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>filter</code></td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td><code>first</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>first_valid_index</code></td>
<td>Return index for first non-NA value or None, if no non-NA value is found.</td>
</tr>
<tr>
<td><code>floordiv</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>from_dict</code></td>
<td>Construct DataFrame from dict of array-like or dicts.</td>
</tr>
<tr>
<td><code>from_records</code></td>
<td>Convert structured or record ndarray to DataFrame.</td>
</tr>
<tr>
<td><code>ge</code></td>
<td>Get Greater than or equal to of dataframe and other, element-wise (binary operator <code>ge</code>).</td>
</tr>

<tr>
<td>pop(item)</td>
<td>Return item and drop from frame.</td>
</tr>
<tr>
<td>pow(other[, axis, level, fill_value])</td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator pow).</td>
</tr>
<tr>
<td>prod([axis, skipna, level, numeric_only, ...])</td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td>product([axis, skipna, level, numeric_only, ...])</td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td>quantile([q, axis, numeric_only, interpolation])</td>
<td>Return values at the given quantile over requested axis.</td>
</tr>
<tr>
<td>query(expr[, inplace])</td>
<td>Query the columns of a DataFrame with a boolean expression.</td>
</tr>
<tr>
<td>radd(other[, axis, level, fill_value])</td>
<td>Get Addition of dataframe and other, element-wise (binary operator radd).</td>
</tr>
<tr>
<td>rank([axis, method, numeric_only, ...])</td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td>rdiv(other[, axis, level, fill_value])</td>
<td>Get Floating division of dataframe and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td>reindex([labels, index, columns, axis, ...])</td>
<td>Conform Series/DataFrame to new index with optional filling logic.</td>
</tr>
<tr>
<td>reindex_like(other[, method, copy, limit, ...])</td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td>rename({mapper, index, columns, axis, copy, ...})</td>
<td>Alter axes labels.</td>
</tr>
<tr>
<td>rename_axis({mapper, index, columns, axis, copy, ...})</td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
</tbody>
</table>

Table 4 – continued from previous page

- **reorder_levels(order[, axis])** Rearrange index levels using input order.
- **replace(to_replace, value, inplace, limit, ...)** Replace values given in `to_replace` with `value`.
- **resample(rule[, axis, closed, label, ...])** Resample time-series data.
- **reset_index([level, drop, inplace, ...])** Reset the index, or a level of it.
- **rfloordiv(other[, axis, level, fill_value])** Get Integer division of dataframe and other, element-wise (binary operator `rfloordiv`).
- **rmod(other[, axis, level, fill_value])** Get Modulo of dataframe and other, element-wise (binary operator `rmod`).
- **rmul(other[, axis, level, fill_value])** Get Multiplication of dataframe and other, element-wise (binary operator `rmul`).
- **rolling(window[, min_periods, center, ...])** Provide rolling window calculations.
- **round([decimals])** Round a DataFrame to a variable number of decimal places.
- **rpow(other[, axis, level, fill_value])** Get Exponential power of dataframe and other, element-wise (binary operator `rpow`).
- **rsub(other[, axis, level, fill_value])** Get Subtraction of dataframe and other, element-wise (binary operator `rsub`).
- **rtruediv(other[, axis, level, fill_value])** Get Floating division of dataframe and other, element-wise (binary operator `rtruediv`).
- **sample([n, frac, replace, weights, ...])** Return a random sample of items from an axis of object.
- **select_dtypes([include, exclude])** Return a subset of the DataFrame's columns based on the column dtypes.
- **sem([axis, skipna, level, ddof, numeric_only])** Return unbiased standard error of the mean over requested axis.
- **set_axis(labels[, axis, inplace])** Assign desired index to given axis.
- **set_index(keys[, drop, append, inplace, ...])** Set the DataFrame index using existing columns.
- **shift([periods, freq, axis, fill_value])** Shift index by desired number of periods with an optional time `freq`.
- **skew([axis, skipna, level, numeric_only])** Return unbiased skew over requested axis.
- **slice_shift([periods, axis])** (DEPRECATED) Equivalent to `shift` without copying data.
- **sort_index([axis, level, ascending, ...])** Sort object by labels (along an axis).
- **sort_values(by[, axis, ascending, inplace, ...])** Sort by the values along either axis.
- **sparse** alias of `pandas.core.arrays.sparse.accessor.SparseFrameAccessor`
- **squeeze(axis)** Squeeze 1 dimensional axis objects into scalars.
- **stack([level, dropna])** Stack the prescribed level(s) from columns to index.
- **std([axis, skipna, level, ddof, numeric_only])** Return sample standard deviation over requested axis.
- **sub(other[, axis, level, fill_value])** Get Subtraction of dataframe and other, element-wise (binary operator `sub`).
- **subtract(other[, axis, level, fill_value])** Get Subtraction of dataframe and other, element-wise (binary operator `sub`).
- **sum([axis, skipna, level, numeric_only, ...])** Return the sum of the values over the requested axis.
- **swapaxes(axis1, axis2[, copy])** Interchange axes and swap values axes appropriately.
- **swaplevel(i, j, axis)** Swap levels `i` and `j` in a `MultiIndex`.
- **tail([n])** Return the last `n` rows.
- **take(indices[, axis, is_copy])** Return the elements in the given positional indices along an axis.

</tbody>
</table>
DataFrame.abs

DataFrame.abs()

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs Series/DataFrame containing the absolute value of each element.

See also:

numpy.absolute Calculate the absolute value element-wise.

Notes

For complex inputs, 1.2 + 1j, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0   1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```python
>>> df = pd.DataFrame(
...     {'a': [4, 5, 6, 7],
...      'b': [10, 20, 30, 40],
...      'c': [100, 50, -30, -50]
...     })
>>> df
   a   b   c
0  4  10  100
1  5  20   50
2  6  30  -30
3  7  40  -50
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

(continued from previous page)

```
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
a   b   c
1   5  20   50
0   4  10  100
2   6  30  -30
3   7  40  -50
```

**pandas.DataFrame.add**

DataFrame.add(other, axis='columns', level=None, fill_value=None)

Get Addition of dataframe and other, element-wise (binary operator add).

Equivalent to dataframe + other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, radd.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [(0 or ‘index’, 1 or ‘columns’)] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

Dataframe Result of the arithmetic operation.

See also:

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
- **DataFrame.truediv** Divide DataFrames (float division).
- **DataFrame.floordiv** Divide DataFrames (integer division).
- **DataFrame.mod** Calculate modulo (remainder after division).
- **DataFrame.pow** Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```
>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td></td>
</tr>
<tr>
<td>triangle</td>
<td></td>
</tr>
<tr>
<td>rectangle</td>
<td></td>
</tr>
</tbody>
</table>

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         ...    axis='index')
```

Multply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        ...    index=['circle', 'triangle', 'rectangle'])
```

```
>>> df * other
```

```
>>> df.mul(other, fill_value=0)
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                               ...    'degrees': [360, 180, 360, 540, 720]},
                               ...    index=[['A', 'A', 'A', 'B', 'B', 'B'],
                               ...    ['circle', 'triangle', 'rectangle',
                               ...       'square', 'pentagon', 'hexagon']])
```

```
>>> df_multindex
```

```
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
   A circle   NaN     1.0
      triangle  1.0     1.0
         rectangle  1.0     1.0
       B square   0.0     0.0
          pentagon  0.0     0.0
          hexagon  0.0     0.0
```

**pandas.DataFrame.add_prefix**

DataFrame.add_prefix(prefix)

Prefix labels with string prefix.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters**

- **prefix** [str] The string to add before each label.

**Returns**

- **Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

- **Series.add_suffix** Suffix row labels with string suffix.
- **DataFrame.add_suffix** Suffix column labels with string suffix.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0   1
1   2
2   3
3   4
dtype: int64

>>> s.add_prefix('item_')
item_0  1
item_1  2
item_2  3
item_3  4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
```

   col_A  col_B
0    1    3
1    2    4
2    3    5
3    4    6
```

**pandas.DataFrame.add_suffix**

DataFrame.add_suffix(suffix)

Suffix labels with string suffix.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**

- **suffix** [str] The string to add after each label.

**Returns**

- **Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

- **Series.add_prefix** Prefix row labels with string prefix.
- **DataFrame.add_prefix** Prefix column labels with string prefix.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])

>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_suffix('_item')
   0_item  1_item  2_item  3_item
0       1       2       3       4
dtype: int64

0  1  3
```

(continues on next page)
1  2  4
2  3  5
3  4  6

```python
>>> df.add_suffix('_col')
   A_col  B_col
0   1     3
1   2     4
2   3     5
3   4     6
```

**pandas.DataFrame.agg**

`.agg()`функция для проведения агрегации.

**DataFrame.agg(func=None, axis=0, *args, **kwargs)**

Агрегировать с помощью одного или нескольких операций по указанной оси.

**Параметры**

- **func** — функция, список функций или словарь с функциями для каждой оси. Если функция, то она должна быть определена для DataFrame, или быть передаваемой в `DataFrame.apply`. Разрешенные комбинации:
  - функция
  - строка названия функции
  - список функций и/или строк названий функций, например `[np.sum, 'mean']`
  - словарь для каждой оси — функции, строки названий функций или список таких.

- **axis** — `0` (по умолчанию или 'index') — применяет функцию к каждому столбцу. `1` (или 'columns') — применяет функцию к каждому ряду.

- **args** — позиционные аргументы, передаваемые `func`.

- **kwargs** — ключевые аргументы, передаваемые `func`.

**Возвращает**

- `scalar`, `Series` или `DataFrame` — возвращаемое значение:

  - `scalar` — когда `Series.agg` вызывается с одной функцией
  - `Series` — когда `DataFrame.agg` вызывается с одной функцией
  - `DataFrame` — когда `DataFrame.agg` вызывается с несколькими функциями

Возвращается скалярное значение, `Series` или `DataFrame`.

**The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0).`**
agg is an alias for aggregate. Use the alias.

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
... [4, 5, 6],
... [7, 8, 9],
... [np.nan, np.nan, np.nan]],
... columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```python
>>> df.agg(['sum', 'min'])
    A  B  C
sum 12.0 15.0 18.0
min  1.0  2.0  3.0
```

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
    A  B
sum 12.0 NaN
min  1.0  2.0
max  NaN  8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))
    A   B   C
x  7.0 NaN NaN
y  NaN  2.0 NaN
z  NaN  NaN  6.0
```
Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")
0   2.0
1   5.0
2   8.0
3  NaN
dtype: float64
```

**pandas.DataFrame.aggregate**

DataFrames aggregate ([func=None, axis=0, *args, **kwargs])

Aggregate using one or more operations over the specified axis.

**Parameters**

- `func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. `[np.sum, 'mean']`
  - dict of axis labels -> functions, function names or list of such.

- `axis` [[0 or ‘index’, 1 or ‘columns’], default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.

- `*args` Positional arguments to pass to `func`.

- `**kwargs` Keyword arguments to pass to `func`.

**Returns**

- scalar, Series or DataFrame The return can be:

  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (`mean`, `median`, `prod`, `sum`, `std`, `var`), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

`agg` is an alias for `aggregate`. Use the alias.

See also:
DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.
core.resample.Resampler Perform operations over resampled bins.
core.window.Rolling Perform operations over rolling window.
core.window.Expanding Perform operations over expanding window.
core.window.ExponentialMovingWindow Perform operation over exponential weighted window.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
def df = pd.DataFrame([[1, 2, 3],
                        [4, 5, 6],
                        [7, 8, 9],
                        [np.nan, np.nan, np.nan]],
                        columns=['A', 'B', 'C'])

Aggregate these functions over the rows.
```  
```python
>>> df.agg(['sum', 'min'])

   A   B   C
sum 12.0 15.0 18.0
min  1.0  2.0  3.0
```

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})

   A         B
sum 12.0   NaN
min  1.0  2.0
max   NaN  8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))

   A   B   C
x  7.0 NaN NaN
y  NaN 2.0 NaN
z  NaN NaN 6.0
```

Aggregate over the columns.
```python
>>> df.agg("mean", axis="columns")
0  2.0
1  5.0
2  8.0
3   NaN
dtype: float64
```

**pandas.DataFrame.align**

`DataFrame.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)`

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

**Parameters**

- **other** [DataFrame or Series]
- **join** [\{'outer', 'inner', 'left', 'right'\}, default 'outer']
- **axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
- **level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **copy** [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.
- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
- **method** [\{'backfill', 'bfill', 'pad', 'ffill', None\}, default None] Method to use for filling holes in reindexed Series:
  - pad / ffill: propagate last valid observation forward to next valid.
  - backfill / bfill: use NEXT valid observation to fill gap.
- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.
- **fill_axis** [0 or 'index', 1 or 'columns'], default 0] Filling axis, method and limit.
- **broadcast_axis** [0 or 'index', 1 or 'columns'], default None] Broadcast values along this axis, if aligning two objects of different dimensions.

**Returns**

- (left, right) [(DataFrame, type of other)] Aligned objects.
Examples

```python
>>> df = pd.DataFrame(
...     [[1, 2, 3, 4], [6, 7, 8, 9]], columns=["D", "B", "E", "A"], index=[1, 2])
>>> other = pd.DataFrame(
...     [[10, 20, 30, 40], [60, 70, 80, 90], [600, 700, 800, 900]],
...     columns=["A", "B", "C", "D"],
...     index=[2, 3, 4])
>>> df
D  B  E  A
1  1  2  3  4  
2  6  7  8  9  
```

Align on columns:

```python
>>> left, right = df.align(other, join="outer", axis=1)
>>> left
A  B  C  D  E
1  4  2  NaN  1  3  
2  9  7  NaN  6  8  
```

We can also align on the index:

```python
>>> left, right = df.align(other, join="outer", axis=0)
>>> left
D  B  E  A
1  1.0  2.0  3.0  4.0
2  6.0  7.0  8.0  9.0
3  NaN  NaN  NaN  NaN
4  NaN  NaN  NaN  NaN
```

Finally, the default `axis=None` will align on both index and columns:

```python
>>> left, right = df.align(other, join="outer", axis=None)
>>> left
```

**pandas.DataFrame.all**

DataFrame.all(axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

**Parameters**

- **axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.
  - 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
  - 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
  - None : reduce all axes, return a scalar.
- **bool_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.
- **skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Series or DataFrame If level is specified, then DataFrame is returned; otherwise, Series is returned.

See also:

- **Series.all** Return True if all elements are True.
- **DataFrame.any** Return True if one (or more) elements are True.
Examples

Series

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([], dtype="float64").all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
     col1  col2
0    True  True
1    True  False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
    col1  col2
0    True  True
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
    0  1
0  True False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

pandas.DataFrame.any

DataFrame.any(axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a DataFrame axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters
**axis**  [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- **0 / 'index'**: reduce the index, return a Series whose index is the original column labels.
- **1 / 'columns'**: reduce the columns, return a Series whose index is the original index.
- **None**: reduce all axes, return a scalar.

**bool_only**  [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna**  [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level**  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**kwargs**  [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

**Series or DataFrame**  If level is specified, then, DataFrame is returned; otherwise, Series is returned.

**See also:**

numpy.any  Numpy version of this method.

**Series.any**  Return whether any element is True.

**Series.all**  Return whether all elements are True.

**DataFrame.any**  Return whether any element is True over requested axis.

**DataFrame.all**  Return whether all elements are True over requested axis.

**Examples**

**Series**

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

**DataFrame**

Whether each column contains at least one True element (the default).
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0

>>> df.any()
A   True
B   True
C  False
dtype: bool

Aggregating over the columns.

>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True 1
1  False 2

>>> df.any(axis='columns')
0   True
1   True
dtype: bool

>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True 1
1 False 0

>>> df.any(axis='columns')
0   True
1  False
dtype: bool

Aggregating over the entire DataFrame with axis=None.

>>> df.any(axis=None)
True

df.any() for an empty DataFrame is an empty Series.

>>> pd.DataFrame([]).any()
Series([], dtype: bool)
DataFrame.append

DataFrame.append(other, ignore_index=False, verify_integrity=False, sort=False)

Append rows of other to the end of caller, returning a new object.

Deprecated since version 1.4.0: Use concat() instead. For further details see Deprecated DataFrame.append and Series.append

Columns in other that are not in the caller are added as new columns.

Parameters

other [DataFrame or Series/dict-like object, or list of these] The data to append.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

verify_integrity [bool, default False] If True, raise ValueError on creating index with duplicates.

sort [bool, default False] Sort columns if the columns of self and other are not aligned.

Changed in version 1.0.0: Changed to not sort by default.

Returns

DataFrame A new DataFrame consisting of the rows of caller and the rows of other.

See also:

concat General function to concatenate DataFrame or Series objects.

Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame’s index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

Examples

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'), index=['x', 'y'])
>>> df
   A  B
  x 1  2
  y 3  4

>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'), index=['x', 'y'])
>>> df.append(df2)
   A  B
  x 1  2
  y 3  4
  x 5  6
  y 7  8
```

With ignore_index set to True:
The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```python
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4
```

More efficient:

```python
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)], ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

**pandas.DataFrame.apply**

`DataFrame.apply(func, axis=0, raw=False, result_type=None, args=(), **kwargs)`

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame’s index (`axis=0`) or the DataFrame’s columns (`axis=1`). By default (`result_type=None`), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the `result_type` argument.

**Parameters**

- `func` [function] Function to apply to each column or row.
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the function is applied:
  - 0 or ‘index’: apply function to each column.
  - 1 or ‘columns’: apply function to each row.
- `raw` [bool, default False] Determines if row or column is passed as a Series or ndarray object:
  - False: passes each row or column as a Series to the function.
• True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

result_type [{'expand', 'reduce', 'broadcast', None}, default None] These only act when axis=1 (columns):
  • ‘expand’: list-like results will be turned into columns.
  • ‘reduce’: returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
  • ‘broadcast’: results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

args [tuple] Positional arguments to pass to func in addition to the array/series.

**kwargs Additional keyword arguments to pass as keywords arguments to func.

Returns

Series or DataFrame Result of applying func along the given axis of the DataFrame.

See also:

DataFrame.applymap For elementwise operations.

DataFrame.aggregate Only perform aggregating type operations.

DataFrame.transform Only perform transforming type operations.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

Examples

```python
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
     A  B
0    4  9
1    4  9
2    4  9

Using a numpy universal function (in this case the same as np.sqrt(df)):

```python
>>> df.apply(np.sqrt)
     A    B
0   2.0  3.0
1   2.0  3.0
2   2.0  3.0
```

Using a reducing function on either axis
>>> df.apply(np.sum, axis=0)
A 12
B 27
dtype: int64

>>> df.apply(np.sum, axis=1)
0 13
1 13
2 13
dtype: int64

Returning a list-like will result in a Series

>>> df.apply(lambda x: [1, 2], axis=1)
0 [1, 2]
1 [1, 2]
2 [1, 2]
dtype: object

Passing result_type='expand' will expand list-like results to columns of a Dataframe

>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   0  1
0 [1, 2]
1 [1, 2]
2 [1, 2]

Returning a Series inside the function is similar to passing result_type='expand'. The resulting column names will be the Series index.

>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
0   1   2
1   1   2
2   1   2

Passing result_type='broadcast' will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2
**DataFrame.applymap**

DataFrame.applymap(func, na_action=None, **kwargs)

Apply a function to a DataFrame elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

**Parameters**

- **func** [callable] Python function, returns a single value from a single value.
- **na_action** [{None, ’ignore’}, default None] If ‘ignore’, propagate NaN values, without passing them to func.
  - New in version 1.2.
- **kwargs** Additional keyword arguments to pass as keywords arguments to `func`.
  - New in version 1.3.0.

**Returns**

DataFrame Transformed DataFrame.

**See also:**

DataFrame.apply Apply a function along input axis of DataFrame.

**Examples**

```python
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0   1
0  1.0  2.12
1  3.36 4.567

>>> df.applymap(lambda x: len(str(x)))
   0   1
0   3   4
1   5   5

Like Series.map, NA values can be ignored:

```python
>>> df_copy = df.copy()
>>> df_copy.iloc[0, 0] = pd.NA
>>> df_copy.applymap(lambda x: len(str(x)), na_action='ignore')
   0   1
0   <NA> 4
1   5   5
```  

Note that a vectorized version of `func` often exists, which will be much faster. You could square each number elementwise.

```python
>>> df.applymap(lambda x: x**2)
   0   1
0  1.000000 4.494400
1 11.262736 20.857489
```
But it’s better to avoid applymap in that case.

```python
>>> df ** 2
0  1.000000  4.494400
1 11.262736 20.857489
```

**pandas.DataFrame.asfreq**

```python
DataFrame.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)
```

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this DataFrame is a PeriodIndex, the new index is the result of transforming the original index with PeriodIndex.asfreq (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to pd.date_range(start, end, freq=freq) where start and end are, respectively, the first and last entries in the original index (see pandas.date_range()). The values corresponding to any timesteps in the new index which were not present in the original index will be null (NaN), unless a method for filling such unknowns is provided (see the method parameter below).

The resample() method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

**Parameters**

- `freq` [DateOffset or str] Frequency DateOffset or string.
- `method` [{‘backfill’/’bfill’, ‘pad’/’ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  - ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
  - ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.
- `how` [{‘start’, ‘end’}, default end] For PeriodIndex only (see PeriodIndex.asfreq).
- `normalize` [bool, default False] Whether to reset output index to midnight.
- `fill_value` [scalar, optional] Value to use for missing values, applied during upampling (note this does not fill NaNs that already were present).

**Returns**

- `DataFrame` DataFrame object reindexed to the specified frequency.

**See also:**

- `reindex` Conform DataFrame to new index with optional filling logic.
Notes

To learn more about the frequency strings, please see this link.

Examples

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df

          s
2000-01-01 00:00:00  0.0
2000-01-01 00:01:00  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:03:00  3.0
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')

          s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)

          s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```

Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')

          s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  2.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  3.0
2000-01-01 00:03:00  3.0
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.DataFrame.asof

DataFrame.asof(where, subset=None)

Return the last row(s) without any NaNs before where.
The last row (for each element in where, if list) without any NaN is taken. In case of a DataFrame, the last row without NaN considering only the subset of columns (if not None)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.
subset [str or array-like of str, default None] For DataFrame, if not None, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar : when self is a Series and where is a scalar
- Series: when self is a Series and where is an array-like, or when self is a DataFrame and where is a scalar
- DataFrame : when self is a DataFrame and where is an array-like

Return scalar, Series, or DataFrame.

See also:

merge_asof Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10  1.0
20  2.0
30  NaN
40  4.0
dtype: float64
```

```python
>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.
Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

Take all columns into consideration

```python
df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30', '2018-02-27 09:04:30']))
```

<table>
<thead>
<tr>
<th></th>
<th>40</th>
<th>50</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-02-27 09:03:30</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2018-02-27 09:04:30</td>
<td>30.0</td>
<td>NaN</td>
</tr>
<tr>
<td>2018-02-27 09:04:30</td>
<td>40.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Take a single column into consideration

```python
df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30', '2018-02-27 09:04:30']), subset=['a'])
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-02-27 09:03:30</td>
<td>30.0</td>
</tr>
<tr>
<td>2018-02-27 09:04:30</td>
<td>40.0</td>
</tr>
</tbody>
</table>

**pandas.Dataframe.assign**

Dataframe.assign(**kwargs)

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are reassigned will be overwritten.

**Parameters**

- **kwargs**: [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn’t check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

**Returns**

- **Dataframe**: A new DataFrame with the new columns in addition to all the existing columns.
Assigning multiple columns within the same `assign` is possible. Later items in `**kwargs` may refer to newly created or modified columns in `df`; items are computed and assigned into `df` in order.

**Examples**

```python
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0],
...                    index=['Portland', 'Berkeley'])
>>> df
temp_c
Portland 17.0
Berkeley 25.0
```

Where the value is a callable, evaluated on `df`:

```python
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
```

```text
temp_c  temp_f
Portland 17.0  62.6
Berkeley 25.0  77.0
```

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```python
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
```

```text
temp_c  temp_f
Portland 17.0  62.6
Berkeley 25.0  77.0
```

You can create multiple columns within the same `assign` where one of the columns depends on another one defined within the same `assign`:

```python
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...            temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
```

```text
temp_c  temp_f  temp_k
Portland 17.0  62.6  290.15
Berkeley 25.0  77.0  298.15
```

`pandas.DataFrame.astype`

`DataFrame.astype(dtype, copy=True, errors='raise')`

Cast a pandas object to a specified `dtype` `dtype`.

**Parameters**

- `dtype` [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

- `copy` [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

- `errors` [['raise', 'ignore'], default ‘raise’] Control raising of exceptions on invalid data for provided `dtype`.
• **raise**: allow exceptions to be raised
• **ignore**: suppress exceptions. On error return original object.

**Returns**

- **casted** [same type as caller]

**See also:**

- **to_datetime** Convert argument to datetime.
- **to_timedelta** Convert argument to timedelta.
- **to_numeric** Convert argument to a numeric type.
- **numpy.ndarray.astype** Cast a numpy array to a specified type.

**Notes**

Deprecated since version 1.3.0: Using `astype` to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use `Series.dt.tz_localize()` instead.

**Examples**

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1   int64
col2   int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
col1   int32
col2   int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
col1   int32
col2   int64
dtype: object
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
```

(continues on next page)
Convert to categorical type:

```python
>>> ser.astype('category')
0 1
1 2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> from pandas.api.types import CategoricalDtype
... cat_dtype = CategoricalDtype(... categories=[2, 1], ordered=True)
... ser.astype(cat_dtype)
0 1
1 2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1
# note that s1[0] has changed too
0 10
1 2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0 2020-01-01
1 2020-01-02
2 2020-01-03
dtype: datetime64[ns]
```

**pandas.DataFrame.at_time**

`DataFrame.at_time(time, asof=False, axis=None)`

Select values at particular time of day (e.g., 9:30AM).

**Parameters**

- `time` [datetime.time or str]
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0]

**Returns**
Series or DataFrame

Raises

**TypeError** If the index is not a `DatetimeIndex`

See also:

- `between_time` Select values between particular times of the day.
- `first` Select initial periods of time series based on a date offset.
- `last` Select final periods of time series based on a date offset.
- `DatetimeIndex.indexer_at_time` Get just the index locations for values at particular time of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00 1
2018-04-09 12:00:00 2
2018-04-10 00:00:00 3
2018-04-10 12:00:00 4
```

```python
>>> ts.at_time('12:00')
   A
2018-04-09 12:00:00 2
2018-04-10 12:00:00 4
```

**pandas.DataFrame.backfill**

DataFrame.backfill(*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for `DataFrame.fillna()` with method='bfill'.

Returns

- Series/DataFrame or None Object with missing values filled or None if inplace=True.

**pandas.DataFrame.between_time**

DataFrame.between_time(*start_time, end_time, include_start=NoDefault.no_default, include_end=NoDefault.no_default, inclusive=None, axis=None*)

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting start_time to be later than end_time, you can get the times that are not between the two times.

Parameters

- **start_time** [datetime.time or str] Initial time as a time filter limit.
- **end_time** [datetime.time or str] End time as a time filter limit.
include_start [bool, default True] Whether the start time needs to be included in the result.

Deprecated since version 1.4.0: Arguments include_start and include_end have been deprecated to standardize boundary inputs. Use inclusive instead, to set each bound as closed or open.

include_end [bool, default True] Whether the end time needs to be included in the result.

Deprecated since version 1.4.0: Arguments include_start and include_end have been deprecated to standardize boundary inputs. Use inclusive instead, to set each bound as closed or open.

inclusive [{"both", “neither”, “left”, “right”}, default “both”] Include boundaries; whether to set each bound as closed or open.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Determine range time on index or columns value.

Returns

Series or DataFrame Data from the original object filtered to the specified dates range.

Raises

TypeError If the index is not a DatetimeIndex

See also:

at_time Select values at a particular time of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4

>>> ts.between_time('0:15', '0:45')
   A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
```

You get the times that are not between two times by setting start_time later than end_time:
```python
>>> ts.between_time('0:45', '0:15')
A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4
```

**pandas.DataFrame.bfill**

DataFrame.bfill(*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for DataFrame.fillna() with method='bfill'.

**Returns**

Series/DataFrame or None Object with missing values filled or None if inplace=True.

**pandas.DataFrame.bool**

DataFrame.bool()

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

**Returns**

bool The value in the Series or DataFrame.

**See also:**

Series.astype Change the data type of a Series, including to boolean.

DataFrame.astype Change the data type of a DataFrame, including to boolean.

numpy.bool_ NumPy boolean data type, used by pandas for boolean values.

**Examples**

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```
pandas.DataFrame.boxplot

DataFrame.boxplot(column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, backend=None, **kwargs)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR = Q3 - Q1) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia’s entry for boxplot.

Parameters

- **column** [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to pandas.DataFrame.groupby().
- **by** [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.groupby(). One box-plot will be done per value of columns in by.
- **ax** [object class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.
- **fontsize** [float or str] Tick label font size in points or as a string (e.g., large).
- **rot** [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.
- **grid** [bool, default True] Setting this to True will show the grid.
- **figsize** [A tuple (width, height) in inches] The size of the figure to create in matplotlib.
- **layout** [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.
- **return_type** [‘axes’, ‘dict’, ‘both’ or None, default ‘axes’] The kind of object to return. The default is axes.
  - ‘axes’ returns the matplotlib axes the boxplot is drawn on.
  - ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
  - ‘both’ returns a namedtuple with the axes and dict.
  - when grouping with by, a Series mapping columns to return_type is returned.
  - If return_type is None, a NumPy array of axes with the same shape as layout is returned.
- **backend** [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.
  - New in version 1.0.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib.pyplot.boxplot().

Returns
result  See Notes.

See also:

Series.plot.hist  Make a histogram.

matplotlib.pyplot.boxplot  Matplotlib equivalent plot.

Notes

The return type depends on the return_type parameter:

- 'axes': object of class matplotlib.axes.Axes
- 'dict': dict of matplotlib.lines.Line2D objects
- 'both': a namedtuple with structure (ax, lines)

For data grouped with by, return a Series of the above or a numpy array:

- Series
- array (for return_type = None)

Use return_type='dict' when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by df.boxplot() or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option by. For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                   columns=['Col1', 'Col2'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                   columns=['Col1', 'Col2', 'Col3'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to layout:
Boxplot grouped by X

Col1

Col2
```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       layout=(2, 1))
```

Boxplot grouped by X

![Boxplot grouped by X](image)

Additional formatting can be done to the boxplot, like suppressing the grid (grid=False), rotating the labels in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                      return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>

pandas.DataFrame.clip

DataFrame.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)

Trim values at input threshold(s).
Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and
in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- **lower** [float or array-like, default None] Minimum threshold value. All values below
  this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.
- **upper** [float or array-like, default None] Maximum threshold value. All values above
  this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.
- **axis** [int or str axis name, optional] Align object with lower and upper along the given
  axis.
- **inplace** [bool, default False] Whether to perform the operation in place on the data.
- **args, **kwargs** Additional keywords have no effect but might be accepted for comp-
  atibility with numpy.

**Returns**

- **Series or DataFrame or None** Same type as calling object with the values outside the
  clip boundaries replaced or None if inplace=True.

**See also:**

- Series.clip Trim values at input threshold in series.
- DataFrame.clip Trim values at input threshold in dataframe.
- numpy.clip Clip (limit) the values in an array.

**Examples**

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9   -2
1     -3   -7
2      0     6
3     -1     8
4      5   -5
```

Clips per column using lower and upper thresholds:
```python
>>> df.clip(-4, 6)
col_0  col_1
 0    6   -2
 1   -3    -4
 2     0     6
 3   -1     6
 4     5   -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0  2
1 -4
2 -1
3  6
4  3
dtype: int64

>>> df.clip(t, t + 4, axis=0)
col_0  col_1
 0    6     2
 1   -3    -4
 2     0     3
 3    6     8
 4     5     3
```

Clips using specific lower threshold per column element, with missing values:

```python
>>> t = pd.Series([2, -4, np.nan, 6, 3])
>>> t
0   2.0
1  -4.0
2     NaN
3   6.0
4   3.0
dtype: float64

>>> df.clip(t, axis=0)
col_0  col_1
 0    9     2
 1   -3    -4
 2     0     6
 3    6     8
 4     5     3
```
pandas.DataFrame.combine

DataFrame.combine(other, func, fill_value=None, overwrite=True)

Perform column-wise combine with another DataFrame.

Combines a DataFrame with other DataFrame using func to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

- **other** [DataFrame] The DataFrame to merge column-wise.
- **func** [function] Function that takes two series as inputs and return a Series or a scalar. Used to merge the two dataframes column by columns.
- **fill_value** [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.
- **overwrite** [bool, default True] If True, columns in self that do not exist in other will be overwritten with NaNs.

Returns

- **DataFrame** Combination of the provided DataFrames.

See also:

- **DataFrame.combine_first** Combine two DataFrame objects and default to non-null values in frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3
1  0  3
```

Example using a true element-wise combine function.

```python
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
   A  B
0  1  2
1  0  3
```

Using fill_value fills Nones prior to passing the column to the merge function.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0  3
1  0  3
```
However, if the same element in both dataframes is None, that None is preserved

```python
>>> df1 = pd.DataFrame({'A': [0, 1], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0 -5.0
1  0  4.0
```

Example that demonstrates the use of `overwrite` and behavior when the axis differ between the dataframes.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller, overwrite=False)
     A  B  C
0  NaN NaN NaN
1  3.0 3.0 -10.0
2  NaN 3.0  1.0
```

Demonstrating the preference of the passed in dataframe.

```python
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], }, index=[1, 2])
>>> df2.combine(df1, take_smaller, overwrite=False)
     A  B  C
0  0.0 NaN NaN
1  3.0  3.0 -10.0
2  NaN  3.0  1.0
```
pandas.DataFrame.combine_first

DataFrame.combine_first(other)
Update null elements with value in the same location in other.
Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] Provided DataFrame to use to fill null values.

Returns

DataFrame The result of combining the provided DataFrame with the other object.

See also:

DataFrame.combine Perform series-wise operation on two DataFrames using a given function.

Examples

```python
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
   A   B
0  1.0  3.0
1  0.0  4.0
```

Null values still persist if the location of that null value does not exist in other

```python
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], index=[1, 2]})
>>> df1.combine_first(df2)
   A   B   C
0  NaN  4.0  NaN
1  0.0  3.0  1.0
2  NaN  3.0  1.0
```

pandas.DataFrame.compare

DataFrame.compare(other, align_axis=1, keep_shape=False, keep_equal=False)
Compare to another DataFrame and show the differences.
New in version 1.1.0.

Parameters

other [DataFrame] Object to compare with.

align_axis [{0 or ‘index’, 1 or ‘columns’}, default 1] Determine which axis to align the comparison on.

• 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
• 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns
drawn alternately from self and other.

keep_shape [bool, default False] If true, all rows and columns are kept. Otherwise,
only the ones with different values are kept.

keep_equal [bool, default False] If true, the result keeps values that are equal. Other-
wise, equal values are shown as NaNs.

Returns

DataFrame DataFrame that shows the differences stacked side by side.

The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately
at the inner level.

Raises

ValueError When the two DataFrames don’t have identical labels or shape.

See also:

Series.compare Compare with another Series and show differences.

DataFrame.equals Test whether two objects contain the same elements.

Notes

Matching NaNs will not appear as a difference.

Can only compare identically-labeled (i.e. same shape, identical row and column labels) DataFrames.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         "col1": ["a", "a", "b", "b", "a"],
...         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
...         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
...     },
...     columns=["col1", "col2", "col3"],
... )
>>> df
   col1  col2  col3
0     a   1.0   1.0
1     a   2.0   2.0
2     b   3.0   3.0
3     b   NaN   4.0
4     a   5.0   5.0

>>> df2 = df.copy()
>>> df2.loc[0, 'col1'] = 'c'
>>> df2.loc[2, 'col3'] = 4.0
>>> df2
   col1  col2  col3
0   c   1.0   1.0
1   a   2.0   2.0
2   b   3.0   4.0
3   b   NaN   4.0
4   a   5.0   5.0
```

(continues on next page)
Align the differences on columns

```python
>>> df.compare(df2)
col1  col3
     self  other  self  other
0     a    c  NaN    NaN
2     NaN  NaN   3.0  4.0
```

Stack the differences on rows

```python
>>> df.compare(df2, align_axis=0)
col1  col3
      self  other  self  other
0     a    c  NaN    NaN
2     NaN  NaN   3.0  4.0
```

Keep the equal values

```python
>>> df.compare(df2, keep_equal=True)
col1  col3
      self  other  self  other
0     a    c  1.0  1.0
2     b    b  3.0  4.0
```

Keep all original rows and columns

```python
>>> df.compare(df2, keep_shape=True)
col1  col2  col3
     self  other  self  other  self  other
0     a    c    NaN  NaN    NaN  NaN
1     NaN  NaN    NaN  NaN    NaN  NaN
2     NaN  NaN    NaN  NaN    3.0  4.0
3     NaN  NaN    NaN  NaN    NaN  NaN
4     NaN  NaN    NaN  NaN    NaN  NaN
```

Keep all original rows and columns and also all original values

```python
>>> df.compare(df2, keep_shape=True, keep_equal=True)
col1  col2  col3
     self  other  self  other  self  other
0     a    c    1.0  1.0    1.0  1.0
1     a    a    2.0  2.0    2.0  2.0
2     b    b    3.0  3.0    3.0  4.0
3     b    b    NaN  NaN    4.0  4.0
4     a    a    5.0  5.0    5.0  5.0
```
pandas.DataFrame.convert_dtypes

DataFrame.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True, convert_floating=True)

Convert columns to best possible dtypes using dtypes supporting pd.NA.

New in version 1.0.0.

Parameters

- **infer_objects** [bool, default True] Whether object dtypes should be converted to the best possible types.
- **convert_string** [bool, default True] Whether object dtypes should be converted to StringDtype().
- **convert_integer** [bool, default True] Whether, if possible, conversion can be done to integer extension types.
- **convert_boolean** [bool, defaults True] Whether object dtypes should be converted to BooleanDtypes().
- **convert_floating** [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If convert_integer is also True, preference will be give to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

Returns

- **Series or DataFrame** Copy of input object with new dtype.

See also:

- **infer_objects** Infer dtypes of objects.
- **to_datetime** Convert argument to datetime.
- **to_timedelta** Convert argument to timedelta.
- **to_numeric** Convert argument to a numeric type.

Notes

By default, convert_dtypes will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support pd.NA. By using the options convert_string, convert_integer, convert_boolean and convert_boolean, it is possible to turn off individual conversions to StringDtype, the integer extension types, BooleanDtype or floating extension types, respectively.

For object-dtyped columns, if infer_objects is True, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to StringDtype, BooleanDtype or an appropriate integer or floating extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.
In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

**Examples**

```python
>>> df = pd.DataFrame(
    ... {  
    ...     "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),  
    ...     "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),  
    ...     "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),  
    ...     "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),  
    ...     "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),  
    ...     "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),  
    ...  }
    ...
)
Start with a DataFrame with default dtypes.

>>> df
  a      b     c      d      e      f
0  1      x  True   h  10.0   NaN
1  2  y  False   i  NaN  100.5
2  3  z   NaN   NaN  20.0  200.0

>>> df.dtypes
a  int32
b  object
c  object
d  object
e  float64
f  float64
dtype: object

Convert the DataFrame to use best possible dtypes.

```python
>>> dfn = df.convert_dtypes()

>>> dfn
  a    b     c    d    e    f
0  1  x  True   h  10  <NA>
1  2  y  False  i  <NA>  100.5
2  3  z  <NA>  <NA>  20  200.0

>>> dfn.dtypes
a  Int32
b  string
c  boolean
d  string
e  Int64
f  Float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`. 

---

3.4. DataFrame 1693
```python
>>> s = pd.Series(['a', 'b', np.nan])
>>> s
0    a
1    b
2    NaN
dtype: object
```

Obtain a Series with dtype `StringDtype`.

```python
>>> s.convert_dtypes()
0    a
1    b
2    <NA>
dtype: string
```

### pandas.DataFrame.copy

**DataFrame.copy**(deep=True)

Make a copy of this object’s indices and data.

When deep=True (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When deep=False, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

**Parameters**

- **deep** [bool, default True] Make a deep copy, including a copy of the data and the indices. With deep=False neither the indices nor the data are copied.

**Returns**

- **copy** [Series or DataFrame] Object type matches caller.

**Notes**

When deep=True, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While Index objects are copied when deep=True, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.
Examples

```python
>>> s = pd.Series([1, 2], index=['a', 'b'])
>>> s
a  1
b  2
dtype: int64

>>> s_copy = s.copy()
>>> s_copy
a  1
b  2
dtype: int64

Shallow copy versus default (deep) copy:

```python
>>> s = pd.Series([1, 2], index=['a', 'b'])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)

Shallow copy shares data and index with original.

```python
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True

Deep copy has own copy of data and index.

```python
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a  3
b  2
dtype: int64
>>> shallow
a  3
b  4
dtype: int64
>>> deep
a  1
b  2
dtype: int64

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.
```python
>>> s = pd.Series([\[1, 2\], \[3, 4\]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0 \[10, 2\]
1 \[3, 4\]
dtype: object
>>> deep
0 \[10, 2\]
1 \[3, 4\]
dtype: object
```

**pandas.DataFrame.corr**

Dataframe.corr(method='pearson', min_periods=1)

Compute pairwise correlation of columns, excluding NA/null values.

**Parameters**

- **method** [\{‘pearson’, ‘kendall’, ‘spearman’\} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

- **min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

**Returns**

DataFrame Correlation matrix.

**See also:**

- DataFrame.corrwith Compute pairwise correlation with another DataFrame or Series.
- Series.corr Compute the correlation between two Series.

**Examples**

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
... >>> df = pd.DataFrame([[.2, .3], (.0, .6), (.6, .0), (.2, .1)],
...                     columns=['dogs', 'cats'])
... >>> df.corr(method=histogram_intersection)
dogs cats
dogs 1.0 0.3
cats 0.3 1.0
```
pandas.DataFrame.corrwith

DataFrame.corrwith(other, axis=0, drop=False, method='pearson')

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters**

- **other** [DataFrame, Series] Object with which to compute correlations.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.
- **drop** [bool, default False] Drop missing indices from result.
- **method** [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float.

**Returns**

- **Series** Pairwise correlations.

See also:

DataFrame.corr Compute pairwise correlation of columns.

pandas.DataFrame.count

DataFrame.count(axis=0, level=None, numeric_only=False)

Count non-NA cells for each column or row.

The values None, NaN, NaT, and optionally numpy.inf (depending on pandas.options.mode.use_inf_as_na) are considered NA.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] If 0 or ‘index’ counts are generated for each column. If 1 or ‘columns’ counts are generated for each row.
- **level** [int or str, optional] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame. A str specifies the level name.
- **numeric_only** [bool, default False] Include only float, int or boolean data.

**Returns**

- **Series or DataFrame** For each column/row the number of non-NA/null entries. If level is specified returns a DataFrame.

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.value_counts Count unique combinations of columns.
**DataFrame.shape**  Number of DataFrame rows and columns (including NA elements).

**DataFrame.isna**  Boolean same-sized DataFrame showing places of NA elements.

### Examples

Constructing DataFrame from a dictionary:

```python
>>> df = pd.DataFrame({"Person":
...                     ["John", "Myla", "Lewis", "John", "Myla"],
...                     "Age": [24., np.nan, 21., 33, 26],
...                     "Single": [False, True, True, True, False]})
```

```plaintext
<table>
<thead>
<tr>
<th></th>
<th>Person</th>
<th>Age</th>
<th>Single</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>John</td>
<td>24.0</td>
<td>False</td>
</tr>
<tr>
<td>1</td>
<td>Myla</td>
<td>NaN</td>
<td>True</td>
</tr>
<tr>
<td>2</td>
<td>Lewis</td>
<td>21.0</td>
<td>True</td>
</tr>
<tr>
<td>3</td>
<td>John</td>
<td>33.0</td>
<td>True</td>
</tr>
<tr>
<td>4</td>
<td>Myla</td>
<td>26.0</td>
<td>False</td>
</tr>
</tbody>
</table>
```

Notice the uncounted NA values:

```python
>>> df.count()
Person    5
Age       4
Single    5
dtype: int64
```

Counts for each row:

```python
>>> df.count(axis='columns')
0 3
1 2
2 3
3 3
4 3
dtype: int64
```

### pandas.DataFrame.cov

**DataFrame.cov**(*min_periods=None, ddof=1*)

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

**min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.

**ddof** [int, default 1] Delta degrees of freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

New in version 1.1.0.

**Returns**

**DataFrame** The covariance matrix of the series of the DataFrame.

**See also:**

- **Series.cov** Compute covariance with another Series.
- **core.window.ExponentialMovingWindow.cov** Exponential weighted sample covariance.
- **core.window.Expanding.cov** Expanding sample covariance.
- **core.window.Rolling.cov** Rolling sample covariance.

**Notes**

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

**Examples**

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
                   columns=['dogs', 'cats'])
>>> df.cov()
dogs  cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667

>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
                   columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
a   b   c   d   e
a 0.998438 -0.020161 0.059277 -0.008943 0.014144
b -0.020161 1.059352 -0.008543 -0.024738 0.009826
c 0.059277 -0.008543 1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486 0.921297 -0.013692
e 0.014144 0.009826 -0.000271 -0.013692 0.977795
```
Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
      a       b        c
    a  0.316741 NaN -0.150812
    b  NaN  1.248003  0.191417
    c -0.150812  0.191417  0.895202
```

**pandas.DataFrame.cummax**

DataFrame.cummax(*axis=None, skipna=True, *args, **kwargs*)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

**Parameters**

- `axis` ([0 or ‘index’, 1 or ‘columns’], default 0) The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- `Series` or `DataFrame` Return cumulative maximum of Series or DataFrame.

See also:

- `core.window.Expanding.max` Similar functionality but ignores NaN values.
- `DataFrame.max` Return the maximum over DataFrame axis.
- `DataFrame.cummax` Return cumulative maximum over DataFrame axis.
- `DataFrame.cummin` Return cumulative minimum over DataFrame axis.
- `DataFrame.cumsum` Return cumulative sum over DataFrame axis.
- `DataFrame.cumprod` Return cumulative product over DataFrame axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
0  2.0
1  NaN
2  5.0
3  5.0
4  5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummax(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
                      [3.0, np.nan],
                      [1.0, 0.0]],
                      columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummax()
   A  B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`
>>> df.cummax(axis=1)
     A  B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0

pandas.DataFrame.cummin

DataFrame.cummin(axis=None, skipna=True, *args, **kwargs)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

- **axis** ([0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- *args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

- **Series or DataFrame** Return cumulative minimum of Series or DataFrame.

See also:

- core.window.Expanding.min Similar functionality but ignores NaN values.
- DataFrame.min Return the minimum over DataFrame axis.
- DataFrame.cummax Return cumulative maximum over DataFrame axis.
- DataFrame.cummin Return cumulative minimum over DataFrame axis.
- DataFrame.cumsum Return cumulative sum over DataFrame axis.
- DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
```
```
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> s.cummin()
0 2.0
1 NaN
2 2.0
3 -1.0
4 -1.0
dtype: float64
To include NA values in the operation, use skipna=False

```python
>>> s.cummin(skipna=False)
0 2.0
1 NaN
2 NaN
3 NaN
4 NaN
dtype: float64

```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

By default, iterates over rows and finds the minimum in each column. This is equivalent to axis=None or axis='index'.

```python
>>> df.cummin()
   A  B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0

To iterate over columns and find the minimum in each row, use axis=1

```python
>>> df.cummin(axis=1)
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.DataFrame.cumprod

DataFrame.cumprod(axis=None, skipna=True, *args, **kwargs)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis ([0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative product of Series or DataFrame.

See also:

core.window.Expanding.prod Similar functionality but ignores NaN values.

DataFrame.prod Return the product over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
0  2.0
1  NaN
2  10.0
3 -10.0
4  -0.0
dtype: float64
```

To include NA values in the operation, use skipna=False
```python
>>> s.cumprod(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumprod()
   A  B
0  2.0 1.0
1  6.0 NaN
2  6.0 0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```python
>>> df.cumprod(axis=1)
   A  B
0  2.0 2.0
1  3.0 NaN
2  1.0 0.0
```

**pandas.DataFrame.cumsum**

`DataFrame.cumsum(axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

**Parameters**

- `axis` ([0 or ‘index’, 1 or ‘columns’], default 0) The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

---

3.4. DataFrame
**Returns**

**Series or DataFrame** Return cumulative sum of Series or DataFrame.

**See also:**

- `core.window.Expanding.sum` Similar functionality but ignores NaN values.
- `DataFrame.sum` Return the sum over DataFrame axis.
- `DataFrame.cummax` Return cumulative maximum over DataFrame axis.
- `DataFrame.cummin` Return cumulative minimum over DataFrame axis.
- `DataFrame.cumsum` Return cumulative sum over DataFrame axis.
- `DataFrame.cumprod` Return cumulative product over DataFrame axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1     NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0    2.0
1     NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumsum(skipna=False)
0    2.0
1     NaN
2     NaN
3     NaN
4     NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
```

(continues on next page)
By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A  B
0  2.0 1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A  B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

**pandas.DataFrame.describe**

`DataFrame.describe(percentiles=None, include=None, exclude=None, datetime_is_numeric=False)`

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

- **percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

- **include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
  - ‘all’ : All columns of the input will be included in the output.
  - A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])). To select pandas categorical columns, use 'category'
  - None (default) : The result will include all numeric columns.

- **exclude** [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
• A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(exclude=['O'])`). To exclude pandas categorical columns, use `category`

• None (default): The result will exclude nothing.

`datetime_is_numeric` [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

*Series or DataFrame* Summary statistics of the Series or DataFrame provided.

See also:

*DataFrame.count* Count number of non-NA/null observations.

*DataFrame.max* Maximum of the values in the object.

*DataFrame.min* Minimum of the values in the object.

*DataFrame.mean* Mean of the values.

*DataFrame.std* Standard deviation of the observations.

*DataFrame.select_dtypes* Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a `Series`. 

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count    3.0
mean      2.0
std       1.0
min       1.0
25%       1.5
50%       2.0
75%       2.5
max       3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count    4
unique   3
top      a
freq     2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([...
...    np.datetime64("2000-01-01"),
...    np.datetime64("2010-01-01"),
...    np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count    3
mean 2006-09-01 08:00:00
min 2000-01-01 00:00:00
25% 2004-12-31 12:00:00
50% 2010-01-01 00:00:00
75% 2010-01-01 00:00:00
max 2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f'],
...    [1, 2, 3],
...    ['object': ['a', 'b', 'c']
... ])
>>> df.describe()
count    numeric
mean      2.0
std       1.0
```

(continues on next page)
Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
```

<table>

</table>

Name: numeric, dtype: float64

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
```

<table>
<thead>
<tr>
<th></th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>count</td>
</tr>
<tr>

<td>2.0</td>
</tr>
<tr>
<td>75%</td>
<td>2.5</td>
</tr>
<tr>
<td>max</td>
<td>3.0</td>
</tr>
</tbody>
</table>

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
```

<table>
<thead>
<tr>
<th></th>
<th>object</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>count</td>
</tr>
<tr>
<td></td>
<td>3</td>
</tr>
</tbody>
</table>
including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
categorical
   count 3
   unique 3
top  d
freq  1
```

excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
categorical  object
   count   3   3
   unique   3   3
top  f   a
freq  1   1
```

excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])
categorical  numeric
   count   3   3.0
   unique   3   NaN
top  f   NaN
freq  1   NaN
mean  NaN   2.0
std   NaN   1.0
min   NaN   1.0
25%   NaN   1.5
50%   NaN   2.0
75%   NaN   2.5
max   NaN   3.0
```

**pandas.DataFrame.diff**

DataFrame.diff(periods=1, axis=0)

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

**Parameters**

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Take difference over rows (0) or columns (1).
Returns

**Dataframe**  First differences of the Series.

See also:

**Dataframe.pct_change**  Percent change over given number of periods.

**Dataframe.shift**  Shift index by desired number of periods with an optional time freq.

**Series.diff**  First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
                      'b': [1, 1, 2, 3, 5, 8],
                      'c': [1, 4, 9, 16, 25, 36]})

>>> df
da   b   c
0   1   1   1
1   2   1   4
2   3   2   9
3   4   3  16
4   5   5  25
5   6   8  36
```

```python
>>> df.diff()
da   b   c
0  NaN  NaN  NaN
1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

Difference with previous column

```python
>>> df.diff(axis=1)
da   b   c
0  NaN  NaN  NaN
1  NaN -1  3
2  NaN -1  7
3  NaN -1 13
4  NaN  0 20
5  NaN  2 28
```

Difference with 3rd previous row
```python
>>> df.diff(periods=3)
    a    b    c
0   NaN  NaN  NaN
1   NaN  NaN  NaN
2   NaN  NaN  NaN
3  3.0  2.0  15.0
4  3.0  4.0  21.0
5  3.0  6.0  27.0
```
Difference with following row
```python
>>> df.diff(periods=-1)
    a    b    c
0  -1.0  0.0  -3.0
1  -1.0 -1.0  -5.0
2  -1.0 -1.0  -7.0
3  -1.0 -2.0  -9.0
4  -1.0 -3.0 -11.0
5   NaN  NaN  NaN
```
Overflow in input dtype
```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
a
0  NaN
1  255.0
```

**pandas.DataFrame.div**

`DataFrame.div(other, axis='columns', level=None, fill_value=None)`

Get Floating division of dataframe and other, element-wise (binary operator `truediv`).
Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rtruediv`.
Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.
See also:

- **DataFrame.add**  Add DataFrames.
- **DataFrame.sub**  Subtract DataFrames.
- **DataFrame.mul**  Multiply DataFrames.
- **DataFrame.div**  Divide DataFrames (float division).
- **DataFrame.truediv**  Divide DataFrames (float division).
- **DataFrame.floordiv**  Divide DataFrames (integer division).
- **DataFrame.mod**  Calculate modulo (remainder after division).
- **DataFrame.pow**  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
def = pd.DataFrame({'angles': [0, 3, 4],
                   'degrees': [360, 180, 360],
                   'index': ['circle', 'triangle', 'rectangle']})
def
```

```
angles   degrees
circle   0     360
triangle 3     180
rectangle 4     360
```

Add a scalar with operator version which return the same results.

```python
def + 1
```

```
angles   degrees
circle   1     361
triangle 4     181
rectangle 5     361
```

```python
def.add(1)
```

```
angles   degrees
circle   1     361
triangle 4     181
rectangle 5     361
```

Divide by constant with reverse version.

```python
def.div(10)
```

```
angles   degrees
circle   0.0   36.0
triangle 0.3   18.0
rectangle 0.4   36.0
```
Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]

angles  degrees
  circle    -1   358
  triangle    2   178
  rectangle    3   358
```

```python
>>> df.sub([1, 2], axis='columns')

angles  degrees
  circle    -1   358
  triangle    2   178
  rectangle    3   358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         axis='index')

angles  degrees
  circle    -1   359
  triangle    2   179
  rectangle    3   359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4],
                         'index': ['circle', 'triangle', 'rectangle']})

>>> other

  angles
  circle    0
  triangle    3
  rectangle    4
```

```python
>>> df * other

angles  degrees
  circle     0  NaN
  triangle    9  NaN
  rectangle   16  NaN
```

```python
>>> df.mul(other, fill_value=0)

angles  degrees
  circle     0  0.0
  triangle    9  0.0
  rectangle   16  0.0
```

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
... 'degrees': [360, 180, 360, 540, 720],
... index=['A', 'A', 'B', 'B', 'B'],
... ['circle', 'triangle', 'rectangle',
... 'square', 'pentagon', 'hexagon'])

>>> df_multindex
   angles degrees
A circle 0 360
    triangle 3 180
    rectangle 4 360
B square 4 360
    pentagon 5 540
    hexagon 6 720

>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A circle   NaN     1.0
    triangle   1.0    1.0
    rectangle   1.0    1.0
B square   0.0     0.0
    pentagon   0.0     0.0
    hexagon   0.0     0.0
```

**pandas.DataFrame.divide**

DataFrame.divide(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator \texttt{truediv}).

Equivalent to \texttt{dataframe / other}, but with support to substitute a \texttt{fill_value} for missing data in one of the inputs. With reverse version, \texttt{rtruediv}.

Among flexible wrappers \texttt{(add, sub, mul, div, mod, pow)} to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes
Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                      'degrees': [360, 180, 360],
                      index=['circle', 'triangle', 'rectangle'])
```

```
      angles  degrees
    ---  -------
circle  0   360
triangle  3   180
rectangle  4   360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
      angles  degrees
    ---  -------
circle   1   361
triangle   4   181
rectangle   5   361
```

```python
>>> df.add(1)
      angles  degrees
    ---  -------
circle   1   361
triangle   4   181
rectangle   5   361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
      angles  degrees
    ---  -------
circle  0.0   36.0
triangle  0.3  18.0
rectangle  0.4   36.0
```

```python
>>> df.rdiv(10)
      angles  degrees
    ---  -------
circle  inf   0.027778
```

(continues on next page)
triangle  3.333333  0.055556  
rectangle  2.500000  0.027778  

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
  angles  degrees
  circle   -1     358
  triangle  2      178
  rectangle 3      358
```

```python
>>> df.sub([1, 2], axis='columns')
  angles  degrees
  circle   -1     358
  triangle  2      178
  rectangle 3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
  angles  degrees
  circle   -1     359
  triangle  2      179
  rectangle 3      359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4], 'degrees': [360, 180, 360]}, index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
  angles  degrees
  circle    0       NaN
  triangle  9       NaN
  rectangle 16      NaN
```

```python
>>> df.mul(other, fill_value=0)
  angles  degrees
  circle    0       0.0
  triangle  9       0.0
  rectangle 16      0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6], 'degrees': [360, 180, 360, 360, 540, 720]}, index=['A', 'A', 'A', 'B', 'B', 'B'])
```

(continues on next page)
...<br>
...<br>
```python
>>> df_multindex
   angles  degrees
  A  circle    0    360
      triangle  3    180
      rectangle 4    360
  B  square    4    360
      pentagon  5    540
      hexagon  6    720

>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
  A  circle  NaN     1
      triangle  1.0   1.0
      rectangle  1.0   1.0
  B  square   0.0   0.0
      pentagon  0.0   0.0
      hexagon  0.0   0.0
```

### pandas.DataFrame.dot

**DataFrame.dot**(other)

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using `self @ other` in Python >= 3.5.

**Parameters**

- **other** [Series, DataFrame or array-like] The other object to compute the matrix product with.

**Returns**

- **Series or DataFrame** If other is a Series, return the matrix product between self and other as a Series. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

**See also:**

- **Series.dot** Similar method for Series.
Notes

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

Examples

Here we multiply a DataFrame with a Series.

```python
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0  -4
1   5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```python
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
    0  1
0  1  4
1  2  2
```

Note that the dot method give the same result as @

```python
>>> df @ other
    0  1
0  1  4
1  2  2
```

The dot method works also if other is an np.array.

```python
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
    0  1
0  1  4
1  2  2
```

Note how shuffling of the objects does not change the result.

```python
>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
0   -4
1    5
dtype: int64
```
pandas.DataFrame.drop

DataFrame.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Drop specified labels from rows or columns.
Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level. See the user guide <advanced.shown_levels> for more information about the now unused levels.

**Parameters**

- **labels** [single label or list-like] Index or column labels to drop. A tuple will be used as a single label and not treated as a list-like.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Whether to drop labels from the index (0 or ‘index’) or columns (1 or ‘columns’).
- **index** [single label or list-like] Alternative to specifying axis (labels, axis=0 is equivalent to index=labels).
- **columns** [single label or list-like] Alternative to specifying axis (labels, axis=1 is equivalent to columns=labels).
- **level** [int or level name, optional] For MultiIndex, level from which the labels will be removed.
- **inplace** [bool, default False] If False, return a copy. Otherwise, do operation inplace and return None.
- **errors** [{'ignore', 'raise'}, default 'raise'] If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

- **DataFrame or None** DataFrame without the removed index or column labels or None if inplace=True.

**Raises**

- **KeyError** If any of the labels is not found in the selected axis.

**See also:**

- **DataFrame.loc** Label-location based indexer for selection by label.
- **DataFrame.dropna** Return DataFrame with labels on given axis omitted where (all or any) data are missing.
- **DataFrame.drop_duplicates** Return DataFrame with duplicate rows removed, optionally only considering certain columns.
- **Series.drop** Return Series with specified index labels removed.
## Examples

```python
>>> df = pd.DataFrame(np.arange(12).reshape(3, 4),
...                   columns=['A', 'B', 'C', 'D'])
>>> df
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
2  8  9 10 11
```

### Drop columns

```python
>>> df.drop(['B', 'C'], axis=1)
   A  D
0  0  3
1  4  7
2  8 11
```

```python
>>> df.drop(columns=['B', 'C'])
   A  D
0  0  3
1  4  7
2  8 11
```

### Drop a row by index

```python
>>> df.drop([0, 1])
   A  B  C  D
2  8  9 10 11
```

### Drop columns and/or rows of MultiIndex DataFrame

```python
>>> midx = pd.MultiIndex(levels=[[['lama', 'cow', 'falcon'],
                                ['speed', 'weight', 'length']],
                            ...                          
                                [0, 1, 2, 0, 1, 2, 0, 1, 2]],
                            ...                          
                            codes=[[0, 0, 0, 1, 1, 2, 2, 2, 2, 2],
                                   [0, 1, 2, 0, 1, 2, 0, 1, 2, 0]])
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
                    data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
                          [250, 150], [1.5, 0.8], [320, 250],
                          [1, 0.8], [0.3, 0.2]])
>>> df
       big    small
lama speed  45.0    30.0
         weight 200.0   100.0
             length  1.5     1.0
cow  speed  30.0     20.0
       weight 250.0   150.0
          length  1.5     0.8
falcon speed 320.0   250.0
       weight  1.0    250.0
            length  0.3     0.2
```

Drop a specific index combination from the MultiIndex DataFrame, i.e., drop the combination 'falcon' and 'weight', which deletes only the corresponding row
```python
>>> df.drop(index=('falcon', 'weight'))
   big    small
lama  speed  45.0   30.0
       weight 200.0  100.0
       length  1.5    1.0
cow   speed  30.0   20.0
       weight 250.0  150.0
       length  1.5    0.8
falcon speed 320.0  250.0
         length  0.3    0.2
```

```python
>>> df.drop(index='cow', columns='small')
big
lama  speed  45.0
       weight 200.0
       length  1.5
falcon speed 320.0
            weight 1.0
            length  0.3
```

```python
>>> df.drop(index='length', level=1)
   big   small
lama  speed  45.0   30.0
       weight 200.0  100.0
       length  1.5   1.0
cow   speed  30.0   20.0
       weight 250.0  150.0
       length  1.5   0.8
falcon speed 320.0  250.0
          weight  1.0   0.8
```

### pandas.DataFrame.drop_duplicates

DataFrame.drop_duplicates(subset=None, keep='first', inplace=False, ignore_index=False)

Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

**Parameters**

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- **keep** ['first', 'last', False], default 'first'] Determines which duplicates (if any) to keep.
  - first : Drop duplicates except for the first occurrence.
  - last : Drop duplicates except for the last occurrence.
  - False : Drop all duplicates.
- **inplace** [bool, default False] Whether to drop duplicates in place or to return a copy.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

**Returns**

DataFrame or None  DataFrame with duplicates removed or None if inplace=True.
See also:

_pandas.DataFrame.value_counts_ Count unique combinations of columns.

**Examples**

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
```

```python
>>> df
     brand  style  rating
0      Yum Yum  cup      4.0
1      Yum Yum  cup      4.0
2    Indomie  cup      3.5
3    Indomie  pack     15.0
4    Indomie  pack      5.0
```

By default, it removes duplicate rows based on all columns.

```python
>>> df.drop_duplicates()
     brand  style  rating
0      Yum Yum  cup      4.0
2    Indomie  cup      3.5
3    Indomie  pack     15.0
4    Indomie  pack      5.0
```

To remove duplicates on specific column(s), use `subset`.

```python
>>> df.drop_duplicates(subset=['brand'])
     brand  style  rating
0      Yum Yum  cup      4.0
2    Indomie  cup      3.5
```

To remove duplicates and keep last occurrences, use `keep`.

```python
>>> df.drop_duplicates(subset=['brand', 'style'], keep='last')
     brand  style  rating
1      Yum Yum  cup      4.0
2    Indomie  cup      3.5
4    Indomie  pack      5.0
```
DataFrame.droplevel

DataFrame.droplevel(level, axis=0)
Return Series/DataFrame with requested index / column level(s) removed.

Parameters
level [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.
axis [0 or 'index', 1 or 'columns'], default 0] Axis along which the level(s) is removed:
• 0 or ‘index’: remove level(s) in column.
• 1 or ‘columns’: remove level(s) in row.

Returns
Series/DataFrame Series/DataFrame with requested index / column level(s) removed.

Examples

```python
def = pd.DataFrame([                  ...
...  [1, 2, 3, 4],                  ...
...  [5, 6, 7, 8],                  ...
...  [9, 10, 11, 12]               ...
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```python
def.columns = pd.MultiIndex.from_tuples([...
...  ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```python
def
level_1  c  d
level_2  e  f
a  b
1  2  3  4
5  6  7  8
9 10 11 12
```

```python
def.droplevel('a')
level_1  c  d
level_2  e  f
b
2  3  4
6  7  8
10 11 12
```

```python
def.droplevel('level_2', axis=1)
level_1  c  d
a  b
1  2  3  4
5  6  7  8
9 10 11 12
```
pandas.DataFrame.dropna

`DataFrame.dropna(axis=0, how='any', thresh=None, subset=None, inplace=False)`

Remove missing values.

See the User Guide for more on which values are considered missing, and how to work with missing data.

**Parameters**

- **axis**
  - 0, or ‘index’ : Drop rows which contain missing values.
  - 1, or ‘columns’ : Drop columns which contain missing value.

  Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

- **how**
  - ‘any’ : If any NA values are present, drop that row or column.
  - ‘all’ : If all values are NA, drop that row or column.

- **thresh**
  - [int, optional] Require that many non-NA values.

- **subset**
  - [column label or sequence of labels, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

- **inplace**
  - [bool, default False] If True, do operation inplace and return None.

**Returns**

- **DataFrame or None**

  DataFrame with NA entries dropped from it or None if inplace=True.

See also:

- `DataFrame.isna` Indicate missing values.
- `DataFrame.notna` Indicate existing (non-missing) values.
- `DataFrame.fillna` Replace missing values.
- `Series.dropna` Drop missing values.
- `Index.dropna` Drop missing indices.

**Examples**

```python
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
...                      "toy": [np.nan, 'Batmobile', 'Bullwhip'],
...                      "born": [pd.NaT, pd.Timestamp("1940-04-25"),
...                               pd.NaT]})
>>> df
    name  toy        born
0   Alfred  NaN  NaT
1    Batman  Batmobile  1940-04-25
2  Catwoman   Bullwhip  NaT
```
Drop the rows where at least one element is missing.

```python
df.dropna()
```

<table>
<thead>
<tr>
<th>name</th>
<th>toy</th>
<th>born</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Batman</td>
<td>1940-04-25</td>
</tr>
</tbody>
</table>

Drop the columns where at least one element is missing.

```python
df.dropna(axis='columns')
```

<table>
<thead>
<tr>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
</tbody>
</table>

Drop the rows where all elements are missing.

```python
df.dropna(how='all')
```

<table>
<thead>
<tr>
<th>name</th>
<th>toy</th>
<th>born</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Alfred</td>
<td>NaN NaT</td>
</tr>
<tr>
<td>1</td>
<td>Batman</td>
<td>Batmobile 1940-04-25</td>
</tr>
<tr>
<td>2</td>
<td>Catwoman</td>
<td>Bullwhip NaT</td>
</tr>
</tbody>
</table>

Keep only the rows with at least 2 non-NA values.

```python
df.dropna(thresh=2)
```

<table>
<thead>
<tr>
<th>name</th>
<th>toy</th>
<th>born</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Batman</td>
<td>Batmobile 1940-04-25</td>
</tr>
<tr>
<td>2</td>
<td>Catwoman</td>
<td>Bullwhip NaT</td>
</tr>
</tbody>
</table>

Define in which columns to look for missing values.

```python
df.dropna(subset=['name', 'toy'])
```

<table>
<thead>
<tr>
<th>name</th>
<th>toy</th>
<th>born</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Batman</td>
<td>Batmobile 1940-04-25</td>
</tr>
<tr>
<td>2</td>
<td>Catwoman</td>
<td>Bullwhip NaT</td>
</tr>
</tbody>
</table>

Keep the DataFrame with valid entries in the same variable.

```python
df.dropna(inplace=True)
```

<table>
<thead>
<tr>
<th>name</th>
<th>toy</th>
<th>born</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Batman</td>
<td>Batmobile 1940-04-25</td>
</tr>
</tbody>
</table>

### pandas.DataFrame.duplicated

DataFrame.duplicated(subset=None, keep='first')

Return boolean Series denoting duplicate rows.

Considering certain columns is optional.

**Parameters**

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- **keep** [‘first’, ‘last’, False], default ‘first’ Determines which duplicates (if any) to mark.
• **first**: Mark duplicates as True except for the first occurrence.
• **last**: Mark duplicates as True except for the last occurrence.
• **False**: Mark all duplicates as True.

**Returns**

Series  Boolean series for each duplicated rows.

**See also:**

*Index.duplicated*  Equivalent method on index.
*Series.duplicated*  Equivalent method on Series.
*Series.drop_duplicates*  Remove duplicate values from Series.
*DataFrame.drop_duplicates*  Remove duplicate values from DataFrame.

**Examples**

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame(
...     {'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...      'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...      'rating': [4, 4, 3.5, 15, 5]}
... )
```

<table>
<thead>
<tr>
<th>brand</th>
<th>style</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yum Yum</td>
<td>cup</td>
<td>4.0</td>
</tr>
<tr>
<td>Yum Yum</td>
<td>cup</td>
<td>4.0</td>
</tr>
<tr>
<td>Indomie</td>
<td>cup</td>
<td>3.5</td>
</tr>
<tr>
<td>Indomie</td>
<td>pack</td>
<td>15.0</td>
</tr>
<tr>
<td>Indomie</td>
<td>pack</td>
<td>5.0</td>
</tr>
</tbody>
</table>

By default, for each set of duplicated values, the first occurrence is set on False and all others on True.

```python
>>> df.duplicated()
0   False
1    True
2   False
3    False
4    False
dtype: bool
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True.

```python
>>> df.duplicated(keep='last')
0    True
1    False
2    False
3    False
4    False
dtype: bool
```

By setting keep on False, all duplicates are True.
To find duplicates on specific column(s), use subset.

```python
>>> df.duplicated(subset=['brand'])
0  False
1   True
2   False
3   True
4  True
dtype: bool
```

**pandas.DataFrame.eq**

`DataFrame.eq(other, axis='columns', level=None)`
Get Equal to of dataframe and other, element-wise (binary operator `eq`).
Among flexible wrappers (`eq`, `ne`, `le`, `lt`, `ge`, `gt`) to comparison operators.
Equivalent to `==, /=, <=, <, >=, >` with support to choose axis (rows or columns) and level for comparison.

**Parameters**
- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**
- `DataFrame of bool` Result of the comparison.

**See also:**
- `DataFrame.eq` Compare DataFrames for equality elementwise.
- `DataFrame.ne` Compare DataFrames for inequality elementwise.
- `DataFrame.le` Compare DataFrames for less than inequality or equality elementwise.
- `DataFrame.lt` Compare DataFrames for strictly less than inequality elementwise.
- `DataFrame.ge` Compare DataFrames for greater than inequality or equality elementwise.
- `DataFrame.gt` Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
                      'revenue': [100, 250, 300],
                      index=['A', 'B', 'C'])
>>> df
   cost  revenue
A  250     100
B  150     250
C  100     300
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False   True
B  False  False
C  True  False
```

```python
>>> df.eq(100)
   cost  revenue
A  False   True
B  False  False
C  True  False
```

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True     True
B   True  False
C  False     True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A   True    False
B   True     True
C  False     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A   True     True
(continues on next page)
Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A   True     False
B   False     True
C   True     False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                      index=['A', 'B', 'C', 'D'])
```

```python
>>> df.gt(other)
   cost  revenue
A   False     False
B   False     False
C   False     True
D   False     False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225]},
                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2'],
                                     ['A', 'B', 'C', 'A', 'B', 'C']])
```

```python
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1   True     True
B   True     True
C   True     True
Q2   False     True
B   True     False
C   True     False
```
pandas.DataFrame.equals

DataFrame.equals(other)
Test whether two objects contain the same elements.
This function allows two Series or DataFrames to be compared against each other to see if they have the 
same shape and elements. NaNs in the same location are considered equal.
The row/column index do not need to have the same type, as long as the values are considered equal. 
Corresponding columns must be of the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the 
first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is 
True if the element in each Series is equal, False otherwise.

Dataframe.eq Compare two DataFrame objects of the same shape and return a DataFrame where each 
element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides an 
easy interface to ignore inequality in dtypes, indexes and precision among others.
testing.assert_frame_equal Like assert_series_equal, but targets DataFrames.
numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Examples

```python
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
   1    2
0  10  20
```

DataFrames df and exactly_equal have the same types and values for their elements and column labels, 
which will return True.

```python
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1    2
0  10  20
>>> df.equals(exactly_equal)
True
```

DataFrames df and different_column_type have the same element types and values, but have different types 
for the column labels, which will still return True.

```python
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
(continues on next page)
```
DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
  1  2
0 10.0 20.0
>>> df.equals(different_data_type)
False
```

**pandas.DataFrame.eval**

DataFrame.eval(expr, inplace=False, **kwargs)

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows eval to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

**Parameters**

- **expr** [str] The expression string to evaluate.
- **inplace** [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.
- **kwargs** See the documentation for eval() for complete details on the keyword arguments accepted by query().

**Returns**

- ndarray, scalar, pandas object, or None The result of the evaluation or None if inplace=True.

See also:

- DataFrame.query Evaluates a boolean expression to query the columns of a frame.
- DataFrame.assign Can evaluate an expression or function to create new values for a column.
- eval Evaluate a Python expression as a string using various backends.
Notes

For more details see the API documentation for `eval()`. For detailed examples see *enhancing performance with eval*.

Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
    A  B
0  1  10
1  2   8
2  3   6
3  4   4
4  5   2
>>> df.eval('A + B')
     0   1
0   11
1  10
2   9
3   8
4   7
dtype: int64
```

Assignment is allowed though by default the original DataFrame is not modified.

```python
>>> df.eval('C = A + B')
    A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
>>> df
    A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
```

Use `inplace=True` to modify the original DataFrame.

```python
>>> df.eval('C = A + B', inplace=True)
>>> df
    A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
```

Multiple columns can be assigned to using multi-line expressions:
```python
>>> df.eval(
...     "C = A + B
...     D = A - B"
... )
A  B  C  D
0  1  10 11 -9
1  2  8 10 -6
2  3  6  9 -3
3  4  4  8  0
4  5  2  7  3
```

**pandas.DataFrame.ewm**

DataFrame.ewm(  
com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True,  
ignore_na=False, axis=0, times=None, method='single')

Provide exponentially weighted (EW) calculations.

Exactly one parameter: `com`, `span`, `halflife`, or `alpha` must be provided.

**Parameters**

- **com** [float, optional] Specify decay in terms of center of mass
  \[ \alpha = \frac{1}{1 + com}, \text{ for } com \geq 0. \]
- **span** [float, optional] Specify decay in terms of span
  \[ \alpha = \frac{2}{(span + 1)}, \text{ for } span \geq 1. \]
- **halflife** [float, str, timedelta, optional] Specify decay in terms of half-life
  \[ \alpha = 1 - \exp\left( -\ln(2)/\text{halflife}\right), \text{ for } \text{halflife} > 0. \]
  If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()`, and halflife value will not apply to the other functions.
  New in version 1.1.0.
- **alpha** [float, optional] Specify smoothing factor \( \alpha \) directly
  \[ 0 < \alpha \leq 1. \]
- **min_periods** [int, default 0] Minimum number of observations in window required to have a value; otherwise, result is `np.nan`.
- **adjust** [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).
  - When `adjust=True` (default), the EW function is calculated using weights \( w_i = (1 - \alpha)^i \). For example, the EW moving average of the series \([x_0, x_1, \ldots, x_t]\) would be:
  \[
  y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots + (1 - \alpha)^t}
  \]
• When adjust=False, the exponentially weighted function is calculated recursively:

\[
y_0 = x_0 \\
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]

**ignore_na** [bool, default False] Ignore missing values when calculating weights.

• When ignore_na=False (default), weights are based on absolute positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, None, x_2]\) are \((1 - \alpha)^2\) and 1 if adjust=True, and \((1 - \alpha)^2\) and \(\alpha\) if adjust=False.

• When ignore_na=True, weights are based on relative positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, None, x_2]\) are \(1 - \alpha\) and 1 if adjust=True, and \(1 - \alpha\) and \(\alpha\) if adjust=False.

**axis** [[0, 1], default 0] If 0 or 'index', calculate across the rows.

If 1 or 'columns', calculate across the columns.

**times** [str, np.ndarray, Series, default None] New in version 1.1.0.

Only applicable to mean().

Times corresponding to the observations. Must be monotonically increasing and datetime64[ns] dtype.

If 1-D array like, a sequence with the same shape as the observations.

Deprecated since version 1.4.0: If str, the name of the column in the DataFrame representing the times.

**method** [str {'single', 'table'}, default 'single'] New in version 1.4.0.

Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying engine='numba' in the method call.

Only applicable to mean()

**Returns**

ExponentialMovingWindow subclass

See also:

*rolling* Provides rolling window calculations.

*expanding* Provides expanding transformations.
Notes

See *Windowing Operations* for further usage details and examples.

Examples

```python
def = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
def
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

def.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

def.ewm(alpha=2 / 3).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

adjust

def.ewm(com=0.5, adjust=True).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

def.ewm(com=0.5, adjust=False).mean()
   B
0  0.000000
1  0.666667
2  1.555556
3  1.555556
4  3.650794

ignore_na

def.ewm(com=0.5, ignore_na=True).mean()
   B
0  0.000000
(continues on next page)
1  0.750000
2  1.615385
3  1.615385
4  3.225000

>>> df.ewm(com=0.5, ignore_na=False).mean()
          B
    0  0.000000
    1  0.750000
    2  1.615385
    3  1.615385
    4  3.670213

**times**

Exponentially weighted mean with weights calculated with a timedelta *halflife* relative to *times*.

>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']

>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
          B
    0  0.000000
    1  0.585786
    2  1.523889
    3  1.523889
    4  3.233686

**pandas.DataFrame.expanding**

Dataframe.expanding(*min_periods=1, center=None, axis=0, method='single')

Provide expanding window calculations.

**Parameters**

- **min_periods** [int, default 1] Minimum number of observations in window required to have a value; otherwise, result is np.nan.
- **center** [bool, default False] If False, set the window labels as the right edge of the window index.
  
  If True, set the window labels as the center of the window index.

  Deprecated since version 1.1.0.
- **axis** [int or str, default 0] If 0 or 'index', roll across the rows.
  
  If 1 or 'columns', roll across the columns.
- **method** [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

  This argument is only implemented when specifying engine='numba' in the method call.

  New in version 1.3.0.

**Returns**

Expanding subclass
See also:

**rolling** Provides rolling window calculations.

**ewm** Provides exponential weighted functions.

**Notes**

See *Windowing Operations* for further usage details and examples.

**Examples**

```python
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
```

```plaintext
B
0 0.0
1 1.0
2 2.0
3 NaN
4 4.0
```

**min_periods**

Expanding sum with 1 vs 3 observations needed to calculate a value.

```python
>>> df.expanding(1).sum()
```

```plaintext
B
0 0.0
1 1.0
2 3.0
3 3.0
4 7.0
```

```python
>>> df.expanding(3).sum()
```

```plaintext
B
0 NaN
1 NaN
2 3.0
3 3.0
4 7.0
```

**pandas.DataFrame.explode**

DataFrame.explode(*column*, *ignore_index=False*)

Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

**Parameters**

- **column** [IndexLabel] Column(s) to explode. For multiple columns, specify a non-empty list with each element be str or tuple, and all specified columns their list-like data on same row of the frame must have matching length.

  New in version 1.3.0: Multi-column explode
ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, …, n - 1.

New in version 1.1.0.

Returns

DataFrame Exploded lists to rows of the subset columns; index will be duplicated for these rows.

Raises

ValueError :

• If columns of the frame are not unique.
• If specified columns to explode is empty list.
• If specified columns to explode have not matching count of elements rowwise in the frame.

See also:

DataFrame.unstack Pivot a level of the (necessarily hierarchical) index labels.
DataFrame.melt Unpivot a DataFrame from wide format to long format.
Series.explode Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of rows in the output will be non-deterministic when exploding sets.

Reference the user guide for more examples.

Examples

```python
def = pd.DataFrame({'A': [[0, 1, 2], 'foo', [], [3, 4]],
                   ...
                   'B': 1,
                   ...
                   'C': [['a', 'b', 'c'], np.nan, [], ['d', 'e']])
>>> df
    A     B     C
 0 [0, 1, 2] 1 [a, b, c]
 1  foo 1  NaN
 2    [] 1   []
 3 [3, 4] 1   [d, e]

Single-column explode.
```

```python
>>> df.explode('A')
      A     B     C
 0  0  0 1 [a, b, c]
 0  1  1 [a, b, c]
 0  2  1 [a, b, c]
 1  foo 1  NaN
```

(continues on next page)
Multi-column explode.

```python
>>> df.explode(list('AC'))
   A  B  C
0  0  1  a
0  1  1  b
0  2  1  c
1  foo 1  NaN
2  NaN 1  NaN
3  3  1  d
3  4  1  e
```

**pandas.DataFrame.``ffill``**

```
DataFrame.ffill(axis=None, inplace=False, limit=None, downcast=None)
```

Synonym for `DataFrame.fillna()` with method='ffill'.

Returns

- **Series/DataFrame or None** Object with missing values filled or None if inplace=True.

**pandas.DataFrame.fillna**

```
DataFrame.fillna(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)
```

Fill NA/NaN values using the specified method.

Parameters

- **value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **axis** [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.

- **inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.
**downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**

- **DataFrame or None** Object with missing values filled or None if `inplace=True`.

**See also:**

- **interpolate** Fill NaN values using interpolation.
- **reindex** Conform object to new index.
- **asfreq** Convert TimeSeries to specified frequency.

**Examples**

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, np.nan],
...                     [np.nan, 3, np.nan, 4]],
...                     columns=list("ABCD"))
>>> df
   A    B    C    D
0  NaN  2.0  NaN  0.0
1  3.0  4.0  NaN  1.0
2  NaN  NaN  NaN  NaN
3  NaN  3.0  NaN  4.0

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0.0
1  3.0  4.0  0.0  1.0
2  0.0  0.0  0.0  0.0
3  0.0  3.0  0.0  4.0
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method="ffill")
   A    B    C    D
0  NaN  2.0  NaN  0.0
1  3.0  4.0  NaN  1.0
2  3.0  4.0  NaN  1.0
3  3.0  3.0  NaN  4.0
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  2.0  1.0
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

(continued from previous page)

```
2 0.0 1.0 2.0 3.0
3 0.0 3.0 2.0 4.0
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
```

```
A   B   C   D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  NaN  1.0
2  NaN  1.0  NaN  3.0
3  NaN  3.0  NaN  4.0
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```python
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
```

```
A   B   C   D
0  0.0  2.0  0.0  0.0
1  3.0  4.0  0.0  1.0
2  0.0  0.0  0.0  NaN
3  0.0  3.0  0.0  4.0
```

Note that column D is not affected since it is not present in df2.

**pandas.DataFrame.filter**

*DataFrame.filter*(items=None, like=None, regex=None, axis=None)

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items** [list-like] Keep labels from axis which are in items.
- **like** [str] Keep labels from axis for which “like in label == True”.
- **regex** [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.
- **axis** [{0 or 'index', 1 or 'columns', None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

**Returns**

same type as input object

**See also:**

*DataFrame.loc* Access a group of rows and columns by label(s) or a boolean array.
Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

Examples

```python
>>> df = pd.DataFrame(np.array(((1, 2, 3), (4, 5, 6))),
...                    index=['mouse', 'rabbit'],
...                    columns=['one', 'two', 'three'])
>>> df
one  two  three
mouse 1  2  3
rabbit 4  5  6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
    one  three
mouse  1   3
rabbit  4   6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
    one  three
mouse  1   3
rabbit  4   6

>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
     one  two  three
rabbit  4   5   6
```

*pandas.DataFrame.first*

`DataFrame.first(offset)`

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

**Parameters**

`offset` [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

**Returns**

Series or DataFrame A subset of the caller.

**Raises**

TypeError If the index is not a DatetimeIndex
See also:

**last** Select final periods of time series based on a date offset.

**at_time** Select values at a particular time of the day.

**between_time** Select values between particular times of the day.

### Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
         A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
         A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

**pandas.DataFrame.first_valid_index**

*DataFrame.first_valid_index*()

Return index for first non-NA value or None, if no non-NA value is found.

**Returns**

*scalar [type of index]*

**Notes**

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.DataFrame.floordiv**

*DataFrame.floordiv*(*other*, axis='columns', level=None, fill_value=None)

Get Integer division of dataframe and other, element-wise (binary operator `floordiv`).

Equivalent to *dataframe // other*, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *rfloordiv*.

Among flexible wrappers (*add, sub, mul, div, mod, pow*) to arithmetic operators: +, -, *, /, //, %, **.
other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
```
```
angles  degrees
circle   0       360
triangle 3       180
rectangle 4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```
```
angles  degrees
circle   1       361
triangle 4       181
rectangle 5       361
```
>>> df.add(1)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

>>> df.div(10)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>

>>> df.rdiv(10)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.500000</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4], ... index=['circle', 'triangle', 'rectangle']})

>>> other

<table>
<thead>
<tr>
<th>angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
</tr>
<tr>
<td>triangle</td>
</tr>
<tr>
<td>rectangle</td>
</tr>
</tbody>
</table>

3.4. DataFrame
```python
>>> df * other
   angles  degrees
circle    0      NaN
triangle  9      NaN
rectangle 16      NaN
```

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
circle    0      0.0
triangle  9      0.0
rectangle 16     0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index':[['A', 'A', 'A', 'B', 'B', 'B'],
                                        ['circle', 'triangle', 'rectangle',
                                         'square', 'pentagon', 'hexagon']]})
```

```python
>>> df_multindex
   angles  degrees
    A circle   0   360
       triangle  3  180
          rectangle  4  360
         square  4  360
       pentagon  5  540
         hexagon  6  720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
    A circle  NaN    1.0
       triangle    1  1.0
          rectangle    1  1.0
         square    0  0.0
       pentagon    0  0.0
         hexagon    0  0.0
```

**pandas.DataFrame.from_dict**

**classmethod** `DataFrame.from_dict(data, orient='columns', dtype=None, columns=None)`

Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

**Parameters**

- `data` [dict] Of the form {field : array-like} or {field : dict}.
- `orient` [{‘columns’, ‘index’, ‘tight’}, default ‘columns’] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’. If ‘tight’, assume a dict with keys [‘index’, ‘columns’, ‘data’, ‘index_names’, ‘column_names’].

New in version 1.4.0: ‘tight’ as an allowed value for the orient argument
dtype [dtype, default None] Data type to force, otherwise infer.

columns [list, default None] Column labels to use when orient='index'. Raises a ValueError if used with orient='columns' or orient='tight'.

Returns
DataFrame

See also:

DataFrame.from_records DataFrame from structured ndarray, sequence of tuples or dicts, or DataFrame.

DataFrame DataFrame object creation using constructor.

DataFrame.to_dict Convert the DataFrame to a dictionary.

Examples

By default the keys of the dict become the DataFrame columns:

```python
data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0     3    a
1     2    b
2     1    c
3     0    d
```

Specify orient='index' to create the DataFrame using dictionary keys as rows:

```python
data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
   0  1  2  3
row_1 3  2  1  0
row_2 a  b  c  d
```

When using the ‘index’ orientation, the column names can be specified manually:

```python
>>> pd.DataFrame.from_dict(data, orient='index',
... columns=['A', 'B', 'C', 'D'])
   A  B  C  D
row_1 3  2  1  0
row_2 a  b  c  d
```

Specify orient='tight' to create the DataFrame using a 'tight' format:

```python
>>> data = {'index': [('a', 'b'), ('a', 'c')],
... 'columns': [('x', 1), ('y', 2)],
... 'data': [[1, 3], [2, 4]],
... 'index_names': ['n1', 'n2'],
... 'column_names': ['z1', 'z2']}
>>> pd.DataFrame.from_dict(data, orient='tight')
z1  x  y
z2  1  2
```

(continues on next page)
pandas.DataFrame.from_records

**classmethod**  
`DataFrame.from_records(data, index=None, exclude=None, columns=None, coerce_float=False, nrows=None)`

Convert structured or record ndarray to DataFrame.

Creates a DataFrame object from a structured ndarray, sequence of tuples or dicts, or DataFrame.

**Parameters**

- `data` [structured ndarray, sequence of tuples or dicts, or DataFrame] Structured input data.
- `index` [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.
- `exclude` [sequence, default None] Columns or fields to exclude.
- `columns` [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).
- `coerce_float` [bool, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
- `nrows` [int, default None] Number of rows to read if data is an iterator.

**Returns**

DataFrame

See also:

- `DataFrame.from_dict` DataFrame from dict of array-like or dicts.
- `DataFrame` DataFrame object creation using constructor.

**Examples**

Data can be provided as a structured ndarray:

```python
>>> data = np.array([(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')],
                  dtype=[('col_1', 'i4'), ('col_2', 'U1')])
>>> pd.DataFrame.from_records(data)
   col_1  col_2
0     3     a
1     2     b
2     1     c
3     0     d
```

Data can be provided as a list of dicts:

```python
>>> data = [{0: 3, 'col_1': 'a'}, {1: 2, 'col_1': 'b'}, {2: 1, 'col_1': 'c'}, {0: 0, 'col_1': 'd'}]
>>> pd.DataFrame.from_records(data)
   col_1  col_2
0     3     a
1     2     b
2     1     c
3     0     d
```
```python
>>> data = [{'col_1': 3, 'col_2': 'a'},
          {'col_1': 2, 'col_2': 'b'},
          {'col_1': 1, 'col_2': 'c'},
          {'col_1': 0, 'col_2': 'd'}]
>>> pd.DataFrame.from_records(data)
    col_1  col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

Data can be provided as a list of tuples with corresponding columns:

```python
>>> data = [(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')]
>>> pd.DataFrame.from_records(data, columns=['col_1', 'col_2'])
    col_1  col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

**pandas.DataFrame.ge**

DataFrame.ge(other, axis='columns', level=None)

Get Greater than or equal to of dataframe and other, element-wise (binary operator ge).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

DataFrame of bool Result of the comparison.

See also:

- **DataFrame.eq** Compare DataFrames for equality elementwise.
- **DataFrame.ne** Compare DataFrames for inequality elementwise.
- **DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.
- **DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.
- **DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.
- **DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
                      'revenue': [100, 250, 300],
                      index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A   False    True
B   False   False
C   True    False
```

```python
>>> df.eq(100)
   cost  revenue
A   False    True
B   False   False
C   True    False
```

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True    True
B   True   False
C   False   True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D'], axis='index'))
   cost  revenue
A   True    False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A   True    True
```

(continues on next page)
Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A   True    False
B   False   True
C   True    False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> df.gt(other)
   cost  revenue
A  False   False
B  False   False
C  False   True
D  False   False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               ...
                               'revenue': [100, 250, 300, 200, 175, 225]},
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                               ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A     True   True
   B     True   True
   C     True   True
Q2 A    False   True
   B     True   False
   C     True   False
```
**pandas.DataFrame.get**

`DataFrame.get(key, default=None)`

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

**Parameters**

- **key** [object]

**Returns**

- **value** [same type as items contained in object]

**Examples**

```python
>>> df = pd.DataFrame(
...     [  
...         [24.3, 75.7, "high"],
...         [31, 87.8, "high"],
...         [22, 71.6, "medium"],
...         [35, 95, "medium"],
...     ],
...     columns=["temp_celsius", "temp_fahrenheit", "windspeed"],
...     index=pd.date_range(start="2014-02-12", end="2014-02-15", freq="D"),
... )

>>>
```

<table>
<thead>
<tr>
<th>Date</th>
<th>Temp Celsius</th>
<th>Temp Fahrenheit</th>
<th>Windspeed</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014-02-12</td>
<td>24.3</td>
<td>75.7</td>
<td>high</td>
</tr>
<tr>
<td>2014-02-13</td>
<td>31.0</td>
<td>87.8</td>
<td>high</td>
</tr>
<tr>
<td>2014-02-14</td>
<td>22.0</td>
<td>71.6</td>
<td>medium</td>
</tr>
<tr>
<td>2014-02-15</td>
<td>35.0</td>
<td>95.0</td>
<td>medium</td>
</tr>
</tbody>
</table>

```python
>>> df.get(["temp_celsius", "windspeed"])
```

```python
>>> df.get(["temp_celsius", "temp_kelvin"], default="default_value")
'default_value'
```
pandas.DataFrame.groupby

DataFrame.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=NoDefault.no_default, observed=False, dropna=True)

Group DataFrame using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

**Parameters**

- **by** [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If by is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see .align() method). If a list or ndarray of length equal to the selected axis is passed (see the groupby user guide), the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in self. Notice that a tuple is interpreted as a (single) key.

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Split along rows (0) or columns (1).

- **level** [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

- **as_index** [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. as_index=False is effectively “SQL-style” grouped output.

- **sort** [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

- **group_keys** [bool, default True] When calling apply, add group keys to index to identify pieces.

- **squeeze** [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

  Deprecated since version 1.1.0.

- **observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

- **dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

  New in version 1.1.0.

**Returns**

DataFrameGroupBy Returns a groupby object that contains information about the groups.

**See also:**

- **resample** Convenienc method for frequency conversion and resampling of time series.
Notes

See the user guide for more detailed usage and examples, including splitting an object into groups, iterating through groups, selecting a group, aggregation, and more.

Examples

```python
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon', 'Parrot', 'Parrot'],
                     'Max Speed': [380., 370., 24., 26.]})
>>> df
   Max Speed
Animal  
0  Falcon  380.0
1  Falcon  370.0
2  Parrot  24.0
3  Parrot  26.0

>>> df.groupby(['Animal']).mean()
   Max Speed
Animal
Falcon  375.0
Parrot  25.0

Hierarchical Indexes

We can groupby different levels of a hierarchical index using the level parameter:

```python
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
             ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.],
                     'index': index})
>>> df
    Max Speed
Animal Type
Falcon Captive  390.0
    Wild     350.0
Parrot Captive  30.0
    Wild     20.0

>>> df.groupby(level=0).mean()
   Max Speed
Animal
Falcon  370.0
Parrot  25.0

>>> df.groupby(level='Type').mean()
   Max Speed
Type
Captive  210.0
Wild     185.0
```

We can also choose to include NA in group keys or not by setting dropna parameter, the default setting is True.
```python
>>> l = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
>>> df = pd.DataFrame(l, columns=['a', 'b', 'c'])

>>> df.groupby(by=['b']).sum()
a    b
c 1.0  2  3
   2.0  2  5

>>> df.groupby(by=['b'], dropna=False).sum()
a    b
   1.0  2  3
   2.0  2  5
   NaN  1  4

>>> l = [['a', 12], [None, 12.3, 33.], ['b', 12.3, 123.], ['a', 1, 1]]
>>> df = pd.DataFrame(l, columns=['a', 'b', 'c'])

>>> df.groupby(by='a').sum()
a       b    c
  a  13.0  13.0
  b  12.3  123.0

>>> df.groupby(by='a', dropna=False).sum()
a       b    c
  a  13.0  13.0
  b  12.3  123.0
  NaN 12.3  33.0
```

---

**pandas.DataFrame.gt**

`DataFrame.gt(other, axis='columns', level=None)`

Get Greater than of dataframe and other, element-wise (binary operator `gt`).

Among flexible wrappers (`eq`, `ne`, `le`, `lt`, `ge`, `gt`) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>`, `>` with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- `other` [ scalar, sequence, Series, or DataFrame ] Any single or multiple element data structure, or list-like object.
- `axis` [0 or ‘index’, 1 or ‘columns’], default ‘columns’ Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
- `level` [ int or label ] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**
**DataFrame of bool** Result of the comparison.

See also:

- **DataFrame.eq** Compare DataFrames for equality elementwise.
- **DataFrame.ne** Compare DataFrames for inequality elementwise.
- **DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.
- **DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.
- **DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.
- **DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

**Examples**

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300],
...                    index=['A', 'B', 'C'])
```

```
<table>
<thead>
<tr>
<th>cost</th>
<th>revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>250</td>
<td>100</td>
</tr>
<tr>
<td>150</td>
<td>250</td>
</tr>
<tr>
<td>100</td>
<td>300</td>
</tr>
</tbody>
</table>
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
```

```
<table>
<thead>
<tr>
<th>cost</th>
<th>revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>
```

```python
>>> df.eq(100)
```

```
<table>
<thead>
<tr>
<th>cost</th>
<th>revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
```

```
<table>
<thead>
<tr>
<th>cost</th>
<th>revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>False</td>
<td>True</td>
</tr>
</tbody>
</table>
```

Use the method to control the broadcast axis:
When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A   True   True
B   False  False
C   True   False
D   False  False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A   True   False
B   False  True
C   True   False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                       index=['A', 'B', 'C', 'D'])
   revenue
A   300
B   250
C   100
D   150
```

```python
>>> df.gt(other)
   cost  revenue
A  False  False
B  False  False
C  False  True
D  False  False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                      ['A', 'B', 'C', 'A', 'B', 'C']])
   cost  revenue
Q1 A   250    100
      B   150    250
      C   100    300
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```

pandas.DataFrame.head

DataFrame.head(n=5)

Return the first \( n \) rows.

This function returns the first \( n \) rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of \( n \), this function returns all rows except the last \( n \) rows, equivalent to \( df[:-n] \).

Parameters

- \( n \) [int, default 5] Number of rows to select.

Returns

- same type as caller The first \( n \) rows of the caller object.

See also:

- DataFrame.tail Returns the last \( n \) rows.

Examples

```python
>>> df = pd.DataFrame(['animal': ['alligator', 'bee', 'falcon', 'lion', ...
                      'monkey', 'parrot', 'shark', 'whale', 'zebra']])
```

```python
>>> df
animal
0  alligator
1   bee
2  falcon
3   lion
4 monkey
5  parrot
6   shark
7  whale
8  zebra
```

Viewing the first 5 lines
```python
>>> df.head()
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey

Viewing the first $n$ lines (three in this case)

```  
```python
>>> df.head(3)
animal
0  alligator
1    bee
2  falcon

For negative values of $n$

```  
```python
>>> df.head(-3)
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey
5 parrot
```

**pandas.DataFrame.hist**

DataFrame.hist(column=None, by=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, backend=None, legend=False, **kwargs)

Make a histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function calls matplotlib.pyplot.hist(), on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

- **data** [DataFrame] The pandas object holding the data.
- **column** [str or sequence, optional] If passed, will be used to limit data to a subset of columns.
- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
ax [Matplotlib axes object, default None] The axes to plot the histogram on.

sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

figsize [tuple, optional] The size in inches of the figure to create. Uses the value in matplotlib.rcParams by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, 'matplotlib'. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib.pyplot.hist().

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

matplotlib.pyplot.hist Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```
3.4. DataFrame

length

width
pandas.DataFrame.idxmax

DataFrame.idxmax(axis=0, skipna=True)

Return index of first occurrence of maximum over requested axis.
NA/null values are excluded.

Parameters

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

- **Series** Indexes of maxima along the specified axis.

Raises

- **ValueError**
  - If the row/column is empty

See also:

- **Series.idxmax** Return index of the maximum element.

Notes

This method is the DataFrame version of ndarray.argmax.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                     'co2_emissions': [37.2, 19.66, 1712]},
...                     index=['Pork', 'Wheat Products', 'Beef'])
```

<table>
<thead>
<tr>
<th></th>
<th>consumption</th>
<th>co2_emissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pork</td>
<td>10.51</td>
<td>37.20</td>
</tr>
<tr>
<td>Wheat Products</td>
<td>103.11</td>
<td>19.66</td>
</tr>
<tr>
<td>Beef</td>
<td>55.48</td>
<td>1712.00</td>
</tr>
</tbody>
</table>

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption    Wheat Products
co2_emissions  Beef
```

dtype: object

To return the index for the maximum value in each row, use `axis='columns'`.
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> df.idxmax(axis="columns")
Pork        co2_emissions
Wheat Products    consumption
Beef        co2_emissions
dtype: object
```

**pandas.Dataframe.idxmin**

DataFrame.idxmin(\(axis=0, \text{skipna}=\text{True}\))

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

**Parameters**

- **axis**  \([0 \text{ or 'index'}, 1 \text{ or 'columns'}, \text{default 0}]\) The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

- **skipna**  [\text{bool, default True}] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- **Series** Indexes of minima along the specified axis.

**Raises**

- **ValueError**  
  - If the row/column is empty

**See also:**

- **Series.idxmin** Return index of the minimum element.

**Notes**

This method is the DataFrame version of ndarray.argmin.

**Examples**

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48], ...
...     'co2_emissions': [37.2, 19.66, 1712]}, ...
...     index=['Pork', 'Wheat Products', 'Beef'])
```

```python
>>> df
   consumption  co2_emissions
Pork       10.51         37.20
Wheat Products  103.11       19.66
Beef         55.48       1712.00
```

By default, it returns the index for the minimum value in each column.
>>> df.idxmin()
consumption       Pork
co2_emissions    Wheat Products
dtype: object

To return the index for the minimum value in each row, use axis="columns".

>>> df.idxmin(axis="columns")
Pork            consumption
Wheat Products  co2_emissions
Beef            consumption
dtype: object

pandas.DataFrame.infer_objects

DataFrame.infer_objects()

Attempt to infer better dtypes for object columns.
Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns
converted [same type as input object]

See also:
to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric Convert argument to numeric type.
convert_dtypes Convert argument to best possible dtype.

Examples

>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
  A
0  1
1  2
2  3

>>> df.dtypes
A    object
dtype: object

>>> df.infer_objects().dtypes
A    int64
dtype: object
`pandas.DataFrame.info`

`DataFrame.info( verbose=None, buf=None, max_cols=None, memory_usage=None, show_counts=None, null_counts=None)`

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and columns, non-null values and memory usage.

**Parameters**

- **data** [DataFrame] DataFrame to print information about.
- **verbose** [bool, optional] Whether to print the full summary. By default, the setting in `pandas.options.display.max_info_columns` is followed.
- **buf** [writable buffer, defaults to `sys.stdout`] Where to send the output. By default, the output is printed to `sys.stdout`. Pass a writable buffer if you need to further process the output. 
- **max_cols** : int, optional When to switch from the verbose to the truncated output. If the DataFrame has more than `max_cols` columns, the truncated output is used. By default, the setting in `pandas.options.display.max_info_columns` is used.
- **memory_usage** [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the `pandas.options.display.memory_usage` setting. 
  - True always show memory usage. False never shows memory usage. A value of ‘deep’ is equivalent to “True with deep introspection”. Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.
- **show_counts** [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than `pandas.options.display.max_info_rows` and `pandas.options.display.max_info_columns`. A value of True always shows the counts, and False never shows the counts.
- **null_counts** [bool, optional] Deprecated since version 1.2.0: Use `show_counts` instead.

**Returns**

- **None** This method prints a summary of a DataFrame and returns None.

**See also**

- `DataFrame.describe` Generate descriptive statistics of DataFrame columns.
- `DataFrame.memory_usage` Memory usage of DataFrame columns.
Examples

```python
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({'int_col': int_values, 'text_col': text_values,
"float_col": float_values})
```

Prints information of all columns:

```python
>>> df.info(_verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
    # Column Non-Null Count  Dtype
    --- ------ -------------- -----
    0   int_col  5 non-null int64
    1   text_col 5 non-null object
    2   float_col 5 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```python
>>> df.info(_verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```python
>>> import io

>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w", encoding="utf-8") as f:
...     f.write(s)
260
```

The *memory_usage* parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```python
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
```

(continues on next page)
... 'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
... 'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
... 'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
... })
>>>
In [5]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column  Non-Null Count  Dtype
---  ------  --------------  -----  
0 column_1 1000000 non-null  object
1 column_2 1000000 non-null  object
2 column_3 1000000 non-null  object
dtypes: object(3)
memory usage: 22.9+ MB

In [6]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column  Non-Null Count  Dtype
---  ------  --------------  -----  
0 column_1 1000000 non-null  object
1 column_2 1000000 non-null  object
2 column_3 1000000 non-null  object
dtypes: object(3)
memory usage: 165.9 MB

pandas.DataFrame.insert

DataFrame.insert(loc, column, value, allow_duplicates=False)

Insert column into DataFrame at specified location.

Raises a ValueError if column is already contained in the DataFrame, unless allow_duplicates is set to True.

Parameters

- **loc** [int] Insertion index. Must verify 0 <= loc <= len(columns).
- **column** [str, number, or hashable object] Label of the inserted column.
- **value** [Scalar, Series, or array-like]
- **allow_duplicates** [bool, optional default False]

See also:

- **Index.insert**  Insert new item by index.
Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df
   col1 col2
0    1    3
1    2    4
>>> df.insert(1, "newcol", [99, 99])
>>> df
   col1  newcol col2
0    1      99    3
1    2      99    4
>>> df.insert(0, "col1", [100, 100], allow_duplicates=True)
>>> df
   col1  col1  newcol col2
0  100    1      99    3
1  100    2      99    4
```

Notice that pandas uses index alignment in case of value from type Series:

```python
>>> df.insert(0, "col0", pd.Series([5, 6], index=[1, 2]))
>>> df
   col0  col1  col1  newcol col2
0   NaN    1      99    3
1   5.0    1      99    4
```

### pandas.DataFrame.interpolate

DataFrame.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)

Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

**Parameters**

- **method** [str, default ‘linear’] Interpolation technique to use. One of:
  - ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
  - ‘index’, ‘values’: use the actual numerical values of the index.
  - ‘pad’: Fill in NaNs using existing values.
  - ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
pandas: powerful Python data analysis toolkit, Release 1.4.3

- ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

**axis** [(0 or ‘index’, 1 or ‘columns’, None)], default None Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit_direction** [(‘forward’, ‘backward’, ‘both’)], Optional Consecutive NaNs will be filled in this direction.

If limit is specified:
- If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
- If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:
- If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
- else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if `limit_direction` is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if `limit_direction` is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

**limit_area** [(None, ‘inside’, ‘outside’)], default None If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

**downcast** [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**kwargs** [optional] Keyword arguments to pass on to the interpolating function.

**Returns**

**Series or DataFrame or None** Returns the same object type as the caller, interpolated at some or all NaN values or None if `inplace=True`.

See also:

**fillna** Fill missing values using different methods.

**scipy.interpolate.Akima1DInterpolator** Piecewise cubic polynomials (Akima interpolator).

**scipy.interpolate.BPoly.from_derivatives** Piecewise polynomial in the Bernstein basis.

**scipy.interpolate.interp1d** Interpolate a 1-D function.

**scipy.interpolate.KroghInterpolator** Interpolate polynomial (Krogh interpolator).

**scipy.interpolate.PchipInterpolator** PCHIP 1-d monotonic cubic interpolation.

**scipy.interpolate.CubicSpline** Cubic spline data interpolator.
Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0 0.0
1 1.0
2 NaN
3 3.0
dtype: float64
>>> s.interpolate()
0 0.0
1 1.0
2 2.0
3 3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ...
... "fill_two_more", np.nan, np.nan, np.nan, ...
... 4.71, np.nan])
>>> s
0 NaN
1 single_one
2 NaN
3 fill_two_more
4 NaN
5 NaN
6 NaN
7 4.71
8 NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0 NaN
1 single_one
2 single_one
3 fill_two_more
4 fill_two_more
5 fill_two_more
6 NaN
7 4.71
8 4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).
```python
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0   0.000000
1   2.000000
2   4.666667
3   8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```python
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
... (np.nan, 2.0, np.nan, np.nan),
... (2.0, 3.0, np.nan, 9.0),
... (np.nan, 4.0, -4.0, 16.0)],
... columns=list('abcd'))
>>> df
   a     b     c    d
0  0.0   NaN  -1.0   1.0
1  NaN   2.0   NaN   NaN
2  2.0   3.0   NaN   9.0
3  NaN   4.0  -4.0  16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a     b     c    d
0  0.0   NaN  -1.0   1.0
1  1.0   2.0  -2.0   5.0
2  2.0   3.0  -3.0   9.0
3  2.0   4.0  -4.0  16.0
```

Using polynomial interpolation.

```python
>>> df['d'].interpolate(method='polynomial', order=2)
0   1.0
1   4.0
2   9.0
3  16.0
Name: d, dtype: float64
```

### pandas.DataFrame.isin

DataFrame.isin(values)

Whether each element in the DataFrame is contained in values.

**Parameters**

- **values** [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If values is a Series, that’s the index. If values is a dict, the keys must be the column names, which must match. If values is a DataFrame, then both the index and column labels must match.

**Returns**

**DataFrame**

DataFrame of booleans showing whether each element in the DataFrame is contained in values.

**See also:**

- **DataFrame.eq**  Equality test for DataFrame.
- **Series.isin**  Equivalent method on Series.
- **Series.str.contains**  Test if pattern or regex is contained within a string of a Series or Index.

**Examples**

```python
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
                   index=['falcon', 'dog'])
>>> df
   num_legs num_wings
falcon      2           2
dog         4           0

When values is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```python
>>> df.isin([0, 2])
   num_legs num_wings
falcon   True      True
dog     False      True
```n

To check if values is *not* in the DataFrame, use the ~ operator:

```python
>>> ~df.isin([0, 2])
   num_legs num_wings
falcon  False     False
dog     True      False
```

When values is a dict, we can pass values to check for each column separately:

```python
>>> df.isin({'num_wings': [0, 3]})
   num_legs num_wings
falcon  False     False
dog     False      True
```

When values is a Series or DataFrame the index and column must match. Note that ‘falcon’ does not match based on the number of legs in other.

```python
>>> other = pd.DataFrame({'num_legs': [8, 3], 'num_wings': [0, 2]},
                        index=['spider', 'falcon'])
>>> df.isin(other)
   num_legs num_wings
falcon  False      True
dog     False     False
```
pandas.DataFrame.isna

DataFrame.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy \nNaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as \nempty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.\nuse_inf_as_na = True).

Returns

DataFrame  Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

See also:

DataFrame.isnull  Alias of isna.
DataFrame.notna  Boolean inverse of isna.
DataFrame.dropna  Omit axes labels with missing values.
isna  Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                     born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                          pd.Timestamp('1940-04-25')],
...                     name=['Alfred', 'Batman', ''],
...                     toy=[None, 'Batmobile', 'Joker']))
```

```
>>> df
   age  born           name  toy
0   5.0  NaT         Alfred  None
1   6.0 1939-05-27       Batman  Batmobile
2  NaN 1940-04-25         Joker
```

```
>>> df.isna()

   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2  True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
```

```
>>> ser
0   5.0
1   6.0
2  NaN
dtype: float64
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> ser.isna()
0   False
1   False
2    True
dtype: bool
```

**pandas.DataFrame.isnull**

**DataFrame.isnull()**

DataFrame.isnull is an alias for DataFrame.isna.

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.
NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.
use_inf_as_na = True).

**Returns**

- **DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

**See also:**

- **DataFrame.isnull** Alias of isna.
- **DataFrame.notna** Boolean inverse of isna.
- **DataFrame.dropna** Omit axes labels with missing values.
- **isna** Top-level isna.

**Examples**

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                    born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                        pd.Timestamp('1940-04-25')],
...                    name=['Alfred', 'Batman', ''],
...                    toy=[None, 'Batmobile', 'Joker']))
```

```plaintext
    age  born   name   toy
   0  5.0  NaT    Alfred None
   1  6.0 1939-05-27 Batman Batmobile
   2  NaN 1940-04-25    Joker
```

```python
>>> df.isna()
    age  born   name   toy
   0  False   True False True
   1  False  False  False False
   2  True   False  False False
```

Show which entries in a Series are NA.
```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0   5.0
1   6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0   False
1   False
2   True
dtype: bool
```

### pandas.DataFrame.items

**DataFrame.items()**

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

**Yields**

- **label** [object] The column names for the DataFrame being iterated over.
- **content** [Series] The column entries belonging to each label, as a Series.

**See also:**

- *DataFrame.iterrows* Iterate over DataFrame rows as (index, Series) pairs.
- *DataFrame.itertuples* Iterate over DataFrame rows as namedtuples of the values.

**Examples**

```python
>>> df = pd.DataFrame(
    {'species': ['bear', 'bear', 'marsupial'],
     'population': [1864, 22000, 80000],
     'index': ['panda', 'polar', 'koala']}
)
>>> df
  species  population
panda   bear       1864
polar   bear      22000
koala   marsupial  80000
```

```python
>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='
')
...```

(label: species
content:
panda   bear
polar   bear
koala   marsupial
Name: species, dtype: object
label: population
```
pandas.DataFrame.iteritems

Dataframe.iteritems()

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

- **label** [object] The column names for the DataFrame being iterated over.
- **content** [Series] The column entries belonging to each label, as a Series.

See also:

- **Dataframe.iterrows** Iterate over DataFrame rows as (index, Series) pairs.
- **Dataframe.itertuples** Iterate over DataFrame rows as namedtuples of the values.

Examples

```python
>>> df = pd.DataFrame({
    'species': ['bear', 'bear', 'marsupial'],
    'population': [1864, 22000, 80000],
    'index': ['panda', 'polar', 'koala']
})
>>> df
species  population
panda    bear  1864
polar    bear  22000
koala    marsupial  80000

>>> for label, content in df.items():
...    print(f'label: {label}')
...    print(f'content: {content}', sep='
')
...    print(f'Name: species, dtype: object')
...    print(f'label: population')
...    print(f'content: panda 1864
polar 22000
koala 80000
Name: population, dtype: int64
```

pandas.DataFrame.iterrows

DataFrame.iterrows()
Iterate over DataFrame rows as (index, Series) pairs.

Yields

index [label or tuple of label] The index of the row. A tuple for a MultiIndex.
data [Series] The data of the row as a Series.

See also:

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.
DataFrame.items Iterate over (column name, Series) pairs.

Notes

1. Because iterrows returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int 1.0
float 1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use itertuples() which returns namedtuples of the values and which is generally faster than iterrows.

2. You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

pandas.DataFrame.itertuples

DataFrame.itertuples(index=True, name='Pandas')
Iterate over DataFrame rows as namedtuples.

Parameters

index [bool, default True] If True, return the index as the first element of the tuple.
name [str or None, default “Pandas”] The name of the returned namedtuples or None to return regular tuples.

Returns

iterator An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:
**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.items** Iterate over (column name, Series) pairs.

**Notes**

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).

**Examples**

```python
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
                   index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog        4           0
hawk       2           2
>>> for row in df.itertuples():
...     print(row)
...Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the `index` parameter to False we can remove the index as the first element of the tuple:

```python
>>> for row in df.itertuples(index=False):
...     print(row)
...Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the `name` parameter set we set a custom name for the yielded namedtuples:

```python
>>> for row in df.itertuples(name='Animal'):
...     print(row)
...Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

**pandas.DataFrame.join**

**DataFrame.join**(other, on=None, how='left', lsuffix='', rsuffix='', sort=False)

Join columns of another DataFrame.

Join columns with `other` DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

**Parameters**

- **other** [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.
on [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in other, otherwise joins index-on-index. If multiple values given, the other DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

how [{'left', 'right', 'outer', 'inner'}, default 'left'] How to handle the operation of the two objects.
  • left: use calling frame’s index (or column if on is specified)
  • right: use other’s index.
  • outer: form union of calling frame’s index (or column if on is specified) with other’s index, and sort it. lexicographically.
  • inner: form intersection of calling frame’s index (or column if on is specified) with other’s index, preserving the order of the calling’s one.
  • cross: creates the cartesian product from both frames, preserves the order of the left keys.

New in version 1.2.0.

lsuffix [str, default ‘’] Suffix to use from left frame’s overlapping columns.

rsuffix [str, default ‘’] Suffix to use from right frame’s overlapping columns.

sort [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns

DataFrame A dataframe containing columns from both the caller and other.

See also:

DataFrame.merge For column(s)-on-column(s) operations.

Notes

Parameters on, lsuffix, and rsuffix are not supported when passing a list of DataFrame objects.

Support for specifying index levels as the on parameter was added in version 0.23.0.

Examples

```python
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
...                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```ruby
>>> df
   key  A
0   K0  A0
1   K1  A1
2   K2  A2
3   K3  A3
4   K4  A4
5   K5  A5
```
Join DataFrames using their indexes.

```python
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller  A  key_other  B
0       K0  A0   K0  B0
1       K1  A1   K1  B1
2       K2  A2   K2  B2
3       K3  A3  NaN  NaN
4       K4  A4  NaN  NaN
5       K5  A5  NaN  NaN
```

If we want to join using the key columns, we need to set key to be the index in both `df` and `other`. The joined DataFrame will have key as its index.

```python
>>> df.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```

Another option to join using the key columns is to use the `on` parameter. DataFrame.join always uses `other`’s index but we can use any column in `df`. This method preserves the original DataFrame’s index in the result.

```python
>>> df.join(other.set_index('key'), on='key')
   key  A  B
0  K0  A0  B0
1  K1  A1  B1
2  K2  A2  B2
3  K3  A3  NaN
4  K4  A4  NaN
5  K5  A5  NaN
```

Using non-unique key values shows how they are matched.

```python
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K1', 'K3', 'K0', 'K1'], 'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```python
>>> df
   key  A
0  K0  A0
1  K1  A1
2  K2  A2
3  K3  A3
4  K4  A4
5  K5  A5
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

(continued from previous page)

```
0  K0  A0
1  K1  A1
2  K1  A2
3  K3  A3
4  K0  A4
5  K1  A5
```

```python
>>> df.join(other.set_index('key'), on='key')
  key   A  B
0  K0  A0  B0
1  K1  A1  B1
2  K1  A2  B1
3  K3  A3  NaN
4  K0  A4  B0
5  K1  A5  B1
```

**pandas.DataFrame.keys**

DataFrame.keys()

Get the ‘info axis’ (see Indexing for more).

This is index for Series, columns for DataFrame.

Returns

- **Index** Info axis.

**pandas.DataFrame.kurt**

DataFrame.kurt(axis=NoDefault.no_default, skipna=True, level=None, numeric_only=None, **kwargs)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

- **axis** ([index (0), columns (1)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

- Series or DataFrame (if level specified)
pandas.DataFrame.kurtosis

DataFrame.kurtosis(axis=NoDefault.no_default, skipna=True, level=None, numeric_only=None, 
**kwargs)

Return unbiased kurtosis over requested axis.
Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [index (0), columns (1)] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count 
along a particular level, collapsing into a Series.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, 
will attempt to use everything, then use only numeric data. Not implemented for 
Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.last

DataFrame.last(offset)

Select final periods of time series data based on a date offset.
For a DataFrame with a sorted DatetimeIndex, this function selects the last few rows based on a date offset.

Parameters

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be 
selected. For instance, ‘3D’ will display all the rows having their index within the 
last 3 days.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a DatetimeIndex

See also:

first Select initial periods of time series based on a date offset.
at_time Select values at a particular time of the day.
between_time Select values between particular times of the day.
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
     A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
     A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

pandas.DataFrame.last_valid_index

DataFrame.last_valid_index()

Return index for last non-NA value or None, if no non-NA value is found.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.le

DataFrame.le(other, axis='columns', level=None)

Get Less than or equal to of dataframe and other, element-wise (binary operator le).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ===, !==, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [[0 or ‘index’, 1 or ‘columns’], default ‘columns’) Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
**Returns**

DataFrame of bool  Result of the comparison.

See also:

- **DataFrame.eq**  Compare DataFrames for equality elementwise.
- **DataFrame.ne**  Compare DataFrames for inequality elementwise.
- **DataFrame.le**  Compare DataFrames for less than inequality or equality elementwise.
- **DataFrame.lt**  Compare DataFrames for strictly less than inequality elementwise.
- **DataFrame.ge**  Compare DataFrames for greater than inequality or equality elementwise.
- **DataFrame.gt**  Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

**Examples**

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
  cost  revenue
A     250      100
B     150      250
C     100      300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
  cost  revenue
A     False     True
B     False     False
C     True     False
```

```python
>>> df.eq(100)
  cost  revenue
A     False     True
B     False     False
C     True     False
```

When other is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
  cost  revenue
A     True     True
B     True     False
C     False     True
```

Use the method to control the broadcast axis:
When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A   True     True
B   False    False
C   False    False
```

Use the method to control the axis:

```python
>>> df.ad([250, 250, 100], axis='index')
   cost  revenue
A   True     False
B   False    True
C   True     False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> other
     revenue
A      300
B      250
C      100
D      150
```

```python
>>> df.gt(other)
   cost  revenue
A   False    False
B   False    False
C   False    True
D   False    False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                              'revenue': [100, 250, 300, 200, 175, 225],
                              index=['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                              ['A', 'B', 'C', 'A', 'B', 'C'])
>>> df_multindex
   cost  revenue
Q1 A  250     100
   B  150     250
   C  100     300

(continues on next page)
pandas.DataFrame.lookup

DataFrame.lookup(row_labels, col_labels)
Label-based “fancy indexing” function for DataFrame. Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

Deprecated since version 1.2.0: DataFrame.lookup is deprecated, use DataFrame.melt and DataFrame.loc instead. For further details see Looking up values by index/column labels.

Parameters
row_labels [sequence] The row labels to use for lookup.
col_labels [sequence] The column labels to use for lookup.

Returns
numpy.ndarray The found values.

pandas.DataFrame.lt

DataFrame.lt(other, axis=’columns’, level=None)
Get Less than of dataframe and other, element-wise (binary operator lt).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters
other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns
DataFrame of bool Result of the comparison.
See also:

- `DataFrame.eq` Compare DataFrames for equality elementwise.
- `DataFrame.ne` Compare DataFrames for inequality elementwise.
- `DataFrame.le` Compare DataFrames for less than inequality or equality elementwise.
- `DataFrame.lt` Compare DataFrames for strictly less than inequality elementwise.
- `DataFrame.ge` Compare DataFrames for greater than inequality or equality elementwise.
- `DataFrame.gt` Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. `NaN` values are considered different (i.e. `NaN != NaN`).

**Examples**

```python
def = pd.DataFrame({'cost': [250, 150, 100],
                    'revenue': [100, 250, 300],
                    'index': ['A', 'B', 'C']})
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
  cost  revenue
A   False   True
B   False   False
C    True   False
```

```python
>>> df.eq(100)
  cost  revenue
A   False   True
B   False   False
C    True   False
```

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
  cost  revenue
A    True   True
B    True   False
C   False   True
```

Use the method to control the broadcast axis:
When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost revenue
A  True  True
B  False  False
C  True  False
D  False  False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost revenue
A  True  False
B  False  True
C  True  False
```

Compare to a DataFrame of different shape:

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                      index=['A', 'B', 'C', 'D'])
```

```python
>>> df.gt(other)
   cost revenue
A  False  False
B  False  False
C  False  True
D  False  False
```

Compare to a MultiIndex by level:

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                               index=['A', 'B', 'C', 'A', 'B', 'C']})
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

(continued from previous page)

| Q2 | A   | 150  | 200 |
|    | B   | 300  | 175 |
|    | C   | 220  | 225 |

```python
>>> df.le(df_multindex, level=1)
  cost  revenue
Q1  A  True  True
   B  True  True
   C  True  True
Q2  A  False True
   B  True False
   C  True False
```

### pandas.DataFrame.mad

**DataFrame.mad**(axis=None, skipna=True, level=None)

Return the mean absolute deviation of the values over the requested axis.

**Parameters**

- **axis** ([index (0), columns (1)] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**Returns**

Series or DataFrame (if level specified)

### pandas.DataFrame.mask

**DataFrame.mask**(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=NoDefault.no_default)

Replace values where the condition is True.

**Parameters**

- **cond** [bool Series/DataFrame, array-like, or callable] Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **other** [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **inplace** [bool, default False] Whether to perform the operation in place on the data.
- **axis** [int, default None] Alignment axis if needed.
- **level** [int, default None] Alignment level if needed.
errors [str, {'raise', 'ignore'}, default ‘raise’] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

- ‘raise’: allow exceptions to be raised.
- ‘ignore’: suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if inplace=True.

See also:

DataFrame.where() Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is False the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the mask documentation in indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0  NaN
1  1.0
2  2.0
3  3.0
4  4.0
dtype: float64

>>> s.mask(s > 0)
0  0.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64

>>> s.where(s > 1, 10)
0  10
1  10
2  2
3  3
4  4
dtype: int64

>>> s.mask(s > 1, 10)
```
0 0
1 1
2 10
3 10
4 10
dtype: int64

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
    A  B
0  0  1
1  1  3
2  2  5
3  3  7
4  4  9
```

```python
>>> m = df % 3 == 0
>>> df.where(m, -df)
    A  B
0 -1  1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
```

```python
>>> df.where(m, -df) == np.where(m, df, -df)
    A  B
0  True True
1  True True
2  True True
3  True True
4  True True
```

```python
>>> df.where(m, -df) == df.mask(~m, -df)
    A  B
0  True True
1  True True
2  True True
3  True True
4  True True
```

### pandas.DataFrame.max

DataFrame.max(axis=NoDefault.no_default, skipna=True, level=None, numeric_only=None, **kwargs)

Return the maximum of the values over the requested axis.

If you want the index of the maximum, use idxmax. This is the equivalent of the numpy.ndarray method argmax.

**Parameters**

- **axis** ([index (0), columns (1)]): Axis for the function to be applied on.
- **skipna** [bool, default True]: Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```python
df = DataFrame({'A': [1, 2, 3, 4], 'B': [0, 1, 2, 3], 'C': [0, 2, 3, 4], 'D': [0, 2, 0, 2]})
df
```

```
      A  B  C  D
0   1.0 0  0  0
1   2.0 1  2  2
2   3.0 2  3  0
3   4.0 3  4  2
```

```python
>>> df.sum()  # A: 10, B: 6, C: 10, D: 6
```

```
       A  B  C  D
Name: 0, dtype: float64
```

```python
>>> df.max()  # A: 4, B: 3, C: 4, D: 2
```

```
       A  B  C  D
Name: 0, dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

**pandas.DataFrame.mean**

DataFrame.mean(axis=NoDefault.no_default, skipna=True, level=None, numeric_only=None, **kwargs)

Return the mean of the values over the requested axis.

**Parameters**

- **axis** [{index (0), columns (1)] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**pandas.DataFrame.median**

DataFrame.median(axis=NoDefault.no_default, skipna=True, level=None, numeric_only=None, **kwargs)

Return the median of the values over the requested axis.

**Parameters**

- **axis** [{index (0), columns (1)] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**pandas.DataFrame.melt**

DataFrame.melt(id_vars=None, value_vars=None, var_name=None, value_name=None, col_level=None, ignore_index=True)

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

**Parameters**
**id_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

**value_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.

**var_name** [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.

**value_name** [scalar, default ‘value’] Name to use for the ‘value’ column.

**col_level** [int or str, optional] If columns are a MultiIndex then use this level to melt.

**ignore_index** [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

**Returns**

**DataFrame** Unpivoted DataFrame.

**See also:**

melt Identical method.

pivot_table Create a spreadsheet-style pivot table as a DataFrame.

DataFrame.pivot Return reshaped DataFrame organized by given index / column values.

DataFrame.explode Explode a DataFrame from list-like columns to long format.

**Notes**

Reference the user guide for more examples.

**Examples**

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
                      ...        'B': {0: 1, 1: 3, 2: 5},
                      ...        'C': {0: 2, 1: 4, 2: 6}})

>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6

>>> df.melt(id_vars=['A'], value_vars=['B'])
   A   variable  value
0  a          B    1
1  b          B    3
2  c          B    5

>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
   A   variable  value
0  a          B    1
1  b          B    3
2  c          B    5
```

(continues on next page)
The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> df.melt(id_vars=['A'], value_vars=['B'],
...          var_name='myVarname', value_name='myValname')
   A  myVarname  myValname
0  a       B         1
1  b       B         3
2  c       B         5
```

Original index values can be kept around:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
   A  variable  value
0  a       B      1
1  b       B      3
2  c       B      5
0  a       C      2
1  b       C      4
2  c       C      6
```

If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C
   D  E  F
0  a  1  2
1  b  3  4
2  c  5  6
```

```python
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
   A  variable  value
0  a       B      1
1  b       B      3
2  c       B      5
```

```python
>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D) variable_0  variable_1  value
0   a     B         E      1
1   b     B         E      3
2   c     B         E      5
```
pandas.DataFrame.memory_usage

DataFrame.memory_usage(index=True, deep=False)

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of object dtype.

This value is displayed in DataFrame.info by default. This can be suppressed by setting pandas.options.display.memory_usage to False.

Parameters

- **index** [bool, default True] Specifies whether to include the memory usage of the DataFrame’s index in returned Series. If index=True, the memory usage of the index is the first item in the output.

- **deep** [bool, default False] If True, introspect the data deeply by interrogating object dtypes for system-level memory consumption, and include it in the returned values.

Returns

Series A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

See also:

- numpy.ndarray.nbytes Total bytes consumed by the elements of an ndarray.
- Series.memory_usage Bytes consumed by a Series.
- Categorical Memory-efficient array for string values with many repeated values.
- DataFrame.info Concise summary of a DataFrame.

Examples

```python
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000, dtype=int).astype(t))
...              for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
     int64  float64  complex128  object  bool
0     1.0  1.0     1.0+0.0j   True
1     1.0  1.0     1.0+0.0j   True
2     1.0  1.0     1.0+0.0j   True
3     1.0  1.0     1.0+0.0j   True
4     1.0  1.0     1.0+0.0j   True

>>> df.memory_usage()
      Index
int64     128
float64   40000
complex128 80000
object     40000
bool       50000
dtype: int64
```
The memory footprint of `object` dtype columns is ignored by default:

```python
>>> df.memory_usage(deep=True)
Index 128
int64 40000
float64 40000
complex128 80000
object 180000
bool 5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```python
>>> df['object'].astype('category').memory_usage(deep=True)
5244
```

### pandas.DataFrame.merge

DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

**Warning:** If both key columns contain rows where the key is a null value, those rows will be matched against each other. This is different from usual SQL join behaviour and can lead to unexpected results.

**Parameters**

- `right` [DataFrame or named Series] Object to merge with.
- `how` [{‘left’, ‘right’, ‘outer’, ‘inner’, ‘cross’}, default ‘inner’] Type of merge to be performed.
  - left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
  - right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
• outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
• inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
• cross: creates the cartesian product from both frames, preserves the order of the left keys.

New in version 1.2.0.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame, “right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

• “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
• “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
• “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
• “many_to_many” or “m:m”: allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.
See also:

*merge_ordered*  Merge with optional filling/interpolation.

*merge_asof*  Merge on nearest keys.

*DataFrames.join*  Similar method using indices.

Notes

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```python
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
                      'value': [1, 2, 3, 5]})
...>
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
                      'value': [5, 6, 7, 8]})

>>> df1
    lkey  value
0   foo     1
1   bar     2
2   baz     3
3   foo     5

>>> df2
    rkey  value
0   foo     5
1   bar     6
2   baz     7
3   foo     8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x  rkey  value_y
0   foo       1   foo       5
1   foo       1  foo_x       8
2   foo       5  foo_y       5
3   foo       5  foo_y       8
4   bar       2  bar       6
5   baz       3  baz       7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
            suffixes=('_left', '_right'))
   lkey  value_left  rkey  value_right
0   foo        1   foo        5
1   foo        1  foo_x        8
2   foo        5  foo_y        5
3   foo        5  foo_y        8
```

(continues on next page)
Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```python
>>> df1 = pd.DataFrame({'a': ['foo', 'bar'], 'b': [1, 2]})
>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})
>>> df1.merge(df2, how='inner', on='a')
  a  b  c
0 foo 1 3
1 bar 2 NaN
```

```python
>>> df1 = pd.DataFrame({'left': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'right': [7, 8]})
>>> df1.merge(df2, how='cross')
  left  right
0 foo     7
1 foo     8
2 bar     7
3 bar     8
```
DataFrame.min

DataFrame.min(\texttt{axis=NoDefault.no_default, skipna=True, level=\texttt{None}, numeric_only=\texttt{None}, **\texttt{kwargs}})

Return the minimum of the values over the requested axis.

If you want the index of the minimum, use \texttt{idxmin}. This is the equivalent of the \texttt{numpy.ndarray} method \texttt{argmin}.

**Parameters**

\begin{itemize}
\item \texttt{axis} \ [\{index (0), columns (1)\}] Axis for the function to be applied on.
\item \texttt{skipna} \ [\texttt{bool}, default \texttt{True}] Exclude NA/null values when computing the result.
\item \texttt{level} \ [\texttt{int} or level name, default \texttt{None}] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
\item \texttt{numeric_only} \ [\texttt{bool}, default \texttt{None}] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
\item \texttt{**kwargs} \ Additional keyword arguments to be passed to the function.
\end{itemize}

**Returns**

Series or DataFrame (if level specified)

See also:

\begin{itemize}
\item \texttt{Series.sum} \ Return the sum.
\item \texttt{Series.min} \ Return the minimum.
\item \texttt{Series.max} \ Return the maximum.
\item \texttt{Series.idxmin} \ Return the index of the minimum.
\item \texttt{Series.idxmax} \ Return the index of the maximum.
\item \texttt{DataFrame.sum} \ Return the sum over the requested axis.
\item \texttt{DataFrame.min} \ Return the minimum over the requested axis.
\item \texttt{DataFrame.max} \ Return the maximum over the requested axis.
\item \texttt{DataFrame.idxmin} \ Return the index of the minimum over the requested axis.
\item \texttt{DataFrame.idxmax} \ Return the index of the maximum over the requested axis.
\end{itemize}

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays([
... ['warm', 'warm', 'cold', 'cold'],
... ['dog', 'falcon', 'fish', 'spider']],
... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
     warm  dog  4
        falcon  2
     cold  fish  0
```

```

**pandas.DataFrame.mod**

`DataFrame.mod(other, axis='columns', level=None, fill_value=None)`

Get Modulo of dataframe and other, element-wise (binary operator `mod`).

Equivalent to `dataframe % other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rmod`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- `DataFrame` Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     'index':['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0    360
triangle   3    180
rectangle  4    360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1    360
triangle   4    180
rectangle  5    360
```

```python
>>> df.add(1)
   angles  degrees
circle    1    360
triangle   4    180
rectangle  5    360
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle    0.0   36.0
triangle   0.3   18.0
rectangle  0.4   36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle    inf   0.027778
triangle  3.333333   0.055556
rectangle 2.500000   0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1    358
triangle    2    178
rectangle   3    358
```
```python
>>> df.sub([1, 2], axis='columns')
angles  degrees
circle   -1   358
triangle  2   178
rectangle 3   358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles  degrees
circle   -1   359
triangle  2   179
rectangle 3   359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
index=['circle', 'triangle', 'rectangle'])

>>> other
angles
circle    0
triangle   3
rectangle  4

>>> df * other
angles   degrees
circle    0   NaN
triangle   9   NaN
rectangle 16   NaN

>>> df.mul(other, fill_value=0)
angles   degrees
circle    0     0.0
triangle   9     0.0
rectangle 16     0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
'degrees': [360, 180, 360, 540, 720],
index=['A', 'A', 'A', 'B', 'B', 'B'],
['circle', 'triangle', 'rectangle',
'square', 'pentagon', 'hexagon'])

>>> df_multindex
angles  degrees
A circle   0   360
triangle   3   180
rectangle  4   360
B square   4   360
pentagon   5   540
hexagon   6   720
```
\begin{verbatim}
>>> df = pd.DataFrame([('bird', 2, 2),
...                     ('mammal', 4, np.nan),
...                     ('arthropod', 8, 0),
...                     ('bird', 2, np.nan)],
...                    index=['falcon', 'horse', 'spider', 'ostrich'],
...                    columns=['species', 'legs', 'wings'])

>>> df
   species   legs  wings
falcon    bird  2   2.0
horse     mammal 4   NaN
spider    arthropod 8  0.0
ostrich   bird  2   NaN
\end{verbatim}

By default, missing values are not considered, and the mode of wings are both 0 and 2. Because the resulting DataFrame has two rows, the second row of species and legs contains NaN.
```python
>>> df.mode()
species  legs  wings
t0  bird  2.0  0.0
t1  NaN   NaN  2.0
```

Setting `dropna=False` NaN values are considered and they can be the mode (like for wings).

```python
>>> df.mode(dropna=False)
species  legs  wings
t0  bird  2  NaN
```

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```python
>>> df.mode(numeric_only=True)
legs  wings
0  2.0  0.0
1  NaN  2.0
```

To compute the mode over columns and not rows, use the axis parameter:

```python
>>> df.mode(axis='columns', numeric_only=True)
0  1
falcon  2.0  NaN
horse   4.0  NaN
spider  0.0  8.0
ostrich 2.0  NaN
```

**pandas.DataFrame.mul**

Get Multiplication of dataframe and other, element-wise (binary operator `mul`). Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rmul`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- `DataFrame` Result of the arithmetic operation.
See also:

*Dataframe.add*  Add DataFrames.
*Dataframe.sub*  Subtract DataFrames.
*Dataframe.mul*  Multiply DataFrames.
*Dataframe.div*  Divide DataFrames (float division).
*Dataframe.truediv*  Divide DataFrames (float division).
*Dataframe.floordiv*  Divide DataFrames (integer division).
*Dataframe.mod*  Calculate modulo (remainder after division).
*Dataframe.pow*  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],  
                    'degrees': [360, 180, 360]},  
                   index=['circle', 'triangle', 'rectangle'])
>>> df
     angles  degrees
circle   0      360
triangle  3      180
rectangle 4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
     angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
     angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
     angles  degrees
circle   0.0     36.0
triangle 0.3      18.0
rectangle 0.4     36.0
```
Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles   degrees
circle   -1   358
triangle   2   178
rectangle   3   358
```

```python
>>> df.sub([1, 2], axis='columns')
angles   degrees
circle   -1   358
triangle   2   178
rectangle   3   358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles   degrees
circle   -1   359
triangle   2   179
rectangle   3   359
```

Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4],
                      'index': ['circle', 'triangle', 'rectangle']})

other
angles
circle   0
triangle   3
rectangle   4

>>> df * other
angles   degrees
circle   0   NaN
triangle   9   NaN
rectangle  16   NaN
```

```python
>>> df.mul(other, fill_value=0)
angles   degrees
circle   0   0.0
triangle   9   0.0
rectangle  16   0.0
```

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
...    'degrees': [360, 180, 360, 540, 720]},
...    index=['A', 'A', 'A', 'B', 'B', 'B'],
...    ['circle', 'triangle', 'rectangle',
...     'square', 'pentagon', 'hexagon'])

>>> df_multindex
   angles  degrees
A  0      360
triangle  3     180
rectangle  4     360
B  4      360
pentagon  5      540
hexagon  6      720

>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A  NaN     1.0
triangle    1.0     1.0
rectangle    1.0     1.0
B  0.0     0.0
pentagon    0.0     0.0
hexagon    0.0     0.0
```

**pandas.DataFrame.multiply**

DataFrame.multiply(other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator mul).

Equivalent to dataframe * other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or `index`) or columns (1 or `columns`). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

DataFrame.add Add DataFrames.
DataFrame.sub  Subtract DataFrames.
DataFrame.mul  Multiply DataFrames.
DataFrame.div  Divide DataFrames (float division).
DataFrame.truediv  Divide DataFrames (float division).
DataFrame.floordiv  Divide DataFrames (integer division).
DataFrame.mod  Calculate modulo (remainder after division).
DataFrame.pow  Calculate exponential power.

Notes
Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                      'degrees': [360, 180, 360],
                      index=['circle', 'triangle', 'rectangle'])

>>> df
   angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361

```python
>>> df.add(1)
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0      36.0
triangle 0.3      18.0
rectangle 0.4      36.0

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf     0.027778
... (continues on next page)
Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles     degrees
    circle  -1     358
    triangle  2     178
    rectangle  3     358
```

```python
>>> df.sub([1, 2], axis='columns')
angles     degrees
    circle  -1     358
    triangle  2     178
    rectangle  3     358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles     degrees
    circle  -1     359
    triangle  2     179
    rectangle  3     359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
angles     degrees
    circle      0   NaN
    triangle     9   NaN
    rectangle    16   NaN
```

```python
>>> df.mul(other, fill_value=0)
angles     degrees
    circle      0    0.0
    triangle     9    0.0
    rectangle    16    0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6], ...
    'degrees': [360, 180, 360, 360, 540, 720]}, ...
    index=['A', 'A', 'A', 'B', 'B', 'B'], ...
```

(continues on next page)
...['circle', 'triangle', 'rectangle',
'square', 'pentagon', 'hexagon'])

>>> df_multindex

<table>
<thead>

</tr>
</tbody>
</table>

*pandas.DataFrame.ne*

`DataFrame.ne(other, axis='columns', level=None)`

Get Not equal to of dataframe and other, element-wise (binary operator ne).

Among flexible wrappers (`eq`, `ne`, `le`, `lt`, `ge`, `gt`) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [(0 or 'index', 1 or 'columns'), default 'columns'] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- **DataFrame of bool** Result of the comparison.

**See also:**

- `DataFrame.eq` Compare DataFrames for equality elementwise.
- `DataFrame.ne` Compare DataFrames for inequality elementwise.
- `DataFrame.le` Compare DataFrames for less than inequality or equality elementwise.
- `DataFrame.lt` Compare DataFrames for strictly less than inequality elementwise.
- `DataFrame.ge` Compare DataFrames for greater than inequality or equality elementwise.
- `DataFrame.gt` Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
def df = pd.DataFrame({'cost': [250, 150, 100],
                      'revenue': [100, 250, 300],
                      index=['A', 'B', 'C'])
def df
  cost  revenue
A    250     100
B    150     250
C    100     300

Comparison with a scalar, using either the operator or method:

```python
def df == 100
  cost  revenue
A   False    True
B   False    False
C   True    False
```

```python
def df.eq(100)
  cost  revenue
A   False    True
B   False    False
C   True    False
```

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
def df != pd.Series([100, 250], index=['cost', 'revenue'])
  cost      revenue
A   True     True
B   True    False
C   False    True
```

Use the method to control the broadcast axis:

```python
def df.ne(pd.Series([100, 300], index=['A', 'B'], axis='index'))
  cost      revenue
A   True    False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
def df == [250, 100]
  cost  revenue
A   True     True
```
Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
     cost  revenue
A    True  False
B   False   True
C    True  False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])

>>> df.gt(other)
     cost  revenue
A  False  False
B  False  False
C  False   True
D  False  False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               'index':[['Q1', 'Q1', 'Q1', 'Q2', 'Q2'],
                                        ['A', 'B', 'C', 'A', 'B', 'C']])

>>> df.le(df_multindex, level=1)
     cost  revenue
Q1 A   True   True
B   True   True
C   True   True
Q2 A  False   True
B  False   True
C   True  False
**DataFrame.nlargest**

Return the first \( n \) rows ordered by \( \text{columns} \) in descending order.

Return the first \( n \) rows with the largest values in \( \text{columns} \), in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to \( \text{df.sort_values(columns, ascending=False).head(n)} \), but more performant.

**Parameters**

- \( n \) [int] Number of rows to return.
- \( \text{columns} \) [label or list of labels] Column label(s) to order by.
- \( \text{keep} \) [‘first’, ‘last’, ‘all’], default ‘first’ Where there are duplicate values:
  - first: prioritize the first occurrence(s)
  - last: prioritize the last occurrence(s)
  - all: do not drop any duplicates, even it means selecting more than \( n \) items.

**Returns**

- **DataFrame** The first \( n \) rows ordered by the given columns in descending order.

**See also:**

- **DataFrame.nsmallest** Return the first \( n \) rows ordered by \( \text{columns} \) in ascending order.
- **DataFrame.sort_values** Sort DataFrame by the values.
- **DataFrame.head** Return the first \( n \) rows without re-ordering.

**Notes**

This function cannot be used with all column types. For example, when specifying columns with \textit{object} or \textit{category} dtypes, \texttt{TypeError} is raised.

**Examples**

```python
>>> df = pd.DataFrame({
    'population': [59000000, 65000000, 4340000, 434000, 434000, 337000, 11300, ...
    ..., 11300, 11300],
    ...
    'GDP': [1937894, 2583560, 12011, 4520, 12128, 17036, 182, 38, 311],
    ...
    'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN', 'IS', 'NR', 'TV', 'AI'],
    ...
    'index': ['Italy', 'France', 'Malta', 'Maldives', 'Brunei', 'Iceland', 'Nauru', 'Tuvalu', 'Anguilla']
})
```

```text
(continues on next page)
```
In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```python
>>> df.nlargest(3, 'population')
   population  GDP   alpha-2
0  France     65000000  2583560  FR
1  Italy      59000000  1937894  IT
2  Malta      4340000   12011    MT
```

When using `keep='last'`, ties are resolved in reverse order:

```python
>>> df.nlargest(3, 'population', keep='last')
   population  GDP   alpha-2
0  France     65000000  2583560  FR
1  Italy      59000000  1937894  IT
2  Brunei     4340000   12128    BN
```

When using `keep='all'`, all duplicate items are maintained:

```python
>>> df.nlargest(3, 'population', keep='all')
   population  GDP   alpha-2
0  France     65000000  2583560  FR
1  Italy      59000000  1937894  IT
2  Malta      4340000   12011    MT
3  Maldives   4340000   4520    MV
4  Brunei     4340000   12128    BN
```

To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```python
>>> df.nlargest(3, ['population', 'GDP'])
   population  GDP   alpha-2
0  France     65000000  2583560  FR
1  Italy      59000000  1937894  IT
2  Brunei     4340000   12128    BN
```
pandas.DataFrame.notna

DataFrame.notna()
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull Alias of notna.
DataFrame.isna Boolean inverse of notna.
DataFrame.dropna Omit axes labels with missing values.
notna Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
                            pd.Timestamp('1940-04-25')],
                      name=['Alfred', 'Batman', ''],
                      toy=[None, 'Batmobile', 'Joker']))
>>> df
     age  born               name  toy
0    5.0  NaT       Alfred      None
1    6.0 1939-05-27   Batman  Batmobile
2   NaN 1940-04-25      Joker
```

```python
>>> df.notna()
     age  born   name   toy
0   True  False   True  False
1   True   True   True   True
2  False  True   True   True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0   5.0
1   6.0
2  NaN
dtype: float64
```
pandas.DataFrame.notnull

DataFrame.notnull()

DataFrame.notnull is an alias for DataFrame.notna.

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

DataFrame  Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull  Alias of notna.
DataFrame.isna  Boolean inverse of notna.
DataFrame.dropna  Omit axes labels with missing values.
notna  Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                    born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                         pd.Timestamp('1940-04-25')],
...                    name=['Alfred', 'Batman', ''],
...                    toy=[None, 'Batmobile', 'Joker']))

>>> df
   age born     name    toy
0   5.0  NaT    Alfred  None
1   6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25  Joker

>>> df.notna()

   age born     name    toy
0   True  False  True  False
1   True  True   True   True
2  False  True   True   True

Show which entries in a Series are not NA.
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0   5.0
1   6.0
2    NaN
dtype: float64

>>> ser.notna()
0   True
1   True
2   False
dtype: bool
```

**pandas.DataFrame.nsmallest**

`DataFrame.nsmallest(n, columns, keep='first')`

Return the first `n` rows ordered by `columns` in ascending order.

Return the first `n` rows with the smallest values in `columns`, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

**Parameters**

- `n` [int] Number of items to retrieve.
- `columns` [list or str] Column name or names to order by.
- `keep` [[‘first’, ‘last’, ‘all’], default ‘first’] Where there are duplicate values:
  - `first`: take the first occurrence.
  - `last`: take the last occurrence.
  - `all`: do not drop any duplicates, even it means selecting more than `n` items.

**Returns**

`DataFrame`

See also:

- `DataFrame.nlargest` Return the first `n` rows ordered by `columns` in descending order.
- `DataFrame.sort_values` Sort DataFrame by the values.
- `DataFrame.head` Return the first `n` rows without re-ordering.
Examples

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
... 434000, 337000, 337000, 11300, 11300],
... 'GDP': [1937894, 2583560, 12011, 4520, 12128,
... 17036, 182, 311],
... 'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN',
... 'IS', 'NR', 'TV', 'AI'],
... index=['Italy', 'France', 'Malta',
... 'Maldives', 'Brunei', 'Iceland',
... 'Nauru', 'Tuvalu', 'Anguilla'])
```  

```text
In the following example, we will use `nsmallest` to select the three rows having the smallest values in column “population”.

```python
>>> df.nsmallest(3, 'population')
```

```text
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
<td>17036</td>
</tr>
</tbody>
</table>
```

When using `keep='last'`, ties are resolved in reverse order:

```python
>>> df.nsmallest(3, 'population', keep='last')
```

```text
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38</td>
</tr>
<tr>
<td>Nauru</td>
<td>337000</td>
<td>182</td>
</tr>
</tbody>
</table>
```

When using `keep='all'`, all duplicate items are maintained:

```python
>>> df.nsmallest(3, 'population', keep='all')
```

```text
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
<td>17036</td>
</tr>
<tr>
<td>Nauru</td>
<td>337000</td>
<td>182</td>
</tr>
</tbody>
</table>
```

To order by the smallest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.
>>> df.nsmallest(3, ['population', 'GDP'])
   population  GDP  alpha-2
Tuvalu     11300   38   TV
Anguilla   11300   311  AI
Nauru     337000  182  NR

pandas.DataFrame.nunique

DataFrame.nunique(axis=0, dropna=True)

Count number of distinct elements in specified axis.

Return Series with number of distinct elements. Can ignore NaN values.

Parameters

axis  [[0 or 'index', 1 or 'columns'], default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

dropna  [bool, default True] Don't include NaN in the counts.

Returns

Series

See also:

Series.nunique  Method nunique for Series.
DataFrame.count  Count non-NA cells for each column or row.

Examples

>>> df = pd.DataFrame({'A': [4, 5, 6], 'B': [4, 1, 1]})
>>> df.nunique()
A  3
B  2
dtype: int64

>>> df.nunique(axis=1)
0  1
1  2
2  2
dtype: int64
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.DataFrame.pad

DataFrame.pad(\texttt{axis=None, inplace=False, limit=None, downcast=None})

Synonym for DataFrame.fillna() with method='ffill'.

Returns

Series/DataFrame or None Object with missing values filled or None if inplace=True.

pandas.DataFrame.pct_change

DataFrame.pct_change(\texttt{periods=1, fill_method='pad', limit=None, freq=None, **kwargs})

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

\begin{itemize}
\item \texttt{periods} [int, default 1] Periods to shift for forming percent change.
\item \texttt{fill_method} [str, default ‘pad’] How to handle NAs before computing percent changes.
\item \texttt{limit} [int, default None] The number of consecutive NAs to fill before stopping.
\item \texttt{freq} [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
\item **\texttt{kwargs} Additional keyword arguments are passed into DataFrame.shift or Series.shift.
\end{itemize}

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

\begin{itemize}
\item \texttt{Series.diff} Compute the difference of two elements in a Series.
\item \texttt{DataFrame.diff} Compute the difference of two elements in a DataFrame.
\item \texttt{Series.shift} Shift the index by some number of periods.
\item \texttt{DataFrame.shift} Shift the index by some number of periods.
\end{itemize}

Examples

Series

\begin{verbatim}
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64
\end{verbatim}
See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```python
>>> s.pct_change(fill_method='ffill')
0       NaN
1       NaN
2  0.000000
3 -0.065934
```

### DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame(
...     {'FR': [4.0405, 4.0963, 4.3149],
...      'GR': [1.7246, 1.7482, 1.8519],
...      'IT': [804.74, 810.01, 860.13],
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
```

```python
>>> df
      FR   GR   IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13
```

```python
>>> df.pct_change()
   FR  GR   IT
1980-01-01  NaN  NaN  NaN
1980-02-01  0.013810  0.013684  0.006549
1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.
pandas.DataFrame.pipe

DataFrame.pipe(func, *args, **kwargs)

Apply chainable functions that expect Series or DataFrames.

Parameters

func [function] Function to apply to the Series/DataFrame. args, and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Series/DataFrame.

args [iterable, optional] Positional arguments passed into func.

kwargs [mapping, optional] A dictionary of keyword arguments passed into func.

Returns

object [the return type of func.]

See also:

DataFrame.apply Apply a function along input axis of DataFrame.

DataFrame.applymap Apply a function elementwise on a whole DataFrame.

Series.map Apply a mapping correspondence on a Series.

Notes

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
```

(continues on next page)
If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose f takes its data as arg2:

```python
>>> (df.pipe(h)
...     .pipe(g, arg1=a)
...     .pipe((func, 'arg2'), arg1=a, arg3=c)
... )
```

### pandas.DataFrame.pivot

DataFrame.pivot(index=None, columns=None, values=None)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified index / columns to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the User Guide for more on reshaping.

**Parameters**

- **index** [str or object or a list of str, optional] Column to use to make new frame’s index.
  
  If None, uses existing index.

  Changed in version 1.1.0: Also accept list of index names.

- **columns** [str or object or a list of str] Column to use to make new frame’s columns.

  Changed in version 1.1.0: Also accept list of columns names.

- **values** [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

**Returns**

DataFrame Returns reshaped DataFrame.

**Raises**

ValueError: When there are any index, columns combinations with multiple values. DataFrame.pivot_table when you need to aggregate.

**See also:**

- DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.
- DataFrame.unstack Pivot based on the index values instead of a column.
- wide_to_long Wide panel to long format. Less flexible but more user-friendly than melt.
Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Reference the user guide for more examples.

Examples

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', ...
  ...   'two'],
  ...   'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
  ...   'baz': [1, 2, 3, 4, 5, 6],
  ...   'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
```

```python
>>> df
foo  bar  baz  zoo
0   one  A    1    x
1   one  B    2    y
2   one  C    3    z
3   two  A    4    q
4   two  B    5    w
5   two  C    6    t
```

```python
>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A  B  C
foo
  one  1  2  3
  two  4  5  6
```

```python
>>> df.pivot(index='foo', columns='bar')['baz']
bar  A  B  C
foo
  one  1  2  3
  two  4  5  6
```

```python
>>> df.pivot(index='foo', columns='bar')['zoo']
baz  zoo
bar  A  B  C  A  B  C
foo
  one  1  2  3  x  y  z
  two  4  5  6  q  w  t
```

You could also assign a list of column names or a list of index names.

```python
>>> df = pd.DataFrame({
  ...   "lev1": [1, 1, 2, 2, 2],
  ...   "lev2": [1, 1, 2, 1, 2],
  ...   "lev3": [1, 2, 1, 2, 1],
  ...   "lev4": [1, 2, 3, 4, 5, 6],
  ...   "values": [0, 1, 2, 3, 4, 5]})
```

```python
>>> df
lev1  lev2  lev3  lev4  values
```

</table>

```python
>>> df.pivot(index="lev1", columns=["lev2", "lev3"],values="values")
lev2 1 2
lev3 1 2 1 2
lev1 1 0.0 1.0 2.0 NaN
2 4.0 3.0 NaN 5.0
```

```python
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"],values="values")
lev3 1 2
lev1 lev2
1 1 0.0 1.0
2 2.0 NaN
2 1 4.0 3.0
2 NaN 5.0
```

A ValueError is raised if there are any duplicates.

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'two', 'two'],
...                    'bar': ['A', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4]})
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
  ...
ValueError: Index contains duplicate entries, cannot reshape
```

**pandas.DataFrame.pivot_table**

DataFrame.pivot_table(values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False, sort=True)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

**Parameters**
values  [column to aggregate, optional]

index  [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns  [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc  [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value  [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

margins  [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna  [bool, default True] Do not include columns whose entries are all NaN.

margins_name  [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.

observed  [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

sort  [bool, default True] Specifies if the result should be sorted.

New in version 1.3.0.

Returns

DataFrame  An Excel style pivot table.

See also:

DataFrame.pivot  Pivot without aggregation that can handle non-numeric data.

DataFrame.melt  Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

wide_to_long  Wide panel to long format. Less flexible but more user-friendly than melt.

Notes

Reference the user guide for more examples.
Examples

```python
>>> df = pd.DataFrame({
    "A": ["foo", "foo", "foo", "foo", "foo", "bar", "bar", "bar", "bar"],
    "B": ["one", "one", "one", "two", "two", "one", "one", "two", "two"],
    "C": ["small", "large", "large", "small", "small", "large", "small", "small", "large"],
    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]
})
```

```python
>>> df
A  B  C   D   E
0  foo one  small  1  2
1  foo one  large  2  4
2  foo one  large  2  5
3  foo two  small  3  5
4  foo two  small  3  6
5  bar one  large  4  6
6  bar one  small  5  8
7  bar two  small  6  9
8  bar two  large  7  9
```

This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values="D", index=['A', 'B'], columns=['C'], aggfunc=np.sum)
```

```python
>>> table
C      large  small
   A   B
bar one  4.0  5.0
    two  7.0  6.0
foo one  4.0  1.0
    two  NaN  6.0
```

We can also fill missing values using the `fill_value` parameter.

```python
>>> table = pd.pivot_table(df, values="D", index=['A', 'B'], columns=['C'], aggfunc=np.sum, fill_value=0)
```

```python
>>> table
C      large  small
   A   B
bar one  4   5
    two  7   6
foo one  4   1
    two  0   6
```

The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                          aggfunc={'D': np.mean,
                                  'E': np.mean})
```

(continues on next page)
We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                'E': [min, max, np.mean]})
>>> table

          D     E
         mean max  mean min
A C bar large 5.500000 7.500000 6
     small 5.500000 8.500000 8
foo large 2.000000 4.500000 4
     small 2.333333 4.333333 2
```

**pandas.DataFrame.plot**

DataFrame.plot(*args, **kwargs)

Make plots of Series or DataFrame.

Uses the backend specified by the option plotting.backend. By default, matplotlib is used.

**Parameters**

- **data** [Series or DataFrame] The object for which the method is called.
- **x** [label or position, default None] Only used if data is a DataFrame.
- **y** [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.
- **kind** [str] The kind of plot to produce:
  - ‘line’ : line plot (default)
  - ‘bar’ : vertical bar plot
  - ‘barh’ : horizontal bar plot
  - ‘hist’ : histogram
  - ‘box’ : boxplot
  - ‘kde’ : Kernel Density Estimation plot
  - ‘density’ : same as ‘kde’
  - ‘area’ : area plot
  - ‘pie’ : pie plot
  - ‘scatter’ : scatter plot (DataFrame only)
  - ‘hexbin’ : hexbin plot (DataFrame only)
ax [matplotlib axes object, default None] An axes of the current figure.

subplots [bool, default False] Make separate subplots for each column.

sharex [bool, default True if ax is None else False] In case subplots=True, share x
axis and set some x axis labels to invisible; defaults to True if ax is None otherwise
False if an ax is passed in; Be aware, that passing in both an ax and sharex=True
will alter all x axis labels for all axis in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis
labels to invisible.

layout [tuple, optional] (rows, columns) for the layout of subplots.

figsize [a tuple (width, height) in inches] Size of a figure object.

use_index [bool, default True] Use index as ticks for x axis.

title [str or list] Title to use for the plot. If a string is passed, print the string at the top
of the figure. If a list is passed and subplots is True, print each item in the list above
the corresponding subplot.

grid [bool, default None (matlab style default)] Axis grid lines.

legend [bool or { ‘reverse’}] Place legend on axis subplots.

style [list or dict] The matplotlib line style per column.

logx [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. .. ver-
sionchanged:: 0.25.0

logy [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. .. ver-
sionchanged:: 0.25.0

loglog [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y
axes. .. versionchanged:: 0.25.0

xticks [sequence] Values to use for the xticks.

yticks [sequence] Values to use for the yticks.

xlim [2-tuple/list] Set the x limits of the current axes.

ylim [2-tuple/list] Set the y limits of the current axes.

xlabel [label, optional] Name to use for the xlabel on x-axis. Default uses index name
as xlabel, or the x-column name for planar plots.

   New in version 1.1.0.
   Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no
ylabel, or the y-column name for planar plots.

   New in version 1.1.0.
   Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

fontsize [int, default None] Font size for xticks and yticks.

colormap [str or matplotlib colormap object, default None] Colormap to select colors
from. If string, load colormap with that name from matplotlib.
**colorbar** [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

**position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

**table** [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

**xerr** [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

**stacked** [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

**sort_columns** [bool, default False] Sort column names to determine plot ordering.

**secondary_y** [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

**mark_right** [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

**include_bool** [bool, default is False] If True, boolean values can be plotted.

**backend** [str, default None] Backend to use instead of the backend specified in the option *plotting.backend*. For instance, ‘matplotlib’. Alternatively, to specify the *plotting.backend* for the whole session, set *pd.options.plotting.backend*.

New in version 1.0.0.

**kwargs** Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

**Notes**

- See matplotlib documentation online for more on this subject
- If *kind* = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

---

**pandas.DataFrame.pop**

DataFrame.pop(*item*)

Return item and drop from frame. Raise KeyError if not found.

**Parameters**

item [label] Label of column to be popped.

**Returns**

Series
Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
                      ('parrot', 'bird', 24.0),
                      ('lion', 'mammal', 80.5),
                      ('monkey', 'mammal', np.nan)],
                      columns=('name', 'class', 'max_speed'))
```

```python
>>> df
    name  class  max_speed
0  falcon  bird    389.0
1  parrot  bird     24.0
2   lion  mammal    80.5
3  monkey  mammal     NaN
```

```python
>>> df.pop('class')
0   bird
1   bird
2  mammal
3  mammal
Name: class, dtype: object
```

```python
>>> df
    name  max_speed
0  falcon    389.0
1  parrot    24.0
2   lion    80.5
3  monkey      NaN
```

pandas.DataFrame.pow

`DataFrame.pow(other, axis='columns', level=None, fill_value=None)`

Get Exponential power of dataframe and other, element-wise (binary operator pow).

Equivalent to `dataframe ** other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `rpow`.

Among flexible wrappers (`add, sub, mul, div, mod, pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns
DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
def = pd.DataFrame({'angles': [0, 3, 4],
                   'degrees': [360, 180, 360],
                   'index':['circle', 'triangle', 'rectangle']})
def
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
<td>360</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
<td>180</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
<td>360</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
def + 1
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
<td>361</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
<td>181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
<td>361</td>
</tr>
</tbody>
</table>

```python
def.add(1)
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
<td>361</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
<td>181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
<td>361</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
def.div(10)
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
<td>36.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
<td>18.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
<td>36.0</td>
</tr>
</tbody>
</table>
>>> df.rdiv(10)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf 0.027778</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333 0.055556</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.500000 0.027778</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 358</td>
</tr>
<tr>
<td>triangle</td>
<td>2 178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 358</td>
</tr>
</tbody>
</table>

>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 358</td>
</tr>
<tr>
<td>triangle</td>
<td>2 178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 358</td>
</tr>
</tbody>
</table>

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 359</td>
</tr>
<tr>
<td>triangle</td>
<td>2 179</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 359</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])

>>> other

<table>
<thead>
<tr>
<th>angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
</tr>
<tr>
<td>triangle</td>
</tr>
<tr>
<td>rectangle</td>
</tr>
</tbody>
</table>

>>> df * other

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0 NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>9 NaN</td>
</tr>
<tr>
<td>rectangle</td>
<td>16 NaN</td>
</tr>
</tbody>
</table>

>>> df.mul(other, fill_value=0)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0 0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>9 0.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>16 0.0</td>
</tr>
</tbody>
</table>

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             'index':[['A', 'A', 'A', 'B', 'B', 'B'],
                                      ['circle', 'triangle', 'rectangle',
                                       'square', 'pentagon', 'hexagon']])
```

```python
>>> df_multindex
   angles degrees
   A circle   0   360
         triangle   3   180
           rectangle   4   360
   B square   4   360
          pentagon   5   540
          hexagon   6   720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```python
   angles degrees
   A circle    NaN    1.0
         triangle   1.0   1.0
           rectangle   1.0   1.0
   B square     0.0    0.0
          pentagon     0.0    0.0
          hexagon     0.0    0.0
```

`pandas.DataFrame.prod`

`DataFrame.prod(axis=None, skipna=True, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the product of the values over the requested axis.

**Parameters**

- `axis` [{index (0), columns (1)] Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `min_count` [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

- `Series` or `DataFrame` (if level specified)

See also:

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
pandas: powerful Python data analysis toolkit, Release 1.4.3

Series.idxmin Return the index of the minimum.
Series.idxmax Return the index of the maximum.
DataFrame.sum Return the sum over the requested axis.
DataFrame.min Return the minimum over the requested axis.
DataFrame.max Return the maximum over the requested axis.
DataFrame.idxmin Return the index of the minimum over the requested axis.
DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.product

DataFrame.product (axis=None, skipna=True, level=None, numeric_only=None, min_count=0, **kwargs)
Return the product of the values over the requested axis.

Parameters

axis  [[index (0), columns (1)]] Axis for the function to be applied on.
skipna  [bool, default True] Exclude NA/null values when computing the result.
level  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
numeric_only  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
min_count  [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
**kwargs Additional keyword arguments to be passed to the function.

Returns
Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.
Series.min Return the minimum.
Series.max Return the maximum.
Series.idxmin Return the index of the minimum.
Series.idxmax Return the index of the maximum.
DataFrame.sum Return the sum over the requested axis.
DataFrame.min Return the minimum over the requested axis.
DataFrame.max Return the maximum over the requested axis.
DataFrame.idxmin Return the index of the minimum over the requested axis.
DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the min_count parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.quantile

DataFrame.quantile(q=0.5, axis=0, numeric_only=True, interpolation='linear')

Return values at the given quantile over requested axis.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value between 0 <= q <= 1, the quantile(s) to compute.
axis [(0, 1, ‘index’, ‘columns’), default 0] Equals 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
numeric_only [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.
interpolation  [‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points \( i \) and \( j \):

- **linear**: \( i + (j - i) * \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
- **lower**: \( i \).
- **higher**: \( j \).
- **nearest**: \( i \) or \( j \) whichever is nearest.
- **midpoint**: \( (i + j) / 2 \).

**Returns**

*Series or DataFrame*

- **Series or DataFrame**
  - If \( q \) is an array, a DataFrame will be returned where the index is \( q \). the columns are the columns of self, and the values are the quantiles.
  - If \( q \) is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.

**See also:**

*core.window.Rolling.quantile* Rolling quantile.

*numpy.percentile* Numpy function to compute the percentile.

**Examples**

```python
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
                  columns=['a', 'b'])
>>> df.quantile(.1)
a  1.3
b  3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
a  b
0.1 1.3 3.7
0.5 2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```python
>>> df = pd.DataFrame({'A': [1, 2],
...                    'B': [pd.Timestamp('2010'),
...                         pd.Timestamp('2011')],
...                    'C': [pd.Timedelta('1 days'),
...                         pd.Timedelta('2 days')]})
>>> df.quantile(0.5, numeric_only=False)
A   1.5
B  2010-07-02 12:00:00
C    1 days 12:00:00
Name: 0.5, dtype: object
```
pandas.DataFrame.query

DataFrame.query(expr, inplace=False, **kwargs)
Query the columns of a DataFrame with a boolean expression.

Parameters

expr [str] The query string to evaluate.

You can refer to variables in the environment by prefixing them with an ‘@’ character like @a + b.

You can refer to column names that are not valid Python variable names by surrounding them in backticks. Thus, column names containing spaces or punctuations (besides underscores) or starting with digits must be surrounded by backticks. (For example, a column named “Area (cm^2)” would be referenced as `Area (cm^2)`).

Column names which are Python keywords (like “list”, “for”, “import”, etc) cannot be used.

For example, if one of your columns is called a a and you want to sum it with b, your query should be `a a` + b.

New in version 0.25.0: Backtick quoting introduced.

New in version 1.0.0: Expanding functionality of backtick quoting for more than only spaces.

inplace [bool] Whether the query should modify the data in place or return a modified copy.

**kwargs See the documentation for eval() for complete details on the keyword arguments accepted by DataFrame.query().

Returns

DataFrame or None DataFrame resulting from the provided query expression or None if inplace=True.

See also:

eval Evaluate a string describing operations on DataFrame columns.
DataFrame.eval Evaluate a string describing operations on DataFrame columns.

Notes

The result of the evaluation of this expression is first passed to DataFrame.loc and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to DataFrame.__getitem__().

This method uses the top-level eval() function to evaluate the passed query.

The query() method uses a slightly modified Python syntax by default. For example, the & and | (bitwise) operators have the precedence of their boolean cousins, and and or. This is syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument parser=’python’. This enforces the same semantics as evaluation in Python space. Likewise, you can pass engine=’python’ to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using numexpr as the engine.
The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the query documentation in `indexing`.

**Backtick quoted variables**

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings that are allowed as a Python identifier. These characters include all operators in Python, the space character, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the query parser will raise an error. This excludes whitespace different than the space character, but also the hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, `it's` > `that's` will raise an error, as it forms a quoted string (`'s > `that`) with a backtick inside.

See also the Python documentation about lexical analysis (https://docs.python.org/3/reference/lexical_analysis.html) in combination with the source code in `pandas.core.computation.parsing`.

**Examples**

```python
>>> df = pd.DataFrame({'A': range(1, 6),
...                     'B': range(0, 10, -2),
...                     'C C': range(10, 5, -1)})

>>> df
   A  B    C
0  1  10   10
1  2   8   9
2  3   6   8
3  4   4   7
4  5   2   6

>>> df.query('A > B')
   A  B    C
4  5   2   6

The previous expression is equivalent to

```python
>>> df[df.A > df.B]
   A  B    C
4  5   2   6

For columns with spaces in their name, you can use backtick quoting.

```python
>>> df.query('B == `C C``')
   A  B    C
0  1  10   10

The previous expression is equivalent to
```
pandas.DataFrame.radd

DataFrame.radd(other, axis='columns', level=None, fill_value=None)

Get Addition of dataframe and other, element-wise (binary operator radd).

Equivalent to other + dataframe, but with support to substitute a fill_value for missing data in one of
the inputs. With reverse version, add.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /=, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data
structure, or list-like object.

axis [(0 or ‘index’, 1 or ‘columns’)] Whether to compare by the index (0 or ‘index’) or
columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed Mul-
tiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any
new element needed for successful DataFrame alignment, with this value before
computation. If data in both corresponding DataFrame locations is missing the
result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.
## Notes

Mismatched indices will be unioned together.

## Examples

```python
>>> df = pd.DataFrame(
    {
        'angles': [0, 3, 4],
        'degrees': [360, 180, 360],
    },
    index=['circle', 'triangle', 'rectangle']
)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

```python
>>> df.add(1)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
>>> df.div(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>

```python
>>> df.rdiv(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>3.33333</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.50000</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>
Multiply a DataFrame of different shape with operator version.

```python
def * other
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN
```

Divide by a MultiIndex by level.

```python
def_multindex = pd.DataFrame({
    'angles': [0, 3, 4, 5, 6],
    'degrees': [360, 180, 360, 360, 540, 720],
    'index': [['A', 'A', 'A', 'B', 'B', 'B'],
               ['circle', 'triangle', 'rectangle',
                'square', 'pentagon', 'hexagon']]
})
def_multindex
```

```
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```
```python
>>> df.div(df_multindex, level=1, fill_value=0)
    angles  degrees
   A  circle   NaN   1.0
        triangle   1.0   1.0
        rectangle   1.0   1.0
   B  square    0.0    0.0
        pentagon    0.0    0.0
        hexagon    0.0    0.0
```

**pandas.DataFrame.rank**

*pandas.DataFrame.rank*(axis=0, method='average', numeric_only=NoDefault.no_default, na_option='keep', ascending=True, pct=False)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

**Parameters**

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Index to direct ranking.
- **method** [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups.
- **numeric_only** [bool, optional] For DataFrame objects, rank only numeric columns if set to True.
- **na_option** [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’] How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign lowest rank to NaN values
  - bottom: assign highest rank to NaN values
- **ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.
- **pct** [bool, default False] Whether or not to display the returned rankings in percentile form.

**Returns**

- **same type as caller** Return a Series or DataFrame with data ranks as values.

**See also:**

- *core.groupby.GroupBy.rank* Rank of values within each group.
Examples

```python
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog', 'spider', 'snake'],
                          'Number_legs': [4, 2, 4, 8, np.nan]})
```

The following example shows how the method behaves with the above parameters:

- default_rank: this is the default behaviour obtained without using any parameter.
- max_rank: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since 'cat' and 'dog' are both in the 2nd and 3rd position, rank 3 is assigned.)
- NA_bottom: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- pct_rank: when setting `pct = True`, the ranking is expressed as percentile rank.

```python
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
```

```plaintext
Animal   Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0        cat          4.0           2.5       3.0        2.5       0.625
1        penguin     2.0           1.0       1.0        1.0       0.250
2        dog          4.0           2.5       3.0        2.5       0.625
3        spider      8.0           4.0       4.0        4.0       1.000
4        snake       NaN           NaN       NaN        5.0       NaN
```

**pandas.DataFrame.rdiv**

DataFrame.rdiv(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator rtruediv).

Equivalent to `other / dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `truediv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+, -, *, /, //, %, **`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
def = pd.DataFrame({'angles': [0, 3, 4],
                   'degrees': [360, 180, 360],
                   'index': ['circle', 'triangle', 'rectangle']})
def + 1
```

Add a scalar with operator version which return the same results.

```python
def.add(1)
```

Divide by constant with reverse version.
```python
>>> df.div(10)
angles  degrees
circle  0.0  36.0
triangle 0.3  18.0
rectangle 0.4  36.0

>>> df.rdiv(10)
angles  degrees
circle  inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees
circle  -1  358
triangle  2  178
rectangle  3  358

```python
>>> df.sub([1, 2], axis='columns')
angles  degrees
circle  -1  358
triangle  2  178
rectangle  3  358

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles  degrees
circle  -1  359
triangle  2  179
rectangle  3  359

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles':[0, 3, 4]},
... index=['circle', 'triangle', 'rectangle'])

```python
>>> df * other
angles  degrees
circle  0  NaN
triangle  9  NaN
rectangle 16  NaN

```python
>>> df.mul(other, fill_value=0)
angles  degrees
circle  0  0.0
```

(continues on next page)
divide by a multiindex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                               'degrees': [360, 180, 360, 540, 720],
                               index=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
```

```python
>>> df_multindex
   angles  degrees
A   circle  0      360
     triangle  3       180
     rectangle  4      360
B    square  4      360
     pentagon  5      540
    hexagon  6      720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A   circle  NaN      1.0
     triangle  1.0      1.0
     rectangle  1.0      1.0
B    square  0.0      0.0
     pentagon  0.0      0.0
    hexagon  0.0      0.0
```

```python
pandas.DataFrame.reindex
```

`DataFrame.reindex(labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill_value=np.nan, limit=None, tolerance=None)`

Conform Series/DataFrame to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **keywords for axes** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

- **method** [[None, ‘backfill’/‘bfill’, ‘pad’/‘ffill’, ‘nearest’]] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don't fill gaps
  - pad / ffill: Propagate last valid observation forward to next valid.
  - backfill / bfill: Use next valid observation to fill gap.
  - nearest: Use nearest valid observations to fill gap.

- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**3.4. DataFrame**
level  [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value  [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

limit  [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance  [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

Series/DataFrame with changed index.

See also:

DataFrame.set_index  Set row labels.

DataFrame.reset_index  Remove row labels or move them to new columns.

DataFrame.reindex_like  Change to same indices as other DataFrame.

Examples

DataFrame.reindex supports two calling conventions

• (index=index_labels, columns=column_labels, ...)

• (labels, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                    index=index)
>>> df
       http_status  response_time
Firefox   200          0.04
Chrome    200          0.02
Safari    404          0.07
IE10      404          0.08
Konqueror 301          1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10', 'Chrome']
```
We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
```

<table>
<thead>
<tr>
<th>http_status</th>
<th>response_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Safari</td>
<td>404 0.07</td>
</tr>
<tr>
<td>Iceweasel</td>
<td>0 0.00</td>
</tr>
<tr>
<td>Comodo Dragon</td>
<td>0 0.00</td>
</tr>
<tr>
<td>IE10</td>
<td>404 0.08</td>
</tr>
<tr>
<td>Chrome</td>
<td>200 0.02</td>
</tr>
</tbody>
</table>

We can also reindex the columns.

```python
>>> df.reindex(columns=['http_status', 'user_agent'])
```

<table>
<thead>
<tr>
<th>http_status</th>
<th>user_agent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>200 NaN</td>
</tr>
<tr>
<td>Chrome</td>
<td>200 NaN</td>
</tr>
<tr>
<td>Safari</td>
<td>404 NaN</td>
</tr>
<tr>
<td>IE10</td>
<td>404 NaN</td>
</tr>
<tr>
<td>Konqueror</td>
<td>301 NaN</td>
</tr>
</tbody>
</table>

Or we can use “axis-style” keyword arguments

```python
>>> df.reindex(['http_status', 'user_agent'], axis='columns')
```

<table>
<thead>
<tr>
<th>http_status</th>
<th>user_agent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firefox</td>
<td>200 NaN</td>
</tr>
<tr>
<td>Chrome</td>
<td>200 NaN</td>
</tr>
<tr>
<td>Safari</td>
<td>404 NaN</td>
</tr>
<tr>
<td>IE10</td>
<td>404 NaN</td>
</tr>
<tr>
<td>Konqueror</td>
<td>301 NaN</td>
</tr>
</tbody>
</table>

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```python
date_index = pd.date_range('1/1/2010', periods=6, freq='D')
df2 = pd.DataFrame({'prices': [100, 101, np.nan, 100, 89, 88]})
```
Suppose we decide to expand the dataframe to cover a wider date range.

```python
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
   prices
2009-12-29   NaN
2009-12-30   NaN
2009-12-31   NaN
2010-01-01   100.0
2010-01-02   101.0
2010-01-03   NaN
2010-01-04   100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass bfill as an argument to the method keyword.

```python
>>> df2.reindex(date_index2, method='bfill')
   prices
2009-12-29  100.0
2009-12-30  100.0
2009-12-31  100.0
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the `user guide` for more.
pandas.DataFrame.reindex_like

DataFrame.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.
- **method** [(None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’)] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs(index[indexer] - target)} \leq \text{tolerance}$.
  
  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

- **Series or DataFrame** Same type as caller, but with changed indices on each axis.

**See also:**

- *DataFrame.set_index* Set row labels.
- *DataFrame.reset_index* Remove row labels or move them to new columns.
- *DataFrame.reindex* Change to new indices or expand indices.
Notes

Same as calling `.reindex(index=other.index, columns=other.columns,...)`.

Examples

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
                      ...                       [31, 87.8, 'high'],
                      ...                       [22, 71.6, 'medium'],
                      ...                       [35, 95, 'medium']],
                      ...                       columns=['temp_celsius', 'temp_fahrenheit',
                      ...                       'windspeed'],
                      ...                       index=pd.date_range(start='2014-02-12',
                      ...                       end='2014-02-15', freq='D'))

>>> df1
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12      24.3            75.7        high
2014-02-13      31.0            87.8        high
2014-02-14      22.0            71.6       medium
2014-02-15      35.0            95.0       medium

>>> df2 = pd.DataFrame([[28, 'low'],
                      ...                       [30, 'low'],
                      ...                       [35.1, 'medium']],
                      ...                       columns=['temp_celsius', 'windspeed'],
                      ...                       index=pd.DatetimeIndex(['2014-02-12', '2014-02-13','2014-02-15']))

>>> df2
   temp_celsius  windspeed
2014-02-12      28.0        low
2014-02-13      30.0        low
2014-02-15      35.1       medium

>>> df2.reindex_like(df1)
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12      28.0              NaN        low
2014-02-13      30.0              NaN        low
2014-02-14      NaN              NaN        NaN
2014-02-15      35.1              NaN       medium
```
DataFrame.rename

DataFrame.rename(mapper=None, *, index=None, columns=None, axis=None, copy=True, inplace=False, level=None, errors='ignore')

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

See the user guide for more.

Parameters

mapper [dict-like or function] Dict-like or function transformations to apply to that axis’ values. Use either mapper and axis to specify the axis to target with mapper, or index and columns.

index [dict-like or function] Alternative to specifying axis (mapper, axis=0 is equivalent to index=mapper).

columns [dict-like or function] Alternative to specifying axis (mapper, axis=1 is equivalent to columns=mapper).

axis [[0 or ‘index’, 1 or ‘columns’], default 0] Axis to target with mapper. Can be either the axis name (‘index’, ‘columns’) or number (0, 1). The default is ‘index’.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Whether to return a new DataFrame. If True then value of copy is ignored.

level [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

errors [[‘ignore’, ‘raise’], default ‘ignore’] If ‘raise’, raise a KeyError when a dict-like mapper, index, or columns contains labels that are not present in the Index being transformed. If ‘ignore’, existing keys will be renamed and extra keys will be ignored.

Returns

DataFrame or None DataFrame with the renamed axis labels or None if inplace=True.

Raises

KeyError If any of the labels is not found in the selected axis and “errors=’raise’”.

See also:

DataFrame.rename_axis Set the name of the axis.
Examples

DataFrame.rename supports two calling conventions

- (index=index_mapper, columns=columns_mapper, ...)
- (mapper, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})
>>> df.rename(columns={'A': 'a', 'B': 'c'})
   a  c
0  1  4
1  2  5
2  3  6
```

Rename index using a mapping:

```python
>>> df.rename(index={0: 'x', 1: 'y', 2: 'z'})
    A  B
   x  1  4
   y  2  5
   z  3  6
```

Cast index labels to a different type:

```python
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index([0, 1, 2], dtype='object')
```

Using axis-style parameters:

```python
>>> df.rename(str.lower, axis='columns')
   a  b
0  1  4
1  2  5
2  3  6
```

```python
>>> df.rename({1: 2, 2: 4}, axis='index')
     A  B
0   1  4
2   2  5
4   3  6
```
DataFrame.rename_axis

DataFrame.rename_axis(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values. Note that the columns parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.

Use either mapper and axis to specify the axis to target with mapper, or index and/or columns.

(axis={0 or 'index', 1 or 'columns'}, default 0) The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if inplace=True.

See also:

Series.rename Alter Series index labels or name.

DataFrame.rename Alter DataFrame index labels or name.

Index.rename Set set names on index.

Notes

DataFrame.rename_axis supports two calling conventions

• (index=index_mapper, columns=columns_mapper, ...)

• (mapper, axis={'index', 'columns'}, ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter copy is ignored.

The second calling convention will modify the names of the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis labels.

We highly recommend using keyword arguments to clarify your intent.
Examples

Series

```python
>>> s = pd.Series(['dog', 'cat', 'monkey'])
>>> s
0   dog
1   cat
2  monkey
dtype: object
>>> s.rename_axis('animal')
animal
0   dog
1   cat
2  monkey
dtype: object
```

DataFrame

```python
>>> df = pd.DataFrame({'num_legs': [4, 4, 2],
                     'num_arms': [0, 0, 2]})
>>> df
     num_legs num_arms
dog      4        0
cat      4        0
monkey   2        2
>>> df = df.rename_axis('animal')
>>> df
     num_legs num_arms
animal
dog      4        0
cat      4        0
monkey   2        2
```

MultiIndex

```python
>>> df.index = pd.MultiIndex.from_product([['mammal'], ['dog', 'cat', 'monkey']], names=['type', 'name'])
>>> df
     num_legs num_arms
limbs  type name
mammal dog      4        0
       cat      4        0
       monkey   2        2
```
pandas.DataFrame.reorder_levels

DataFrame.reorder_levels(order, axis=0)
Rearrange index levels using input order. May not drop or duplicate levels.

Parameters

- order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).
- axis [{0 or 'index', 1 or 'columns'}, default 0] Where to reorder levels.

Returns

DataFrame

Examples

```python
>>> data = {
    ...     "class": ["Mammals", "Mammals", "Reptiles"],
    ...     "diet": ["Omnivore", "Carnivore", "Carnivore"],
    ...     "species": ["Humans", "Dogs", "Snakes"],
    ... }
>>> df = pd.DataFrame(data, columns=["class", "diet", "species"])
>>> df = df.set_index(["class", "diet"])
>>> df
            species
class     diet  
Mammals   Omnivore  Humans
          Carnivore  Dogs
Reptiles  Carnivore  Snakes

Let's reorder the levels of the index:

```
pandas.DataFrame.replace

DataFrame.replace(to_replace=None, value=NoDefault.no_default, inplace=False, limit=None, regex=False, method=NoDefault.no_default)

Replace values given in to_replace with value.

Values of the DataFrame are replaced with other values dynamically.

This differs from updating with .loc or .iloc, which require you to specify a location to update with some value.

Parameters

to_replace [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
  - numeric: numeric values equal to to_replace will be replaced with value
  - str: string exactly matching to_replace will be replaced with value
  - regex: regexs matching to_replace will be replaced with value

- list of str, regex, or numeric:
  - First, if to_replace and value are both lists, they must be the same length.
  - Second, if regex=True then all of the strings in both lists will be interpreted as regexes otherwise they will match directly. This doesn’t matter much for value since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.

- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, {'a': 'b', 'y': 'z'} replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the value parameter should be None.
  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, {'a': 1, 'b': 'z'} looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in value. The value parameter should not be None in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
  - For a DataFrame nested dictionaries, e.g., {'a': {'b': np.nan}}, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The value parameter should be None to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) cannot be regular expressions.

- None:
- This means that the regex argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If value is also None then this must be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching to_replace with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, performs operation inplace and returns None.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as to_replace, default False] Whether to interpret to_replace and/or value as regular expressions. If this is True then to_replace must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case to_replace must be None.

method [{‘pad’, ‘ffill’, ‘bfill’, None}] The method to use when for replacement, when to_replace is a scalar, list or tuple and value is None.

Changed in version 0.23.0: Added to DataFrame.

Returns

DataFrame Object after replacement.

Raises

AssertionError

- If regex is not a bool and to_replace is not None.

TypeError

- If to_replace is not a scalar, array-like, dict, or None
- If to_replace is a dict and value is not a list, dict, ndarray, or Series
- If to_replace is None and regex is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple bool or datetime64 objects and the arguments to to_replace does not match the type of the value being replaced

ValueError

- If a list or an ndarray is passed to to_replace and value but they are not the same length.

See also:

DataFrame.fillna Fill NA values.
DataFrame.where Replace values based on boolean condition.
Series.str.replace Simple string replacement.
Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

- This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

- When dict is used as the `to_replace` value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s.replace(1, 5)
0    5
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3], ...) 'B': [5, 6, 7, 8, 9], ...) 'C': ['a', 'b', 'c', 'd', 'e']})
```

```
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

List-like `to_replace`

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
```

(continues on next page)
>> s.replace([1, 2], method='bfill')
0 3
1 3
2 3
3 4
4 5
dtype: int64

dict-like `to_replace`

>>> df.replace({0: 10, 1: 100})
   A  B  C
0 10 5 a
1 100 6 b
2 2 7 c
3 3 8 d
4 4 9 e

>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100 a
1 1 6 b
2 2 7 c
3 3 8 d
4 4 9 e

>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100 5 a
1 1 6 b
2 2 7 c
3 3 8 d
4 400 9 e

Regular expression `to_replace`

>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'], ... 'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz

>>> df.replace({'A': r'^ba.$', 'A': 'new'}, regex=True)
   A  B
0  new abc
(continues on next page)
Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0   10
1   None
2  None
3   b
4   None
dtype: object
```

When `value` is not explicitly passed and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default ‘pad’) to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case.

```python
>>> s.replace('a')
0   10
1   10
2   10
3   b
4   b
dtype: object
```

On the other hand, if `None` is explicitly passed for value, it will be respected:
>>> s.replace('a', None)
0 10
1 None
2 None
3 b
4 None
dtype: object

Changed in version 1.4.0: Previously the explicit None was silently ignored.

**pandas.DataFrame.resample**

`DataFrame.resample(rule, axis=0, closed=None, label=None, convention='start', kind=None, loffset=None, base=None, on=None, level=None, origin='start_day', offset=None)`

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. The object must have a
datetime-like index (`DatetimeIndex`, `PeriodIndex`, or `TimedeltaIndex`), or the caller must pass the label of
a datetime-like series/index to the `on/level` keyword parameter.

**Parameters**

- `rule` [DateOffset, Timedelta or str] The offset string or object representing target con-
version.

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Which axis to use for up- or down-
sampling. For Series this will default to 0, i.e. along the rows. Must be `DatetimeIn-
dex`, `TimedeltaIndex` or `PeriodIndex`.

- `closed` [{‘right’, ‘left’}, default None] Which side of bin interval is closed. The default
which all have a default of ‘right’.

- `label` [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The
and ‘W’ which all have a default of ‘right’.

- `convention` [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For `PeriodIndex` only, controls
whether to use the start or end of `rule`.

- `kind` [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the
resulting index to a `DateTimeIndex` or ‘period’ to convert it to a `PeriodIndex`. By
default the input representation is retained.

- `loffset` [timedelta, default None] Adjust the resampled time labels.

  Deprecated since version 1.1.0: You should add the loffset to the `df.index` after the
resample. See below.

- `base` [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the
aggregated intervals. For example, for ‘5min’ frequency, base could range from 0
through 4. Defaults to 0.

  Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’
or ‘origin’.

- `on` [str, optional] For a DataFrame, column to use instead of index for resampling. Col-
umn must be datetime-like.
level [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. level must be datetime-like.

origin [Timestamp or str, default ‘start_day’] The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If string, must be one of the following:

- ‘epoch’: origin is 1970-01-01
- ‘start’: origin is the first value of the timeseries
- ‘start_day’: origin is the first day at midnight of the timeseries

New in version 1.1.0.

- ‘end’: origin is the last value of the timeseries
- ‘end_day’: origin is the ceiling midnight of the last day

New in version 1.3.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns

pandas.core.Resampler Resampler object.

See also:

Series.resample Resample a Series.

DataFrame.resample Resample a DataFrame.

groupby Group DataFrame by mapping, function, label, or list of labels.

asfreq Reindex a DataFrame with the given frequency without grouping.

Notes

See the user guide for more.

To learn more about the offset strings, please see this link.

Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
```
(continues on next page)
Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket `2000-01-01 00:03:00` contains the value 3, but the summed value in the resampled bucket with the label `2000-01-01 00:03:00` does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00      1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00      2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the `NaN` values using the `pad` method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the `NaN` values using the `bfill` method.
>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   1
2000-01-01 00:01:00   1
2000-01-01 00:01:30   2
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64

Pass a custom function via apply

>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
...

>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64

For a Series with a PeriodIndex, the keyword convention can be used to control whether to use the start or end of rule.

Resample a year by quarter using 'start' convention. Values are assigned to the first quarter of the period.

>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...     freq='A',
...     periods=2))

>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64

>>> s.resample('Q', convention='start').asfreq()
2012Q1 1.0
2012Q2 NaN
2012Q3 NaN
2012Q4 NaN
2013Q1 2.0
2013Q2 NaN
2013Q3 NaN
2013Q4 NaN
Freq: Q-DEC, dtype: float64

Resample quarters by month using 'end' convention. Values are assigned to the last month of the period.

>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...     freq='Q',
...     periods=4))

>>> q
2018Q1 1
2018Q2 2
2018Q3 3
2018Q4 4
Freq: Q-DEC, dtype: int64

>>> q.resample('M', convention='end').asfreq()
For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
      'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018', periods=8, freq='W')
>>> df
   price  volume  week_starting
0     10      50   2018-01-07
1     11      60   2018-01-14
2      9      40   2018-01-21
3     13      100  2018-01-28
4     14       50  2018-02-04
5     18      100  2018-02-11
6     17       40  2018-02-18
7     19       50  2018-02-25
```

```python
>>> df.resample('M', on='week_starting').mean()

<table>
<thead>
<tr>
<th>week_starting</th>
<th>price</th>
<th>volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-01-31</td>
<td>10.75</td>
<td>62.5</td>
</tr>
<tr>
<td>2018-02-28</td>
<td>17.00</td>
<td>60.0</td>
</tr>
</tbody>
</table>
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
      'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(d2, index=pd.MultiIndex.from_product([days, ['morning', 'afternoon']]))
>>> df2
   price  volume           week_starting
2000-01-01 morning 10 50     2000-01-01 morning
```

(continues on next page)
If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64
```

```python
>>> ts.resample('17min').sum()
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='epoch').sum()
2000-10-01 23:18:00    0
2000-10-01 23:35:00   18
2000-10-01 23:52:00   27
2000-10-02 00:09:00   39
2000-10-02 00:26:00   24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='2000-01-01').sum()
2000-10-01 23:24:00    3
2000-10-01 23:41:00   15
2000-10-01 23:58:00   45
```

(continues on next page)
If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

If you want to take the largest Timestamp as the end of the bins:

```python
>>> ts.resample('17min', origin='end').sum()
2000-10-01 23:35:00     0
2000-10-01 23:52:00    18
2000-10-02 00:09:00    27
2000-10-02 00:26:00    63
Freq: 17T, dtype: int64
```

In contrast with the `start_day`, you can use `end_day` to take the ceiling midnight of the largest Timestamp as the end of the bins and drop the bins not containing data:

```python
>>> ts.resample('17min', origin='end_day').sum()
2000-10-01 23:38:00     3
2000-10-01 23:55:00    15
2000-10-02 00:12:00    45
2000-10-02 00:29:00    45
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `base` argument, you can now use `offset`, in this example it is equivalent to have `base=2`:

```python
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00     0
2000-10-01 23:33:00     9
2000-10-01 23:50:00    36
2000-10-02 00:07:00    39
2000-10-02 00:24:00    24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `loffset` argument:

```python
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
```
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)

2000-10-01 23:33:00 0
2000-10-01 23:50:00 9
2000-10-02 00:07:00 21
2000-10-02 00:24:00 54
2000-10-02 00:41:00 24

Freq: 17T, dtype: int64

pandas.DataFrame.reset_index

DataFrame.reset_index(level=None, drop=False, inplace=False, col_level=0, col_fill='')

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

Parameters

- **level** [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.
- **drop** [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.
- **inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).
- **col_level** [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.
- **col_fill** [object, default ‘’] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

Returns

- **DataFrame or None** DataFrame with the new index or None if inplace=True.

See also:

- **DataFrame.set_index** Opposite of reset_index.
- **DataFrame.reindex** Change to new indices or expand indices.
- **DataFrame.reindex_like** Change to same indices as other DataFrame.
Examples

```python
>>> df = pd.DataFrame([('bird', 389.0),
...                     ('bird', 24.0),
...                     ('mammal', 80.5),
...                     ('mammal', np.nan)],
...                     index=['falcon', 'parrot', 'lion', 'monkey'],
...                     columns=('class', 'max_speed'))

>>> df
    class   max_speed
falcon  bird     389.0
parrot  bird     24.0
lion    mammal   80.5
monkey  mammal   NaN
```

When we reset the index, the old index is added as a column, and a new sequential index is used:

```python
>>> df.reset_index()

     index  class   max_speed
 0    falcon  bird     389.0
 1   parrot  bird     24.0
 2     lion  mammal   80.5
 3  monkey  mammal    NaN
```

We can use the `drop` parameter to avoid the old index being added as a column:

```python
>>> df.reset_index(drop=True)
    class   max_speed
 0  bird     389.0
 1  bird     24.0
 2  mammal   80.5
 3  mammal    NaN
```

You can also use `reset_index` with `MultiIndex`.

```python
>>> index = pd.MultiIndex.from_tuples([(class, name),
...                                      ('bird', 'falcon'),
...                                      ('bird', 'parrot'),
...                                      ('mammal', 'lion'),
...                                      ('mammal', 'monkey')],
...                                      names=['class', 'name'])

>>> columns = pd.MultiIndex.from_tuples([(speed, max),
...                                         ('species', 'type')])

>>> df = pd.DataFrame([([389.0, 'fly'],
...                      (24.0, 'fly'),
...                      (80.5, 'run'),
...                      (np.nan, 'jump')],
...                     index=index,
...                     columns=columns)

>>> df
     speed species
   max  type
class name
bird  falcon     389.0  fly
```

(continues on next page)
If the index has multiple levels, we can reset a subset of them:

```python
>>> df.reset_index(level='class')
```

<table>
<thead>
<tr>
<th>name</th>
<th>class</th>
<th>max</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
<td>fly</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>24.0</td>
<td>fly</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
<td>run</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
<td>jump</td>
</tr>
</tbody>
</table>

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```python
>>> df.reset_index(level='class', col_level=1)
```

<table>
<thead>
<tr>
<th>name</th>
<th>class</th>
<th>max</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
<td>fly</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>24.0</td>
<td>fly</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
<td>run</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
<td>jump</td>
</tr>
</tbody>
</table>

When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='species')
```

<table>
<thead>
<tr>
<th>name</th>
<th>species</th>
<th>speed</th>
<th>species</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
<td>fly</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>24.0</td>
<td>fly</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
<td>run</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
<td>jump</td>
</tr>
</tbody>
</table>

If we specify a nonexistent level for `col_fill`, it is created:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='genus')
```

<table>
<thead>
<tr>
<th>name</th>
<th>genus</th>
<th>speed</th>
<th>species</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
<td>fly</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>24.0</td>
<td>fly</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
<td>run</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
<td>jump</td>
</tr>
</tbody>
</table>
DataFrame.rfloordiv

DataFrame.rfloordiv(other, axis='columns', level=None, fill_value=None)

Get integer division of dataframe and other, element-wise (binary operator \( \rfloor \)).

Equivalent to other // dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, floordiv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame(
    {'angles': [0, 3, 4],
     'degrees': [360, 180, 360],
    ...     index=['circle', 'triangle', 'rectangle'])

>>> df
angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

```python
>>> df.add(1)
angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
angles  degrees
circle    0.0     36.0
triangle  0.3      18.0
rectangle 0.4      36.0
```

```python
>>> df.rdiv(10)
angles  degrees
circle  inf       0.027778
triangle 3.333333 0.055556
rectangle 2.5      0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees
circle    -1     358
triangle    2      178
rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')
angles  degrees
circle    -1     358
triangle    2      178
rectangle   3      358
```
Multiply a DataFrame of different shape with operator version.

```
other = pd.DataFrame({'angles': [0, 3, 4],
                      'index':['circle', 'triangle', 'rectangle']})
```

```
>>> other
angles
circle 0
triangle 3
rectangle 4
```

```
>>> df * other
angles  degrees
circle  0     NaN
triangle 3     NaN
rectangle 4     NaN
```

```
>>> df.mul(other, fill_value=0)
angles  degrees
circle  0.0   0.0
triangle 9.0   9.0
rectangle 16.0 16.0
```

Divide by a MultiIndex by level.

```
>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                               'degrees': [360, 180, 360, 540, 720],
                               'index':[['A', 'A', 'A', 'B', 'B'],
                                        ['circle', 'triangle', 'rectangle',
                                         'square', 'pentagon', 'hexagon']])
```

```
>>> df_multindex
angles  degrees
A circle 0   360
triangle 3   180
rectangle 4   360
B square 4   360
pentagon 5   540
hexagon 6   720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A NaN   1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.rmod

DataFrame.rmod(other, axis='columns', level=None, fill_value=None)

Get Modulo of dataframe and other, element-wise (binary operator rmod).

Equivalent to other % dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     index=['circle', 'triangle', 'rectangle'])

>>> df
angles  degrees
circle    0     360
triangle   3     180
rectangle  4     360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
angles  degrees
circle   1     361
triangle  4     181
rectangle  5     361
```

```python
>>> df.add(1)
angles  degrees
circle   1     361
triangle  4     181
rectangle  5     361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
angles  degrees
circle  0.0   36.0
triangle 0.3   18.0
rectangle 0.4  36.0
```

```python
>>> df.rdiv(10)
angles  degrees
circle  inf   0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees
circle  -1    358
triangle    2    178
rectangle    3    358
```

```python
>>> df.sub([1, 2], axis='columns')
angles  degrees
circle  -1    358
triangle    2    178
rectangle    3    358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
```

```python
>>> other
angles
circle    0
triangle   3
rectangle  4
```

```python
>>> df * other
angles  degrees
circle   0 NaN
triangle  9 NaN
rectangle 16 NaN
```

```python
>>> df.mul(other, fill_value=0)
angles  degrees
circle   0 0.0
triangle  9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': [['A', 'A', 'A', 'B', 'B', 'B'],
                                         ['circle', 'triangle', 'rectangle',
                                          'square', 'pentagon', 'hexagon']])
```

```python
>>> df_multindex
angles  degrees
A circle   0 360
triangle   3 180
rectangle  4 360
B square   4 360
pentagon   5 540
hexagon    6 720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon  0.0 0.0
```
pandas.DataFrame.rmul

DataFrame.rmul(other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator rmul).

Equivalent to other * dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
### Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0 360</td>
</tr>
<tr>
<td>triangle</td>
<td>3 180</td>
</tr>
<tr>
<td>rectangle</td>
<td>4 360</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1 361</td>
</tr>
<tr>
<td>triangle</td>
<td>4 181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5 361</td>
</tr>
</tbody>
</table>

```python
>>> df.add(1)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1 361</td>
</tr>
<tr>
<td>triangle</td>
<td>4 181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5 361</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
>>> df.div(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0 36.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3 18.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4 36.0</td>
</tr>
</tbody>
</table>

```python
>>> df.rdiv(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf 0.027778</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333 0.055556</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.5 0.027778</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 358</td>
</tr>
<tr>
<td>triangle</td>
<td>2 178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 358</td>
</tr>
</tbody>
</table>

```python
>>> df.sub([1, 2], axis='columns')
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 358</td>
</tr>
<tr>
<td>triangle</td>
<td>2 178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 358</td>
</tr>
</tbody>
</table>
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
angles  degrees
   circle   -1  359
   triangle    2  179
   rectangle   3  359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])

>>> other
angles
circle   0
triangle   3
rectangle   4

>>> df * other
angles  degrees
   circle   0   NaN
   triangle   9   NaN
   rectangle  16   NaN

>>> df.mul(other, fill_value=0)
angles  degrees
   circle   0   0.0
   triangle   9   0.0
   rectangle  16   0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                                'degrees': [360, 180, 360, 540, 720],
                                index=['A', 'A', 'A', 'B', 'B'],
                                ['circle', 'triangle', 'rectangle',
                                 'square', 'pentagon', 'hexagon']})

>>> df_multindex
angles  degrees
   A circle   0  360
   triangle   3  180
   rectangle   4  360
   B square   4  360
   pentagon   5  540
   hexagon   6  720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
   A circle   NaN   1.0
   triangle   1.0   1.0
   rectangle   1.0   1.0
   B square   0.0   0.0
   pentagon   0.0   0.0
   hexagon   0.0   0.0
**pandas.DataFrame.rolling**

DataFrame.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None, method='single')

Provide rolling window calculations.

**Parameters**

- **window** [int, offset, or BaseIndexer subclass] Size of the moving window.
  - If an integer, the fixed number of observations used for each window.
  - If an offset, the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. To learn more about the offsets & frequency strings, please see this link.
  - If a BaseIndexer subclass, the window boundaries based on the defined get_window_bounds method. Additional rolling keyword arguments, namely min_periods, center, and closed will be passed to get_window_bounds.

- **min_periods** [int, default None] Minimum number of observations in window required to have a value; otherwise, result is np.nan.
  - For a window that is specified by an offset, min_periods will default to 1.
  - For a window that is specified by an integer, min_periods will default to the size of the window.

- **center** [bool, default False] If False, set the window labels as the right edge of the window index.
  - If True, set the window labels as the center of the window index.

- **win_type** [str, default None] If None, all points are evenly weighted.
  - If a string, it must be a valid scipy.signal window function.
  - Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature.

- **on** [str, optional] For a DataFrame, a column label or Index level on which to calculate the rolling window, rather than the DataFrame’s index.
  - Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

- **axis** [int or str, default 0] If 0 or 'index', roll across the rows.
  - If 1 or 'columns', roll across the columns.

- **closed** [str, default None] If 'right', the first point in the window is excluded from calculations.
  - If 'left', the last point in the window is excluded from calculations.
  - If 'both', the no points in the window are excluded from calculations.
  - If 'neither', the first and last points in the window are excluded from calculations.
  - Default None ('right').
  - Changed in version 1.2.0: The closed parameter with fixed windows is now supported.
method [str {'single', 'table'}, default 'single'] New in version 1.3.0.

Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying engine='numba' in the method call.

Returns

Window subclass if a win_type is passed
Rolling subclass if win_type is not passed

See also:

expanding Provides expanding transformations.
ewm Provides exponential weighted functions.

Notes

See Windowing Operations for further usage details and examples.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

window

Rolling sum with a window length of 2 observations.

```python
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Rolling sum with a window span of 2 seconds.

```python
>>> df_time = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                         index=[pd.Timestamp('20130101 09:00:00'),
                               pd.Timestamp('20130101 09:00:02'),
                               pd.Timestamp('20130101 09:00:03'),
                               pd.Timestamp('20130101 09:00:05'),
                               pd.Timestamp('20130101 09:00:06')])
```
>>> df_time

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01 09:00:00</td>
<td>0.0</td>
<td></td>
</tr>
<tr>
<td>2013-01-01 09:00:02</td>

</tr>
<tr>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>
(continues on next page)
win_type

Rolling sum with a window length of 2, using the Scipy 'gaussian' window type. std is required in the aggregation function.

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
       B
0      NaN
1  0.986207
2  2.958621
3      NaN
4      NaN
```

**pandas.DataFrame.round**

**DataFrame.round**(decimals=0, *args, **kwargs)

Round a DataFrame to a variable number of decimal places.

**Parameters**

- **decimals** [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if `decimals` is a dict-like, or in the index if `decimals` is a Series. Any columns not included in `decimals` will be left as is. Elements of `decimals` which are not columns of the input will be ignored.

- *args Additional keywords have no effect but might be accepted for compatibility with numpy.

- **kwargs Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

**DataFrame** A DataFrame with the affected columns rounded to the specified number of decimal places.

**See also:**

- **numpy.around** Round a numpy array to the given number of decimals.

- **Series.round** Round a Series to the given number of decimals.
Examples

```python
>>> df = pd.DataFrame([(0.21, 0.32), (0.01, 0.67), (0.66, 0.03), (0.21, 0.18)],
                   columns=['dogs', 'cats'])
>>> df
   dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18
```

By providing an integer each column is rounded to the same number of decimal places

```python
>>> df.round(1)
   dogs  cats
0   0.2  0.3
1   0.0  0.7
2   0.7  0.0
3   0.2  0.2
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```python
>>> df.round({'dogs': 1, 'cats': 0})
   dogs  cats
0   0.2  0.0
1   0.0  1.0
2   0.7  0.0
3   0.2  0.0
```

Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value

```python
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
   dogs  cats
0   0.2  0.0
1   0.0  1.0
2   0.7  0.0
3   0.2  0.0
```

**pandas.DataFrame.rpow**

DataFrame.rpow(other, axis='columns', level=None, fill_value=None)

Get Exponential power of dataframe and other, element-wise (binary operator rpow).
Equivalent to other ** dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, pow.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [[0 or 'index', 1 or 'columns']] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                     'degrees': [360, 180, 360]},
                     index=['circle', 'triangle', 'rectangle'])
```

```
angles  degrees
circle   0  360
triangle 3  180
rectangle 4  360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```
angles   degrees
circle   1  361
triangle 4  181
rectangle 5  361
```
Divide by constant with reverse version.

```python
>>> df.div(10)
angles  degrees
circle  0.0  36.0
triangle 0.3  18.0
rectangle 0.4  36.0
```

```python
>>> df.rdiv(10)
angles  degrees
circle  inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees
circle  -1  358
triangle  2  178
rectangle  3  358
```

```python
>>> df.sub([1, 2], axis='columns')
angles  degrees
circle  -1  358
triangle  2  178
rectangle  3  358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles  degrees
circle  -1  359
triangle  2  179
rectangle  3  359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4],
...                        'index': ['circle', 'triangle', 'rectangle']})
>>> other
angles
circle 0
triangle 3
rectangle 4
```
>>> df * other
         angles  degrees
    circle    0       NaN
      triangle    9       NaN
     rectangle   16       NaN

>>> df.mul(other, fill_value=0)
         angles  degrees
    circle    0       0.0
      triangle    9       0.0
     rectangle   16       0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
...       'degrees': [360, 180, 360, 360, 540, 720],
...       'index': [['A', 'A', 'A', 'B', 'B', 'B'],
...                ['circle', 'triangle', 'rectangle',
...                'square', 'pentagon', 'hexagon']])

>>> df_multindex
       angles  degrees
     A circle    0      360
       triangle    3      180
      rectangle    4      360
     B square    4      360
    pentagon    5      540
      hexagon    6      720

>>> df.div(df_multindex, level=1, fill_value=0)
         angles  degrees
    A circle       NaN      1.0
      triangle      1.0      1.0
     rectangle      1.0      1.0
     B square       NaN       0
    pentagon       NaN       0
      hexagon       NaN       0

**pandas.DataFrame.rsub**

DataFrame.rsub(other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator rsub).

Equivalent to other - dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, sub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [(0 or 'index', 1 or 'columns')] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

**See also:**

*DataFrame.add* Add DataFrames.

*DataFrame.sub* Subtract DataFrames.

*DataFrame.mul* Multiply DataFrames.

*DataFrame.div* Divide DataFrames (float division).

*DataFrame.truediv* Divide DataFrames (float division).

*DataFrame.floordiv* Divide DataFrames (integer division).

*DataFrame.mod* Calculate modulo (remainder after division).

*DataFrame.pow* Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                     'degrees': [360, 180, 360],
                     index=['circle', 'triangle', 'rectangle'])
```

```plaintext
   angles  degrees
  circle    0      360
  triangle   3      180
  rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```plaintext
   angles  degrees
  circle    1      361
  triangle   4      181
  rectangle  5      361
```

```python
>>> df.add(1)
```

```plaintext
   angles  degrees
  circle    1      361
```

(continues on next page)
triangle 4 181
rectangle 5 361

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle    0.0    36.0
triangle   0.3    18.0
rectangle  0.4    36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf    0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1    358
triangle    2    178
rectangle   3    358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1    358
triangle    2    178
rectangle   3    358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
   angles  degrees
circle   -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])
```

```python
>>> other
   angles
circle   0
triangle  3
rectangle 4
```

```python
>>> df * other
   angles  degrees
circle   0       NaN
```

(continues on next page)
triangle 9 NaN
rectangle 16 NaN

```python
>>> df.mul(other, fill_value=0)
angles  degrees
circle 0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
... 'degrees': [360, 180, 360, 540, 720],
... index=['A', 'A', 'A', 'B', 'B'],
... ['circle', 'triangle', 'rectangle',
... 'square', 'pentagon', 'hexagon']}

>>> df_multindex
angles  degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```

**pandas.DataFrame.rtruediv**

**DataFrame.rtruediv**(other, axis=’columns’, level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator `rtruediv`). Equivalent to `other / dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `truediv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
def = pd.DataFrame({'angles': [0, 3, 4],
                   'degrees': [360, 180, 360],
                   'index': ['circle', 'triangle', 'rectangle']})
def + 1
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
angles  
circle  1  
triangle 4  
rectangle 5
degrees
0 361
181
361
```

```python
>>> df.add(1)
angles  
circle  1  
triangle 4  
rectangle 5
degrees
0 361
181
361
```

Divide by constant with reverse version.
>>> df.div(10)
   angles  degrees
   circle   0.0  36.0
   triangle  0.3  18.0
   rectangle 0.4  36.0

>>> df.rdiv(10)
   angles  degrees
   circle   inf  0.027778
   triangle 3.333333  0.055556
   rectangle 2.500000  0.027778

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]
   angles  degrees
   circle   -1  358
   triangle   2  178
   rectangle   3  358

>>> df.sub([1, 2], axis='columns')
   angles  degrees
   circle   -1  358
   triangle   2  178
   rectangle   3  358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         axis='index')
   angles  degrees
   circle   -1  359
   triangle   2  179
   rectangle   3  359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4],
                        ... index=['circle', 'triangle', 'rectangle']})

>>> df * other
   angles  degrees
   circle   0    NaN
   triangle  9    NaN
   rectangle 16    NaN

>>> df.mul(other, fill_value=0)
   angles  degrees
   circle   0    0.0

(continues on next page)
Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             'index': ['A', 'A', 'A', 'B', 'B', 'B'],
                             ['circle', 'triangle', 'rectangle',
                             'square', 'pentagon', 'hexagon'])
>>> df_multindex
   angles  degrees
A  circle     0     360
    triangle   3     180
    rectangle  4     360
B  square    4     360
    pentagon   5     540
    hexagon   6     720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A  circle     NaN     1.0
    triangle   1.0     1.0
    rectangle  1.0     1.0
B  square     0.0     0.0
    pentagon   0.0     0.0
    hexagon   0.0     0.0
```

### pandas.DataFrame.sample

DataFrame.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None, ignore_index=False)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

**Parameters**

- `n` [int, optional] Number of items from axis to return. Cannot be used with `frac`. Default = 1 if `frac` = None.
- `frac` [float, optional] Fraction of axis items to return. Cannot be used with `n`.
- `replace` [bool, default False] Allow or disallow sampling of the same row more than once.
- `weights` [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.
random_state [int, array-like, BitGenerator, np.random.RandomState, np.random.Generator, optional] If int, array-like, or BitGenerator, seed for random number generator. If np.random.RandomState or np.random.Generator, use as given.

Changed in version 1.1.0: array-like and BitGenerator object now passed to np.random.RandomState() as seed

Changed in version 1.4.0: np.random.Generator objects now accepted

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, …, n - 1.

New in version 1.3.0.

Returns

Series or DataFrame A new object of same type as caller containing n items randomly sampled from the caller object.

See also:

DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.

SeriesGroupBy.sample Generates random samples from each group of a Series object.

numpy.random.choice Generates a random sample from a given 1-D numpy array.

Notes

If frac > 1, replacement should be set to True.

Examples

>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...    'num_wings': [2, 0, 0, 0],
...    'num_specimen_seen': [10, 2, 1, 8]},
...   index=['falcon', 'dog', 'spider', 'fish'])

>>> df

<table>
<thead>
<tr>
<th></th>
<th>num_legs</th>
<th>num_wings</th>
<th>num_specimen_seen</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>2</td>
<td>2</td>
<td>10</td>
</tr>
<tr>
<td>dog</td>
<td>4</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>spider</td>
<td>8</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>fish</td>
<td>0</td>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>

Extract 3 random elements from the Series df['num_legs']: Note that we use random_state to ensure the reproducibility of the examples.

>>> df['num_legs'].sample(n=3, random_state=1)

fish     0
spider   8
falcon   2
Name: num_legs, dtype: int64
A random 50% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
  dog      4          0                2
  fish     0          0                8
```

An upsample sample of the DataFrame with replacement: Note that `replace` parameter has to be `True` for `frac parameter > 1`.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
  dog      4          0                2
  fish     0          0                8
  falcon   2          2                10
  falcon   2          2                10
  fish     0          0                8
  dog      4          0                2
  fish     0          0                8
  dog      4          0                2
```

Using a DataFrame column as weights. Rows with larger value in the num_specimen_seen column are more likely to be sampled.

```python
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
  falcon   2          2                10
  fish     0          0                8
```

**pandas.DataFrame.select_dtypes**

DataFrame.select_dtypes(include=None, exclude=None)

Return a subset of the DataFrame’s columns based on the column dtypes.

**Parameters**

- `include`, `exclude` [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

**Returns**

DataFrame The subset of the frame including the dtypes in `include` and excluding the dtypes in `exclude`.

**Raises**

- ValueError
  - If both of `include` and `exclude` are empty
  - If `include` and `exclude` have overlapping elements
  - If any kind of string dtype is passed in.

**See also:**

- DataFrame.dtypes Return Series with the data type of each column.
Notes

- To select all numeric types, use np.number or 'number'
- To select strings you must use the object dtype, but note that this will return all object dtype columns
- See the numpy dtype hierarchy
- To select datetimes, use np.datetime64, 'datetime' or 'datetime64'
- To select timedeltas, use np.timedelta64, 'timedelta' or 'timedelta64'
- To select Pandas categorical dtypes, use 'category'
- To select Pandas datetimetz dtypes, use 'datetimetz' (new in 0.20.0) or 'datetime64[ns, tz]'

Examples

```python
def = pd.DataFrame({'a': [1, 2] * 3,
                   'b': [True, False] * 3,
                   'c': [1.0, 2.0] * 3})
```

```bash
>>> df
     a  b   c
0   1  True  1.0
1   2  False 2.0
2   1  True  1.0
3   2  False 2.0
4   1  True  1.0
5   2  False 2.0
```

```python
def.select_dtypes(include='bool')
```

```bash
b
0  True
1  False
2  True
3  False
4  True
5  False
```

```python
def.select_dtypes(include=['float64'])
```

```bash
c
0  1.0
1  2.0
2  1.0
3  2.0
4  1.0
5  2.0
```

```python
def.select_dtypes(exclude=['int64'])
```

```bash
b  c
0  True  1.0
1  False 2.0
```

(continues on next page)
pandas.DataFrame.sem

DataFrame.sem(axis=None, skipna=True, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.set_axis

DataFrame.set_axis(labels, axis=0, inplace=False)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Parameters

labels [list-like, Index] The values for the new index.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace [bool, default False] Whether to return a new DataFrame instance.

Returns

renamed [DataFrame or None] An object of type DataFrame or None if inplace=True.

See also:

DataFrame.rename_axis Alter the name of the index or columns.

3.4. DataFrame
Examples

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```python
>>> df.set_axis(['a', 'b', 'c'], axis='index')
```

```
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>b</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>c</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>
```

Change the column labels.

```python
>>> df.set_axis(['I', 'II'], axis='columns')
```

```
<table>
<thead>
<tr>
<th></th>
<th>I</th>
<th>II</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>
```

Now, update the labels inplace.

```python
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
```

```python
i  ii
0  1  4
1  2  5
2  3  6
```

### pandas.DataFrame.set_flags

DataFrame.set_flags(*, copy=False, allows_duplicate_labels=None)

Return a new object with updated flags.

- **Parameters**
  - allows_duplicate_labels [bool, optional] Whether the returned object allows duplicate labels.

- **Returns**
  - Series or DataFrame The same type as the caller.

See also:

- DataFrame.attrs Global metadata applying to this dataset.
- DataFrame.flags Global flags applying to this object.
Notes

This method returns a new object that’s a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in DataFrame.attrs.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags.allows_duplicate_labels
True
>>> df2 = df.set_flags(allows_duplicate_labels=False)
>>> df2.flags.allows_duplicate_labels
False
```

pandas.DataFrame.set_index

DataFrame.set_index(keys, drop=True, append=False, inplace=False, verify_integrity=False)

Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

Parameters

- **keys** [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses Series, Index, np.ndarray, and instances of Iterator.

- **drop** [bool, default True] Delete columns to be used as the new index.

- **append** [bool, default False] Whether to append columns to existing index.

- **inplace** [bool, default False] If True, modifies the DataFrame in place (do not create a new object).

- **verify_integrity** [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

Returns

DataFrame or None Changed row labels or None if inplace=True.

See also:

- **DataFrame.reset_index** Opposite of set_index.
- **DataFrame.reindex** Change to new indices or expand indices.
- **DataFrame.reindex_like** Change to same indices as other DataFrame.
Examples

```python
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
...                     'year': [2012, 2014, 2013, 2014],
...                     'sale': [55, 40, 84, 31]})

>>> df
    month  year  sale
0      1  2012   55
1      4  2014   40
2      7  2013   84
3     10  2014   31
```

Set the index to become the ‘month’ column:

```python
>>> df.set_index('month')
     year  sale
month  
1  2012   55
4  2014   40
7  2013   84
10 2014   31
```

Create a MultiIndex using columns ‘year’ and ‘month’:

```python
>>> df.set_index(['year', 'month'])
    sale
year month  
2012 1  55
2014 4  40
2013 7  84
2014 10 31
```

Create a MultiIndex using an Index and a column:

```python
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
  month  year  sale
    1  2012   55
    2  2014   40
    3  2013   84
    4  2014   31
```

Create a MultiIndex using two Series:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
    month  year  sale
      1  1  2012   55
      2  4  2014   40
      3  9  2013   84
      4 16  2014   31
```
pandas.DataFrame.shift

DataFrame.shift(periods=1, freq=None, axis=0, fill_value=NoDefault.no_default)

Shift index by desired number of periods with an optional time freq.

When freq is not passed, shift the index without realigning the data. If freq is passed (in this case, the index must be date or datetime, or it will raise a NotImplementedError), the index will be increased using the periods and the freq. freq can be inferred when specified as “infer” as long as either freq or inferred_freq attribute is set in the index.

Parameters

- **periods** [int] Number of periods to shift. Can be positive or negative.
- **freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If freq is specified then the index values are shifted but the data is not realigned. That is, use freq if you would like to extend the index when shifting and preserve the original data. If freq is specified as “infer” then it will be inferred from the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.
- **axis** [(0 or ‘index’, 1 or ‘columns’, None), default None] Shift direction.
- **fill_value** [object, optional] The scalar value to use for newly introduced missing values. The default depends on the dtype of self. For numeric data, np.nan is used. For datetime, timedelta, or period data, etc. NaT is used. For extension dtypes, self. dtype.na_value is used.

Changed in version 1.1.0.

Returns

- **DataFrame** Copy of input object, shifted.

See also:

- Index.shift Shift values of Index.
- DatetimeIndex.shift Shift values of DatetimeIndex.
- PeriodIndex.shift Shift values of PeriodIndex.
- tshift Shift the time index, using the index’s frequency if available.

Examples

```python
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
                    'Col2': [13, 23, 18, 33, 48],
                    'Col3': [17, 27, 22, 37, 52]},
                   index=pd.date_range("2020-01-01", "2020-01-05"))
>>> df
     Col1 Col2 Col3
2020-01-01  10   13   17
2020-01-02  20   23   27
2020-01-03  15   18   22
2020-01-04  30   33   37
2020-01-05  45   48   52
```
```python
>>> df.shift(periods=3)
<table>
<thead>
<tr>
<th></th>
<th>Col1</th>
<th>Col2</th>
<th>Col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-01</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2020-01-02</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2020-01-03</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2020-01-04</td>
<td>10.0</td>
<td>13.0</td>
<td>17.0</td>
</tr>
<tr>
<td>2020-01-05</td>
<td>20.0</td>
<td>23.0</td>
<td>27.0</td>
</tr>
</tbody>
</table>
```

```python
>>> df.shift(periods=1, axis="columns")
<table>
<thead>
<tr>
<th></th>
<th>Col1</th>
<th>Col2</th>
<th>Col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-01</td>
<td>NaN</td>
<td>10</td>
<td>13</td>
</tr>
<tr>
<td>2020-01-02</td>
<td>NaN</td>
<td>20</td>
<td>23</td>
</tr>
<tr>
<td>2020-01-03</td>
<td>NaN</td>
<td>15</td>
<td>18</td>
</tr>
<tr>
<td>2020-01-04</td>
<td>NaN</td>
<td>30</td>
<td>33</td>
</tr>
<tr>
<td>2020-01-05</td>
<td>NaN</td>
<td>45</td>
<td>48</td>
</tr>
</tbody>
</table>
```

```python
>>> df.shift(periods=3, fill_value=0)
<table>
<thead>
<tr>
<th></th>
<th>Col1</th>
<th>Col2</th>
<th>Col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-01</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2020-01-02</td>
<td>0</td>
<td>0</td>
<td>0</td>

```

**pandas.DataFrame.skew**

DataFrame. **skew** (axis=NoDefault.no_default, skipna=True, level=None, numeric_only=None, **kwargs)

Return unbiased skew over requested axis.

Normalized by N-1.

**Parameters**

- **axis** ([index (0), columns (1)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

### pandas.DataFrame.slice_shift

**DataFrame.slice_shift(periods=1, axis=0)**

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: slice_shift is deprecated, use DataFrame/Series.shift instead.

**Parameters**

**periods** [int] Number of periods to move, can be positive or negative.

**Returns**

**shifted** [same type as caller]

**Notes**

While the *slice_shift* is faster than *shift*, you may pay for it later during alignment.

### pandas.DataFrame.sort_index

**DataFrame.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)**

Sort object by labels (along an axis).

Returns a new DataFrame sorted by label if *inplace* argument is False, otherwise updates the original DataFrame and returns None.

**Parameters**

**axis** [[0 or ‘index’, 1 or ‘columns’], default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.

**level** [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).

**ascending** [bool or list-like of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.

**inplace** [bool, default False] If True, perform operation in-place.
**kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also *numpy.sort()* for more information. *mergesort* and *stable* are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.

**na_position** [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end. Not implemented for MultiIndex.

**sort_remaining** [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

**ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, …, n - 1.

New in version 1.0.0.

**key** [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the *key* argument in the built-in *sorted()* function, with the notable difference that this *key* function should be *vectorized*. It should expect an *Index* and return an *Index* of the same shape. For MultiIndex inputs, the key is applied per level.

New in version 1.1.0.

**Returns**

*DataFrame or None* The original DataFrame sorted by the labels or None if *inplace=True*.

**See also:**

*Series.sort_index* Sort Series by the index.

*DataFrame.sort_values* Sort DataFrame by the value.

*Series.sort_values* Sort Series by the value.

**Examples**

```python
>>> df = pd.DataFrame([1, 2, 3, 4, 5], index=[100, 29, 234, 1, 150],
                    columns=['A'])
>>> df.sort_index()
   A
1  4
29 2
100 1
150 5
234 3

By default, it sorts in ascending order, to sort in descending order, use *ascending=False*

```python
>>> df.sort_index(ascending=False)
   A
234 3
150 5
100 1
29 2
1  4
```
A key function can be specified which is applied to the index before sorting. For a MultiIndex this is applied to each level separately.

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4]}, index=['A', 'b', 'C', 'd'])
>>> df.sort_index(key=lambda x: x.str.lower())
  a
A  1
b  2
C  3
d  4
```

pandas.DataFrame.sort_values

DataFrame.sort_values(by, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False, key=None)

Sort by the values along either axis.

Parameters

- **by** [str or list of str] Name or list of names to sort by.
  - if axis is 0 or 'index' then by may contain index levels and/or column labels.
  - if axis is 1 or 'columns' then by may contain column levels and/or index labels.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to be sorted.
- **ascending** [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the by.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. mergesort and stable are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if first; last puts NaNs at the end.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
  - New in version 1.0.0.
- **key** [callable, optional] Apply the key function to the values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect a Series and return a Series with the same shape as the input. It will be applied to each column in by independently.
  - New in version 1.1.0.

Returns

- **DataFrame or None** DataFrame with sorted values or None if inplace=True.

See also:

- **DataFrame.sort_index** Sort a DataFrame by the index.
**Series.sort_values**  Similar method for a Series.

### Examples

```python
>>> df = pd.DataFrame({
...     'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2': [2, 1, 9, 8, 7, 4],
...     'col3': [0, 1, 9, 4, 2, 3],
...     'col4': ['a', 'B', 'c', 'D', 'e', 'F']
... })
>>> df
   col1 col2 col3 col4
0    A    2    0    a
1    A    1    1    B
2    B    9    9    c
3  NaN    8    4    D
4    D    7    2    e
5    C    4    3    F
```

Sort by `col1`

```python
>>> df.sort_values(by=['col1'])
   col1 col2 col3 col4
0    A    2    0    a
1    A    1    1    B
2    B    9    9    c
5    C    4    3    F
4    D    7    2    e
3  NaN    8    4    D
```

Sort by multiple columns

```python
>>> df.sort_values(by=['col1', 'col2'])
   col1 col2 col3 col4
1    A    1    1    B
0    A    2    0    a
2    B    9    9    c
5    C    4    3    F
4    D    7    2    e
3  NaN    8    4    D
```

Sort Descending

```python
>>> df.sort_values(by='col1', ascending=False)
   col1 col2 col3 col4
4    D    7    2    e
5    C    4    3    F
2    B    9    9    c
0    A    2    0    a
1    A    1    1    B
3  NaN    8    4    D
```

Putting NAs first
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> df.sort_values(by='col1', ascending=False, na_position='first')
col1  col2  col3  col4
3   NaN   8   4   D
4    D    7   2   e
5    C    4   3   F
2    B    9   9   c
0    A    2   0   a
1    A    1   1   B
```

Sorting with a key function

```python
>>> df.sort_values(by='col4', key=lambda col: col.str.lower())
col1  col2  col3  col4
0    A    2   0   a
1    A    1   1   B
2    B    9   9   c
3   NaN   8   4   D
4    D    7   2   e
5    C    4   3   F
```

Natural sort with the key argument, using the natsort <https://github.com/SethMMorton/natsort> package.

```python
>>> df = pd.DataFrame({
...     "time": ['0hr', '128hr', '72hr', '48hr', '96hr'],
...     "value": [10, 20, 30, 40, 50]
... })
>>> df
   time value
0  0hr   10
1 128hr  20
2 72hr   30
3 48hr   40
4 96hr   50

>>> from natsort import index_natsorted

```python
>>> df.sort_values(  
...     by="time",  
...     key=lambda x: np.argsort(index_natsorted(df["time"])))
   time value
0  0hr   10
3 48hr   40
2 72hr   30
4 96hr   50
1 128hr  20
```
pandas.DataFrame.sparse

DataFrame.sparse()

DataFrame accessor for sparse data.
New in version 0.25.0.

pandas.DataFrame.squeeze

DataFrame.squeeze(axis=None)

Squeeze 1 dimensional axis objects into scalars.
Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call squeeze to ensure you have a Series.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

Returns

DataFrame, Series, or scalar The projection after squeezing axis or all the axes.

See also:

Series.iloc Integer-location based indexing for selecting scalars.
DataFrame.iloc Integer-location based indexing for selecting Series.
Series.to_frame Inverse of DataFrame.squeeze for a single-column DataFrame.

Examples

>>> primes = pd.Series([2, 3, 5, 7])

Slicing might produce a Series with a single value:

>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0  2
dtype: int64

>>> even_primes.squeeze()
2

Squeezing objects with more than one value in every axis does nothing:

>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1  3
2  5
(continues on next page)
Squeezing is even more effective when used with DataFrames.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
>>> df_a = df[['a']]  
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```python
>>> df_a.squeeze('columns')
     a
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```python
>>> df_0a = df.loc[df.index < 1, ['a']]  
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```python
>>> df_0a.squeeze('rows')
   a
0  1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```python
>>> df_0a.squeeze()
1
```
pandas.DataFrame.stack

DataFrame.stack(level=-1, dropna=True)

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

Parameters

level [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

dropna [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

Returns

DataFrame or Series  Stacked dataframe or series.

See also:

DataFrame.unstack  Unstack prescribed level(s) from index axis onto column axis.

DataFrame.pivot  Reshape dataframe from long format to wide format.

DataFrame.pivot_table  Create a spreadsheet-style pivot table as a DataFrame.

Notes

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

Reference the user guide for more examples.

Examples

Single level columns

```python
>>> df_single_level_cols = pd.DataFrame([[[0, 1], [2, 3]],
...                                          index=['cat', 'dog'],
...                                          columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:
>>> df_single_level_cols
   weight  height
  cat     0       1
  dog     2       3
>>> df_single_level_cols.stack()
   weight  height
  cat     0       1
          height  1
  dog     2       2
          height  3
dtype: int64

Multi level columns: simple case

>>> multicoll = pd.MultiIndex.from_tuples([('weight', 'kg'),
                                         ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
                                        index=['cat', 'dog'],
                                        columns=multicoll)

Stacking a dataframe with a multi-level column axis:

>>> df_multi_level_cols1
   weight
  cat  kg  1
        pounds  2
  dog  kg  2
        pounds  4

Missing values

>>> multicoll2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
                                          ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
                                        index=['cat', 'dog'],
                                        columns=multicoll2)

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

>>> df_multi_level_cols2
   weight height
  cat  kg     m
          1.0     2.0
  dog  kg     m
          3.0     4.0

>>> df_multi_level_cols2.stack()
   height  weight
  cat  kg     NaN  1.0
          m     2.0  NaN

(continues on next page)
Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```python
>>> df_multi_level_cols2.stack(0)
  kg  m
cat height NaN 2.0
  weight 1.0 NaN
dog height NaN 4.0
  weight 3.0 NaN
```

```python
>>> df_multi_level_cols2.stack([0, 1])
  cat height m 2.0
    weight kg 1.0
  dog height m 4.0
    weight kg 3.0
dtype: float64
```

Dropping missing values

```python
>>> df_multi_level_cols3 = pd.DataFrame(
    [[None, 1.0], [2.0, 3.0]],
    index=['cat', 'dog'],
    columns=multicol2)
```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the dropna keyword parameter:

```python
>>> df_multi_level_cols3
  weight height
  kg  m
cat NaN 1.0
dog 2.0 3.0
```

```python
>>> df_multi_level_cols3.stack(dropna=False)
  height weight
  cat kg NaN NaN
    m 1.0 NaN
  dog kg NaN 2.0
    m 3.0 NaN
```

```python
>>> df_multi_level_cols3.stack(dropna=True)
  height weight
  cat m 1.0 NaN
dog kg NaN 2.0
    m 3.0 NaN
```
DataFrame.std

DataFrame.std(axis=None, skipna=True, level=None, ddof=1, numeric_only=None, **kwargs)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

- **axis** [[index (0), columns (1)]]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

Notes

To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)

Examples

```python
>>> df = pd.DataFrame({'person_id': [0, 1, 2, 3],
...                    'age': [21, 25, 62, 43],
...                    'height': [1.61, 1.87, 1.49, 2.01]})
...).set_index('person_id')
>>> df
   age  height
person_id
 0   21   1.61
 1   25   1.87
 2   62   1.49
 3   43   2.01

The standard deviation of the columns can be found as follows:

```python
>>> df.std()
age   18.786076
height 0.237417
```

Alternatively, ddof=0 can be set to normalize by N instead of N-1:
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> df.std(ddof=0)
age  16.269219
height  0.205609
```

**pandas.DataFrame.sub**

`DataFrame.sub(other, axis='columns', level=None, fill_value=None)`

Get Subtraction of dataframe and other, element-wise (binary operator `sub`). Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rsub`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `.-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- `Dataframe` Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                   ...                     'degrees': [360, 180, 360],
                   ...                     index=['circle', 'triangle', 'rectangle'])
>>> df
                   angles  degrees
    circle        0       360
    triangle      3       180
    rectangle     4       360
Add a scalar with operator version which return the same results.

>>> df + 1
                   angles  degrees
    circle        1       361
    triangle      4       181
    rectangle     5       361

>>> df.add(1)
                   angles  degrees
    circle        1       361
    triangle      4       181
    rectangle     5       361
Divide by constant with reverse version.

>>> df.div(10)
                   angles  degrees
    circle  0.00      36.0
    triangle  0.30      18.0
    rectangle  0.40      36.0

>>> df.rdiv(10)
                   angles  degrees
    circle    inf      0.027778
    triangle  3.333333  0.055556
    rectangle 2.500000  0.027778
Subtract a list and Series by axis with operator version.

>>> df - [1, 2]
                   angles  degrees
    circle        -1       358
    triangle       2       178
    rectangle       3       358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({
    'angles': [0, 3, 4],
    ... 
    'degrees': [360, 180, 360, 360, 540, 720],
    ... 
    'index': ['A', 'A', 'A', 'B', 'B', 'B'],
    ... 
    ['circle', 'triangle', 'rectangle',
     'square', 'pentagon', 'hexagon']
})
>>> df * other
   angles  degrees
  circle     0       NaN
   triangle   9       NaN
  rectangle  16       NaN
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({
    'angles': [0, 3, 4, 5, 6],
    ... 
    'degrees': [360, 180, 360, 360, 540, 720],
    ... 
    'index': [['A', 'A', 'A', 'B', 'B', 'B'],
               ['circle', 'triangle', 'rectangle',
                'square', 'pentagon', 'hexagon']]
})
>>> df_multindex
   angles  degrees
  A circle     0       360
    triangle   3       180
   rectangle   4       360
  B square     4       360
   pentagon    5       540
   hexagon     6       720
```
```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>circle</td>
</tr>
<tr>
<td></td>
<td>triangle</td>
</tr>
<tr>
<td></td>
<td>rectangle</td>
</tr>
<tr>
<td>B</td>
<td>square</td>
</tr>
<tr>
<td></td>
<td>pentagon</td>
</tr>
<tr>
<td></td>
<td>hexagon</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.subtract**

Dataframe subtract (other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator sub).

Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rsub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [0 or ‘index’, 1 or ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

Dataframe Result of the arithmetic operation.

**See also:**

*DataFrame.add* Add DataFrames.

*DataFrame.sub* Subtract DataFrames.

*DataFrame.mul* Multiply DataFrames.

*DataFrame.div* Divide DataFrames (float division).

*DataFrame.truediv* Divide DataFrames (float division).

*DataFrame.floordiv* Divide DataFrames (integer division).

*DataFrame.mod* Calculate modulo (remainder after division).

*DataFrame.pow* Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                        'degrees': [360, 180, 360],
                        index=['circle', 'triangle', 'rectangle'])

>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle  inf    0.027778
triangle    3.333333  0.055556
rectangle    2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle    -1      358
triangle     2      178
rectangle    3      358
```
 Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                     index=['circle', 'triangle', 'rectangle'])

>>> other
angles
circle  0
triangle 3
rectangle 4

>>> df * other
angles   degrees
circle   0       NaN
triangle 9       NaN
rectangle 16      NaN

>>> df.mul(other, fill_value=0)
angles   degrees
circle   0       0.0
triangle 9       0.0
rectangle 16      0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
...                               'degrees': [360, 180, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                ['circle', 'triangle', 'rectangle',
...                                 'square', 'pentagon', 'hexagon']])

>>> df_multindex
angles   degrees
A circle  0      360
triangle 3      180
rectangle 4      360
B square 4      360
pentagon 5      540
hexagon 6      720
>>> df.div(df_multindex, level=1, fill_value=0)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>circle</td>
</tr>
<tr>
<td></td>
<td>triangle</td>
</tr>
<tr>
<td></td>
<td>rectangle</td>
</tr>
<tr>
<td>B</td>
<td>square</td>
</tr>
<tr>
<td></td>
<td>pentagon</td>
</tr>
<tr>
<td></td>
<td>hexagon</td>
</tr>
</tbody>
</table>

pandas.DataFrame.sum

DataFrame.sum(axis=None, skipna=True, level=None, numeric_only=None, min_count=0, **kwargs)

Return the sum of the values over the requested axis.

This is equivalent to the method numpy.sum.

Parameters

axis [[index (0), columns (1)]] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.
Examples

```python
df = pd.MultiIndex.from_arrays([['warm', 'warm', 'cold', 'cold'], ['dog', 'falcon', 'fish', 'spider']], names=['blooded', 'animal'])
s = pd.Series([4, 2, 0, 8], index=df, name='legs')
s
By default, the sum of an empty or all-NA Series is 0.
```

```python
s.sum()
14
```

This can be controlled with the min_count parameter. For example, if you’d like the sum of an empty series to be NaN, pass min_count=1.

```python
s.sum(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```python
s.sum()  # min_count=0 is the default
0.0
```

```python
s.sum(min_count=1)
nan
```

```python
pd.Series([np.nan]).sum(min_count=1)
nan
```

**pandas.DataFrame.swapaxes**

DataFrame.swapaxes(axis1, axis2, copy=True)

Interchange axes and swap values axes appropriately.

Returns

y [same as input]
pandas.DataFrame.swaplevel

DataFrame.swaplevel(i=-2, j=-1, axis=0)

Swap levels i and j in a MultiIndex.

Default is to swap the two innermost levels of the index.

Parameters

i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] The axis to swap levels on. 0 or ‘index’
for row-wise, 1 or ‘columns’ for column-wise.

Returns

DataFrame DataFrame with levels swapped in MultiIndex.

Examples

```python
>>> df = pd.DataFrame(
...     {"Grade": ["A", "B", "A", "C"],
...      index=[
...             ["Final exam", "Final exam", "Coursework", "Coursework"],
...             ["History", "Geography", "History", "Geography"],
...             ["January", "February", "March", "April"],
...          ],
...     },
... )
>>> df
                      Grade
    Final exam History January     A
                Geography February     B
Coursework History March     A
                Geography April     C
```

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for i and j, we swap the last and second to last indices.

```python
>>> df.swaplevel()
                      Grade
    Final exam January History     A
                February Geography     B
Coursework March History     A
                April Geography     C
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.

```python
>>> df.swaplevel(0)
                      Grade
    January History Final exam     A
                February Geography Final exam     B
Coursework History Coursework     A
                April Geography Coursework     C
```
We can also define explicitly which indices we want to swap by supplying values for both i and j. Here, we for example swap the first and second indices.

```python
>>> df.swaplevel(0, 1)
Grade
History Final exam January A
Geography Final exam February B
History Coursework March A
Geography Coursework April C
```

**pandas.DataFrame.tail**

*DataFrame.tail(n=5)*

Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of n, this function returns all rows except the first n rows, equivalent to df[n:]

**Parameters**

n [int, default 5] Number of rows to select.

**Returns**

*type of caller* The last n rows of the caller object.

**See also:**

*DataFrame.head* The first n rows of the caller object.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
... 'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
animal
0 alligator
1 bee
2 falcon
3 lion
4 monkey
5 parrot
6 shark
7 whale
8 zebra

Viewing the last 5 lines

``` python
>>> df.tail()
animal
4 monkey
5 parrot
```
Viewing the last $n$ lines (three in this case)

```python
>>> df.tail(3)
   animal
6   shark
7   whale
8   zebra
```

For negative values of $n$

```python
>>> df.tail(-3)
   animal
3   lion
4   monkey
5   parrot
6   shark
7   whale
8   zebra
```

**pandas.DataFrame.take**

`DataFrame.take(indices, axis=0, is_copy=None, **kwargs)`

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- `indices` [array-like] An array of ints indicating which positions to take.
- `axis` [[0 or ‘index’, 1 or ‘columns’, None], default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- `is_copy` [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

- **kwargs For compatibility with `numpy.take()` Has no effect on the output.

**Returns**

- `taken` [same type as caller] An array-like containing the elements taken from the object.

**See also:**

- `DataFrame.loc` Select a subset of a DataFrame by labels.
- `DataFrame.iloc` Select a subset of a DataFrame by positions.
- `numpy.take` Take elements from an array along an axis.
Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                      ('parrot', 'bird', 24.0),
...                      ('lion', 'mammal', 80.5),
...                      ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon   bird       389.0
2  parrot   bird        24.0
3   lion  mammal        80.5
1  monkey  mammal         NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
   name  class  max_speed
0  falcon   bird       389.0
1  monkey  mammal         NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
>>> df.take([1, 2], axis=1)
   class  max_speed
0    bird       389.0
2    bird        24.0
3  mammal        80.5
1  mammal         NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
   name  class  max_speed
1  monkey  mammal         NaN
3   lion  mammal        80.5
```

`pandas.DataFrame.to_dict`

`DataFrame.to_dict(orient='dict', into=<class 'dict'>)`

Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

**Parameters**

- ‘dict’ (default) : dict like {column -> {index -> value}}
• ‘list’ : dict like {column -> [values]}
• ‘series’ : dict like {column -> Series(values)}
• ‘split’ : dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
• ‘tight’ : dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values],
  ‘index_names’ -> [index.names], ‘column_names’ -> [column.names]}
• ‘records’ : list like [{column -> value}, ..., {column -> value}]
• ‘index’ : dict like {index -> {column -> value}}

Abbreviations are allowed. s indicates series and sp indicates split.

New in version 1.4.0: ‘tight’ as an allowed value for the orient argument

Returns

dict, list or collections.abc.Mapping Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the orient parameter.

See also:

DataFrame.from_dict Create a DataFrame from a dictionary.
DataFrame.to_json Convert a DataFrame to JSON format.

Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2],
...                     'col2': [0.5, 0.75],
...                     index=['row1', 'row2'])

>>> df
   col1  col2  
row1  1  0.50
row2  2  0.75

>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}
```

You can specify the return orientation.

```python
>>> df.to_dict('series')
{'col1': row1 1
  row2 2
Name: col1, dtype: int64,
'col2': row1 0.50
  row2 0.75
Name: col2, dtype: float64}

>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
 'data': [[1, 0.5], [2, 0.75]]}
```
```
>>> df.to_dict('records')
[['col1': 1, 'col2': 0.5}, {'col1': 2, 'col2': 0.75}]
```

```
>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}
```

```
>>> df.to_dict('tight')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
'data': [[1, 0.5], [2, 0.75]], 'index_names': [None], 'column_names': [None]}
```

You can also specify the mapping type.

```
>>> from collections import OrderedDict, defaultdict
```

```
>>> df.to_dict(into=OrderedDict)  
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)])),
('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])
```

If you want a `defaultdict`, you need to initialize it:

```
>>> dd = defaultdict(list)
```

```
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```

### pandas.DataFrame.to_gbq

DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', 
auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, 
credentials=None)

Write a DataFrame to a Google BigQuery table.

This function requires the pandas-gbq package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

**Parameters**

- **destination_table** [str] Name of table to be written, in the form dataset.tablename.
- **project_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.
- **chunksize** [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to None to load the whole dataframe at once.
- **reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.
- **if_exists** [str, default ‘fail’] Behavior when the destination table exists. Value can be one of:
  - 'fail' If table exists raise pandas_gbq.gbq.TableCreationError.
  - 'replace' If table exists, drop it, recreate it, and insert data.
  - 'append' If table exists, insert data. Create if does not exist.
auth_local_webserver  [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.

New in version 0.2.0 of pandas-gbq.

table_schema  [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. [{'name': 'col1', 'type': 'STRING'}, ...]. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

New in version 0.3.1 of pandas-gbq.

location  [str, optional] Location where the load job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of the target dataset.

New in version 0.5.0 of pandas-gbq.

progress_bar  [bool, default True] Use the library tqdm to show the progress bar for the upload, chunk by chunk.

New in version 0.5.0 of pandas-gbq.

credentials  [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.

New in version 0.8.0 of pandas-gbq.

See also:

pandas_gbq.to_gbq  This function in the pandas-gbq library.

read_gbq  Read a DataFrame from Google BigQuery.

pandas.DataFrame.to_hdf

```
pandas.DataFrame.to_hdf(path_or_buf, key, mode='a', complevel=None, complib=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None, data_columns=None, errors='strict', encoding='UTF-8')
```

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

Warning:  One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

For more information see the user guide.

Parameters

path_or_buf  [str or pandas.HDFStore] File path or HDFStore object.
**key** [str] Identifier for the group in the store.

**mode** [(‘a’, ‘w’, ‘r+’), default ‘a’] Mode to open file:
- ‘w’: write, a new file is created (an existing file with the same name would be deleted).
- ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- ‘r+’: similar to ‘a’, but the file must already exist.

**complevel** [{0-9}, default None] Specifies a compression level for data. A value of 0 or None disables compression.

**append** [bool, default False] For Table formats, append the input data to the existing.

**format** [(‘fixed’, ‘table’, None), default ‘fixed’] Possible values:
- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”.

**errors** [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

**encoding** [str, default “UTF-8”]

**min_itemsize** [dict or int, optional] Map column names to minimum string sizes for columns.

**nan_rep** [Any, optional] How to represent null values as str. Not allowed with append=True.

**data_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via data columns. Applicable only to format=‘table’.

See also:

* **read_hdf** Read from HDF file.

* **DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

* **DataFrame.to_sql** Write to a SQL table.

* **DataFrame.to_feather** Write out feather-format for DataFrames.

* **DataFrame.to_csv** Write out to a csv file.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A    B
a  1   4
b  2   5
c  3   6

>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

pandas.DataFrame.to_markdown

DataFrame.to_markdown(buf=None, mode='wt', index=True, storage_options=None, **kwargs)
Print DataFrame in Markdown-friendly format.
New in version 1.0.0.

Parameters

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **mode** [str, optional] Mode in which file is opened, “wt” by default.
- **index** [bool, optional, default True] Add index (row) labels.
  New in version 1.1.0.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.
  New in version 1.2.0.
- **kwargs** These parameters will be passed to tabulate.

Returns

- **str** DataFrame in Markdown-friendly format.
Notes

Requires the `tabulate` package.

Examples

```python
>>> df = pd.DataFrame(
...     data={"animal_1": ["elk", "pig"], "animal_2": ["dog", "quetzal"]}
... )
>>> print(df.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>animal_1</th>
<th>animal_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
<td>dog</td>
</tr>
<tr>
<td>1</td>
<td>pig</td>
<td>quetzal</td>
</tr>
</tbody>
</table>
```

Output markdown with a tabulate option.

```python
>>> print(df.to_markdown(tablefmt="grid"))
+----+------------+------------+
<table>
<thead>
<tr>
<th></th>
<th>animal_1</th>
<th>animal_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
<td>dog</td>
</tr>
</tbody>
</table>
+----+------------+------------+
```

**pandas.DataFrame.to_numpy**

DataFrame.to_numpy(dtype=None, copy=False, na_value=NoDefault.no_default)

Convert the DataFrame to a NumPy array.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

**Parameters**

- **dtype** [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
- **copy** [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.
- **na_value** [Any, optional] The value to use for missing values. The default value depends on `dtype` and the dtypes of the DataFrame columns.

New in version 1.1.0.

**Returns**

- **numpy.ndarray**

**See also:**

- **Series.to_numpy** Similar method for Series.
Examples

```python
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogeneous data, the lowest common type will have to be used.

```python
>>> df = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
>>> df.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```python
>>> df["C"] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

**pandas.DataFrame.to_period**

**DataFrame.to_period**(freq=None, axis=0, copy=True)

Convert DataFrame from DatetimeIndex to PeriodIndex.

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

**Parameters**

- **freq** [str, default] Frequency of the PeriodIndex.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).
- **copy** [bool, default True] If False then underlying input data is not copied.

**Returns**

DataFrame with PeriodIndex

**Examples**

```python
>>> idx = pd.to_datetime(
...     ["2001-03-31 00:00:00",
...      "2002-05-31 00:00:00",
...      "2003-08-31 00:00:00"],
...     )
```

```python
>>> idx
DatetimeIndex(['2001-03-31', '2002-05-31', '2003-08-31'],
          dtype='datetime64[ns]', freq=None)
```
>>> idx.to_period("M")
PeriodIndex(['2001-03', '2002-05', '2003-08'], dtype='period[M]')

For the yearly frequency

>>> idx.to_period("Y")
PeriodIndex(['2001', '2002', '2003'], dtype='period[A-DEC]')

pandas.DataFrame.to_records

DataFrame.to_records(index=True, column_dtypes=None, index_dtypes=None)

Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

Parameters

- **index** [bool, default True] Include index in resulting record array, stored in ‘index’ field or using the index label, if set.
- **column_dtypes** [str, type, dict, default None] If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.
- **index_dtypes** [str, type, dict, default None] If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if index=True.

Returns

- **numpy.recarray** NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

See also:

DataFrame.from_records  Convert structured or record ndarray to DataFrame.

numpy.recarray  An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
                    index=['a', 'b'])
>>> df
   A   B
a  1  0.50
b  2  0.75
>>> df.to_records()
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[(b'index', 'O'), (b'A', '<f8'), (b'B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to ‘index’. If the index has a label then this is used as the field name:
```python
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([("a", 1, 0.5 ), ("b", 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8'))]
```

The index can be excluded from the record array:

```python
>>> df.to_records(index=False)
rec.array([(1, 0.5 ), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8'))])
```

Data types can be specified for the columns:

```python
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([("a", 1, 0.5 ), ("b", 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8'))])
```

As well as for the index:

```python
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8'))])
```

```python
>>>
index_dtypes = f"<S{df.index.str.len().max()}"
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([("I", 'S1'), ('A', '<i8'), ('B', '<f8'))])
```

**pandas.DataFrame.to_string**

DataFrame.to_string(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, max_cols=None, show_dimensions=False, decimal='.', line_width=None, min_rows=None, max_colwidth=None, encoding=None)

Render a DataFrame to a console-friendly tabular output.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.
- **col_space** [int, list or dict of int, optional] The minimum width of each column. If a list of ints is given every integers corresponds with one column. If a dict is given, the key references the column, while the value defines the space to use.
- **header** [bool or sequence of str, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- **index** [bool, optional, default True] Whether to print index (row) labels.
- **na_rep** [str, optional, default 'NaN'] String representation of NaN to use.
formatters  [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format  [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-
NaN elements, with NaN being handled by na_rep.

Changed in version 1.2.0.

sparsify  [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names  [bool, optional, default True] Prints the names of the indexes.

justify  [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are

• left
• right
• center
• justify
• justify-all
• start
• end
• inherit
• match-parent
• initial
• unset.

max_rows  [int, optional] Maximum number of rows to display in the console.

max_cols  [int, optional] Maximum number of columns to display in the console.

show_dimensions  [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal  [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

line_width  [int, optional] Width to wrap a line in characters.

min_rows  [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above max_rows).

max_colwidth  [int, optional] Max width to truncate each column in characters. By default, no limit.

New in version 1.0.0.

encoding  [str, default “utf-8”] Set character encoding.

New in version 1.0.

Returns

str or None  If buf is None, returns the result as a string. Otherwise returns None.
See also:

\[ \text{to\_html} \] Convert DataFrame to HTML.

**Examples**

```
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
   col1  col2
  0    1    4
  1    2    5
  2    3    6
```

**pandas.DataFrame.to\_timestamp**

\[ \text{DataFrame.to\_timestamp} \] (\(freq=\text{None}, \text{how}='\text{start}', \text{axis}=0, \text{copy}=\text{True}\))

Cast to DatetimeIndex of timestamps, at \textit{beginning} of period.

**Parameters**

- **freq** [str, default frequency of PeriodIndex] Desired frequency.
- **how** [{‘s’, ‘e’, ‘start’, ‘end’}] Convention for converting period to timestamp: start of period vs. end.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to convert (the index by default).
- **copy** [bool, default True] If False then underlying input data is not copied.

**Returns**

DataFrame with DatetimeIndex

**pandas.DataFrame.to\_xarray**

\[ \text{DataFrame.to\_xarray} \]()

Return an xarray object from the pandas object.

**Returns**

\text{xarray.DataArray} or \text{xarray.Dataset} Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

\[ \text{DataFrame.to\_hdf} \] Write DataFrame to an HDF5 file.

\[ \text{DataFrame.to\_parquet} \] Write a DataFrame to the binary parquet format.
Notes

See the xarray docs

Examples

```python
>>> df = pd.DataFrame([(
    'falcon', 'bird', 389.0, 2),
    ('parrot', 'bird', 24.0, 2),
    ('lion', 'mammal', 80.5, 4),
    ('monkey', 'mammal', np.nan, 4),
),
    columns=['name', 'class', 'max_speed', 'num_legs'])
```
```python
df
```
```python
dataframe
name class max_speed num_legs
0   falcon   bird   389.0    2
1   parrot   bird    24.0    2
2    lion   mammal   80.5    4
3  monkey   mammal      NaN    4
```
```python
>>> df.to_xarray()
<xarray.Dataset
Dimensions: (index: 4)
Coordinates:
* index (index) int64 0 1 2 3
Data variables:
name (index) object 'falcon' 'parrot' 'lion' 'monkey'
class (index) object 'bird' 'bird' 'mammal' 'mammal'
max_speed (index) float64 389.0 24.0 80.5 nan
num_legs (index) int64 2 2 4 4
```
```python
>>> df[['max_speed']].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389., 24., 80.5, nan])
```
```python
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
                        '2018-01-02', '2018-01-02'])
```
```python
df_multiindex = pd.DataFrame({'date': dates,
    'animal': ['falcon', 'parrot', 'falcon', 'parrot'],
    'speed': [350, 18, 361, 15]})
```
```python
df_multiindex = df_multiindex.set_index(['date', 'animal'])
```
```python
df_multiindex
```
```python
date   animal  speed
2018-01-01   falcon    350
             parrot     18
2018-01-02   falcon    361
             parrot     15
```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
  * date   (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal (animal) object 'falcon' 'parrot'
Data variables:
   speed   (date, animal) int64 350 18 361 15

pandas.DataFrame.transform

DataFrame.transform(func, axis=0, *args, **kwargs)

Call func on self producing a DataFrame with the same axis shape as self.

Parameters

  func [function, str, list-like or dict-like] Function to use for transforming the data.
  If a function, must either work when passed a DataFrame or when passed to
  DataFrame.apply. If func is both list-like and dict-like, dict-like behavior takes
  precedence.
  Accepted combinations are:
  • function
  • string function name
  • list-like of functions and/or function names, e.g. [np.exp, 'sqrt']
  • dict-like of axis labels -> functions, function names or list-like of such.

  axis [[0 or 'index', 1 or 'columns'], default 0] If 0 or 'index': apply function to each
  column. If 1 or 'columns': apply function to each row.
  *args Positional arguments to pass to func.
  **kwargs Keyword arguments to pass to func.

Returns

DataFrame A DataFrame that must have the same length as self.

Raises

ValueError [If the returned DataFrame has a different length than self.]

See also:

DataFrame.agg Only perform aggregating type operations.
DataFrame.apply Invoke function on a DataFrame.
Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported.
See Mutating with User Defined Function (UDF) methods for more details.

Examples

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
    A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
    A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0  0
1  1
2  2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
          sqrt    exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

You can call transform on a GroupBy object:

```python
>>> df = pd.DataFrame(
...     ...
...     "Date": [
...     ...
...     ...
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120],
...     ...
... )
>>> df
       Date  Data
0  2015-05-08    5
1  2015-05-07    8
2  2015-05-06    6
3  2015-05-05    1
4  2015-05-08   50
5  2015-05-07  100
6  2015-05-06   60
7  2015-05-05  120
>>> df.groupby('Date')['Data'].transform('sum')
```

(continues on next page)
```python
>>> df = pd.DataFrame({
...     "c": [1, 1, 1, 2, 2, 2, 2],
...     "type": ["m", "n", "o", "m", "m", "n", "n"]
... })
>>> df
   c  type
0  1    m
1  1    n
2  1    o
3  2    m
4  2    m
5  2    n
6  2    n
>>> df['size'] = df.groupby('c')['type'].transform(len)
>>> df
   c  type size
0  1    m   3
1  1    n   3
2  1    o   3
3  2    m   4
4  2    m   4
5  2    n   4
6  2    n   4
```

`pandas.DataFrame.transpose`

DataFrame.transpose(*args, copy=False)

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property `T` is an accessor to the method `transpose()`.

**Parameters**

*args [tuple, optional] Accepted for compatibility with NumPy.

**copy** [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtype.

Note that a copy is always required for mixed dtype DataFrames, or for DataFrames with any extension types.

**Returns**
**DataFrame**  The transposed DataFrame.

See also:

- `numpy.transpose` Permute the dimensions of a given array.

**Notes**

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

**Examples**

**Square DataFrame with homogeneous dtype**

```python
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
  col1  col2
0    1    3
1    2    4

>>> df1_transposed = df1.T  # or df1.transpose()
>>> df1_transposed
   0 1
col1 1 2
col2 3 4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```python
>>> df1.dtypes
col1  int64
col2  int64
dtype: object
>>> df1_transposed.dtypes
0     int64
1     int64
dtype: object
```

**Non-square DataFrame with mixed dtypes**

```python
>>> d2 = {'name': ['Alice', 'Bob'],
        'score': [9.5, 8],
        'employed': [False, True],
        'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
     name  score employed  kids
0   Alice   9.5      False   0
1     Bob   8.0       True   0
```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed

<table>
<thead>
<tr>
<th></th>
<th>Alice</th>
<th>Bob</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>9.5</td>
<td>8.0</td>
</tr>
<tr>
<td>1</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the `object` dtype:

```python
>>> df2.dtypes
name    object
score   float64
employed  bool
kids    int64
```

```python
>>> df2_transposed.dtypes
0 object
1 object
dtype: object
```

**pandas.DataFrame.truediv**

DataFrame.truediv(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
**DataFrame.div**  Divide DataFrames (float division).

**DataFrame.truediv**  Divide DataFrames (float division).

**DataFrame.floordiv**  Divide DataFrames (integer division).

**DataFrame.mod**  Calculate modulo (remainder after division).

**DataFrame.pow**  Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
In [1]: df = pd.DataFrame({'angles': [0, 3, 4],
                      'degrees': [360, 180, 360],
                      'index': ['circle', 'triangle', 'rectangle']})

In [2]: df
Out[2]:
   angles  degrees
box  0   360
triangle  3   180
rectangle  4   360
```

Add a scalar with operator version which return the same results.

```python
In [3]: df + 1
Out[3]:
   angles  degrees
box  1   361
triangle  4   181
rectangle  5   361
```

```python
In [4]: df.add(1)
```

Divide by constant with reverse version.

```python
In [5]: df.div(10)
Out[5]:
   angles  degrees
box  0.0  36.0
triangle  0.3  18.0
rectangle  0.4  36.0
```

```python
In [6]: df.rdiv(10)
Out[6]:
   angles  degrees
box  inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.
>>> df = [1, 2]
   angles  degrees
  circle   -1     358
    triangle  2     178
    rectangle  3     358

>>> df.sub([1, 2], axis='columns')
   angles  degrees
  circle   -1     358
    triangle  2     178
    rectangle  3     358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
          axis='index')
   angles  degrees
  circle   -1     359
    triangle  2     179
    rectangle  3     359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                           index=['circle', 'triangle', 'rectangle'])

>>> other
    angles
  circle    0
    triangle    3
    rectangle    4

>>> df * other
   angles  degrees
  circle  0.0     NaN
    triangle  9.0     NaN
    rectangle 16.0     NaN

>>> df.mul(other, fill_value=0)
   angles  degrees
  circle  0.0     0.0
    triangle  9.0     0.0
    rectangle 16.0     0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                              'degrees': [360, 180, 360, 540, 720],
                              index=['A', 'A', 'A', 'B', 'B'],
                              ['circle', 'triangle', 'rectangle',
                               'square', 'pentagon', 'hexagon'])

>>> df_multindex
         angles  degrees
     A circle    0     360
     A triangle    3     180
     A rectangle    5     720
     B circle    0     360
     B triangle    3     180
     B rectangle    5     720
     B square    0     720
     B pentagon    3     720
     B hexagon    5     720
rectangle  4   360
B square   4   360
pentagon   5   540
hexagon    6   720

```python
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
   A  circle    NaN   1.0
     triangle   1.0   1.0
    rectangle   1.0   1.0
   B  square    0.0   0.0
     pentagon   0.0   0.0
    hexagon    0.0   0.0
```

**pandas.DataFrame.truncate**

Dataframe.truncate(before=None, after=None, axis=None, copy=True)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True.] Return a copy of the truncated section.

**Returns**

- **type of caller** The truncated Series or DataFrame.

**See also:**

- Dataframe.loc Select a subset of a DataFrame by label.
- Dataframe.iloc Select a subset of a DataFrame by position.

**Notes**

If the index being truncated contains only datetime values, before and after may be specified as strings instead of Timestamps.
Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
                    'B': ['f', 'g', 'h', 'i', 'j'],
                    'C': ['k', 'l', 'm', 'n', 'o']},
                   index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
0  a  f  k
1  b  g  l
2  c  h  m
3  d  i  n
4  e  j  o
```

The columns of a DataFrame can be truncated.

```python
>>> df.truncate(before=2, after=4)
   A  B  C
0  b  g  l
1  c  h  m
2  d  i  n
```

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
    A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```python
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
              after=pd.Timestamp('2016-01-10')).tail()
```

(continues on next page)
Because the index is a DatetimeIndex containing only dates, we can specify before and after as strings. They will be coerced to Timestamps before truncation.

```python
>>> df.truncate('2016-01-05', '2016-01-10').tail()
   A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```python
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
   A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

### pandas.DataFrame.tshift

**DataFrame.tshift(periods=1, freq=None, axis=0)**

Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use `shift` instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.
- **freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] Corresponds to the axis that contains the Index.

**Returns**

- **shifted** [Series/DataFrame]
Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.DataFrame.tz_convert

**DataFrame.tz_convert**(tz, axis=0, level=None, copy=True)

Convert tz-aware axis to target time zone.

**Parameters**

- **tz** [str or tzinfo object]
- **axis** [the axis to convert]
- **level** [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.
- **copy** [bool, default True] Also make a copy of the underlying data.

**Returns**

-{klass} Object with time zone converted axis.

**Raises**

- **TypeError** If the axis is tz-naive.

pandas.DataFrame.tz_localize

**DataFrame.tz_localize**(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use Series.dt.tz_localize().

**Parameters**

- **tz** [str or tzinfo]
- **axis** [the axis to localize]
- **level** [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.
- **copy** [bool, default True] Also make a copy of the underlying data.
- **ambiguous** ['infer', bool-narray, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-narray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent [str, default ‘raise’] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```python
>>> s = pd.Series([1],
                index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.Series(range(7),
                index=pd.DatetimeIndex(['2018-10-28 01:30:00',
                                         '2018-10-28 02:00:00',
                                         '2018-10-28 02:30:00',
                                         '2018-10-28 02:00:00',
                                         '2018-10-28 02:30:00',
                                         '2018-10-28 03:00:00',
                                         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly.
If the DST transition causes nonexistent times, you can shift these dates forward or backward with a `timedelta` object or 'shift_forward' or 'shift_backward'.

```python
>>> s = pd.Series(range(2),
    index=pd.DatetimeIndex(['2015-03-29 02:30:00',
    '2015-03-29 03:30:00']))

>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64

>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64

>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
```

### pandas.DataFrame.unstack

DataFrame.unstack(level=-1, fill_value=None)

Pivot a level of the (necessarily hierarchical) index labels.

Returns a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex).

**Parameters**

- **level** [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.

- **fill_value** [int, str or dict] Replace NaN with this value if the unstack produces missing values.

**Returns**

Series or DataFrame

**See also:**

DataFrame.pivot Pivot a table based on column values.
**DataFrame.stack** Pivot a level of the column labels (inverse operation from unstack).

**Notes**

Reference the user guide for more examples.

**Examples**

```python
>>> index = pd.MultiIndex.from_tuples([("one", 'a'), ('one', 'b'),
... ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one a 1.0
  b 2.0
two a 3.0
  b 4.0
dtype: float64

>>> s.unstack(level=-1)
a  b
one 1.0 2.0
two 3.0 4.0

>>> s.unstack(level=0)
one two
  a 1.0 3.0
  b 2.0 4.0

>>> df = s.unstack(level=0)
>>> df.unstack()
one a 1.0
  b 2.0
two a 3.0
  b 4.0
dtype: float64
```

**pandas.DataFrame.update**

**DataFrame.update**(other, join='left', overwrite=True, filter_func=None, errors='ignore')

Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

**Parameters**

- **other** [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

- **join** ["left", default='left'] Only left join is implemented, keeping the index and columns of the original object.
overwrite  [bool, default True] How to handle non-NA values for overlapping keys:

• True: overwrite original DataFrame’s values with values from other.
• False: only update values that are NA in the original DataFrame.

filter_func  [callable(1d-array)->bool1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

errors  [(‘raise’, ‘ignore’), default ‘ignore’] If ‘raise’, will raise a ValueError if the DataFrame and other both contain non-NA data in the same place.

Returns

None  [method directly changes calling object]

Raises

ValueError

• When errors=’raise’ and there’s overlapping non-NA data.
• When errors is not either ‘ignore’ or ‘raise’

NotImplementedError

• If join != ‘left’

See also:

dict.update  Similar method for dictionaries.
DataFrame.merge  For column(s)-on-column(s) operations.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
... 'B': [400, 500, 600]})

>>> new_df = pd.DataFrame({'B': [4, 5, 6],
... 'C': [7, 8, 9]})

>>> df.update(new_df)

>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame’s length does not increase as a result of the update, only values at matching index/column labels are updated.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
... 'B': ['x', 'y', 'z']})

>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})

>>> df.update(new_df)

>>> df
   A   B
0  a   d
1  b   e
2  c   f
```
For Series, its name attribute must be set.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
                    'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A   B
0  a   d
1  b   y
2  c   e
```

If other contains NaNs the corresponding values are not updated in the original dataframe.

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A   B
0  1  4.0
1  2  500.0
2  3  6.0
```

**pandas.DataFrame.value_counts**

DataFrame.value_counts(subset=None, normalize=False, sort=True, ascending=False, dropna=True)

Return a Series containing counts of unique rows in the DataFrame.

New in version 1.1.0.

**Parameters**

- **subset** [list-like, optional] Columns to use when counting unique combinations.
- **normalize** [bool, default False] Return proportions rather than frequencies.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.
- **dropna** [bool, default True] Don’t include counts of rows that contain NA values.

New in version 1.3.0.

**Returns**

Series
See also:

* **Series.value_counts** Equivalent method on Series.

Notes

The returned Series will have a MultiIndex with one level per input column. By default, rows that contain any NA values are omitted from the result. By default, the resulting Series will be in descending order so that the first element is the most frequently-occurring row.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 4, 6],
...                    'num_wings': [2, 0, 0, 0]},
...                   index=['falcon', 'dog', 'cat', 'ant'])
>>> df
   num_legs num_wings
falcon     2         2
dog        4         0
cat        4         0
ant        6         0

>>> df.value_counts()
   num_legs  num_wings
4         0             2
2         2             1
6         0             1
dtype: int64

>>> df.value_counts(sort=False)
   num_legs  num_wings
2         2             1
4         0             2
6         0             1
dtype: int64

>>> df.value_counts(ascending=True)
   num_legs  num_wings
2         2             1
6         0             1
4         0             2
dtype: int64

>>> df.value_counts(normalize=True)
   num_legs  num_wings
4         0             0.50
2         2             0.25
6         0             0.25
dtype: float64
```

With `dropna` set to `False` we can also count rows with NA values.
```python
>> df = pd.DataFrame({'first_name': ['John', 'Anne', 'John', 'Beth'],
                    'middle_name': ['Smith', pd.NA, pd.NA, 'Louise']})
>> df
       first_name  middle_name
0        John       Smith
1       Anne       <NA>
2        John          NaN
3       Beth      Louise

>>> df.value_counts()
first_name  middle_name
Beth  Louise    1
John  Smith     1

dtype: int64

>>> df.value_counts(dropna=False)
first_name  middle_name
Anne        NaN     1
Beth  Louise    1
John  Smith     1
       NaN     1

dtype: int64

pandas.DataFrame.var

DataFrame.var(axis=None, skipna=True, level=None, ddof=1, numeric_only=None, **kwargs)
Return unbiased variance over requested axis.
Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters
axis [[index (0), columns (1)]]
skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
Series or DataFrame (if level specified)
Examples

```python
>>> df = pd.DataFrame({'person_id': [0, 1, 2, 3],
...     'age': [21, 25, 62, 43],
...     'height': [1.61, 1.87, 1.49, 2.01]})
>>> df.set_index('person_id')
   age  height
person_id
  0  21.0   1.61
  1  25.0   1.87
  2  62.0   1.49
  3  43.0   2.01
```

```python
>>> df
   age  height
person_id
  0  21.0   1.61
  1  25.0   1.87
  2  62.0   1.49
  3  43.0   2.01
```

```python
>>> df.var()
age  352.916667
height  0.056367
```

Alternatively, ddof=0 can be set to normalize by N instead of N-1:

```python
>>> df.var(ddof=0)
age  264.687500
height  0.042275
```

### pandas.DataFrame.where

`DataFrame.where(cond, other=NoDefault.no_default, inplace=False, axis=None, level=None, errors=\'raise\', try_cast=NoDefault.no_default)`

Replace values where the condition is False.

**Parameters**

- `cond` [bool Series/DataFrame, array-like, or callable] Where `cond` is True, keep the original value. Where False, replace with corresponding value from `other`. If `cond` is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- `other` [scalar, Series/DataFrame, or callable] Entries where `cond` is False are replaced with corresponding value from `other`. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- `inplace` [bool, default False] Whether to perform the operation in place on the data.

- `axis` [int, default None] Alignment axis if needed.

- `level` [int, default None] Alignment level if needed.

- `errors` [str, \{'raise', 'ignore', \} default 'raise'] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

  - `raise` : allow exceptions to be raised.
  - `ignore` : suppress exceptions. On error return original object.
try_cast  [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if inplace=True.

See also:

DataFrame.mask() Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is True the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the where documentation in indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0   NaN
1  1.0
2  2.0
3  3.0
4  4.0
dtype: float64

>>> s.mask(s > 0)
0   0.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

>>> s.where(s > 1, 10)
0   10
1   10
2   2
3   3
4   4
dtype: int64

>>> s.mask(s > 1, 10)
0   0
1   1
2   10
3   10
4   10
dtype: int64
```
```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9

>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0 -1  1
1 -2  3
2 -4  5
3 -6  7
4 -8  9

>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True True
1  True True
2  True True
3  True True
4  True True

>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0  True True
1  True True
2  True True
3  True True
4  True True
```

pandas.DataFrame.xs

DataFrame.xs(key, axis=0, level=None, drop_level=True)

Return cross-section from the Series/DataFrame.

This method takes a key argument to select data at a particular level of a MultiIndex.

Parameters

- **key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.
- **level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- **drop_level** [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:
**DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.

**DataFrame.iloc** Purely integer-location based indexing for selection by position.

**Notes**

`xs` can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of `xs` functionality, see `MultiIndex Slicers`.

**Examples**

```python
>>> d = {'num_legs': [4, 4, 2, 2],
       'num_wings': [0, 0, 2, 2],
       'class': ['mammal', 'mammal', 'mammal', 'bird'],
       'animal': ['cat', 'dog', 'bat', 'penguin'],
       'locomotion': ['walks', 'walks', 'flies', 'walks']}

>>> df = pd.DataFrame(data=d)

>>> df = df.set_index(['class', 'animal', 'locomotion'])

>>> df
            num_legs  num_wings
    class  animal  locomotion
    mammal  cat      walks   4     0
    dog      walks   4     0
    bat      flies    2     2
    bird  penguin  walks   2     2

Get values at specified index

```python
>>> df.xs('mammal')
animal  locomotion
    cat      walks   4     0
    dog      walks   4     0
    bat      flies    2     2
```

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
locomotion
    walks   4     0
```

Get values at specified index and level

```python
>>> df.xs('cat', level=1)
class  locomotion
    mammal  walks   4     0
```

Get values at several indexes and levels
Get values at specified column and axis

```python
>>> df.xs('num_wings', axis=1)
class    animal  locomotion
mammal  cat      walks  0
         dog      walks  0
         bat      flies  2
bird    penguin  walks  2
Name: num_wings, dtype: int64
```

### 3.4.2 Attributes and underlying data

**Axes**

- `DataFrame.index`: The index (row labels) of the DataFrame.
- `DataFrame.columns`: The column labels of the DataFrame.

```python
DataFrame.dtypes
```

Return the dtypes in the DataFrame.

```python
DataFrame.info([verbose, buf, max_cols, ...])
```

Print a concise summary of a DataFrame.

```python
DataFrame.select_dtypes([include, exclude])
```

Return a subset of the DataFrame's columns based on the column dtypes.

```python
DataFrame.values
```

Return a Numpy representation of the DataFrame.

```python
DataFrame.axes
```

Return a list representing the axes of the DataFrame.

```python
DataFrame.ndim
```

Return an int representing the number of axes / array dimensions.

```python
DataFrame.size
```

Return an int representing the number of elements in this object.

```python
DataFrame.shape
```

Return a tuple representing the dimensionality of the DataFrame.

```python
DataFrame.memory_usage([index, deep])
```

Return the memory usage of each column in bytes.

```python
DataFrame.empty
```

Indicator whether Series/DataFrame is empty.

```python
DataFrame.set_flags(*[, copy, ...])
```

Return a new object with updated flags.

### 3.4.3 Conversion

- `DataFrame.astype(dtype[, copy, errors])`: Cast a pandas object to a specified dtype `dtype`.
- `DataFrame.convert_dtypes([infer_objects, ...])`: Convert columns to best possible dtypes using dtypes supporting `pd.NA`.
- `DataFrame.infer_objects()`: Attempt to infer better dtypes for object columns.
- `DataFrame.copy([deep])`: Make a copy of this object's indices and data.
- `DataFrame.bool()`: Return the bool of a single element Series or DataFrame.
3.4.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.head(n)</td>
<td>Return the first $n$ rows.</td>
</tr>
<tr>
<td>DataFrame.at</td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td>DataFrame.iat</td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td>DataFrame.loc</td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td>DataFrame.iloc</td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td>DataFrame.insert</td>
<td>Insert column into DataFrame at specified location.</td>
</tr>
<tr>
<td>DataFrame.<strong>iter</strong></td>
<td>Iterate over info axis.</td>
</tr>
<tr>
<td>DataFrame.items</td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
<tr>
<td>DataFrame.iteritems</td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
<tr>
<td>DataFrame.keys</td>
<td>Get the 'info axis' (see Indexing for more).</td>
</tr>
<tr>
<td>DataFrame.iterrows</td>
<td>Iterate over DataFrame rows as (index, Series) pairs.</td>
</tr>
<tr>
<td>DataFrame.itertuples</td>
<td>Iterate over DataFrame rows as namedtuples.</td>
</tr>
<tr>
<td>DataFrame.lookup</td>
<td>(DEPRECATED) Label-based &quot;fancy indexing&quot; function for DataFrame.</td>
</tr>
<tr>
<td>DataFrame.pop</td>
<td>Return item and drop from frame.</td>
</tr>
<tr>
<td>DataFrame.tail(n)</td>
<td>Return the last $n$ rows.</td>
</tr>
<tr>
<td>DataFrame.xs(key[, axis, level, drop_level])</td>
<td>Return cross-section from the Series/DataFrame.</td>
</tr>
<tr>
<td>DataFrame.get(key[, default])</td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>
<tr>
<td>DataFrame.isin(values)</td>
<td>Whether each element in the DataFrame is contained in values.</td>
</tr>
<tr>
<td>DataFrame.where(cond[, other, inplace, ...])</td>
<td>Replace values where the condition is False.</td>
</tr>
<tr>
<td>DataFrame.mask(cond[, other, inplace, axis, ...])</td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td>DataFrame.query(expr[, inplace])</td>
<td>Query the columns of a DataFrame with a boolean expression.</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.__iter__**

DataFrame.__iter__()

Iterate over info axis.

**Returns**

iterator Info axis as iterator.

For more information on .at, .iat, .loc, and .iloc, see the indexing documentation.
## 3.4.5 Binary operator functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.add()</code></td>
<td>Get Addition of dataframe and other, element-wise (binary operator <code>add</code>).</td>
</tr>
<tr>
<td><code>DataFrame.sub()</code></td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator <code>sub</code>).</td>
</tr>
<tr>
<td><code>DataFrame.mul()</code></td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator <code>mul</code>).</td>
</tr>
<tr>
<td><code>DataFrame.div()</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.truediv()</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.floordiv()</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.mod()</code></td>
<td>Get Modulo of dataframe and other, element-wise (binary operator <code>mod</code>).</td>
</tr>
<tr>
<td><code>DataFrame.pow()</code></td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator <code>pow</code>).</td>
</tr>
<tr>
<td><code>DataFrame.dot()</code></td>
<td>Compute the matrix multiplication between the DataFrame and other.</td>
</tr>
<tr>
<td><code>DataFrame.radd()</code></td>
<td>Get Addition of dataframe and other, element-wise (binary operator <code>radd</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rsub()</code></td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator <code>rsub</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rmul()</code></td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator <code>rmul</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rdiv()</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rtruediv()</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rfloordiv()</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>rfloordiv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rmod()</code></td>
<td>Get Modulo of dataframe and other, element-wise (binary operator <code>rmod</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rpow()</code></td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator <code>rpow</code>).</td>
</tr>
<tr>
<td><code>DataFrame.lt()</code></td>
<td>Get Less than of dataframe and other, element-wise (binary operator <code>lt</code>).</td>
</tr>
<tr>
<td><code>DataFrame.gt()</code></td>
<td>Get Greater than of dataframe and other, element-wise (binary operator <code>gt</code>).</td>
</tr>
<tr>
<td><code>DataFrame.le()</code></td>
<td>Get Less than or equal to of dataframe and other, element-wise (binary operator <code>le</code>).</td>
</tr>
<tr>
<td><code>DataFrame.ge()</code></td>
<td>Get Greater than or equal to of dataframe and other, element-wise (binary operator <code>ge</code>).</td>
</tr>
<tr>
<td><code>DataFrame.ne()</code></td>
<td>Get Not equal to of dataframe and other, element-wise (binary operator <code>ne</code>).</td>
</tr>
<tr>
<td><code>DataFrame.eq()</code></td>
<td>Get Equal to of dataframe and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>DataFrame.combine()</code></td>
<td>Perform column-wise combine with another DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.combine_first()</code></td>
<td>Update null elements with value in the same location in <code>other</code>.</td>
</tr>
</tbody>
</table>
### 3.4.6 Function application, GroupBy & window

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.apply(func[, axis, raw, ...])</td>
<td>Apply a function along an axis of the DataFrame.</td>
</tr>
<tr>
<td>DataFrame.applymap(func[, na_action])</td>
<td>Apply a function to a Dataframe elementwise.</td>
</tr>
<tr>
<td>DataFrame.pipe(func, *args, **kwargs)</td>
<td>Apply chainable functions that expect Series or DataFrames.</td>
</tr>
<tr>
<td>DataFrame.agg([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>DataFrame.aggregate([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>DataFrame.transform(func[, axis])</td>
<td>Call func on self producing a DataFrame with the same axis shape as self.</td>
</tr>
<tr>
<td>DataFrame.groupby([by, axis, level, ...])</td>
<td>Group DataFrame using a mapper or by a Series of columns.</td>
</tr>
<tr>
<td>DataFrame.rolling(window[, min_periods, ...])</td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td>DataFrame.expanding([min_periods, center, ...])</td>
<td>Provide expanding window calculations.</td>
</tr>
<tr>
<td>DataFrame.ewm([com, span, halflife, alpha, ...])</td>
<td>Provide exponentially weighted (EW) calculations.</td>
</tr>
</tbody>
</table>

### 3.4.7 Computations / descriptive stats

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>DataFrame.all([axis, bool_only, skipna, level])</td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td>DataFrame.any([axis, bool_only, skipna, level])</td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td>DataFrame.clip([lower, upper, axis, inplace])</td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td>DataFrame.corr([method, min_periods])</td>
<td>Compute pairwise correlation of columns, excluding NA/null values.</td>
</tr>
<tr>
<td>DataFrame.corrwith(other[, axis, drop, method])</td>
<td>Compute pairwise correlation.</td>
</tr>
<tr>
<td>DataFrame.count([axis, level, numeric_only])</td>
<td>Count non-NA cells for each column or row.</td>
</tr>
<tr>
<td>DataFrame.cov([min_periods, ddof])</td>
<td>Compute pairwise covariance of columns, excluding NA/null values.</td>
</tr>
<tr>
<td>DataFrame.cummax([axis, skipna])</td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>DataFrame.cummin([axis, skipna])</td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>DataFrame.cumprod([axis, skipna])</td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>DataFrame.cumsum([axis, skipna])</td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>DataFrame.describe([percentiles, include, ...])</td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td>DataFrame.diff([periods, axis])</td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td>DataFrame.eval(expr[, inplace])</td>
<td>Evaluate a string describing operations on DataFrame columns.</td>
</tr>
<tr>
<td>DataFrame.kurt([axis, skipna, level, ...])</td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td>DataFrame.kurtosis([axis, skipna, level, ...])</td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td>DataFrame.mad([axis, skipna, level])</td>
<td>Return the mean absolute deviation of the values over the requested axis.</td>
</tr>
</tbody>
</table>

continues on next page
Table 5 – continued from previous page

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.max</code></td>
<td>Return the maximum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.mean</code></td>
<td>Return the mean of the values over the requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.median</code></td>
<td>Return the median of the values over the requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.min</code></td>
<td>Return the minimum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.mode</code></td>
<td>Get the mode(s) of each element along the selected axis.</td>
</tr>
<tr>
<td><code>DataFrame.pct_change</code></td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><code>DataFrame.prod</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.product</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.quantile</code></td>
<td>Return values at the given quantile over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.rank</code></td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td><code>DataFrame.round</code></td>
<td>Round a DataFrame to a variable number of decimal places.</td>
</tr>
<tr>
<td><code>DataFrame.sem</code></td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.skew</code></td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.sum</code></td>
<td>Return the sum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.std</code></td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.var</code></td>
<td>Return unbiased variance over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.nunique</code></td>
<td>Count number of distinct elements in specified axis.</td>
</tr>
<tr>
<td><code>DataFrame.value_counts</code></td>
<td>Return a Series containing counts of unique rows in the DataFrame.</td>
</tr>
</tbody>
</table>
# 3.4.8 Reindexing / selection / label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.add_prefix(prefix)</code></td>
<td>Prefix labels with string <code>prefix</code>.</td>
</tr>
<tr>
<td><code>DataFrame.add_suffix(suffix)</code></td>
<td>Suffix labels with string <code>suffix</code>.</td>
</tr>
<tr>
<td><code>DataFrame.align(other[, join, axis, level, ...])</code></td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>DataFrame.at_time(time[, asof, axis])</code></td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td><code>DataFrame.between_time(start_time, end_time)</code></td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>DataFrame.drop([labels, axis, index, ...])</code></td>
<td>Drop specified labels from rows or columns.</td>
</tr>
<tr>
<td><code>DataFrame.drop_duplicates([subset, keep, ...])</code></td>
<td>Return DataFrame with duplicate rows removed.</td>
</tr>
<tr>
<td><code>DataFrame.duplicated([subset, keep])</code></td>
<td>Return boolean Series denoting duplicate rows.</td>
</tr>
<tr>
<td><code>DataFrame.equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>DataFrame.filter([items, like, regex, axis])</code></td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td><code>DataFrame.first(offset)</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>DataFrame.head([n])</code></td>
<td>Return the first <code>n</code> rows.</td>
</tr>
<tr>
<td><code>DataFrame.idxmax([axis, skipna])</code></td>
<td>Return index of first occurrence of maximum over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.idxmin([axis, skipna])</code></td>
<td>Return index of first occurrence of minimum over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.last(offset)</code></td>
<td>Select final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>DataFrame.reindex([labels, index, columns, ...])</code></td>
<td>Conform Series/DataFrame to new index with optional filling logic.</td>
</tr>
<tr>
<td><code>DataFrame.reindex_like(other[, method, ...])</code></td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td><code>DataFrame.rename([mapper, index, columns, ...])</code></td>
<td>Alter axes labels.</td>
</tr>
<tr>
<td><code>DataFrame.rename_axis([mapper, index, ...])</code></td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
<tr>
<td><code>DataFrame.reset_index([mapper, index, ...])</code></td>
<td>Reset the index, or a level of it.</td>
</tr>
<tr>
<td><code>DataFrame.sample([n, frac, replace, ...])</code></td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td><code>DataFrame.set_axis(labels[, axis, inplace])</code></td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td><code>DataFrame.set_index(keys[, drop, append, ...])</code></td>
<td>Set the DataFrame index using existing columns.</td>
</tr>
<tr>
<td><code>DataFrame.tail([n])</code></td>
<td>Return the last <code>n</code> rows.</td>
</tr>
<tr>
<td><code>DataFrame.take(indices[, axis, is_copy])</code></td>
<td>Return the elements in the given positional indices along an axis.</td>
</tr>
<tr>
<td><code>DataFrame.truncate([before, after, axis, copy])</code></td>
<td>Truncate a Series or DataFrame before and after some index value.</td>
</tr>
</tbody>
</table>
### 3.4.9 Missing data handling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Syntax</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.backfill</td>
<td>Synonym for DataFrame.fillna() with method='bfill'.</td>
<td>DataFrame.backfill(</td>
<td>Synonym for DataFrame.fillna() with method='bfill'.</td>
</tr>
<tr>
<td>DataFrame.bfill</td>
<td>Synonym for DataFrame.fillna() with method='bfill'.</td>
<td>[axis, inplace, limit, ...])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.dropna</td>
<td>Remove missing values.</td>
<td>DataFrame.dropna(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.ffill</td>
<td>Synonym for DataFrame.fillna() with method='ffill'.</td>
<td>[axis, inplace, limit, downcast])</td>
<td></td>

<tr>
<td>DataFrame.fillna</td>
<td>Fill NA/NaN values using the specified method.</td>
<td>DataFrame.fillna(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.isna</td>
<td>Detect missing values.</td>
<td>DataFrame.isna()</td>
<td></td>
</tr>
<tr>
<td>DataFrame.isnull</td>
<td>DataFrame.isnull is an alias for DataFrame.isna.</td>
<td>DataFrame.isnull()</td>
<td></td>
</tr>
<tr>
<td>DataFrame.notna</td>
<td>Detect existing (non-missing) values.</td>
<td>DataFrame.notna()</td>
<td></td>
</tr>
<tr>
<td>DataFrame.notnull</td>
<td>DataFrame.notnull is an alias for DataFrame.notna.</td>
<td>DataFrame.notnull()</td>
<td></td>
</tr>
<tr>
<td>DataFrame.pad</td>
<td>Synonym for DataFrame.fillna() with method='ffill'.</td>
<td>DataFrame.pad(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.replace</td>
<td>Replace values given in to_replace with value.</td>
<td>DataFrame.replace(</td>
<td></td>
</tr>
</tbody>
</table>

### 3.4.10 Reshaping, sorting, transposing

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Syntax</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.droplevel</td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
<td>DataFrame.droplevel(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.pivot</td>
<td>Return reshaped DataFrame organized by given index / column values.</td>
<td>DataFrame.pivot(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.pivot_table</td>
<td>Create a spreadsheet-style pivot table as a DataFrame.</td>
<td>DataFrame.pivot_table(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.reorder_levels</td>
<td>Rearrange index levels using input order.</td>
<td>DataFrame.reorder_levels(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.sort_values</td>
<td>Sort by the values along either axis.</td>
<td>DataFrame.sort_values(by[, axis, ascending, ...])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.sort_index</td>
<td>Sort object by labels (along an axis).</td>
<td>DataFrame.sort_index(</td>
<td></td>
</tr>
<tr>
<td>DataFrame.nlargest</td>
<td>Return the first n rows ordered by columns in descending order.</td>
<td>DataFrame.nlargest(n, columns[, keep])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.nsmallest</td>
<td>Return the first n rows ordered by columns in ascending order.</td>
<td>DataFrame.nsmallest(n, columns[, keep])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.swaplevel</td>
<td>Swap levels i and j in a MultiIndex.</td>
<td>DataFrame.swaplevel([i, j, axis])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.stack</td>
<td>Stack the prescribed level(s) from columns to index.</td>
<td>DataFrame.stack([level, dropna])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.unstack</td>
<td>Pivot a level of the (necessarily hierarchical) index labels.</td>
<td>DataFrame.unstack([level, fill_value])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.swapaxes</td>
<td>Interchange axes and swap values axes appropriately.</td>
<td>DataFrame.swapaxes(axis1, axis2[, copy])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.melt</td>
<td>Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.</td>
<td>DataFrame.melt([id_vars, value_vars, ...])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.explode</td>
<td>Transform each element of a list-like to a row, replicating index values.</td>
<td>DataFrame.explode(column[, ignore_index])</td>
<td></td>
</tr>
<tr>
<td>DataFrame.squeeze</td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
<td>DataFrame.squeeze(axis)</td>
<td></td>
</tr>
<tr>
<td>DataFrame.to_xarray</td>
<td>Return an xarray object from the pandas object.</td>
<td>DataFrame.to_xarray()</td>
<td></td>
</tr>
<tr>
<td>DataFrame.T</td>
<td>Transpose index and columns.</td>
<td>DataFrame.T</td>
<td></td>
</tr>
</tbody>
</table>
```markdown
**pandas.DataFrame.T**

**property** DataFrame.T

### 3.4.11 Combining / comparing / joining / merging

- **pandas.DataFrame.append**(other[, ignore_index, ...]) *(DEPRECATED)* Append rows of other to the end of caller, returning a new object.
- **pandas.DataFrame.assign**(**kwargs) Assign new columns to a DataFrame.
- **pandas.DataFrame.compare**(other[, align_axis, ...]) Compare to another DataFrame and show the differences.
- **pandas.DataFrame.join**(other[, on, how, lsuffix, ...]) Join columns of another DataFrame.
- **pandas.DataFrame.merge**(right[, how, on, left_on, ...]) Merge DataFrame or named Series objects with a database-style join.
- **pandas.DataFrame.update**(other[, join, overwrite, ...]) Modify in place using non-NA values from another DataFrame.

### 3.4.12 Time Series-related

- **pandas.DataFrame.asfreq**(freq[, method, how, ...]) Convert time series to specified frequency.
- **pandas.DataFrame.asof**(where[, subset]) Return the last row(s) without any NaNs before where.
- **pandas.DataFrame.shift**(periods[, freq, axis, ...]) Shift index by desired number of periods with an optional time freq.
- **pandas.DataFrame.slice_shift**(periods, axis) *(DEPRECATED)* Equivalent to shift without copying data.
- **pandas.DataFrame.tshift**(periods[, freq, axis]) *(DEPRECATED)* Shift the time index, using the index's frequency if available.
- **pandas.DataFrame.first_valid_index**() Return index for first non-NA value or None, if no non-NA value is found.
- **pandas.DataFrame.last_valid_index**() Return index for last non-NA value or None, if no non-NA value is found.
- **pandas.DataFrame.resample**(rule[, axis, closed, ...]) Resample time-series data.
- **pandas.DataFrame.to_period**(freq[, axis, copy]) Convert DataFrame from DatetimeIndex to PeriodIndex.
- **pandas.DataFrame.to_timestamp**(freq, how, axis, copy) Cast to DatetimeIndex of timestamps, at beginning of period.
- **pandas.DataFrame.tz_convert**(tz[, axis, level, copy]) Convert tz-aware axis to target time zone.
- **pandas.DataFrame.tz_localize**(tz[, axis, level, ...]) Localize tz-naive index of a Series or DataFrame to target time zone.

### 3.4.13 Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in `DataFrame.attrs`.

**Flags**(obj, *, allows_duplicate_labels) Flags that apply to pandas objects.

---

3.4. DataFrame 1973
### 3.4.14 Metadata

`DataFrame.attrs` is a dictionary for storing global metadata for this DataFrame.

**Warning:** `DataFrame.attrs` is considered experimental and may change without warning.

<table>

</tbody>
</table>

#### pandas.DataFrame.plot.area

`DataFrame.plot.area(x=None, y=None, **kwargs)`

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

**Parameters**

- `x` [label or position, optional] Coordinates for the X axis. By default uses the index.
- `y` [label or position, optional] Column to plot. By default uses all columns.
- `stacked` [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- `**kwargs` Additional keyword arguments are documented in `DataFrame.plot()`.

**Returns**

- `matplotlib.axes.Axes or numpy.ndarray` Area plot, or array of area plots if subplots is True.

See also:
**DataFrame.plot**  Make plots of DataFrame using matplotlib / pylab.

## Examples

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
    'sales': [3, 2, 3, 9, 10, 6],
    'signups': [5, 5, 6, 12, 14, 13],
    'visits': [20, 42, 28, 62, 81, 50],
}, index=pd.date_range(start='2018/01/01', end='2018/07/01', freq='M'))

>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

3.4. **DataFrame**
>>> df = pd.DataFrame({
...    'sales': [3, 2, 3],
...    'visits': [20, 42, 28],
...    'day': [1, 2, 3],
...  })
>>> ax = df.plot.area(x='day')

pandas.DataFrame.plot.bar

DataFrame.plot.bar(x=None, y=None, **kwargs)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
**color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance [‘green’, ‘yellow’] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
- A dict of the form {column name: [color], so that each column will be] colored accordingly. For example, if your columns are called a and b, then passing {‘a’: ‘green’, ‘b’: ‘red’} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.barh  Horizontal bar plot.
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.bar Make a bar plot with matplotlib.

Examples

Basic plot.

```python
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
... 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
... 'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Plot stacked bar charts for the DataFrame

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with subplots=True. In this case, a numpy.ndarray of matplotlib.axes.Axes are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```
3.4. DataFrame
If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
>>> axes = df.plot.bar(
    ...     rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
    ... )
>>> axes[1].legend(loc=2)
```

Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

Chapter 3. API reference
pandas.DataFrame.plot.barh

DataFrame.plot.barh(x=None, y=None, **kwargs)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance [‘green’, ‘yellow’] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.bar Vertical bar plot.
DataFrame.plot Make plots of DataFrame using matplotlib.
matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Examples

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

... 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()

![Horizontal bar chart example]

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```python
>>> ax = df.plot.barh(color={'speed': 'red', 'lifespan': 'green'})
```

Plot a column of the DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```
Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
    'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
    ...
    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```

![Bar chart](image)

---

**pandas.DataFrame.plot.box**

`DataFrame.plot.box(by=None, **kwargs)`

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.
Parameters

by [str or sequence] Column in the DataFrame to group by.

Changed in version 1.4.0: Previously, by is silently ignore and makes no groupings

**kwargs Additional keywords are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```
You can also generate groupings if you specify the `by` parameter (which can take a column name, or a list or tuple of column names):

Changed in version 1.4.0.

```python
>>> age_list = [8, 10, 12, 14, 72, 74, 76, 78, 20, 25, 30, 35, 60, 85]
>>> df = pd.DataFrame({"gender": list("MMMMMMMMMMFFFFF"), "age": age_list})
>>> ax = df.plot.box(column="age", by="gender", figsize=(10, 8))
```

![Box plot example](image)

### `pandas.DataFrame.plot.density`

`DataFrame.plot.density(bw_method=None, ind=None, **kwargs)`

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- `bw_method` [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See `scipy.stats.gaussian_kde` for more information.
ind  [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwars**  Additional keyword arguments are documented in `DataFrame.plot()`.

Returns  matplotlib.axes.Axes or numpy.ndarray of them

See also:  scipy.stats.gaussian_kde  Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:
Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame(
...     {'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6]},
... )
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```
Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

**pandas.DataFrame.plot.hexbin**

`DataFrame.plot.hexbin(x, y, C=None, reduce_C_function=None, gridsize=None, **kwargs)`

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of `x` versus `y`. If `C` is `None` (the default), this is a histogram of the number of occurrences of the observations at `(x[i], y[i])`.

If `C` is specified, specifies values at given coordinates `(x[i], y[i])`. These values are accumulated for each hexagonal bin and then reduced according to `reduce_C_function`, having as default the NumPy’s mean function (`numpy.mean()`). (If `C` is specified, it must also be a 1-D sequence of the same length as `x` and `y`, or a column label.)

**Parameters**

- `x` [int or str] The column label or position for `x` points.
- `y` [int or str] The column label or position for `y` points.
- `C` [int or str, optional] The column label or position for the value of `(x, y)` point.
- `reduce_C_function` [callable, default `np.mean`] Function of one argument that reduces all the values in a bin to a single number (e.g. `np.mean`, `np.max`, `np.sum`, `np.std`).
gridsize [int or tuple of (int, int), default 100] The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.AxesSubplot The matplotlib Axes on which the hexbin is plotted.

See also:

DataFrame.plot Make plots of a DataFrame.

matplotlib.pyplot.hexbin Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```python
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                     'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```
The next example uses \texttt{C} and \texttt{np.sum} as \texttt{reduce\_C\_function}. Note that ‘observations’ values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the \texttt{reduce\_C\_function}.

```python
>>> n = 500
>>> df = pd.DataFrame({
...     'coord_x': np.random.uniform(-3, 3, size=n),
...     'coord_y': np.random.uniform(30, 50, size=n),
...     'observations': np.random.randint(1,5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
...     y='coord_y',
...     C='observations',
...     reduce_C_function=np.sum,
...     gridsize=10,
...     cmap="viridis")
```

pandas: powerful Python data analysis toolkit, Release 1.4.3

**pandas.DataFrame.plot.hist**

`DataFrame.plot.hist(by=None, bins=10, **kwargs)`

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

**Parameters**

- **by** [str or sequence, optional] Column in the DataFrame to group by.
  - Changed in version 1.4.0: Previously, `by` is silently ignored and makes no groupings

- **bins** [int, default 10] Number of histogram bins to be used.

- **kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

**Returns**

- `class: matplotlib.AxesSubplot` Return a histogram plot.

**See also:**

- `DataFrame.hist` Draw histograms per DataFrame's Series.
- `Series.hist` Draw a histogram with Series' data.

**Examples**

When we roll a die 6000 times, we expect to get each value around 1000 times. But when we roll two dice and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(...
... np.random.randint(1, 7, 6000),
... columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

A grouped histogram can be generated by providing the parameter `by` (which can be a column name, or a list of column names):

```python
>>> age_list = [8, 10, 12, 14, 72, 74, 76, 78, 20, 25, 30, 35, 60, 85]
>>> df = pd.DataFrame({"gender": list("MMMMMMMMMMMMM"), "age": age_list})
>>> ax = df.plot.hist(column="age", by="gender", figsize=(10, 8))
```

**pandas.DataFrame.plot.kde**

`DataFrame.plot.kde(by=None, ind=None, **kwargs)`

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.
ind  [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default),
1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at
the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs  Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde  Representation of a kernel-density estimate using Gaussian kernels. This is the
function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with
automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large
bandwidth value may result in under-fitting:
Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame(
...     {'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
...    })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

```python
>>> ax = df.plot.kde(bw_method=3)
```
3.4. DataFrame

\textbf{pandas: powerful Python data analysis toolkit, Release 1.4.3}
Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

---

**pandas.DataFrame.plot.line**

`DataFrame.plot.line(x=None, y=None, **kwargs)`

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each
column’s line will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.

• A dict of the form {column name : color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color lines for column a in green and lines for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

matplotlib.pyplot.plot Plot y versus x as lines and/or markers.

Examples

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
<AxesSubplot:ylabel='Density'>
```

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame({
...   'pig': [20, 18, 489, 675, 1776],
...   'horse': [4, 25, 281, 600, 1900]
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).

```python
>>> axes = df.plot.line(
...     subplots=True, color={"pig": "pink", "horse": "#742802"}
... )
```

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```
pandas.DataFrame.plot.pie

DataFrame.plot.pie(**kwargs)

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps matplotlib.pyplot.pie() for the specified column. If no column reference is passed and subplots=True a pie plot is drawn for each numerical column independently.

**Parameters**

- **y** [int or label, optional] Label or position of the column to plot. If not provided, subplots=True argument must be passed.
- **kwargs** Keyword arguments to pass on to DataFrame.plot().

**Returns**

- matplotlib.axes.Axes or np.ndarray of them

A NumPy array is returned when subplots is True.

**See also:**

Series.plot.pie Generate a pie plot for a Series.
DataFrame.plot Make plots of a DataFrame.

**Examples**

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```python
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

pandas.DataFrame.plot.scatter

DataFrame.plot.scatter(x, y, s=None, c=None, **kwargs)

Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

**Parameters**

- **x** [int or str] The column name or column position to be used as horizontal coordinates for each point.
- **y** [int or str] The column name or column position to be used as vertical coordinates for each point.
- **s** [str, scalar or array-like, optional] The size of each point. Possible values are:
  - A string with the name of the column to be used for marker’s size.
• A single scalar so all points have the same size.
• A sequence of scalars, which will be used for each point’s size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

Changed in version 1.1.0.

c [str, int or array-like, optional] The color of each point. Possible values are:

• A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
• A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point’s color recursively. For instance ['green', 'yellow'] all points will be filled in green or yellow, alternatively.
• A column name or position whose values will be used to color the marker points according to a colormap.

**kwargs Keyword arguments to pass on to DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

matplotlib.pyplot.scatter Scatter plot using multiple input data formats.

Examples

Let’s see how to draw a scatter plot using coordinates from the values in a DataFrame’s columns.

```python
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1], ...
                   [6.4, 3.2, 1], [5.9, 3.0, 2]],
                   columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
                      y='width',
                      c='DarkBlue')
```

And now with the color determined by a column as well.

```python
>>> ax2 = df.plot.scatter(x='length',
                      y='width',
                      c='species',
                      colormap='viridis')
```

DataFrame.boxplot([column, by, ax, ...]) Make a box plot from DataFrame columns.
DataFrame.hist([column, by, grid, ...]) Make a histogram of the DataFrame's columns.
3.4.16 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the DataFrame.sparse accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.sparse.density</code></td>
<td>Ratio of non-sparse points to total (dense) data points.</td>
</tr>
<tr>
<td><code>DataFrame.sparse.from_spmatrix(data[, ...])</code></td>
<td>Create a new DataFrame from a scipy sparse matrix.</td>
</tr>
<tr>
<td><code>DataFrame.sparse.to_coo()</code></td>
<td>Return the contents of the frame as a sparse SciPy COO matrix.</td>
</tr>
<tr>
<td><code>DataFrame.sparse.to_dense()</code></td>
<td>Convert a DataFrame with sparse values to dense.</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.sparse.density**

DataFrame.sparse.density

Ratio of non-sparse points to total (dense) data points.

**pandas.DataFrame.sparse.from_spmatrix**

_classmethod_ DataFrame.sparse.from_spmatrix(data, index=None, columns=None)

Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

**Parameters**

- `data` [scipy.sparse.spmatrix] Must be convertible to csc format.
- `index, columns` [Index, optional] Row and column labels to use for the resulting DataFrame. Defaults to a RangeIndex.

**Returns**

DataFrame Each column of the DataFrame is stored as a arrays.SparseArray.

**Examples**

```python
>>> import scipy.sparse
>>> mat = scipy.sparse.eye(3)
>>> pd.DataFrame.sparse.from_spmatrix(mat)
0 1 2
0 1.0 0.0 0.0
1 0.0 1.0 0.0
2 0.0 0.0 1.0
```
**pandas.DataFrame.sparse.to_coo**

DataFrame.sparse.to_coo()

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

**Returns**

- coo_matrix [scipy.sparse.spmatrix] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

**Notes**

The dtype will be the lowest-common.denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find_common_type convention, mixing int64 and and uint64 will result in a float64 dtype.

**pandas.DataFrame.sparse.to_dense**

DataFrame.sparse.to_dense()

Convert a DataFrame with sparse values to dense.

New in version 0.25.0.

**Returns**

- DataFrame A DataFrame with the same values stored as dense arrays.

**Examples**

```python
>>> df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()
   A
0  0
1  1
2  0
```
3.4.17 Serialization / IO / conversion

- **DataFrame.from_dict**(data[, orient, dtype, ...]) Construct DataFrame from dict of array-like or dicts.
- **DataFrame.from_records**(data[, index, ...]) Convert structured or record ndarray to DataFrame.
- **DataFrame.to_parquet**(path[, engine, ...]) Write a DataFrame to the binary parquet format.
- **DataFrame.to_pickle**(path[, compression, ...]) Pickle (serialize) object to file.
- **DataFrame.to_csv**(path_or_buf[, sep, na_rep, ...]) Write object to a comma-separated values (csv) file.
- **DataFrame.to_hdf**(path_or_buf, key[, mode, ...]) Write the contained data to an HDF5 file using HDFS-store.
- **DataFrame.to_sql**(name, con[, schema, ...]) Write records stored in a DataFrame to a SQL database.
- **DataFrame.to_excel**(excel_writer[, ...]) Write object to an Excel sheet.
- **DataFrame.to_json**(path_or_buf[, orient, ...]) Convert the object to a JSON string.
- **DataFrame.to_feather**(path, **kwargs) Write a DataFrame to the binary Feather format.
- **DataFrame.to_latex**(buf[, columns, ...]) Render object to a LaTeX tabular, longtable, or nested table.
- **DataFrame.to_stata**(path[, convert_dates, ...]) Export DataFrame object to Stata dta format.
- **DataFrame.to_gbq**(destination_table[, ...]) Write a DataFrame to a Google BigQuery table.
- **DataFrame.to_records**(index, column_dtypes[, ...]) Convert DataFrame to a NumPy record array.
- **DataFrame.to_string**(buf[, columns, ...]) Render a DataFrame to a console-friendly tabular output.
- **DataFrame.to_clipboard**(excel, sep) Copy object to the system clipboard.
- **DataFrame.to_markdown**(buf[, mode, index, ...]) Print DataFrame in Markdown-friendly format.
- **DataFrame.style** Returns a Styler object.

3.5 pandas arrays, scalars, and data types

For most data types, pandas uses NumPy arrays as the concrete objects contained with a *Index*, *Series*, or *DataFrame*. For some data types, pandas extends NumPy’s type system. String aliases for these types can be found at *dtypes*.

<table>
<thead>
<tr>
<th>Kind of Data</th>
<th>pandas Data Type</th>
<th>Scalar</th>
<th>Array</th>
</tr>
</thead>
<tbody>
<tr>
<td>TZ-aware datetime</td>
<td>DatetimeTZDtype</td>
<td>Timestamp</td>
<td>Datetime data</td>
</tr>
<tr>
<td>Timedeltas</td>
<td>(none)</td>
<td>Timedelta</td>
<td>Timedelta data</td>
</tr>
<tr>
<td>Period (time spans)</td>
<td>PeriodDtype</td>
<td>Period</td>
<td>Timespan data</td>
</tr>
<tr>
<td>Intervals</td>
<td>IntervalDtype</td>
<td>Interval</td>
<td>Interval data</td>
</tr>
<tr>
<td>Nullable Integer</td>
<td>Int64Dtype, ...</td>
<td>(none)</td>
<td>Nullable integer</td>
</tr>
<tr>
<td>Categorical</td>
<td>CategoricalDtype</td>
<td>(none)</td>
<td>Categorical data</td>
</tr>
<tr>
<td>Sparse</td>
<td>SparseDtype</td>
<td>(none)</td>
<td>Sparse data</td>
</tr>
<tr>
<td>Strings</td>
<td>StringDtype</td>
<td>str</td>
<td>Text data</td>
</tr>
<tr>
<td>Boolean (with NA)</td>
<td>BooleanDtype</td>
<td>bool</td>
<td>Boolean data with missing values</td>
</tr>
</tbody>
</table>

pandas and third-party libraries can extend NumPy’s type system (see *Extension types*). The top-level *array* method can be used to create a new array, which may be stored in a *Series*, *Index*, or as a column in a *DataFrame*.

array(data[, dtype, copy]) Create an array.
3.5.1 pandas.array

```python
pandas.array(data, dtype=None, copy=True)
```

Create an array.

Parameters

- **data** [Sequence of objects] The scalars inside `data` should be instances of the scalar type for `dtype`. It’s expected that `data` represents a 1-dimensional array of data.

  When `data` is an Index or Series, the underlying array will be extracted from `data`.

- **dtype** [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

  If not specified, there are two possibilities:

  1. When `data` is a Series, Index, or ExtensionArray, the dtype will be taken from the data.

  2. Otherwise, pandas will attempt to infer the dtype from the data.

  Note that when `data` is a NumPy array, `data.dtype` is not used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

  Currently, pandas will infer an extension dtype for sequences of

<table>
<thead>
<tr>
<th>Scalar Type</th>
<th>Array Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas.Interval</td>
<td>pandas.arrays.IntervalArray</td>
</tr>
<tr>
<td>pandas.Period</td>
<td>pandas.arrays.PeriodArray</td>
</tr>
<tr>
<td>datetime</td>
<td>pandas.arrays.DatetimeArray</td>
</tr>
<tr>
<td>datetime.timedelta</td>
<td>pandas.arrays.TimedeltaArray</td>
</tr>
<tr>
<td>int</td>
<td>pandas.arrays.IntegerArray</td>
</tr>
<tr>
<td>float</td>
<td>pandas.arrays.FloatingArray</td>
</tr>
<tr>
<td>str</td>
<td>pandas.arrays.StringArray</td>
</tr>
<tr>
<td>bool</td>
<td>pandas.arrays.BooleanArray</td>
</tr>
</tbody>
</table>

  The ExtensionArray created when the scalar type is `str` is determined by `pd.options.mode.string_storage` if the dtype is not explicitly given.

  For all other cases, NumPy’s usual inference rules will be used.

  Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

  Changed in version 1.2.0: Pandas now also infers nullable-floating dtype for float-like input data

- **copy** [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of `data`, creating the new array may require copying data, even if `copy=False`.

Returns

- **ExtensionArray** The newly created array.
Raises

**ValueError** When data is not 1-dimensional.

See also:

- `numpy.array` Construct a NumPy array.
- `Series` Construct a pandas Series.
- `Index` Construct a pandas Index.
- `arrays.PandasArray` ExtensionArray wrapping a NumPy array.
- `Series.array` Extract the array stored within a Series.

Notes

Omitting the `dtype` argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying `dtype` to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn’t change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the `dtype` as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.

```python
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the `dtype`.

```python
>>> pd.array(['a', 'b'], dtype=np.dtype('<U1'))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- `arrays.DatetimeArray`
- `arrays.TimedeltaArray`

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```python
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```python
>>> pd.array(['1H', '2H'], dtype='timedelta64[ns]')
<TimedeltaArray>
['0 days 01:00:00', '0 days 02:00:00']
Length: 2, dtype: timedelta64[ns]
```
Examples

If a dtype is not specified, pandas will infer the best dtype from the values. See the description of *dtype* for the types pandas infers for.

```python
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64

>>> pd.array([1, 2, np.nan])
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

>>> pd.array([1.1, 2.2])
<FloatingArray>
[1.1, 2.2]
Length: 2, dtype: Float64

>>> pd.array(['a', None, 'c'])
<StringArray>
['a', <NA>, 'c']
Length: 3, dtype: string

>>> with pd.option_context("string_storage", "pyarrow"):
...     arr = pd.array(['a', None, 'c'])
...     ...
...     arr

<ArrowStringArray>
['a', <NA>, 'c']
Length: 3, dtype: string

<PeriodArray>
['2000-01-01', '2000-01-01']
Length: 2, dtype: period[D]
```

You can use the string alias for *dtype*

```python
>>> pd.array(['a', 'b', 'a'], dtype='category')
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

Or specify the actual dtype

```python
>>> pd.array(['a', 'b', 'a'],
...          dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
['a', 'b', 'a']
Categories (3, object): ['a' < 'b' < 'c']
```

If pandas does not infer a dedicated extension type a *arrays.PandasArray* is returned.
>>> pd.array([1 + 1j, 3 + 2j])
<PandasArray>
[(1+1j), (3+2j)]
Length: 2, dtype: complex128

As mentioned in the “Notes” section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a `arrays.PandasArray`. Specify the `dtype` as a NumPy dtype if you need to ensure there’s no future change in behavior.

```python
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

data must be 1-dimensional. A ValueError is raised when the input has the wrong dimensionality.

```python
>>> pd.array(1)
Traceback (most recent call last):
... ValueError: Cannot pass scalar '1' to 'pandas.array'.
```

## 3.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. pandas supports this with the `arrays.DatetimeArray` extension array, which can hold timezone-naive or timezone-aware values.

The `Timestamp`, a subclass of `datetime.datetime`, is pandas’ scalar type for timezone-naive or timezone-aware datetime data.

<table>
<thead>
<tr>
<th><code>Timestamp([ts_input, freq, tz, unit, year, ...])</code></th>
<th>Pandas replacement for python datetime.datetime object.</th>
</tr>
</thead>
</table>

**pandas.Timestamp**

```python
class pandas.Timestamp(ts_input=<object object>, freq=None, tz=None, unit=None, year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=None, *, fold=None)
```

Pandas replacement for python datetime.datetime object.

Timestamp is the pandas equivalent of python’s Datetime and is interchangeable with it in most cases. It’s the type used for the entries that make up a DatetimeIndex, and other timeseries oriented data structures in pandas.

**Parameters**

- **ts_input** [datetime-like, str, int, float] Value to be converted to Timestamp.
- **freq** [str, DateOffset] Offset which Timestamp will have.
- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will have.
- **unit** [str] Unit used for conversion if `ts_input` is of type int or float. The valid values are ‘D’, ‘h’, ‘m’, ‘s’, ‘ms’, ‘us’, and ‘ns’. For example, ‘s’ means seconds and ‘ms’ means milliseconds.
year, month, day  [int]
hour, minute, second, microsecond  [int, optional, default 0]
nanosecond  [int, optional, default 0]
tzinfo  [datetime.tzinfo, optional, default None]
fold  [[0, 1], default None, keyword-only] Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time.

New in version 1.1.0.

Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from datetime.datetime. They can be passed by either position or keyword, but not both mixed together.

Examples

Using the primary calling convention:

This converts a datetime-like string

```python
>>> pd.Timestamp('2017-01-01 12:00:00')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```python
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```python
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for datetime.datetime:

```python
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```python
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

<td>Return the week number of the year.</td>
</tr>
</tbody>
</table>

**pandas.Timestamp.asm8**

Return numpy datetime64 format in nanoseconds.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14, 15)
>>> ts.asm8
numpy.datetime64('2020-03-14T15:00:00.000000000')
```

**pandas.Timestamp.day_of_week**

Return day of the week.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_week
5
```
pandas.Timestamp.day_of_year

Timestamp.day_of_year
Return the day of the year.

Examples
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_year
74

pandas.Timestamp.dayofweek

Timestamp.dayofweek
Return day of the week.

Examples
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_week
5

pandas.Timestamp.dayofyear

Timestamp.dayofyear
Return the day of the year.

Examples
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_year
74

pandas.Timestamp.days_in_month

Timestamp.days_in_month
Return the number of days in the month.
Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```

**pandas.Timestamp.daysinmonth**

*Timestamp.daysinmonth*

Return the number of days in the month.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```

**pandas.Timestamp.freqstr**

*property Timestamp.freqstr*

Return the total number of days in the month.

**pandas.Timestamp.is_leap_year**

*Timestamp.is_leap_year*

Return True if year is a leap year.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_leap_year
True
```

**pandas.Timestamp.is_month_end**

*Timestamp.is_month_end*

Return True if date is last day of month.
Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_end
False

>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_month_end
True
```

**pandas.Timestamp.is_month_end**

*pandas.Timestamp.is_month_end*

Return True if date is first day of month.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_start
False

>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_month_start
True
```

**pandas.Timestamp.is_quarter_end**

*pandas.Timestamp.is_quarter_end*

Return True if date is last day of the quarter.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_end
False

>>> ts = pd.Timestamp(2020, 3, 31)
>>> ts.is_quarter_end
True
```
pandas.Timestamp.is_quarter_start

Timestamp.is_quarter_start
Return True if date is first day of the quarter.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_start
False

>>> ts = pd.Timestamp(2020, 4, 1)
>>> ts.is_quarter_start
True
```

pandas.Timestamp.is_year_end

Timestamp.is_year_end
Return True if date is last day of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_end
False

>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_year_end
True
```

pandas.Timestamp.is_year_start

Timestamp.is_year_start
Return True if date is first day of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_start
False

>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_year_start
True
```
pandas.Timestamp.quarter

Timestamp.quarter
Return the quarter of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.quarter
1
```

pandas.Timestamp.tz

property Timestamp.tz
Alias for tzinfo.

Examples

```python
>>> ts = pd.Timestamp(1584226800, unit='s', tz='Europe/Stockholm')
>>> ts.tz
<DstTzInfo 'Europe/Stockholm' CET+1:00:00 STD>
```

pandas.Timestamp.week

Timestamp.week
Return the week number of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```

pandas.Timestamp.weekofyear

Timestamp.weekofyear
Return the week number of the year.
Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```

<table>

Methods

- `astimezone(tz)` Convert timezone-aware Timestamp to another timezone.
- `ceil(freq[, ambiguous, nonexistent])` Return a new Timestamp ceiled to this resolution.
- `combine(date, time)` Combine date, time into datetime with same date and time fields.
- `ctime` Return ctime() style string.
- `date` Return date object with same year, month and day.
- `day_name` Return the day name of the Timestamp with specified locale.
- `dst` Return self.tzinfo.dst(self).
- `floor(freq[, ambiguous, nonexistent])` Return a new Timestamp floored to this resolution.
- `fromisocalendar` int, int, int -> Construct a date from the ISO year, week number and weekday.
- `fromisoformat` string -> datetime from datetime.isoformat() output
- `fromordinal(ordinal[, freq, tz])` Passed an ordinal, translate and convert to a ts.
- `fromtimestamp(ts)` Transform timestamp[, tz] to tz's local time from POSIX timestamp.
- `isocalendar` Return a 3-tuple containing ISO year, week number, and weekday.
- `isoformat` Return the time formatted according to ISO 8610.
- `isoweekday()` Return the day of the week represented by the date.
- `month_name` Return the month name of the Timestamp with specified locale.
- `normalize` Normalize Timestamp to midnight, preserving tz information.
- `now([tz])` Return new Timestamp object representing current time local to tz.
- `replace([year, month, day, hour, minute, ...])` Implements datetime.replace, handles nanoseconds.

#### pandas.Timestamp.astimezone

`pandas.Timestamp.astimezone(tz)`

Convert timezone-aware Timestamp to another time zone.

**Parameters**

- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

**Returns**

- `converted` [Timestamp]

**Raises**

- `TypeError` If Timestamp is tz-naive.
**Examples**

Create a timestamp object with UTC timezone:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Change to Tokyo timezone:

```python
>>> ts.tz_convert(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Can also use `astimezone`:

```python
>>> ts.astimezone(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT
```

**pandas.Timestamp.ceil**

```
Timestamp.ceil(freq, ambiguous='raise', nonexistent='raise')
```

Return a new Timestamp ceiled to this resolution.

**Parameters**

- `freq` [str] Frequency string indicating the ceiling resolution.
- `ambiguous` [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - `bool` contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - `NaT` will return NaT for an ambiguous time.
  - `raise` will raise an AmbiguousTimeError for an ambiguous time.
- `nonexistent` [{'raise', 'shift_forward', 'shift_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - `shift_forward` will shift the nonexistent time forward to the closest existing time.
  - `shift_backward` will shift the nonexistent time backward to the closest existing time.
  - `NaT` will return NaT where there are nonexistent times.
  - `timedelta` objects will shift nonexistent times by the timedelta.
  - `raise` will raise an NonExistentTimeError if there are nonexistent times.

** Raises **

* `ValueError` if the freq cannot be converted.
Notes

If the Timestamp has a timezone, ceiling will take place relative to the local ("wall") time and re-localized to the same timezone. When ceiling near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

Examples

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be ceiled using multiple frequency units:

```python
>>> ts.ceil(freq='H') # hour
Timestamp('2020-03-14 16:00:00')
```

```python
>>> ts.ceil(freq='T') # minute
Timestamp('2020-03-14 15:33:00')
```

```python
>>> ts.ceil(freq='S') # seconds
Timestamp('2020-03-14 15:32:53')
```

```python
>>> ts.ceil(freq='U') # microseconds
Timestamp('2020-03-14 15:32:52.192549')
```

Freq can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):

```python
>>> ts.ceil(freq='5T')
Timestamp('2020-03-14 15:35:00')
```

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.ceil(freq='1H30T')
Timestamp('2020-03-14 16:30:00')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.ceil()
NaT
```

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

```python
>>> ts_tz = pd.Timestamp("2021-10-31 01:30:00").tz_localize("Europe/Amsterdam")
```

```python
>>> ts_tz.ceil("H", ambiguous=False)
Timestamp('2021-10-31 02:00:00+0100', tz='Europe/Amsterdam')
```

```python
>>> ts_tz.ceil("H", ambiguous=True)
Timestamp('2021-10-31 02:00:00+0200', tz='Europe/Amsterdam')
```

pandas.Timestamp.combine

classmethod Timestamp.combine(date, time)
    Combine date, time into datetime with same date and time fields.

Examples

```python
>>> from datetime import date, time
>>> pd.Timestamp.combine(date(2020, 3, 14), time(15, 30, 15))
Timestamp('2020-03-14 15:30:15')
```

pandas.Timestamp.ctime

Timestamp.ctime()
    Return ctime() style string.

pandas.Timestamp.date

Timestamp.date()
    Return date object with same year, month and day.

pandas.Timestamp.day_name

Timestamp.day_name()
    Return the day name of the Timestamp with specified locale.

Parameters

locale [str, default None (English locale)] Locale determining the language in which to return the day name.

Returns

str

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.day_name()
'Saturday'

Analogous for pd.NaT:

```python
>>> pd.NaT.day_name()
nan
```
pandas.Timestamp.dst

Timestamp.dst()
    Return self.tzinfo.dst(self).

pandas.Timestamp.floor

Timestamp.floor(freq, ambiguous='raise', nonexistent='raise')
    Return a new Timestamp floored to this resolution.

    Parameters
    
    freq [str] Frequency string indicating the flooring resolution.
    
    ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
    
    • bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
    • 'NaT' will return NaT for an ambiguous time.
    • 'raise' will raise an AmbiguousTimeError for an ambiguous time.
    
    nonexistent [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
    
    • ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
    • ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
    • ‘NaT’ will return NaT where there are nonexistent times.
    • timedelta objects will shift nonexistent times by the timedelta.
    • ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

    Raises
    
    ValueError if the freq cannot be converted.

    Notes
    
    If the Timestamp has a timezone, flooring will take place relative to the local ("wall") time and re-localized to the same timezone. When flooring near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.
### Examples

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be floored using multiple frequency units:

```python
>>> ts.floor(freq='H')  # hour
Timestamp('2020-03-14 15:00:00')
```

```python
>>> ts.floor(freq='T')  # minute
Timestamp('2020-03-14 15:32:00')
```

```python
>>> ts.floor(freq='S')  # seconds
Timestamp('2020-03-14 15:32:52')
```

```python
>>> ts.floor(freq='N')  # nanoseconds
Timestamp('2020-03-14 15:32:52.192548651')
```

`freq` can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):

```python
>>> ts.floor(freq='5T')
Timestamp('2020-03-14 15:30:00')
```

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.floor(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.floor()
NaT
```

When rounding near a daylight savings time transition, use `ambiguous` or `nonexistent` to control how the timestamp should be re-localized.

```python
>>> ts_tz = pd.Timestamp("2021-10-31 03:30:00").tz_localize("Europe/Amsterdam")
```

```python
>>> ts_tz.floor("2H", ambiguous=False)
Timestamp('2021-10-31 02:00:00+0100', tz='Europe/Amsterdam')
```

```python
>>> ts_tz.floor("2H", ambiguous=True)
Timestamp('2021-10-31 02:00:00+0200', tz='Europe/Amsterdam')
```
pandas.Timestamp.fromisocalendar

Timestamp.fromisocalendar()  
int, int, int -> Construct a date from the ISO year, week number and weekday.  
This is the inverse of the date.isocalendar() function

pandas.Timestamp.fromisoformat

Timestamp.fromisoformat()  
string -> datetime from datetime.isoformat() output

pandas.Timestamp.fromordinal

classmethod Timestamp.fromordinal(ordinal, freq=None, tz=None)  
Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the  
ordinal itself.

Parameters
  ordinal  [int] Date corresponding to a proleptic Gregorian ordinal.
  freq  [str, DateOffset] Offset to apply to the Timestamp.
  tz  [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.

Examples

```python
>>> pd.Timestamp.fromordinal(737425)
Timestamp('2020-01-01 00:00:00')
```

pandas.Timestamp.fromtimestamp

classmethod Timestamp.fromtimestamp(ts)  
Transform timestamp[, tz] to tz's local time from POSIX timestamp.

Examples

```python
>>> pd.Timestamp.fromtimestamp(1584199972)
Timestamp('2020-03-14 15:32:52')
```

Note that the output may change depending on your local time.
pandas.Timestamp.isocalendar

**Timestamp.isocalendar()**
Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoformat

**Timestamp.isoformat()**
Return the time formatted according to ISO 8610.

The full format looks like ‘YYYY-MM-DD HH:MM:SS.mmmmmmmm’. By default, the fractional part is omitted if self.microsecond == 0 and self.nanosecond == 0.

If self.tzinfo is not None, the UTC offset is also attached, giving a full format of ‘YYYY-MM-DD HH:MM:SS.mmmmmmmm+HH:MM’.

**Parameters**
- **sep** [str, default ‘T’] String used as the separator between the date and time.
- **timespec** [str, default ‘auto’] Specifies the number of additional terms of the time to include. The valid values are ‘auto’, ‘hours’, ‘minutes’, ‘seconds’, ‘milliseconds’, ‘microseconds’, and ‘nanoseconds’.

**Returns**
- **str**

**Examples**

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.isoformat()  
'2020-03-14T15:32:52.192548651'
>>> ts.isoformat(timespec='microseconds')
'2020-03-14T15:32:52.192548'
```

pandas.Timestamp.isoweekday

**Timestamp.isoweekday()**
Return the day of the week represented by the date. Monday == 1 ... Sunday == 7.

pandas.Timestamp.month_name

**Timestamp.month_name()**
Return the month name of the Timestamp with specified locale.

**Parameters**
- **locale** [str, default None (English locale)] Locale determining the language in which to return the month name.

**Returns**
- **str**
Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.month_name()
'March'
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.month_name()
nan
```

**pandas.Timestamp.normalize**

`Timestamp.normalize()`

Normalize Timestamp to midnight, preserving tz information.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14, 15, 30)
>>> ts.normalize()
Timestamp('2020-03-14 00:00:00')
```

**pandas.Timestamp.now**

`classmethod Timestamp.now(tz=None)`

Return new Timestamp object representing current time local to tz.

**Parameters**

- `tz` [str or timezone object, default None] Timezone to localize to.

**Examples**

```python
>>> pd.Timestamp.now()
Timestamp('2020-11-16 22:06:16.378782')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.now()
NaT
```
pandas.Timestamp.replace

**pandas.Timestamp.replace**

```
Timestamp.replace(year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=None)
```

Implements datetime.replace, handles nanoseconds.

**Parameters**

- `year` [int, optional]
- `month` [int, optional]
- `day` [int, optional]
- `hour` [int, optional]
- `minute` [int, optional]
- `second` [int, optional]
- `microsecond` [int, optional]
- `nanosecond` [int, optional]
- `tzinfo` [tz-convertible, optional]
- `fold` [int, optional]

**Returns**

Timestamp with fields replaced

**Examples**

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Replace year and the hour:

```python
>>> ts.replace(year=1999, hour=10)
Timestamp('1999-03-14 10:32:52.192548651+0000', tz='UTC')
```

Replace timezone (not a conversion):

```python
>>> import pytz

>>> ts.replace(tzinfo=pytz.timezone('US/Pacific'))
Timestamp('2020-03-14 15:32:52.192548651-0700', tz='US/Pacific')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.replace(tzinfo=pytz.timezone('US/Pacific'))
NaT
```
pandas.Timestamp.round

**pandas.Timestamp.round**

```
Timestamp.round(freq, ambiguous='raise', nonexistent='raise')
```

Round the Timestamp to the specified resolution.

**Parameters**

- **freq** [str] Frequency string indicating the rounding resolution.
- **ambiguous** [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - 'NaT' will return NaT for an ambiguous time.
  - 'raise' will raise an AmbiguousTimeError for an ambiguous time.
- **nonexistent** [{'raise', 'shift_forward', 'shift_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - 'shift_forward' will shift the nonexistent time forward to the closest existing time.
  - 'shift_backward' will shift the nonexistent time backward to the closest existing time.
  - 'NaT' will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - 'raise' will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

A new Timestamp rounded to the given resolution of *freq*

**Raises**

ValueError if the *freq* cannot be converted

**Notes**

If the Timestamp has a timezone, rounding will take place relative to the local ("wall") time and re-localized to the same timezone. When rounding near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

**Examples**

Create a timestamp object:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be rounded using multiple frequency units:

```
>>> ts.round(freq='H')  # hour
Timestamp('2020-03-14 16:00:00')
```
```python
>>> ts.round(freq='T')  # minute
Timestamp('2020-03-14 15:33:00')

>>> ts.round(freq='S')  # seconds
Timestamp('2020-03-14 15:32:52')

>>> ts.round(freq='L')  # milliseconds
Timestamp('2020-03-14 15:32:52.193000')
```

Freq can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):

```python
>>> ts.round(freq='5T')
Timestamp('2020-03-14 15:35:00')
```

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.round(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.round()
NaT
```

When rounding near a daylight savings time transition, use `ambiguous` or `nonexistent` to control how the timestamp should be re-localized.

```python
>>> ts_tz = pd.Timestamp("2021-10-31 01:30:00").tz_localize("Europe/Amsterdam")

>>> ts_tz.round("H", ambiguous=False)
Timestamp('2021-10-31 02:00:00+0100', tz='Europe/Amsterdam')

>>> ts_tz.round("H", ambiguous=True)
Timestamp('2021-10-31 02:00:00+0200', tz='Europe/Amsterdam')
```

`pandas.Timestamp.strftime`

`Timestamp.strftime(format)`

Return a string representing the given POSIX timestamp controlled by an explicit format string.

**Parameters**

- `format` [str] Format string to convert Timestamp to string. See strftime documentation for more information on the format string: https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior.
Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.strftime('%Y-%m-%d %X')
'2020-03-14 15:32:52'
```

**pandas.Timestamp.strptime**

`classmethod pandas.Timestamp.strptime(string, format)`

Function is not implemented. Use `pd.to_datetime()`.

**pandas.Timestamp.time**

`pandas.Timestamp.time()`

Return time object with same time but with tzinfo=None.

**pandas.Timestamp.timestamp**

`pandas.Timestamp.timestamp()`

Return POSIX timestamp as float.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548')
>>> ts.timestamp()
1584199972.192548
```

**pandas.Timestamp.timetuple**

`pandas.Timestamp.timetuple()`

Return time tuple, compatible with `time.localtime()`.

**pandas.Timestamp.timetz**

`pandas.Timestamp.timetz()`

Return time object with same time and tzinfo.
**pandas.Timestamp.to_datetime64**

`Timestamp.to_datetime64()`

Return a `numpy.datetime64` object with ‘ns’ precision.

**pandas.Timestamp.to_julian_date**

`Timestamp.to_julian_date()`

Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

**Examples**

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52')
>>> ts.to_julian_date()
2458923.147824074
```

**pandas.Timestamp.to_numpy**

`Timestamp.to_numpy()`

Convert the Timestamp to a NumPy datetime64.

New in version 0.25.0.

This is an alias method for `Timestamp.to_datetime64()`. The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

**Returns**

`numpy.datetime64`

**See also:**

`DatetimeIndex.to_numpy` Similar method for DatetimeIndex.

**Examples**

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.to_numpy()
numpy.datetime64('2020-03-14T15:32:52.192548651')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.to_numpy()
numpy.datetime64('NaT')
```
pandas.Timestamp.to_period

Return an period of which this timestamp is an observation.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.to_period(freq='Y')
Period('2020', 'A-DEC')

>>> ts.to_period(freq='M')
Period('2020-03', 'M')

>>> ts.to_period(freq='W')
Period('2020-03-09/2020-03-15', 'W-SUN')

>>> ts.to_period(freq='Q')
Period('2020Q1', 'Q-DEC')
```

pandas.Timestamp.to_pydatetime

Convert a Timestamp object to a native Python datetime object.

If warn=True, issue a warning if nanoseconds is nonzero.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548')
>>> ts.to_pydatetime()
datetime.datetime(2020, 3, 14, 15, 32, 52, 192548)

Analogous for pd.NaT:

>>> pd.NaT.to_pydatetime()
NaT
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.Timestamp.today

classmethod Timestamp.today(cls, tz=None)

Return the current time in the local timezone. This differs from datetime.today() in that it can be localized to a passed timezone.

Parameters

tz [str or timezone object, default None] Timezone to localize to.

Examples

```python
>>> pd.Timestamp.today()
Timestamp('2020-11-16 22:37:39.969883')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.today()
NaT
```

pandas.Timestamp.toordinal

Timestamp.toordinal()

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

pandas.Timestamp.tz_convert

Timestamp.tz_convert(tz)

Convert timezone-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

Examples

Create a timestamp object with UTC timezone:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
```

Change to Tokyo timezone:

```python
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```
>>> ts.tz_convert(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')

Can also use astimezone:

>>> ts.astimezone(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')

Analogous for pd.NaT:

>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT

**pandas.Timestamp.tz_localize**

Timestamp.tz_localize(tz, ambiguous='raise', nonexistent='raise')

Convert naive Timestamp to local time zone, or remove timezone from timezone-aware Timestamp.

**Parameters**

- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.
- **ambiguous** [bool, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- **nonexistent** ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- **localized** [Timestamp]

**Raises**
**TypeError**  If the Timestamp is tz-aware and tz is not None.

### Examples

Create a naive timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651'
>>> ts
Timestamp('2020-03-14 15:32:52.192548651')
```

Add 'Europe/Stockholm' as timezone:

```python
>>> ts.tz_localize(tz='Europe/Stockholm')
Timestamp('2020-03-14 15:32:52.192548651+0100', tz='Europe/Stockholm')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.tz_localize()
NaT
```

### pandas.Timestamp.tzname

**Timestamp.tzname()**

Return `self.tzinfo.tzname(self)`.

### pandas.Timestamp.utcfromtimestamp

**classmethod**  `Timestamp.utcfromtimestamp(ts)`

Construct a naive UTC datetime from a POSIX timestamp.

### Examples

```python
>>> pd.Timestamp.utcfromtimestamp(1584199972)
Timestamp('2020-03-14 15:32:52')
```

### pandas.Timestamp.utcnow

**classmethod**  `Timestamp.utcnow()`

Return a new Timestamp representing UTC day and time.
Examples

```python
>>> pd.Timestamp.utcnow()
Timestamp('2020-11-16 22:50:18.092888+0000', tz='UTC')
```

**pandas.Timestamp.utcoffset**

```python
Timestamp.utcoffset()
```

Return `self.tzinfo.utcoffset(self)`.

**pandas.Timestamp.utctimetuple**

```python
Timestamp.utctimetuple()
```

Return UTC time tuple, compatible with `time.localtime()`.

**pandas.Timestamp.weekday**

```python
Timestamp.weekday()
```

Return the day of the week represented by the date. Monday == 0 ... Sunday == 6.

**Properties**

- **Timestamp.asm8**
  Return numpy datetime64 format in nanoseconds.

- **Timestamp.day**
  Return day of the week.

- **Timestamp.dayofweek**
  Return day of the week.

- **Timestamp.day_of_week**
  Return day of the week.

- **Timestamp.dayofyear**
  Return the day of the year.

- **Timestamp.day_of_year**
  Return the day of the year.

- **Timestamp.days_in_month**
  Return the number of days in the month.

- **Timestamp.daysinmonth**
  Return the number of days in the month.

- **Timestamp.fold**

- **Timestamp.hour**
  Return True if year is a leap year.

- **Timestamp.is_leap_year**
  Return True if date is last day of month.

- **Timestamp.is_month_end**
  Return True if date is first day of month.

- **Timestamp.is_month_start**
  Return True if date is last day of the quarter.

- **Timestamp.is_quarter_end**
  Return True if date is first day of the quarter.

- **Timestamp.is_quarter_start**
  Return True if date is last day of the year.

- **Timestamp.is_year_end**
  Return True if date is first day of the year.

- **Timestamp.is_year_start**

- **Timestamp.max**

- **Timestamp.microsecond**

#### pandas.Timestamp.freq

`Timestamp.freq`

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a `arrays.DatetimeArray` is a `DatetimeTZDtype`. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are timezone-aware, then every value in the array must have the same timezone.

`arrays.DatetimeArray(values[, dtype, freq, copy])` Pandas ExtensionArray for tz-naive or tz-aware datetime data.

#### pandas.arrays.DatetimeArray

**class** `pandas.arrays.DatetimeArray(values[, dtype, freq, copy])` Pandas ExtensionArray for tz-naive or tz-aware datetime data.

**Warning:** DatetimeArray is currently experimental, and its API may change without warning. In particular, `DatetimeArray.dtype` is expected to change to always be an instance of an `ExtensionDtype` subclass.

**Parameters**

- `values` [Series, Index, DatetimeArray, ndarray] The datetime data.
  
  For DatetimeArray `values` (or a Series or Index boxing one), `dtype` and `freq` will be extracted from `values`.

- `dtype` [numpy.dtype or DatetimeTZDtype] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.

- `freq` [str or Offset, optional] The frequency.

- `copy` [bool, default False] Whether to copy the underlying array of values.
**Attributes**

None

**Methods**

None

---

**DatetimeTZDtype**([unit, tz])  
An ExtensionDtype for timezone-aware datetime data.

---

```python
pandas.DatetimeTZDtype
```

**class** pandas.DatetimeTZDtype(*unit='ns', tz=None*)  
An ExtensionDtype for timezone-aware datetime data.  

This is not an actual numpy dtype, but a duck type.  

**Parameters**

- **unit** [str, default "ns"] The precision of the datetime data. Currently limited to "ns".
- **tz** [str, int, or datetime.tzinfo] The timezone.

**Raises**

- pytz.UnknownTimeZoneError When the requested timezone cannot be found.

---

**Examples**

```python
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]
```

```python
>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]
```

**Attributes**

<p>| | |</p>
<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>unit</td>
<td>The precision of the datetime data.</td>
</tr>
<tr>
<td>tz</td>
<td>The timezone.</td>
</tr>
</tbody>
</table>
pandas.DatetimeTZDtype.unit

**property** DatetimeTZDtype.unit
The precision of the datetime data.

pandas.DatetimeTZDtype.tz

**property** DatetimeTZDtype.tz
The timezone.

Methods

None

3.5.3 Timedelta data

NumPy can natively represent timedeltas. pandas provides `Timedelta` for symmetry with `Timestamp`.

### Timedelta([value, unit])

Represents a duration, the difference between two dates or times.

---

**pandas.Timedelta**

**class** pandas.Timedelta(\[value=<object object>, unit=None, **kwargs\])

Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.

**Parameters**

- **value** [Timedelta, timedelta, np.timedelta64, str, or int]
- **unit** [str, default 'ns'] Denote the unit of the input, if input is an integer.

Possible values:
- ‘days’ or ‘day’
- ‘hours’, ‘hour’, ‘hr’, or ‘h’
- ‘minutes’, ‘minute’, ‘min’, or ‘m’
- ‘seconds’, ‘second’, or ‘sec’
- ‘milliseconds’, ‘millisecond’, ‘millis’, or ‘milli’
- ‘microseconds’, ‘microsecond’, ‘micros’, or ‘micro’

**kwargs** Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with datetime.timedelta. Numpy ints and floats will be coerced to python ints and floats.
**Notes**

The constructor may take in either both values of value and unit or kwargs as above. Either one of them must be used during initialization.

The `.value` attribute is always in ns.

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds.

**Examples**

Here we initialize Timedelta object with both value and unit

```python
>>> td = pd.Timedelta(1, "d")
>>> td
Timedelta('1 days 00:00:00')
```

Here we initialize the Timedelta object with kwargs

```python
>>> td2 = pd.Timedelta(days=1)
>>> td2
Timedelta('1 days 00:00:00')
```

We see that either way we get the same result.

**Attributes**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>asm8</code></td>
<td>Return a numpy timedelta64 array scalar view.</td>
</tr>
<tr>

<td>Return a components namedtuple-like.</td>
</tr>
<tr>
<td><code>days</code></td>
<td>Number of days.</td>
</tr>
<tr>
<td><code>delta</code></td>
<td>Return the timedelta in nanoseconds (ns), for internal compatibility.</td>
</tr>
<tr>
<td><code>microseconds</code></td>
<td>Number of microseconds (&gt;= 0 and less than 1 second).</td>
</tr>
<tr>
<td><code>nanoseconds</code></td>
<td>Return the number of nanoseconds (n), where 0 &lt;= n &lt; 1 microsecond.</td>
</tr>
<tr>
<td><code>resolution_string</code></td>
<td>Return a string representing the lowest timedelta resolution.</td>
</tr>
<tr>
<td><code>seconds</code></td>
<td>Number of seconds (&gt;= 0 and less than 1 day).</td>
</tr>
</tbody>
</table>

**pandas.Timedelta.asm8**

`Timedelta.asm8`

Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the `numpy.timedelta64().view()`, including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

**Returns**

- **numpy timedelta64 array scalar view**: Array scalar view of the timedelta in nanoseconds.
### Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042,'ns')

>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000,'ns')

>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000,'ns')

>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42,'ns')
```

### pandas.Timedelta.components

`Timedelta.components`  
Return a components namedtuple-like.

### pandas.Timedelta.days

`Timedelta.days`  
Number of days.

### pandas.Timedelta.delta

`Timedelta.delta`  
Return the timedelta in nanoseconds (ns), for internal compatibility.

**Returns**

- `int`  Timedelta in nanoseconds.

### Examples

```python
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
8640000000042

>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000

>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

**pandas.Timedelta.microseconds**

Timedelta.microseconds

Number of microseconds (≥ 0 and less than 1 second).

**pandas.Timedelta.nanoseconds**

Timedelta.nanoseconds

Return the number of nanoseconds (n), where 0 ≤ n < 1 microsecond.

Returns

int Number of nanoseconds.

See also:

Timedelta.components Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

**Examples**

**Using string input**

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')

>>> td.nanoseconds
42
```

**Using integer input**

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```
pandas.Timedelta.resolution_string

Timedelta.resolution_string

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

• Days: ‘D’
• Hours: ‘H’
• Minutes: ‘T’
• Seconds: ‘S’
• Milliseconds: ‘L’
• Microseconds: ‘U’
• Nanoseconds: ‘N’

Returns

str Timedelta resolution.

Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution_string
'N'

>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution_string
'U'

>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution_string
'S'

>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution_string
'U'
```
**pandas.Timedelta.seconds**

Timedelta.seconds

Number of seconds (>= 0 and less than 1 day).

<table>
<thead>
<tr>
<th>freq</th>
<th>is_populated</th>
<th>value</th>
</tr>
</thead>
</table>

**Methods**

- **ceil**(freq) Return a new Timedelta ceiled to this resolution.
- **floor**(freq) Return a new Timedelta floored to this resolution.
- **round**(freq) Round the Timedelta to the specified resolution.
- **to_numpy** Convert the Timedelta to a NumPy timedelta64.
- **to_pytimedelta** Convert a pandas Timedelta object into a python datetime.timedelta object.
- **to_timedelta64** Return a numpy.timedelta64 object with 'ns' precision.
- **total_seconds** Total seconds in the duration.
- **view** Array view compatibility.

**pandas.Timedelta.ceil**

Timedelta.ceil(freq)

Return a new Timedelta ceiled to this resolution.

**Parameters**

freq [str] Frequency string indicating the ceiling resolution.

**pandas.Timedelta.floor**

Timedelta.floor(freq)

Return a new Timedelta floored to this resolution.

**Parameters**

freq [str] Frequency string indicating the flooring resolution.
pandas.Timedelta.isoformat

Timedelta.isoformat()

Returns

str

See also:

Timestamp.isoformat Function is used to convert the given Timestamp object into the ISO format.

Notes

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0's are removed from the seconds component after the decimal. We do not 0 pad components, so it's ...TSH... not ...T0SH...

Examples

```python
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3, ...
... milliseconds=10, microseconds=10, nanoseconds=12)

>>> td.isoformat()
'P6DT0H50M3.010010012S'

>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT1H0M10S'

>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0M0S'
```

pandas.Timedelta.round

Timedelta.round(freq)

Round the Timedelta to the specified resolution.

Parameters

freq [str] Frequency string indicating the rounding resolution.

Returns

a new Timedelta rounded to the given resolution of freq

Raises

ValueError if the freq cannot be converted
pandas.Timedelta.to_numpy

Timedelta.to_numpy()

Convert the Timedelta to a NumPy timedelta64.

New in version 0.25.0.
This is an alias method for Timedelta.to_timedelta64(). The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns

numpy.timedelta64

See also:

Series.to_numpy Similar method for Series.

pandas.Timedelta.to_pytimedelta

Timedelta.to_pytimedelta()

Convert a pandas Timedelta object into a python datetime.timedelta object.
Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use to_pytimedelta() to convert to object dtype.

Returns

datetime.timedelta or numpy.array of datetime.timedelta

See also:

to_timedelta Convert argument to Timedelta type.

Notes

Any nanosecond resolution will be lost.

pandas.Timedelta.to_timedelta64

Timedelta.to_timedelta64()

Return a numpy.timedelta64 object with ‘ns’ precision.

pandas.Timedelta.total_seconds

Timedelta.total_seconds()

Total seconds in the duration.
### pandas.Timedelta.view

**Timedelta.view()**

Array view compatibility.

#### Properties

## pandas.Timedelta.freq

**Timedelta.freq**

### pandas.Timedelta.is_populated

**Timedelta.is_populated**

### pandas.Timedelta.max

**Timedelta.max** = Timedelta('106751 days 23:47:16.854775807')
pandas: powerful Python data analysis toolkit, Release 1.4.3

**pandas.Timedelta.min**

\[
\text{Timedelta.min} = \text{Timedelta}(-106752 \text{ days } +00:12:43.145224193')
\]

**pandas.Timedelta.resolution**

\[
\text{Timedelta.resolution} = \text{Timedelta}'0 \text{ days } 00:00:00.000000001'
\]

**pandas.Timedelta.value**

\[
\text{Timedelta.value}
\]

### Methods

<table>
<thead>
<tr>
<th><strong>Method</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Timedelta.ceil(freq)</code></td>
<td>Return a new Timedelta ceiled to this resolution.</td>
</tr>
<tr>
<td><code>Timedelta.floor(freq)</code></td>
<td>Return a new Timedelta floored to this resolution.</td>
</tr>
<tr>
<td><code>Timedelta.round(freq)</code></td>
<td>Round the Timedelta to the specified resolution.</td>
</tr>
<tr>
<td><code>Timedelta.to_pytimedelta</code></td>
<td>Convert a pandas Timedelta object into a python datetime.timedelta object.</td>
</tr>
<tr>
<td><code>Timedelta.to_timedelta64</code></td>
<td>Return a numpy.timedelta64 object with 'ns' precision.</td>
</tr>
<tr>
<td><code>Timedelta.to_numpy</code></td>
<td>Convert the Timedelta to a NumPy timedelta64.</td>
</tr>
<tr>
<td><code>Timedelta.total_seconds</code></td>
<td>Total seconds in the duration.</td>
</tr>
</tbody>
</table>

A collection of Timedelta may be stored in a TimedeltaArray.

**arrays.TimedeltaArray(values[, dtype, freq, ...])** Pandas ExtensionArray for timedelta data.

### pandas.arrays.TimedeltaArray

**class** `pandas.arrays.TimedeltaArray(values[, dtype, freq, ...])` Pandas ExtensionArray for timedelta data.

**Warning:** TimedeltaArray is currently experimental, and its API may change without warning. In particular, TimedeltaArray.dtype is expected to change to be an instance of an ExtensionDtype subclass.

**Parameters**

- `values` [array-like] The timedelta data.
- `dtype` [numpy.dtype] Currently, only numpy.dtype("timedelta64[ns]") is accepted.
- `freq` [Offset, optional]
- `copy` [bool, default False] Whether to copy the underlying array of data.
3.5.4 Timespan data

pandas represents spans of times as Period objects.

3.5.5 Period

```
Period([value, freq, ordinal, year, month, ...]) Represents a period of time.
```

```python
class pandas.Period(value=None, freq=None, ordinal=None, year=None, month=None, quarter=None, day=None, hour=None, minute=None, second=None)
```

Represents a period of time.

**Parameters**

- **value** [Period or str, default None] The time period represented (e.g., ‘4Q2005’).
- **freq** [str, default None] One of pandas period strings or corresponding objects.
- **ordinal** [int, default None] The period offset from the proleptic Gregorian epoch.
- **year** [int, default None] Year value of the period.
- **month** [int, default 1] Month value of the period.
- **quarter** [int, default None] Quarter value of the period.
- **day** [int, default 1] Day value of the period.
- **hour** [int, default 0] Hour value of the period.
- **minute** [int, default 0] Minute value of the period.
- **second** [int, default 0] Second value of the period.
### Attributes

<table>

<td>Return the year this Period falls on.</td>
</tr>
</tbody>
</table>

#### pandas.Period.day

`Period.day`

Get day of the month that a Period falls on.

**Returns**

int

**See also:**

- `Period.dayofweek` Get the day of the week.
- `Period.dayofyear` Get the day of the year.
pandas: powerful Python data analysis toolkit, Release 1.4.3

Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

`pandas.Period.day_of_week`

`Period.day_of_week`

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

`int` Day of the week.

See also:

`Period.day_of_week` Day of the week the period lies in.

`Period.weekday` Alias of Period.day_of_week.

`Period.day` Day of the month.

`Period.dayofyear` Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.Period.day_of_year

Period.day_of_year
Return the day of the year.
This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns
int The day of year.

See also:
Period.day Return the day of the month.
Period.day_of_week Return the day of week.
PeriodIndex.day_of_year Return the day of year of all indexes.

Examples

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```

pandas.Period.dayofweek

Period.dayofweek
Day of the week the period lies in, with Monday=0 and Sunday=6.
If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.
If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns
int Day of the week.

See also:
Period.day_of_week Day of the week the period lies in.
Period.weekday Alias of Period.day_of_week.
Period.day Day of the month.
Period.dayofyear Day of the year.
Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

pandas.Period.dayofyear

Period.dayofyear

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns

- `int`: The day of year.

See also:

- `Period.day` Return the day of the month.
- `Period.day_of_week` Return the day of week.
- `PeriodIndex.day_of_year` Return the day of year of all indexes.

Examples

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```
pandas.Period.days_in_month

Period.days_in_month
Get the total number of days in the month that this period falls on.

Returns
int

See also:

Period.daysinmonth  Gets the number of days in the month.
DatetimeIndex.daysinmonth  Gets the number of days in the month.
calendar.monthrange  Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

Examples

```python
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```python
>>> pd.Period('2018-03-01').days_in_month
31
```
Handles the leap year case as well:

```python
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

pandas.Period.daysinmonth

Period.daysinmonth
Get the total number of days of the month that the Period falls in.

Returns
int

See also:

Period.days_in_month  Return the days of the month.
Period.dayofyear  Return the day of the year.
**Examples**

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

`pandas.Period.end_time`

*Period.end_time*

Get the Timestamp for the end of the period.

Returns

*Timestamp*

See also:

- *Period.start_time* Return the start Timestamp.
- *Period.dayofyear* Return the day of year.
- *Period.daysinmonth* Return the days in that month.
- *Period.dayofweek* Return the day of the week.

`pandas.Period.freqstr`

*Period.freqstr*

Return a string representation of the frequency.

`pandas.Period.hour`

*Period.hour*

Get the hour of the day component of the Period.

Returns

- *int* The hour as an integer, between 0 and 23.

See also:

- *Period.second* Get the second component of the Period.
- *Period.minute* Get the minute component of the Period.
Examples

```python
>>> p.hour
13

Period longer than a day

```python
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```
pandas.Period.quarter

Period.quarter
Return the quarter this Period falls on.

pandas.Period.qyear

Period.qyear
Fiscal year the Period lies in according to its starting-quarter.
The year and the qyear of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

Returns
int The fiscal year of the period.

See also:
Period.year Return the calendar year of the period.

Examples
If the natural and fiscal year are the same, qyear and year will be the same.

```python
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (Q-MAR), the first quarter of 2018 will start in April 2017. year will then be 2018, but qyear will be the fiscal year, 2018.

```python
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

pandas.Period.second

Period.second
Get the second component of the Period.

Returns
int The second of the Period (ranges from 0 to 59).

See also:
Period.hour Get the hour component of the Period.
Period.minute  Get the minute component of the Period.

Examples

```python
>>> p.second
12
```

pandas.Period.start_time

Period.start_time  Get the Timestamp for the start of the period.

Returns

Timestamp

See also:

Period.end_time  Return the end Timestamp.
Period.dayofyear  Return the day of year.
Period.daysinmonth  Return the days in that month.
Period.dayofweek  Return the day of the week.

Examples

```python
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')

>>> period.start_time
Timestamp('2012-01-01 00:00:00')

>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

pandas.Period.week

Period.week  Get the week of the year on the given Period.

Returns

int

See also:

Period.dayofweek  Get the day component of the Period.
Period.weekday  Get the day component of the Period.
Examples

```python
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10

>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5

>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

`pandas.Period.weekday`

Period `.weekday`

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

**Returns**

int  Day of the week.

See also:

- `Period.dayofweek`  Day of the week the period lies in.
- `Period.weekday`   Alias of Period.dayofweek.
- `Period.day`   Day of the month.
- `Period.dayofyear`   Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

**pandas.Period.weekofyear**

Period.weekofyear

Get the week of the year on the given Period.

Returns

int

See also:

- **Period.dayofweek** Get the day component of the Period.
- **Period.weekday** Get the day component of the Period.

**Examples**

```python
>>> p = pd.Period("2018-03-11", "H")
>>> p.weekofyear
10

>>> p = pd.Period("2018-02-01", "D")
>>> p.weekofyear
5

>>> p = pd.Period("2018-01-06", "D")
>>> p.weekofyear
1
```

**pandas.Period.year**

Period.year

Return the year this Period falls on.
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asfreq</td>
<td>Convert Period to desired frequency, at the start or end of the interval.</td>
</tr>
<tr>
<td>now</td>
<td>Return the period of now’s date.</td>
</tr>
<tr>
<td>strftime</td>
<td>Returns the string representation of the Period, depending on the selected fmt.</td>
</tr>
<tr>
<td>to_timestamp</td>
<td>Return the Timestamp representation of the Period.</td>
</tr>
</tbody>
</table>

**pandas.Period.asfreq**

Period.asfreq()

Convert Period to desired frequency, at the start or end of the interval.

**Parameters**

- **freq** [str] The desired frequency.
- **how** [{‘E’, ‘S’, ‘end’, ‘start’}, default ‘end’] Start or end of the timespan.

**Returns**

- **resampled** [Period]

**pandas.Period.now**

Period.now()

Return the period of now’s date.

**pandas.Period.strftime**

Period.strftime()

Returns the string representation of the Period, depending on the selected fmt. fmt must be a string containing one or several directives. The method recognizes the same directives as the time.strftime() function of the standard Python distribution, as well as the specific additional directives %f, %F, %q. (formatting & docs originally from scikits.timers).
<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Locale’s abbreviated weekday name.</td>
<td></td>
</tr>
<tr>
<td>%A</td>
<td>Locale’s full weekday name.</td>
<td></td>
</tr>
<tr>
<td>%b</td>
<td>Locale’s abbreviated month name.</td>
<td></td>
</tr>
<tr>
<td>%B</td>
<td>Locale’s full month name.</td>
<td></td>
</tr>
<tr>
<td>%c</td>
<td>Locale’s appropriate date and time representation.</td>
<td></td>
</tr>
<tr>
<td>%d</td>
<td>Day of the month as a decimal number [01,31].</td>
<td></td>
</tr>
<tr>
<td>%e</td>
<td>‘Fiscal’ year without a century as a decimal number [00,99]</td>
<td>(1)</td>
</tr>
<tr>
<td>%F</td>
<td>‘Fiscal’ year with a century as a decimal number</td>
<td>(2)</td>
</tr>
<tr>
<td>%h</td>
<td>Hour (24-hour clock) as a decimal number [00,23].</td>

<tr>
<td>%H</td>
<td>Hour (12-hour clock) as a decimal number [01,12].</td>
<td></td>
</tr>
<tr>
<td>%j</td>
<td>Day of the year as a decimal number [001,366].</td>
<td></td>
</tr>
<tr>
<td>%m</td>
<td>Month as a decimal number [01,12].</td>
<td></td>
</tr>
<tr>
<td>%m</td>
<td>Minute as a decimal number [00,59].</td>
<td></td>
</tr>
<tr>
<td>%p</td>
<td>Locale’s equivalent of either AM or PM.</td>
<td>(3)</td>
</tr>
<tr>
<td>%q</td>
<td>Quarter as a decimal number [01,04]</td>
<td></td>
</tr>
<tr>
<td>%s</td>
<td>Second as a decimal number [00,61].</td>
<td>(4)</td>
</tr>
<tr>
<td>%w</td>
<td>Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%W</td>
<td>Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%x</td>
<td>Locale’s appropriate date representation.</td>
<td></td>
</tr>
<tr>
<td>%X</td>
<td>Locale’s appropriate time representation.</td>
<td></td>
</tr>
<tr>
<td>%y</td>
<td>Year without century as a decimal number [00,99].</td>
<td></td>
</tr>
<tr>
<td>%Y</td>
<td>Year with century as a decimal number.</td>
<td></td>
</tr>
<tr>
<td>%z</td>
<td>Time zone name (no characters if no time zone exists).</td>
<td></td>
</tr>
<tr>
<td>%Z</td>
<td>A literal ‘%’ character.</td>
<td></td>
</tr>
</tbody>
</table>

**Notes**

(1) The `%e` directive is the same as `%y` if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the `qyear` attribute.

(2) The `%F` directive is the same as `%Y` if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the `qyear` attribute.

(3) The `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.

(4) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.

(5) The `%w` and `%U` directives are only used in calculations when the day of the week and the year are specified.
Examples

```python
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-%Qq')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2001'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

**pandas.Period.to_timestamp**

`Period.to_timestamp()`

Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by `how`, which is either `Start` or `Finish`.

**Parameters**

- `freq` [str or DateOffset] Target frequency. Default is ‘D’ if self.freq is week or longer and ‘S’ otherwise.

**Returns**

- Timestamp

A collection of Period may be stored in a arrays.PeriodArray. Every period in a arrays.PeriodArray must have the same freq.

arrays.PeriodArray(values[, dtype, freq, copy]) Pandas ExtensionArray for storing Period data.

**pandas.arrays.PeriodArray**

class pandas.arrays.PeriodArray(values, dtype=None, freq=None, copy=False)

Pandas ExtensionArray for storing Period data.

Users should use period_array() to create new instances. Alternatively, array() can be used to create new instances from a sequence of Period scalars.

Parameters

- **values** [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).

- **dtype** [PeriodDtype, optional] A PeriodDtype instance from which to extract a freq. If both freq and dtype are specified, then the frequencies must match.

- **freq** [str or DateOffset] The freq to use for the array. Mostly applicable when values is an ndarray of integers, when freq is required. When values is a PeriodArray (or box around), it’s checked that values.freq matches freq.

- **copy** [bool, default False] Whether to copy the ordinals before storing.

See also:

- **Period** Represents a period of time.
- **PeriodIndex** Immutable Index for period data.
- **period_range** Create a fixed-frequency PeriodArray.
- **array** Construct a pandas array.

3.5. pandas arrays, scalars, and data types 2093
Notes

There are two components to a PeriodArray
- ordinals : integer ndarray
- freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The freq indicates the span covered by each element of the array. All elements in the PeriodArray have the same freq.

Attributes

Methods

```
PeriodDtype(freq)
```
An ExtensionDtype for Period data.

```
pandas.PeriodDtype
```

```
class pandas.PeriodDtype(freq=\nNone)
```
An ExtensionDtype for Period data.

This is not an actual numpy dtype, but a duck type.

Parameters

freq [str or DateOffset] The frequency of this PeriodDtype.

Examples

```
>>> pd.PeriodDtype(freq='D')
period[D]
```

```
>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```
Attributes

| freq | The frequency object of this PeriodDtype. |

pandas.PeriodDtype.freq

```
property PeriodDtype.freq
    The frequency object of this PeriodDtype.
```

Methods

None

3.5.6 Interval data

Arbitrary intervals can be represented as `Interval` objects.

```
Interval
    Immutable object implementing an Interval, a bounded slice-like interval.
```

pandas.Interval

```
class pandas.Interval
    Immutable object implementing an Interval, a bounded slice-like interval.
    Parameters
        left [orderable scalar] Left bound for the interval.
        right [orderable scalar] Right bound for the interval.
        closed [‘right’, ‘left’, ‘both’, ‘neither’], default ‘right’] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

See also:
    IntervalIndex An Index of Interval objects that are all closed on the same side.
    cut Convert continuous data into discrete bins (Categorical of Interval objects).
    qcut Convert continuous data into bins (Categorical of Interval objects) based on quantiles.
    Period Represents a period of time.
```

Notes

The parameters `left` and `right` must be from the same type, you must be able to compare them and they must satisfy `left <= right`.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval `[0, 5]` is characterized by the conditions `0 <= x <= 5`. This is what `closed='both'` stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval `(0, 5)` is characterized by the conditions `0 < x < 5`. This is what `closed='neither'` stands for. Intervals can also be half-open or half-closed, i.e. `[0, 5)` is described by `0 <= x < 5 (closed='left')` and `(0, 5]` is described by `0 < x <= 5 (closed='right').`
Examples

It is possible to build Intervals of different types, like numeric ones:

```python
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```python
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so $0 < x \leq 5$):

```python
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```python
>>> iv.length
5
```

You can operate with $+$ and $*$ over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```python
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```python
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
... pd.Timestamp('2018-01-01 00:00:00'),
... closed='left')
>>> pd.Timestamp('2017-01-01 00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

**pandas.Interval.closed**

Interval.closed

Whether the interval is closed on the left-side, right-side, both or neither.

**pandas.Interval.closed_left**

Interval.closed_left

Check if the interval is closed on the left side.

For the meaning of *closed* and *open* see Interval.

Returns

bool True if the Interval is closed on the left-side.

**pandas.Interval.closed_right**

Interval.closed_right

Check if the interval is closed on the right side.

For the meaning of *closed* and *open* see Interval.

Returns

bool True if the Interval is closed on the left-side.
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.Interval.is_empty

Interval.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean
ndarray positionally indicating if an Interval in an IntervalArray or
IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an
Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
          pd.IntervalArray([1, 2, closed='neither'])
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```
**pandas.Interval.left**

`Interval.left`

Left bound for the interval.

**pandas.Interval.length**

`Interval.length`

Return the length of the Interval.

**pandas.Interval.mid**

`Interval.mid`

Return the midpoint of the Interval.

**pandas.Interval.open_left**

`Interval.open_left`

Check if the interval is open on the left side.

For the meaning of `closed` and `open` see `Interval`.

Returns

`bool` True if the Interval is closed on the left-side.

**pandas.Interval.open_right**

`Interval.open_right`

Check if the interval is open on the right side.

For the meaning of `closed` and `open` see `Interval`.

Returns

`bool` True if the Interval is closed on the left-side.

**pandas.Interval.right**

`Interval.right`

Right bound for the interval.
**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>overlaps</code></td>
<td>Check whether two Interval objects overlap.</td>
</tr>
</tbody>
</table>

**pandas.Interval.overlaps**

Interval `overlaps()`

Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

**Parameters**

other [Interval] Interval to check against for an overlap.

**Returns**

bool True if the two intervals overlap.

**Examples**

```python
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```python
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```
### Properties

</table>

A collection of intervals may be stored in an `arrays.IntervalArray`.

```python
arrays.IntervalArray(data[, closed, dtype, ...])  # Pandas array for interval data that are closed on the same side.
```

### pandas.arrays.IntervalArray

**class** `pandas.arrays.IntervalArray(data, closed=None, dtype=None, copy=False, verify_integrity=True)`

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

**Parameters**

- **data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.
- **closed** [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’ Whether the intervals are closed on the left-side, right-side, both or neither.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.
- **copy** [bool, default False] Copy the input data.
- **verify_integrity** [bool, default True] Verify that the IntervalArray is valid.

**See also:**

- **Index** The base pandas Index type.
- **Interval** A bounded slice-like interval; the elements of an IntervalArray.
- **interval_range** Function to create a fixed frequency IntervalIndex.
- **cut** Bin values into discrete Intervals.
- **qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.
Notes

See the user guide for more.

Examples

A new IntervalArray can be constructed directly from an array-like of Interval objects:

```python
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)]
<IntervalArray>
[(0, 1], (1, 5]
Length: 2, dtype: interval[int64, right]
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>left</code></td>
<td>Return the left endpoints of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>right</code></td>
<td>Return the right endpoints of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>closed</code></td>
<td>Whether the intervals are closed on the left-side, right-side, both or neither.</td>
</tr>
<tr>
<td><code>mid</code></td>
<td>Return the midpoint of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>length</code></td>
<td>Return an Index with entries denoting the length of each Interval in the IntervalArray.</td>
</tr>
<tr>
<td><code>is_empty</code></td>
<td>Indicates if an interval is empty, meaning it contains no points.</td>
</tr>
<tr>
<td><code>is_non_overlapping_monotonic</code></td>
<td>Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.</td>
</tr>
</tbody>
</table>

```python
pandas.arrays.IntervalArray.left

property IntervalArray.left

    Return the left endpoints of each Interval in the IntervalArray as an Index.

pandas.arrays.IntervalArray.right

property IntervalArray.right

    Return the right endpoints of each Interval in the IntervalArray as an Index.
```
**pandas.arrays.IntervalArray.closed**

**property** IntervalArray.closed

Whether the intervals are closed on the left-side, right-side, both or neither.

**pandas.arrays.IntervalArray.mid**

**property** IntervalArray.mid

Return the midpoint of each Interval in the IntervalArray as an Index.

**pandas.arrays.IntervalArray.length**

**property** IntervalArray.length

Return an Index with entries denoting the length of each Interval in the IntervalArray.

**pandas.arrays.IntervalArray.is_empty**

IntervalArray.is_empty

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

**Examples**

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([True, False])
```

**pandas.arrays.IntervalArray.is_non_overlapping_monotonic**

**property IntervalArray.is_non_overlapping_monotonic**

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>from_arrays</code> : <code>from_tuples</code></td>
<td>Construct from two arrays defining the left and right bounds.</td>
</tr>
<tr>

<td>Construct an IntervalArray from an array of splits.</td>
</tr>
<tr>
<td><code>contains</code></td>
<td>Check elementwise if the Intervals contain the value.</td>
</tr>
<tr>
<td><code>overlaps</code></td>
<td>Check elementwise if an Interval overlaps the values in the IntervalArray.</td>
</tr>
<tr>
<td><code>set_closed</code></td>
<td>Return an IntervalArray identical to the current one, but closed on the specified side.</td>
</tr>
<tr>
<td><code>to_tuples</code></td>
<td>Return an ndarray of tuples of the form (left, right).</td>
</tr>
</tbody>
</table>

**pandas.arrays.IntervalArray.from_arrays**

**classmethod IntervalArray.from_arrays**

Construct from two arrays defining the left and right bounds.

**Parameters**

- **left**  
  array-like (1-dimensional)] Left bounds for each interval.

- **right**  
  array-like (1-dimensional)] Right bounds for each interval.

- **closed**  
  ['left', 'right', 'both', 'neither'], default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

- **copy**  
  [bool, default False] Copy the data.

- **dtype**  
  [dtype, optional] If None, dtype will be inferred.

**Returns**

IntervalArray
Raises

*ValueError* When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

See also:

- **interval_range** Function to create a fixed frequency `IntervalIndex`.
- **IntervalArray.from_breaks** Construct an `IntervalArray` from an array of splits.
- **IntervalArray.from_tuples** Construct an `IntervalArray` from an array-like of tuples.

Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

```python
>>> pd.arrays.IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
```

### pandas.arrays.IntervalArray.from_tuples

**classmethod** `IntervalArray.from_tuples(data, closed='right', copy=False, dtype=None)`

Construct an `IntervalArray` from an array-like of tuples.

**Parameters**

- **data** [array-like (1-dimensional)] Array of tuples.
- **closed** [['left', 'right', 'both', 'neither'], default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] By-default copy the data, this is compat only and ignored.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

**Returns**

- **IntervalArray**

See also:

- **interval_range** Function to create a fixed frequency `IntervalIndex`.
- **IntervalArray.from_arrays** Construct an `IntervalArray` from a left and right array.
- **IntervalArray.from_breaks** Construct an `IntervalArray` from an array of splits.
Examples

```python
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[(0, 1], (1, 2]
Length: 2, dtype: interval[int64, right]
```

**pandas.arrays.IntervalArray.from_breaks**

**class method** `IntervalArray.from_breaks(breaks, closed='right', copy=False, dtype=None)`

Construct an IntervalArray from an array of splits.

**Parameters**

- `breaks` [array-like (1-dimensional)] Left and right bounds for each interval.
- `closed` [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- `copy` [bool, default False] Copy the data.
- `dtype` [dtype or None, default None] If None, dtype will be inferred.

**Returns**

`IntervalArray`

See also:

- `interval_range` Function to create a fixed frequency IntervallIndex.
- `IntervalArray.from_arrays` Construct from a left and right array.
- `IntervalArray.from_tuples` Construct from a sequence of tuples.

**Examples**

```python
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]
Length: 3, dtype: interval[int64, right]
```

**pandas.arrays.IntervalArray.contains**

`IntervalArray.contains(other)`

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

**Parameters**

- `other` [scalar] The value to check whether it is contained in the Intervals.

**Returns**
boolean array

See also:

- `Interval.contains` Check whether Interval object contains value.
- `IntervalArray.overlaps` Check if an Interval overlaps the values in the IntervalArray.

Examples

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]

>>> intervals.contains(0.5)
aarray([ True, False, False])
```

#### pandas.arrays.IntervalArray.overlaps

`IntervalArray.overlaps(other)`

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

**Parameters**

- `other` [IntervalArray] Interval to check against for an overlap.

**Returns**

- `ndarray` Boolean array positionally indicating where an overlap occurs.

See also:

- `Interval.overlaps` Check whether two Interval objects overlap.

Examples

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
aarray([ True, True, False])
```

Intervals that share closed endpoints overlap:
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True, True, True])

Intervals that only have an open endpoint in common do not overlap:

>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False, True, False])

**pandas.arrays.IntervalArray.set_closed**

**IntervalArray.set_closed(closed)**

Return an IntervalArray identical to the current one, but closed on the specified side.

**Parameters**

`closed` [{’left’, ’right’, ’both’, ’neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

`new_index` [IntervalArray]

**Examples**

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3)]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]
```

**pandas.arrays.IntervalArray.to_tuples**

**IntervalArray.to_tuples(na_tuple=True)**

Return an ndarray of tuples of the form (left, right).

**Parameters**

`na_tuple` [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

**Returns**

`tuples` : ndarray

**IntervalDtype**([subtype, closed]) An ExtensionDtype for Interval data.
pandas.IntervalDtype

class pandas.IntervalDtype(subtype=None, closed=None)
    An ExtensionDtype for Interval data.

This is not an actual numpy dtype, but a duck type.

Parameters

Examples

>>> pd.IntervalDtype(subtype='int64', closed='both')
interval[int64, both]

Attributes

subtype The dtype of the Interval bounds.

pandas.IntervalDtype.subtype

property IntervalDtype.subtype
    The dtype of the Interval bounds.

Methods

None

3.5.7 Nullable integer

numpy.ndarray cannot natively represent integer-data with missing values. pandas provides this through arrays.IntegerArray.

arrays.IntegerArray(values, mask[, copy]) Array of integer (optional missing) values.

pandas.arrays.IntegerArray

class pandas.arrays.IntegerArray(values, mask[, copy])
    Array of integer (optional missing) values.

Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

Warning: IntegerArray is currently experimental, and its API or internal implementation may change without warning.
We represent an IntegerArray with 2 numpy arrays:
- *data*: contains a numpy integer array of the appropriate dtype
- *mask*: a boolean array holding a mask on the data, True is missing

To construct an IntegerArray from generic array-like input, use `pandas.array()` with one of the integer dtypes (see examples).

See [Nullable integer data type](#) for more.

**Parameters**

- **mask** [numpy.ndarray] A 1-d boolean-dtype array indicating missing values.
- **copy** [bool, default False] Whether to copy the *values* and *mask*.

**Returns**

- **IntegerArray**

**Examples**

Create an IntegerArray with `pandas.array()`.

```python
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```python
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

```python
>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

3.5.8 Categorical data

pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a Categorical can be described by a CategoricalDtype.

   CategoricalDtype([categories, ordered]) Type for categorical data with the categories and orderedness.

pandas.CategoricalDtype

class pandas.CategoricalDtype(categories=None, ordered=False)
   Type for categorical data with the categories and orderedness.
   Parameters

      categories [sequence, optional] Must be unique, and must not contain any nulls. The categories are stored in an Index, and if an index is provided the dtype of that index will be used.

      ordered [bool or None, default False] Whether or not this categorical is treated as a ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. astype, and will resolve to False if there is no existing ordered to maintain.

   See also:

      Categorical Represent a categorical variable in classic R / S-plus fashion.
Notes

This class is useful for specifying the type of a `Categorical` independent of the values. See `CategoricalDtype` for more.

Examples

```python
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0   a
1   b
2   a
3  NaN
dtype: category
Categories (2, object): ['b' < 'a']
```

An empty `CategoricalDtype` with a specific dtype can be created by providing an empty index. As follows,

```python
>>> pd.CategoricalDtype(pd.DatetimeIndex([])).categories.dtype
'dtype('<M8[ns]')
```

Attributes

- `categories`: An `Index` containing the unique categories allowed.
- `ordered`: Whether the categories have an ordered relationship.

```python
pandas.CategoricalDtype.categories

property CategoricalDtype.categories
An Index containing the unique categories allowed.
```

```python
pandas.CategoricalDtype.ordered

property CategoricalDtype.ordered
Whether the categories have an ordered relationship.
```

Methods

None

```
CategoricalDtype.categories
An Index containing the unique categories allowed.
```

```
CategoricalDtype.ordered
Whether the categories have an ordered relationship.
```

Categorical data can be stored in a `pandas.Categorical`
Categorical \(\text{values}[\#, \text{categories}, \text{ordered}, ...]\) Represent a categorical variable in classic R / S-plus fashion.

pandas.Categorical

class pandas.Categorical(values, categories=None, ordered=None, dtype=None, fastpath=False, copy=True)
Represent a categorical variable in classic R / S-plus fashion.

Categoricals can only take on only a limited, and usually fixed, number of possible values (categories). In contrast to statistical categorical variables, a Categorical might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the Categorical are either in categories or np.nan. Assigning values outside of categories will raise a ValueError. Order is defined by the order of the categories, not lexical order of the values.

Parameters

- values [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.
- categories [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of values (sorted, if possible, otherwise in the order in which they appear).
- ordered [bool, default False] Whether or not this categorical is treated as a ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects, when sorted, the order of its categories attribute (which in turn is the categories argument, if provided).
- dtype [CategoricalDtype] An instance of CategoricalDtype to use for this categorical.

Raises

- ValueError If the categories do not validate.
- TypeError If an explicit ordered=True is given but no categories and the values are not sortable.

See also:

- CategoricalDtype Type for categorical data.
- CategoricalIndex An Index with an underlying Categorical.

Notes

See the user guide for more.

Examples

```python
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

```python
>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```
Missing values are not included as a category.

```python
>>> c = pd.Categorical([1, 2, 3, 1, 2, 3, np.nan])
>>> c
[1, 2, 3, 1, 2, 3, NaN]
Categories (3, int64): [1, 2, 3]
```

However, their presence is indicated in the codes attribute by code -1.

```python
>>> c.codes
array([ 0, 1, 2, 0, 1, 2, -1], dtype=int8)
```

Ordered Categoricals can be sorted according to the custom order of the categories and can have a min and max value.

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
                      categories=['c', 'b', 'a'])
>>> c
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['c' < 'b' < 'a']
>>> c.min()
'c'
```
removeUnusedCategories Remove categories which are not used.
setCategories Set the categories to the specified ones.

pandas.Categorical.codes

property Categorical.codes
The category codes of this categorical.
Codes are an array of integers which are the positions of the actual values in the categories array.
There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns
ndarray[int] A non-writable view of the codes array.

pandas.Categorical.ordered

property Categorical.ordered
Whether the categories have an ordered relationship.

pandas.Categorical.dtype

property Categorical.dtype
The CategoricalDtype for this instance.

Methods

from_codes(codes[, categories, ordered, dtype]) Make a Categorical type from codes and categories or dtype.
__array__([dtype]) The numpy array interface.

pandas.Categorical.from_codes

classmethod Categorical.from_codes(codes, categories=None, ordered=None, dtype=None)
Make a Categorical type from codes and categories or dtype.
This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.
If your data does not follow this convention, please use the normal constructor.

Parameters

codes [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.
categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in dtype.
ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in dtype, the resulting categorical will be unordered.

dtype [CategoricalDtype or "category", optional] If CategoricalDtype, cannot be used together with categories or ordered.

Returns
Categorical

Examples

```python
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

pandas.Categorical.__array__

Categorical.__array__(dtype=None)
The numpy array interface.

Returns
numpy.array A numpy array of either the specified dtype or, if dtype==None (default),
the same dtype as categorical.categories.dtype.

The alternative Categorical.from_codes() constructor can be used when you have the categories and integer codes already:

```python
Categorical.from_codes(codes[, categories, ...]) Make a Categorical type from codes and categories or dtype.
```

The dtype information is available on the Categorical

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Categorical.dtype</td>
<td>The CategoricalDtype for this instance.</td>
</tr>
<tr>
<td>Categorical.categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>Categorical.ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td>Categorical.codes</td>
<td>The category codes of this categorical.</td>
</tr>
</tbody>
</table>

np.asarray(categorical) works by implementing the array interface. Be aware, that this converts the Categorical back to a NumPy array, so categories and order information is not preserved!

Categorical.__array__([dtype]) The numpy array interface.

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use cat = s. astype(dtype) or Series(..., dtype=dtype) where dtype is either

- the string 'category'
- an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, Series.cat can be used to change the categorical data. See Categorical accessor for more.

3.5. pandas arrays, scalars, and data types
3.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a `arrays.SparseArray`.

```python
arrays.SparseArray(data[, sparse_index, ...])
```

An ExtensionArray for storing sparse data.

**pandas.arrays.SparseArray**

```python
class pandas.arrays.SparseArray(data, sparse_index=None, index=None, fill_value=None, kind='integer', dtype=None, copy=False)
```

An ExtensionArray for storing sparse data.

**Parameters**

- **data** [array-like or scalar] A dense array of values to store in the SparseArray. This may contain `fill_value`.
- **sparse_index** [SparseIndex, optional]
- **index** [Index] Deprecated since version 1.4.0: Use a function like `np.full` to construct an array with the desired repeats of the scalar value instead.
- **fill_value** [scalar, optional] Elements in data that are `fill_value` are not stored in the SparseArray. For memory savings, this should be the most common value in `data`. By default, `fill_value` depends on the dtype of `data`:

<table>
<thead>
<tr>
<th>data.dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The fill value is potentially specified in three ways. In order of precedence, these are

1. The `fill_value` argument
2. `dtype.fill_value` if `fill_value` is None and `dtype` is a `SparseDtype`
3. `data.dtype.fill_value` if `fill_value` is None and `dtype` is not a `SparseDtype` and `data` is a `SparseArray`.

- **kind** [str] Can be ‘integer’ or ‘block’, default is ‘integer’. The type of storage for sparse locations.
  - ‘block’: Stores a block and block_length for each contiguous span of sparse values. This is best when sparse data tends to be clumped together, with large regions of fill_value values between sparse values.
  - ‘integer’: uses an integer to store the location of each sparse value.

- **dtype** [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of self.sp_values. For SparseDtype, this determines self.sp_values and self.fill_value.

- **copy** [bool, default False] Whether to explicitly copy the incoming `data` array.
Examples

```python
>>> from pandas.arrays import SparseArray
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Attributes

<table>
<thead>
<tr>
<th>None</th>
</tr>
</thead>
</table>

Methods

<table>
<thead>
<tr>
<th>None</th>
</tr>
</thead>
</table>

SparseDtype([dtype, fill_value]) Dtype for data stored in SparseArray.

pandas.SparseDtype
class pandas.SparseDtype(dtype=<class 'numpy.float64'>, fill_value=None)

Dtype for data stored in SparseArray.

This dtype implements the pandas ExtensionDtype interface.

Parameters

- dtype [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.
- fill_value [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on dtype.

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The default value may be overridden by specifying a fill_value.
Attributes

None

Methods

None

The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the `Series` contains sparse values. See Sparse accessor for more.

### 3.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using `StringDtype` (with the alias "string").

```python
arrays.StringArray(values[, copy])
arrays.ArrowStringArray(values)
```

**pandas.arrays.StringArray**

**class** pandas.arrays.StringArray(values, copy=False)

Extension array for string data.

New in version 1.0.0.

**Warning:** StringArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

- **values** [array-like] The array of data.

**Warning:** Currently, this expects an object-dtype ndarray where the elements are Python strings or pandas.NA. This may change without warning in the future. Use `pandas.array()` with dtype="string" for a stable way of creating a StringArray from any sequence.

- **copy** [bool, default False] Whether to copy the array of data.

**See also**

- `array` The recommended function for creating a StringArray.
- `Series.str` The string methods are available on Series backed by a StringArray.
Notes

StringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.']
Length: 4, dtype: string
```

Unlike arrays instantiated with `dtype="object"`, StringArray will convert the values to strings.

```python
>>> pd.array(['1', 1], dtype="object")
<PandasArray>
['1', 1]
Length: 2, dtype: object
>>> pd.array(['1', 1], dtype="string")
<StringArray>
['1', '1']
Length: 2, dtype: string
```

However, instantiating StringArrays directly with non-strings will raise an error.

For comparison methods, StringArray returns a pandas.BooleanArray:

```python
>>> pd.array(['a', None, 'c'], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

Attributes

None

Methods

None

pandas.arrays.ArrowStringArray

class pandas.arrays.ArrowStringArray(values)

Extension array for string data in a pyarrow.ChunkedArray.

New in version 1.2.0.

Warning: ArrowStringArray is considered experimental. The implementation and parts of the API may change without warning.
Parameters

values [pyarrow.Array or pyarrow.ChunkedArray] The array of data.

See also:
array The recommended function for creating a ArrowStringArray.
Series.str The string methods are available on Series backed by a ArrowStringArray.

Notes

ArrowStringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string[pyarrow]"
<ArrowStringArray>
['This is', 'some text', <NA>, 'data.]
Length: 4, dtype: string
```

Attributes

| None |

Methods

| None |

**StringDtype**([storage]) Extension dtype for string data.

**pandas.StringDtype**

class pandas.StringDtype(storage=None)

Extension dtype for string data.

New in version 1.0.0.

**Warning:** StringDtype is considered experimental. The implementation and parts of the API may change without warning.

In particular, StringDtype.na_value may change to no longer be numpy.nan.

Parameters

storage ["python", "pyarrow"], optional] If not given, the value of pd.options.mode.
string_storage.
3.5.11 Boolean data with missing values

The boolean dtype (with the alias "boolean") provides support for storing boolean data (True, False) with missing values, which is not possible with a bool numpy.ndarray.

pandas.arrays.BooleanArray

class pandas.arrays.BooleanArray(values, mask[, copy])

Array of boolean (True/False) data with missing values.

This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

BooleanArray implements Kleene logic (sometimes called three-value logic) for logical operations. See Kleene logical operations for more.

To construct an BooleanArray from generic array-like input, use pandas.array() specifying dtype="boolean" (see examples below).

New in version 1.0.0.

Parameters

values [numpy.ndarray] A 1-d boolean-dtype array with the data.
**mask** [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).

**copy** [bool, default False] Whether to copy the `values` and `mask` arrays.

**Returns**

BooleanArray

**Examples**

Create an BooleanArray with `pandas.array()`:

```python
>>> pd.array([True, False, None], dtype="boolean")
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

**Attributes**

None

**Methods**

None

---

**BooleanDtype**

A helper function to create a custom boolean array.

New in version 1.0.0.

**Warning:** BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.

**Examples**

```python
>>> pd.BooleanDtype()
BooleanDtype
```

---

**pandas**

A powerful Python data analysis toolkit. Release 1.4.3
Attributes

3.6 Index objects

3.6.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

```
Index(data, dtype, copy, name, tupleize_cols)
```

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects.

```
pandas.Index
class pandas.Index(data=None, dtype=None, copy=False, name=None, tupleize_cols=True, **kwargs)
```

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects.

**Parameters**

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it’s safe. Otherwise, an error will be raised.
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.
- **tupleize_cols** [bool (default: True)] When True, attempt to create a MultiIndex if possible.

See also:

- **RangeIndex** Index implementing a monotonic integer range.
- **CategoricalIndex** Index of `Categorical` s.
- **MultiIndex** A multi-level, or hierarchical Index.
- **IntervalIndex** An Index of `Interval` s.
- **DatetimeIndex** Index of datetime64 data.
- **TimedeltaIndex** Index of timedelta64 data.
- **PeriodIndex** Index of Period data.
- **NumericIndex** Index of numpy int/uint/float data.
- **Int64Index** Index of purely int64 labels (deprecated).
- **UInt64Index** Index of purely uint64 labels (deprecated).
- **Float64Index** Index of purely float64 labels (deprecated).
Notes

An Index instance can only contain hashable objects.

Examples

```python
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')

>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

Attributes

- `T`: Return the transpose, which is by definition self.
- `array`: The ExtensionArray of the data backing this Series or Index.
- `asi8`: Integer representation of the values.
- `dtype`: Return the dtype object of the underlying data.
- `has_duplicates`: Check if the Index has duplicate values.
- `hasnans`: Return True if there are any NaNs.
- `inferred_type`: Return a string of the type inferred from the values.
- `is_all_dates`: Whether or not the index values only consist of dates.
- `is_monotonic`: Alias for is_monotonic_increasing.
- `is_monotonic_decreasing`: Return if the index is monotonic decreasing (only equal or decreasing) values.
- `is_monotonic_increasing`: Return if the index is monotonic increasing (only equal or increasing) values.
- `is_unique`: Return if the index has unique values.
- `name`: Return Index or MultiIndex name.
- `nbytes`: Return the number of bytes in the underlying data.
- `ndim`: Number of dimensions of the underlying data, by definition 1.
- `nlevels`: Number of levels.
- `shape`: Return a tuple of the shape of the underlying data.
- `size`: Return the number of elements in the underlying data.
- `values`: Return an array representing the data in the Index.

`pandas.Index.T`

@property `Index.T`  
Return the transpose, which is by definition self.
pandas.Index.array

Index.array

The ExtensionArray of the data backing this Series or Index.

Returns

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around numpy.ndarray.

.array differs .values which may require converting the data to a different form.

See also:

Index.to_numpy Similar method that always returns a NumPy array.
Series.to_numpy Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use Series.to_numpy() instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned.

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.Index asi8

property Index asi8

Integer representation of the values.

Returns

ndarray An ndarray with int64 dtype.

pandas.Index dtype

Index dtype

Return the dtype object of the underlying data.

pandas.Index has_duplicates

property Index has_duplicates

Check if the Index has duplicate values.

Returns

bool Whether or not the Index has duplicate values.

Examples

```python
>>> idx = pd.Index([1, 5, 7, 7])
>>> idx.has_duplicates
True

>>> idx = pd.Index([1, 5, 7])
>>> idx.has_duplicates
False

>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ...
    "Watermelon"]).astype("category")
>>> idx.has_duplicates
True

>>> idx = pd.Index(["Orange", "Apple", ...
    "Watermelon"]).astype("category")
>>> idx.has_duplicates
False
```
pandas.Index.hasnans

Index .hasnans
   Return True if there are any NaNs.
   Enables various performance speedups.

pandas.Index.inferred_type

Index.inferred_type
   Return a string of the type inferred from the values.

pandas.Index.is_all_dates

Index.is_all_dates
   Whether or not the index values only consist of dates.

pandas.Index.is_monotonic

property Index.is_monotonic
   Alias for is_monotonic_increasing.

pandas.Index.is_monotonic_decreasing

property Index.is_monotonic_decreasing
   Return if the index is monotonic decreasing (only equal or decreasing) values.

Examples

>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False

pandas.Index.is_monotonic_increasing

property Index.is_monotonic_increasing
   Return if the index is monotonic increasing (only equal or increasing) values.
Examples

```python
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

**pandas.Index.is_unique**

Index.is_unique

Return if the index has unique values.

**pandas.Index.name**

property Index.name

Return Index or MultiIndex name.

**pandas.Index.nbytes**

property Index.nbytes

Return the number of bytes in the underlying data.

**pandas.Index.ndim**

property Index.ndim

Number of dimensions of the underlying data, by definition 1.

**pandas.Index.nlevels**

property Index.nlevels

Number of levels.

**pandas.Index.shape**

property Index.shape

Return a tuple of the shape of the underlying data.
pandas.Index.size

property Index.size

Return the number of elements in the underlying data.

pandas.Index.values

property Index.values

Return an array representing the data in the Index.

Warning: We recommend using Index.array or Index.to_numpy(), depending on whether you need a reference to the underlying data or a NumPy array.

Returns

array: numpy.ndarray or ExtensionArray

See also:

Index.array Reference to the underlying data.

Index.to_numpy A NumPy array representing the underlying data.

Methods

</tbody>
</table>

**pandas.Index.all**

Index.all(*args, **kwargs)

Return whether all elements are Truthy.

**Parameters**

*args Required for compatibility with numpy.

**kwargs Required for compatibility with numpy.

**Returns**

all [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.
See also:

- `Index.any` Return whether any element in an Index is True.
- `Series.any` Return whether any element in a Series is True.
- `Series.all` Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

True, because nonzero integers are considered True.

```python
>>> pd.Index([1, 2, 3]).all()
True
```

False, because 0 is considered False.

```python
>>> pd.Index([0, 1, 2]).all()
False
```

**pandas.Index.any**

`Index.any(*args, **kwargs)`

Return whether any element is Truthy.

Parameters

- `*args` Required for compatibility with numpy.
- `**kwargs` Required for compatibility with numpy.

Returns

- `any` [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.

See also:

- `Index.all` Return whether all elements are True.
- `Series.all` Return whether all elements are True.
Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

```
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True

>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

**pandas.Index.append**

Index.**append***(other)*)

Append a collection of Index options together.

**Parameters**

other [Index or list/tuple of indices]

**Returns**

Index

**pandas.Index.argmax**

Index.**argmax**(axis=None, skipna=True, *args, **kwargs)

Return int position of the largest value in the Series.
If the maximum is achieved in multiple locations, the first row position is returned.

**Parameters**

axis [[None]] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

**Returns**

int Row position of the maximum value.

See also:

**Series.argmax** Return position of the maximum value.

**Series.argmin** Return position of the minimum value.

**numpy.ndarray.argmax** Equivalent method for numpy arrays.

**Series.idxmax** Return index label of the maximum values.

**Series.idxmin** Return index label of the minimum values.
Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0, 
...                  'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff     110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

**pandas.Index.argmin**

`Index.argmin(axis=None, skipna=True, *args, **kwargs)`

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

- **axis**  :  [[None]] Dummy argument for consistency with Series.
- **skipna**  :  [bool, default True] Exclude NA/null values when showing the result.
- ***args, **kwargs**  :  Additional arguments and keywords for compatibility with NumPy.

Returns

- **int**  :  Row position of the minimum value.

See also:

- `Series.argmin`  :  Return position of the minimum value.
- `Series.argmax`  :  Return position of the maximum value.
- `numpy.ndarray.argmin`  :  Equivalent method for numpy arrays.
- `Series.idxmax`  :  Return index label of the maximum values.
- `Series.idxmin`  :  Return index label of the minimum values.
Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0, ...
                   'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes       100.0
Almond Delight   110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff        110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

**pandas.Index.argsort**

`Index.argsort(*args, **kwargs)`

Return the integer indices that would sort the index.

**Parameters**

- *args Passed to `numpy.ndarray.argsort`.
- **kwargs Passed to `numpy.ndarray.argsort`.

**Returns**

`np.ndarray[np.intp]` Integer indices that would sort the index if used as an indexer.

**See also:**

- `numpy.argsort` Similar method for NumPy arrays.
- `Index.sort_values` Return sorted copy of Index.

Examples

```python
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')
```

```python
>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])
```

```python
>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.Index.asof
final Index.asof(label)
Return the label from the index, or, if not present, the previous one.
Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous
index label if the passed one is not in the index.
Parameters
label [object] The label up to which the method returns the latest index label.
Returns
object The passed label if it is in the index. The previous label if the passed label is not
in the sorted index or NaN if there is no such label.
See also:
Series.asof Return the latest value in a Series up to the passed index.
merge_asof Perform an asof merge (similar to left join but it matches on nearest key rather than equal
key).
Index.get_loc An asof is a thin wrapper around get_loc with method=’pad’.
Examples
Index.asof returns the latest index label up to the passed label.
>>> idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
If the label is in the index, the method returns the passed label.
>>> idx.asof('2014-01-02')
'2014-01-02'
If all of the labels in the index are later than the passed label, NaN is returned.
>>> idx.asof('1999-01-02')
nan
If the index is not sorted, an error is raised.
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02',
...
'2014-01-03'])
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
ValueError: index must be monotonic increasing or decreasing

2140

Chapter 3. API reference


pandas.Index.asof_locs

Index.asof_locs(where, mask)

Return the locations (indices) of labels in the index.

As in the asof function, if the label (a particular entry in where) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in where, -1 is returned.

mask is used to ignore NA values in the index during calculation.

Parameters

  where [Index] An Index consisting of an array of timestamps.

  mask [np.ndarray[bool]] Array of booleans denoting where values in the original data are not NA.

Returns

  np.ndarray[np.intp] An array of locations (indices) of the labels from the Index which correspond to the return values of the asof function for every element in where.

pandas.Index.astype

Index.astype(dtype, copy=True)

Create an Index with values cast to dtypes.

The class of a new Index is determined by dtype. When conversion is impossible, a TypeError exception is raised.

Parameters

  dtype [numpy dtype or pandas type] Note that any signed integer dtype is treated as 'int64', and any unsigned integer dtype is treated as 'uint64', regardless of the size.

  copy [bool, default True] By default, astype always returns a newly allocated object. If copy is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.

Returns

  Index Index with values cast to specified dtype.

pandas.Index.copy

Index.copy(name=None, deep=False, dtype=None, names=None)

Make a copy of this object.

Name and dtype sets those attributes on the new object.

Parameters

  name [Label, optional] Set name for new object.

  deep [bool, default False]
dtype [numpy dtype or pandas type, optional] Set dtype for new object.

Deprecated since version 1.2.0: use astype method instead.

names [list-like, optional] Kept for compatibility with MultiIndex. Should not be used.

Deprecated since version 1.4.0: use name instead.

Returns

Index Index refer to new object which is a copy of this object.

Notes

In most cases, there should be no functional difference from using deep, but if deep is passed it will attempt to deepcopy.

df = pd.DataFrame(
    data=[[1.0, 2.0, 3.0],
          [4.0, 5.0, 6.0]],
    index=[0, 1],
    columns=['A', 'B', 'C'])

df[0] = 'a'

# Results in a non-integer-like index

pandas.Index.delete

Index.delete(loc)

Make new Index with passed location(-s) deleted.

Parameters

loc [int or list of int] Location of item(-s) which will be deleted. Use a list of locations to delete more than one value at the same time.

Returns

Index Will be same type as self, except for RangeIndex.

See also:

numpy.delete Delete any rows and column from NumPy array (ndarray).

Examples

>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete(1)
Index(['a', 'c'], dtype='object')

>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete([0, 2])
Index(['b'], dtype='object')

pandas.Index.difference

final Index.difference(other, sort=None)

Return a new Index with elements of index not in other.

This is the set difference of two Index objects.

Parameters

other [Index or array-like]
sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.

- None: Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
- False: Do not sort the result.

Returns
difference [Index]

Examples

```python
dx1 = pd.Index([2, 1, 3, 4])
dx2 = pd.Index([3, 4, 5, 6])
dx1.difference(dx2)
Int64Index([1, 2], dtype='int64')
dx1.difference(dx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

pandas.Index.drop

Index.drop(labels, errors='raise')

Make new Index with passed list of labels deleted.

Parameters

- labels [array-like or scalar]
- errors [‘ignore’, ‘raise’], default ‘raise’ If ‘ignore’, suppress error and existing labels are dropped.

Returns
dropped [Index] Will be same type as self, except for RangelIndex.

Raises

- KeyError If not all of the labels are found in the selected axis

pandas.Index.drop_duplicates

Index.drop_duplicates(keep='first')

Return Index with duplicate values removed.

Parameters

- keep [‘first’, ‘last’, False], default ‘first’]
  - ‘first’: Drop duplicates except for the first occurrence.
  - ‘last’: Drop duplicates except for the last occurrence.
  - False: Drop all duplicates.

Returns
**deduplicated**  [Index]

See also:

- `Series.drop_duplicates` Equivalent method on Series.
- `DataFrame.drop_duplicates` Equivalent method on DataFrame.
- `Index.duplicated` Related method on Index, indicating duplicate Index values.

### Examples

Generate an pandas.Index with duplicate values.

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The `keep` parameter controls which duplicate values are removed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of `keep` is ‘first’.

```python
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value ‘last’ keeps the last occurrence for each set of duplicated entries.

```python
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```python
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

### pandas.Index.droplevel

**final**  `Index.droplevel(level=0)`

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

**Parameters**

- `level`  [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

**Returns**

- `Index` or `MultiIndex`
Examples

```python
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
           names=['x', 'y', 'z'])

>>> mi.droplevel()  
MultiIndex([(3, 5),
            (4, 6)],
           names=['y', 'z'])

>>> mi.droplevel(2)
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])

>>> mi.droplevel('z')
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])

>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')
```

**pandas.Index.dropna**

Index.dropna(how='any')

Return Index without NA/NaN values.

**Parameters**

- **how** [{‘any’, ‘all’}, default ‘any’] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

**Returns**

Index

**pandas.Index.duplicated**

Index.duplicated(keep='first')

Indicate duplicate index values.

Duplicated values are indicated as True values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

**Parameters**

- **keep** [{‘first’, ‘last’, False}, default ‘first’] The value or values in a set of duplicates to mark as missing.

3.6. Index objects
• ‘first’ : Mark duplicates as True except for the first occurrence.
• ‘last’ : Mark duplicates as True except for the last occurrence.
• False : Mark all duplicates as True.

Returns
np.ndarray[bool]

See also:
Series.duplicated Equivalent method on pandas.Series.
DataFrame.duplicated Equivalent method on pandas.DataFrame.
Index.drop_duplicates Remove duplicate values from Index.

Examples
By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
numpy.array([False, False, True, False, True])
```
which is equivalent to

```python
>>> idx.duplicated(keep='first')
numpy.array([False, False, True, False, True])
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> idx.duplicated(keep='last')
numpy.array([ True, False, True, False, False])
```

By setting keep on False, all duplicates are True:

```python
>>> idx.duplicated(keep=False)
numpy.array([ True, False, True, False, True])
```

pandas.Index.equals

Index.equals(other)
Determine if two Index object are equal.
The things that are being compared are:
• The elements inside the Index object.
• The order of the elements inside the Index object.

Parameters

other [Any] The other object to compare against.

Returns
**bool** True if “other” is an Index and it has the same elements and order as the calling index; False otherwise.

**Examples**

```python
>>> idx1 = pd.Index([1, 2, 3])
>>> idx1
Int64Index([1, 2, 3], dtype='int64')
>>> idx1.equals(pd.Index([1, 2, 3]))
True
```

The elements inside are compared

```python
>>> idx2 = pd.Index(['1', '2', '3'])
>>> idx2
Index(['1', '2', '3'], dtype='object')
>>> idx1.equals(idx2)
False
```

The order is compared

```python
>>> ascending_idx = pd.Index([1, 2, 3])
>>> ascending_idx
Int64Index([1, 2, 3], dtype='int64')
>>> descending_idx = pd.Index([3, 2, 1])
>>> descending_idx
Int64Index([3, 2, 1], dtype='int64')
>>> ascending_idx.equals(descending_idx)
False
```

The dtype is not compared

```python
>>> int64_idx = pd.Int64Index([1, 2, 3])
>>> int64_idx
Int64Index([1, 2, 3], dtype='int64')
>>> uint64_idx = pd.UInt64Index([1, 2, 3])
>>> uint64_idx
UInt64Index([1, 2, 3], dtype='uint64')
>>> int64_idx.equals(uint64_idx)
True
```

**pandas.Index.factorize**

`Index.factorize(sort=False, na_sentinel=-1)`  
Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

**Parameters**
sort  [bool, default False] Sort uniques and shuffle codes to maintain the relationship.

na_sentinel  [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

Returns

codes  [ndarray] An integer ndarray that’s an indexer into uniques. uniques.take(codes) will have the same values as values.

uniques  [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in values, uniques will not contain an entry for it.

See also:

cut  Discretize continuous-valued array.
unique  Find the unique value in an array.

Notes

Reference the user guide for more examples.

Examples

These examples all show factorize as a top-level method like pd.factorize(values). The results are identical for methods like Series.factorize().

```python
codes, uniques = pd.factorize([b', 'b', 'a', 'c', 'b'])
codes
array([0, 0, 1, 2, 0]...)
uniques
array([b', 'a', 'c'], dtype=object)
```

With sort=True, the uniques will be sorted, and codes will be shuffled so that the relationship is the maintained.

```python
codes, uniques = pd.factorize([b', 'b', 'a', 'c', 'b'], sort=True)
codes
array([1, 1, 0, 2, 1]...)
uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in codes with na_sentinel (-1 by default). Note that missing values are never included in uniques.
Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype=object)
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([ 1., 2.])
```

```python
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.Index.fillna

Index.fillna(value=None, downcast=None)
Fill NA/NaN values with the specified value.

Parameters

value [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.
downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

Index

See also:

DataFrame.fillna Fill NaN values of a DataFrame.
Series.fillna Fill NaN Values of a Series.

pandas.Index.format

Index.format(name=False, formatter=None, na_rep='NaN')
Render a string representation of the Index.

pandas.Index.get_indexer

final Index.get_indexer(target, method=None, limit=None, tolerance=None)
Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

target [Index]
method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]
• default: exact matches only.
• pad / ffill: find the PREVIOUS index value if no exact match.
• backfill / bfill: use NEXT index value if no exact match
• nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
limit [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.
**Returns**

*indexer* [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**Notes**

Returns -1 for unmatched values, for further explanation see the example below.

**Examples**

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([1, 2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

**pandas.Index.get_indexer_for**

*final* `Index.get_indexer_for(target)`

Guaranteed return of an indexer even when non-unique.

This dispatches to `get_indexer` or `get_indexer_non_unique` as appropriate.

**Returns**

np.ndarray[np.intp] List of indices.

**Examples**

```python
>>> idx = pd.Index([np.nan, 'var1', np.nan])
>>> idx.get_indexer_for([np.nan])
array([0, 2])
```

**pandas.Index.get_indexer_non_unique**

*Index.get_indexer_non_unique(target)*

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

**Parameters**

- **target** [Index]

**Returns**

*indexer* [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

*missing* [np.ndarray[np.intp]] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.
pandas.Index.get_level_values

Index.get_level_values(level)

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

Parameters

level [int or str] It is either the integer position or the name of the level.

Returns

Index Calling object, as there is only one level in the Index.

See also:

MultiIndex.get_level_values Get values for a level of a MultiIndex.

Notes

For Index, level should be 0, since there are no multiple levels.

Examples

```python
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')

Get level values by supplying level as integer:

```python
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

pandas.Index.get_loc

Index.get_loc(key, method=None, tolerance=None)

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [(None, 'pad'/'ffill', ‘backfill’/’bfill’, ‘nearest’), optional]
  • default: exact matches only.
  • pad / ffill: find the PREVIOUS index value if no exact match.
  • backfill / bfill: use NEXT index value if no exact match
  • nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
tolerance [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location must satisfy the equation abs(index[loc] - key) <= tolerance.

Returns

loc [int if unique index, slice if monotonic index, else mask]

Examples

```python
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```python
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```python
>>> non_monotonic_index = pd.Index(list('abc'))
```

```python
array([False, True, False, True])
```

pandas.Index.get_slice_bound

Index.get_slice_bound(label, side, kind=None)

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if side=='right') position of given label.

Parameters

- label [object]
- side [left, right]
- kind ['loc', 'getitem'] or None Deprecated since version 1.4.0.

Returns

- int Index of label.

pandas.Index.get_value

Index.get_value(series, key)

Fast lookup of value from 1-dimensional ndarray.

Only use this if you know what you’re doing.

Returns

- scalar or Series
**pandas.Index.groupby**

`final Index.groupby(values)`

Group the index labels by a given array of values.

**Parameters**

- **values** [array] Values used to determine the groups.

**Returns**

- **dict** {group name -> group labels}

**pandas.Index.holds_integer**

`final Index.holds_integer()`

Whether the type is an integer type.

**pandas.Index.identical**

`final Index.identical(other)`

Similar to equals, but checks that object attributes and types are also equal.

**Returns**

- **bool** If two Index objects have equal elements and same type True, otherwise False.

**pandas.Index.insert**

`Index.insert(loc, item)`

Make new Index inserting new item at location.

Follows Python numpy.insert semantics for negative values.

**Parameters**

- **loc** [int]
- **item** [object]

**Returns**

- **new_index** [Index]

**pandas.Index.intersection**

`final Index.intersection(other, sort=False)`

Form the intersection of two Index objects.

This returns a new Index with elements common to the index and other.

**Parameters**

- **other** [Index or array-like]
- **sort** [False or None, default False] Whether to sort the resulting index.
• False: do not sort the result.
• None: sort the result, except when self and other are equal or when the values cannot be compared.

Returns

intersection [Index]

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

pandas.Index.is_

```python
final Index.is_(other)
```

More flexible, faster check like is but that works through views.

Note: this is not the same as Index.identical(), which checks that metadata is also the same.

Parameters

other [object] Other object to compare against.

Returns

bool True if both have same underlying data, False otherwise.

See also:

Index.identical Works like Index.is_ but also checks metadata.

pandas.Index.is_boolean

```python
final Index.is_boolean()
```

Check if the Index only consists of booleans.

Returns

bool Whether or not the Index only consists of booleans.

See also:

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.
Examples

```python
>>> idx = pd.Index([True, False, True])
>>> idx.is_boolean()
True

>>> idx = pd.Index(["True", "False", "True"])
>>> idx.is_boolean()
False

>>> idx = pd.Index([True, False, "True"])
>>> idx.is_boolean()
False
```

### pandas.Index.is_categorical

**Final** `Index.is_categorical()`

Check if the Index holds categorical data.

**Returns**

- `bool` True if the Index is categorical.

**See also:**

- `CategoricalIndex` Index for categorical data.
- `is_boolean` Check if the Index only consists of booleans.
- `is_integer` Check if the Index only consists of integers.
- `is_floating` Check if the Index is a floating type.
- `is_numeric` Check if the Index only consists of numeric data.
- `is_object` Check if the Index is of the object dtype.
- `is_interval` Check if the Index holds Interval objects.
- `is_mixed` Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ...
                   "Watermelon"]).astype("category")
>>> idx.is_categorical()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```
```python
>>> s = pd.Series(['Peter', 'Victor', 'Elisabeth', 'Mar'])
>>> s
0    Peter
1   Victor
2  Elisabeth
3     Mar
dtype: object
```

**pandas.Index.is_floating**

**final** `Index.is_floating()`

Check if the Index is a floating type.

The Index may consist of only floats, NaNs, or a mix of floats, integers, or NaNs.

**Returns**

bool Whether or not the Index only consists of only consists of floats, NaNs, or a mix of floats, integers, or NaNs.

**See also:**

* `is_boolean` Check if the Index only consists of booleans.
* `is_integer` Check if the Index only consists of integers.
* `is_numeric` Check if the Index only consists of numeric data.
* `is_object` Check if the Index is of the object dtype.
* `is_categorical` Check if the Index holds categorical data.
* `is_interval` Check if the Index holds Interval objects.
* `is_mixed` Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_floating()
True
```

```python
>>> idx = pd.Index([1.0, 2.0, np.nan, 4.0])
>>> idx.is_floating()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4, np.nan])
>>> idx.is_floating()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_floating()
False
```
pandas.Index.is_integer

final Index.is_integer()

Check if the Index only consists of integers.

Returns

bool Whether or not the Index only consists of integers.

See also:

is_boolean Check if the Index only consists of booleans.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_integer()
True

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_integer()
False

>>> idx = pd.Index(["Apple", "Mango", "Watermelon"])
>>> idx.is_integer()
False
```

pandas.Index.is_interval

final Index.is_interval()

Check if the Index holds Interval objects.

Returns

bool Whether or not the Index holds Interval objects.

See also:

IntervalIndex Index for Interval objects.

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.
**is_numeric** Check if the Index only consists of numeric data.

**is_object** Check if the Index is of the object dtype.

**is_categorical** Check if the Index holds categorical data.

**is_mixed** Check if the Index holds data with mixed data types.

### Examples

```python
def check_index(idx):
    return pd.Index([pd.Interval(left=0, right=5), ... pd.Interval(left=5, right=10)])
```

```python
>>> idx = pd.Index([0, 3, 5, 7])
>>> idx.is_interval()
False
```

```python
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_interval()
False
```

### pandas.Index.is_mixed

**final** `Index.is_mixed()`

Check if the Index holds data with mixed data types.

**Returns**

- **bool**: Whether or not the Index holds data with mixed data types.

**See also**:

- **is_boolean** Check if the Index only consists of booleans.
- **is_integer** Check if the Index only consists of integers.
- **is_floating** Check if the Index is a floating type.
- **is_numeric** Check if the Index only consists of numeric data.
- **is_object** Check if the Index is of the object dtype.
- **is_categorical** Check if the Index holds categorical data.
- **is_interval** Check if the Index holds Interval objects.

### Examples

```python
>>> idx = pd.Index(['a', np.nan, 'b'])
>>> idx.is_mixed()
True
```

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 5.0])
>>> idx.is_mixed()
False
```
pandas.Index.is_numeric

**final Index.is_numeric()**

Check if the Index only consists of numeric data.

**Returns**

`bool` Whether or not the Index only consists of numeric data.

**See also:**

* is_boolean Check if the Index only consists of booleans.
* is_integer Check if the Index only consists of integers.
* is_floating Check if the Index is a floating type.
* is_object Check if the Index is of the object dtype.
* is_categorical Check if the Index holds categorical data.
* is_interval Check if the Index holds Interval objects.
* is_mixed Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_numeric()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4.0])
>>> idx.is_numeric()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_numeric()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4.0, np.nan])
>>> idx.is_numeric()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4.0, np.nan, "Apple"])
>>> idx.is_numeric()
False
```
pandas.Index.is_object

**final Index.is_object()**

Check if the Index is of the object dtype.

**Returns**

bool Whether or not the Index is of the object dtype.

**See also:**

- **is_boolean** Check if the Index only consists of booleans.
- **is_integer** Check if the Index only consists of integers.
- **is_floating** Check if the Index is a floating type.
- **is_numeric** Check if the Index only consists of numeric data.
- **is_categorical** Check if the Index holds categorical data.
- **is_interval** Check if the Index holds Interval objects.
- **is_mixed** Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index(['Apple', 'Mango', 'Watermelon'])
>>> idx.is_object()
True

>>> idx = pd.Index(['Apple', 'Mango', 2.0])
>>> idx.is_object()
True

>>> idx = pd.Index(['Watermelon', 'Orange', 'Apple', ...
... 'Watermelon']).astype('category')
>>> idx.is_object()
False

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_object()
False
```

pandas.Index.is_type_compatible

**Index.is_type_compatible(kind)**

Whether the index type is compatible with the provided type.
pandas.Index.isin

Index.isin(values, level=None)

Return a boolean array where the index values are in values.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

Parameters

values [set or list-like] Sought values.
level [str or int, optional] Name or position of the index level to use (if the index is a MultiIndex).

Returns

np.ndarray[bool] NumPy array of boolean values.

See also:

Series.isin Same for Series.
DataFrame.isin Same method for DataFrames.

Notes

In the case of MultiIndex you must either specify values as a list-like object containing tuples that are the same length as the number of levels, or specify level. Otherwise it will raise a ValueError.

If level is specified:

• if it is the name of one and only one index level, use that level;
• otherwise it should be a number indicating level position.

Examples

```python
>>> idx = pd.Index([1,2,3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')

Check whether each index value in a list of values.

>>> idx.isin([1, 4])
array([ True, False, False])

>>> midx = pd.MultiIndex.from_arrays([[1,2,3], ['red', 'blue', 'green']], names=('number', 'color'))
>>> midx
MultiIndex([(1, 'red'), (2, 'blue'), (3, 'green')], names=('number', 'color'))

Check whether the strings in the ‘color’ level of the MultiIndex are in a list of colors.
```
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([ True, False, False])

To check across the levels of a MultiIndex, pass a list of tuples:

```python
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```  

For a DatetimeIndex, string values in `values` are converted to Timestamps.

```python
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
            dtype='datetime64[ns]', freq=None)
```

```python
>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```  

### pandas.DataFrame

#### pandas.Index.isna

**final Index.isna()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings ‘’ or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

`numpy.ndarray[bool]` A boolean array of whether my values are NA.

**See also:**

- `Index.notna` Boolean inverse of `isna`.
- `Index.dropna` Omit entries with missing values.
- `isna` Top-level `isna`.
- `Series.isna` Detect missing values in `Series` object.

**Examples**

Show which entries in a pandas.Index are NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
```

```python
>>> idx.isna()
array([False, False, True])
```

Empty strings are not considered NA values. None is considered an NA value.

3.6. Index objects
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True])

For datetimes, NaT (Not a Time) is considered as an NA value.

>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'), ... pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
               dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False, True, True, True])

pandas.Index.isnull

Index.isnull()  
Detect missing values.  
Return a boolean same-sized object indicating if the values are NA. NA values, such as None, numpy.NaN or pd.NaT, get mapped to True values. Everything else get mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

numpy.ndarray[bool]  A boolean array of whether my values are NA.

See also:

Index.notna  Boolean inverse of isna.

Index.dropna  Omit entries with missing values.

isna  Top-level isna.

Series.isna  Detect missing values in Series object.

Examples

Show which entries in a pandas.Index are NA. The result is an array.

>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False, True])

Empty strings are not considered NA values. None is considered an NA value.
For datetimes, \texttt{NaT} (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
                          ... pd.Timestamp(''),
                          ... pd.NaT])
>>> idx.isna()
array([False, True, True, True])
```

\textbf{pandas.Index.item}

\texttt{Index.item()}  
Return the first element of the underlying data as a Python scalar.

\begin{description}
\item[Returns] \texttt{scalar} The first element of \texttt{%(klass)s}.
\item[Raises] \texttt{ValueError} If the data is not length-1.
\end{description}

\textbf{pandas.Index.join}

\texttt{final Index.join(other, how='left', level=None, return_indexers=False, sort=False)}  
Compute join_index and indexers to conform data structures to the new index.

\begin{description}
\item[Parameters]  
\begin{itemize}
\item \texttt{other} \texttt{[Index]}
\item \texttt{how} \texttt{[\{'left', 'right', 'inner', 'outer'\}]}
\item \texttt{level} \texttt{[int or level name, default None]}
\item \texttt{return_indexers} \texttt{[bool, default False]}
\item \texttt{sort} \texttt{[bool, default False]} Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword).
\end{itemize}
\item[Returns] \texttt{join_index, (left_indexer, right_indexer)}
\end{description}
pandas.Index.map

Index.map(mapper, na_action=None)
Map values using an input mapping or function.

Parameters

mapper [function, dict, or Series] Mapping correspondence.
na_action [None, ‘ignore’] If ‘ignore’, propagate NA values, without passing them to the mapping correspondence.

Returns

applied [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

pandas.Index.max

Index.max(axis=None, skipna=True, *args, **kwargs)
Return the maximum value of the Index.

Parameters

axis [int, optional] For compatibility with NumPy. Only 0 or None are allowed.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

scalar Maximum value.

See also:

Index.min Return the minimum value in an Index.
Series.max Return the maximum value in a Series.
DataFrame.max Return the maximum values in a DataFrame.

Examples

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```
pandas.Index.memory_usage

Index.memory_usage(deep=False)
Memory usage of the values.

Parameters

  deep [bool, default False] Introspect the data deeply, interrogate object dtypes for system-level memory consumption.

Returns

  bytes used

See also:

  numpy.ndarray.nbytes Total bytes consumed by the elements of the array.

Notes

Memory usage does not include memory consumed by elements that are not components of the array if deep=False or if used on PyPy

pandas.Index.min

Index.min(axis=None, skipna=True, *args, **kwargs)
Return the minimum value of the Index.

Parameters

  axis [{None}] Dummy argument for consistency with Series.
  skipna [bool, default True] Exclude NA/null values when showing the result.
  *args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

  scalar Minimum value.

See also:

  Index.max Return the maximum value of the object.
  Series.min Return the minimum value in a Series.
  DataFrame.min Return the minimum values in a DataFrame.

Examples

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```
For a MultiIndex, the minimum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.min()
('a', 1)
```

**pandas.Index.notna**

**final** `Index.notna()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.

**Returns**

`numpy.ndarray[bool]` Boolean array to indicate which entries are not NA.

**See also:**

`Index.notnull` Alias of `notna`.

`Index.isna` Inverse of `notna`.

`notna` Top-level `notna`.

**Examples**

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True, True, True, False])
```
pandas.Index.notnull

Index.notnull()
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

numpy.ndarray[bool]  Boolean array to indicate which entries are not NA.

See also:

Index.notnull  Alias of notna.
Index.isna   Inverse of notna.
notna  Top-level notna.

Examples

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.nan])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([True, True, True, False])
```

pandas.Index.nunique

Index.nunique(dropna=True)
Return number of unique elements in the object.
Excludes NA values by default.

Parameters

dropna [bool, default True]  Don't include NaN in the count.

Returns

int

See also:
DataFrame.nunique  Method nunique for DataFrame.
Series.count  Count non-NA/null observations in the Series.

Examples

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```

pandas.Index.putmask

**final**  Index.putmask(mask, value)
Return a new Index of the values set with the mask.

**Returns**
Index

**See also:**

numpy.ndarray.putmask  Changes elements of an array based on conditional and input values.

pandas.Index.ravel

**final**  Index.ravel(order='C')
Return an ndarray of the flattened values of the underlying data.

**Returns**
	numpy.ndarray  Flattened array.

**See also:**

numpy.ndarray.ravel  Return a flattened array.
**pandas: powerful Python data analysis toolkit, Release 1.4.3**

### pandas.Index.reindex

**Index.reindex**(target, method=None, level=None, limit=None, tolerance=None)

Create index with target’s values.

**Parameters**

- **target** [an iterable]
- **method** [{None, 'pad'/‘ffill’, ‘backfill’/‘bfill’, ‘nearest’}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **level** [int, optional] Level of multiindex.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- **tolerance** [int or float, optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

- **new_index** [pd.Index] Resulting index.
- **indexer** [np.ndarray[np.intp] or None] Indices of output values in original index.

** Raises **

- **TypeError** If method passed along with level.
- **ValueError** If non-unique multi-index
- **ValueError** If non-unique index and method or limit passed.

**See also:**

*Series.reindex*

*DataFrame.reindex*
Examples

```python
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')
>>> idx.reindex(['car', 'bike'])
(Index(['car', 'bike'], dtype='object'), array([0, 1]))
```

**pandas.Index.rename**

```
Index.rename(name, inplace=False)
```

Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

**Parameters**

- `name` [label or list of labels] Name(s) to set.
- `inplace` [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

**Returns**

- `Index` or None The same type as the caller or None if `inplace=True`.

**See also:**

- `Index.set_names` Able to set new names partially and by level.

Examples

```python
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')
```

```python
>>> idx = pd.MultiIndex.from_product([['python', 'cobra'],
                                      [2018, 2019]],
                                      names=['kind', 'year'])
>>> idx
MultiIndex([('python', 2018),
             ('python', 2019),
             ('cobra', 2018),
             ('cobra', 2019)],
            names=['kind', 'year'])
>>> idx.rename(['species', 'year'])
MultiIndex([('python', 2018),
             ('python', 2019),
             ('cobra', 2018),
             ('cobra', 2019)],
            names=['species', 'year'])
>>> idx.rename('species')
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

(continued from previous page)

Traceback (most recent call last):
  TypeError: Must pass list-like as 'names'.

pandas.Index.repeat

Index.repeat(repeats, axis=None)

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

Parameters

- **repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

- **axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

- **repeated_index** [Index] Newly created Index with repeated elements.

See also:

- Series.repeat Equivalent function for Series.
- numpy.repeat Similar method for numpy.ndarray.

Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

pandas.Index.searchsorted

Index.searchsorted(value, side='left', sorter=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index self such that, if the corresponding elements in value were inserted before the indices, the order of self would be preserved.

Note: The Index must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

Parameters

- **value** [array-like or scalar] Values to insert into self.
side  [['left', 'right'], optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of self).

sorter  [1-D array-like, optional] Optional array of integer indices that sort self into ascending order. They are typically the result of np.argsort.

Returns

int or array of int  A scalar or array of insertion points with the same shape as value.

See also:

sort_values  Sort by the values along either axis.

numpy.searchsorted  Similar method from NumPy.

Notes

Binary search is used to find the required insertion points.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0    1
1    2
2    3
dtype: int64

>>> ser.searchsorted(4)
3

>>> ser.searchsorted([0, 4])
array([0, 3])

>>> ser.searchsorted([1, 3], side='left')
array([0, 2])

>>> ser.searchsorted([1, 3], side='right')
array([1, 3])

>>> ser
0    2000-03-11
1    2000-03-12
2    2000-03-13
dtype: datetime64[ns]

>>> ser.searchsorted('3/14/2000')
3
```
>>> ser = pd.Categorical(['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True)
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']

>>> ser.searchsorted('bread')
1

>>> ser.searchsorted(['bread'], side='right')
array([3])

If the values are not monotonically sorted, wrong locations may be returned:

>>> ser = pd.Series([2, 1, 3])
>>> ser
0 2
1 1
2 3
dtype: int64

>>> ser.searchsorted(1)
0  # wrong result, correct would be 1

pandas.Index.set_names

Index.set_names(names, level=None, inplace=False)
Set Index or MultiIndex name.
Able to set new names partially and by level.

Parameters

 names  [label or list of label or dict-like for MultiIndex] Name(s) to set.
         Changed in version 1.3.0.

 level  [int, label or list of int or label, optional] If the index is a MultiIndex and names is
         not dict-like, level(s) to set (None for all levels). Otherwise level must be None.
         Changed in version 1.3.0.

 inplace  [bool, default False] Modifies the object directly, instead of creating a new Index
          or MultiIndex.

Returns

 Index or None  The same type as the caller or None if inplace=True.

See also:

 Index.rename  Able to set new names without level.
## Examples

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'], [2018, 2019]])
>>> idx
MultiIndex([(python, 2018), (python, 2019), (cobra, 2018), (cobra, 2019)],)
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([(python, 2018), (python, 2019), (cobra, 2018), (cobra, 2019)], names=['kind', 'year'])

When renaming levels with a dict, levels can not be passed.

```python
>>> idx.set_names({'kind': 'snake'})
MultiIndex([(python, 2018), (python, 2019), (cobra, 2018), (cobra, 2019)], names=['snake', 'year'])
```
**pandas.Index.set_value**

**final** `Index.set_value(arr, key, value)`

Fast lookup of value from 1-dimensional ndarray.

Deprecated since version 1.0.

**Notes**

Only use this if you know what you’re doing.

**pandas.Index.shift**

`Index.shift(periods=1, freq=None)`

Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

**Parameters**

- `periods` [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.
- `freq` [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own `freq` attribute. Offset aliases are valid strings, e.g., ‘D’, ‘W’, ‘M’ etc.

**Returns**

- `pandas.Index` Shifted index.

**See also:**

`Series.shift` Shift values of Series.

**Notes**

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

**Examples**

Put the first 5 month starts of 2011 into an index.

```python
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
```

Shift the index by 10 days.
The default value of `freq` is the `freq` attribute of the index, which is ‘MS’ (month start) in this example.

```python
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01', '2012-03-01'],
dtype='datetime64[ns]', freq='MS')
```

### pandas.Index.slice_indexer

`Index.slice_indexer(start=None, end=None, step=None, kind=NoDefault.no_default)`

Compute the slice indexer for input labels and step.

Index needs to be ordered and unique.

**Parameters**

- `start` [label, default None] If None, defaults to the beginning.
- `end` [label, default None] If None, defaults to the end.
- `step` [int, default None]
- `kind` [str, default None] Deprecated since version 1.4.0.

**Returns**

- `indexer` [slice]

**Raises**

- `KeyError` [If key does not exist, or key is not unique and index is] not ordered.

### Notes

This function assumes that the data is sorted, so use at your own peril.

### Examples

This is a method on all index types. For example you can do:

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3, None)
```

```python
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3, None)
```
pandas.Index.slice_locs

Index.slice_locs(start=None, end=None, step=None, kind=None)
Compute slice locations for input labels.

Parameters

- **start** [label, default None] If None, defaults to the beginning.
- **end** [label, default None] If None, defaults to the end.
- **step** [int, defaults None] If None, defaults to 1.
- **kind** [{'loc', 'getitem'} or None] Deprecated since version 1.4.0.

Returns

- **start, end** [int]

See also:

- Index.get_loc Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```

pandas.Index.sort

**final** Index.sort(*args, **kwargs)
Use sort_values instead.

pandas.Index.sort_values

Index.sort_values(return_indexer=False, ascending=True, na_position='last', key=None)
Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

Parameters

- **return_indexer** [bool, default False] Should the indices that would sort the index be returned.
- **ascending** [bool, default True] Should the index values be sorted in an ascending order.
- **na_position** [[‘first’ or ‘last’], default ‘last’] Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.

New in version 1.2.0.
key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.

New in version 1.1.0.

Returns

- **sorted_index** [pandas.Index] Sorted copy of the index.
- **indexer** [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

- **Series.sort_values** Sort values of a Series.
- **DataFrame.sort_values** Sort values in a DataFrame.

Examples

```python
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```python
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices `idx` was sorted by.

```python
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

**pandas.Index.sortlevel**

Index.sortlevel(level=None, ascending=True, sort_remaining=None)

For internal compatibility with the Index API.

Sort the Index. This is for compat with MultiIndex

Parameters

- **ascending** [bool, default True] False to sort in descending order
- **level, sort_remaining** are compat parameters

Returns

- **Index**
pandas.Index.str

Index.str()

Vectorized string functions for Series and Index.
NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

Examples

```python
>>> s = pd.Series(['A_Str_Series'])
>>> s
0   A_Str_Series
dtype: object

>>> s.str.split('_')
0    [A, Str, Series]
dtype: object

>>> s.str.replace('_', '')
0   AStrSeries
dtype: object
```

pandas.Index.symmetric_difference

Index.symmetric_difference(other, result_name=None, sort=None)

Compute the symmetric difference of two Index objects.

Parameters

- **other** [Index or array-like]
- **result_name** [str]
- **sort** [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.
  - None: Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
  - False: Do not sort the result.

Returns

- **symmetric_difference** [Index]
Notes

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.

Examples

```python
g>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

`pandas.Index.take`

`Index.take(indices, axis=0, allow_fill=True, fill_value=None, **kwargs)`

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

**Parameters**

- `indices` [array-like] Indices to be taken.
- `axis` [int, optional] The axis over which to select values, always 0.
- `allow_fill` [bool, default True]
- `fill_value` [scalar, default None] If allow_fill=True and fill_value is not None, indices specified by -1 are regarded as NA. If Index doesn't hold NA, raise ValueError.

**Returns**

`Index` An index formed of elements at the given indices. Will be the same type as self, except for RangeIndex.

**See also:**

- `numpy.ndarray.take` Return an array formed from the elements of a at the given indices.

`pandas.Index.to_flat_index`

`Index.to_flat_index()`

Identity method.

This is implemented for compatibility with subclass implementations when chaining.

**Returns**

`pd.Index` Caller.

**See also:**

- `MultiIndex.to_flat_index` Subclass implementation.
pandas.Index.to_frame

Index.to_frame(index=True, name=NoDefault.no_default)
Create a DataFrame with a column containing the Index.

Parameters

- **index** [bool, default True] Set the index of the returned DataFrame as the original Index.
- **name** [object, default None] The passed name should substitute for the index name (if it has one).

Returns

- **DataFrame** DataFrame containing the original Index data.

See also:

- **Index.to_series** Convert an Index to a Series.
- **Series.to_frame** Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
       animal
    Ant     Ant
    Bear    Bear
    Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
       animal
    0    Ant
    1    Bear
    2    Cow
```

To override the name of the resulting column, specify name:

```python
>>> idx.to_frame(index=False, name='zoo')
       zoo
    0    Ant
    1    Bear
    2    Cow
```
pandas.Index.to_list

Index.to_list()
Return a list of the values.
These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns
list
See also:
numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Index.to_native_types

final Index.to_native_types(slicer=None, **kwargs)
Format specified values of self and return them.
Deprecated since version 1.2.0.

Parameters

slicer [int, array-like] An indexer into self that specifies which values are used in the formatting process.

kwargs [dict] Options for specifying how the values should be formatted. These options include the following:

1) na_rep [str] The value that serves as a placeholder for NULL values
2) quoting [bool or None] Whether or not there are quoted values in self
3) date_format [str] The format used to represent date-like values.

Returns

numpy.ndarray Formatted values.

pandas.Index.to_numpy

Index.to_numpy(dtype=None, copy=False, na_value=NoDefault.no_default, **kwargs)
A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the type of the array.
New in version 1.0.0.
**kwargs  Additional keywords passed through to the to_numpy method of the underlying array (for extension arrays).

New in version 1.0.0.

**Returns**

numpy.ndarray

**See also:**

*Series.array*  Get the actual data stored within.

*Index.array*  Get the actual data stored within.

*DataFrame.to_numpy*  Similar method for DataFrame.

**Notes**

The returned array will be the same up to equality (values equal in self will be equal in the returned array; likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, Series.array should be used instead.

This table lays out the different dtypes and default return types of to_numpy() for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>

**Examples**

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
dtype(object)

array(['a', 'b', 'a'], dtype=object)
```

Specify the dtype to control how datetime-aware data is represented. Use dtype=object to return an ndarray of pandas Timestamp objects, each with the correct tz.

```python
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz='CET'))
>>> ser.to_numpy(dtype=object)
dtype(object)

array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
       Timestamp('2000-01-01 00:00:00+0100', tz='CET')])
```

(continues on next page)
Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype="datetime64[ns]"
...array([1999-12-31T23:00:00.000000000, '2000-01-01T23:00:00...'],
... dtype='datetime64[ns]')
```

### pandas.Index.to_series

#### `Index.to_series(index=None, name=None)`

Create a Series with both index and values equal to the index keys.

Useful with `map` for returning an indexer based on an index.

**Parameters**

- `index` [Index, optional] Index of resulting Series. If None, defaults to original index.
- `name` [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

- `Series` The dtype will be based on the type of the Index values.

**See also:**

- `Index.to_frame` Convert an Index to a DataFrame.
- `Series.to_frame` Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
   Ant  Ant
   Bear Bear
   Cow  Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to `index`:

```python
>>> idx.to_series(index=[0, 1, 2])
0   Ant
1   Bear
(continues on next page)```
To override the name of the resulting column, specify `name`:

```python
>>> idx.to_series(name='zoo')
animal
Ant    Ant
Bear   Bear
Cow    Cow
Name: zoo, dtype: object
```

### pandas.Index.tolist

`Index.tolist()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

```
list
```

See also:

- `numpy.ndarray.tolist` Return the array as an a.ndim-levels deep nested list of Python scalars.

### pandas.Index.transpose

`Index.transpose(*args, **kwargs)`

Return the transpose, which is by definition self.

Returns

```
%(klass)s
```

### pandas.Index.union

`final Index.union(other, sort=None)`

Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to `dtype('object')` first.

Changed in version 0.25.0.

Parameters

- `other` [Index or array-like]
- `sort` [bool or None, default None] Whether to sort the resulting Index.
  - None : Sort the result, except when
    1. `self` and `other` are equal.
2. *self* or *other* has length 0.

3. Some values in *self* or *other* cannot be compared. A `RuntimeWarning` is issued in this case.

- `False`: do not sort the result.

**Returns**

*union* [Index]

---

**Examples**

**Union matching dtypes**

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

**Union mismatched dtypes**

```python
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

**MultiIndex case**

```python
>>> idx1 = pd.MultiIndex.from_arrays(...
...   [[1, 1, 2, 2], ['Red', 'Blue', 'Red', 'Blue']]
... )
>>> idx1
MultiIndex([(1, 'Red'),
            (1, 'Blue'),
            (2, 'Red'),
            (2, 'Blue')],
           )
>>> idx2 = pd.MultiIndex.from_arrays(...
...   [[3, 3, 2, 2], ['Red', 'Green', 'Red', 'Green']]
... )
>>> idx2
MultiIndex([(3, 'Red'),
            (3, 'Green'),
            (2, 'Red'),
            (2, 'Green')],
           )
>>> idx1.union(idx2)
MultiIndex([(1, 'Blue'),
            (1, 'Red'),
            (2, 'Blue'),
            (2, 'Green'),
            (2, 'Red'),
            (3, 'Green'),
            (3, 'Red')],
           )
```

(continues on next page)
>>> idx1.union(idx2, sort=False)
MultiIndex([(1, 'Red'),
           (1, 'Blue'),
           (2, 'Red'),
           (2, 'Blue'),
           (3, 'Red'),
           (3, 'Green'),
           (2, 'Green')],
           )

pandas.Index.unique

Index.unique(level=None)

Return unique values in the index.

Unique values are returned in order of appearance, this does NOT sort.

Parameters

level [int or hashable, optional] Only return values from specified level (for MultiIndex).
If int, gets the level by integer position, else by level name.

Returns

Index

See also:

unique Numpy array of unique values in that column.
Series.unique Return unique values of Series object.

pandas.Index.value_counts

Index.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [bool, default True] Sort by frequencies.

ascending [bool, default False] Sort in ascending order.

bins [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.

dropna [bool, default True] Don’t include counts of NaN.

Returns

Series
See also:

**Series.count**  Number of non-NA elements in a Series.

**DataFrame.count**  Number of non-NA elements in a DataFrame.

**DataFrame.value_counts**  Equivalent method on DataFrames.

Examples

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0  2
1.0  1
2.0  1
4.0  1
dtype: int64
```

With `normalize` set to `True`, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0 0.4
1.0 0.2
2.0 0.2
4.0 0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```python
>>> s.value_counts(bins=3)
(0.996, 2.0]  2
(2.0, 3.0]  2
(3.0, 4.0]  1
dtype: int64
```

**dropna**

With `dropna` set to `False` we can also see NaN index values.

```python
>>> s.value_counts(dropna=False)
3.0  2
1.0  1
2.0  1
4.0  1
NaN  1
dtype: int64
```
pandas.Index.where

**final** Index.where(*cond*, *other=None*)
Replace values where the condition is False.
The replacement is taken from other.

**Parameters**

- **cond** [bool array-like with the same length as self] Condition to select the values on.
- **other** [scalar, or array-like, default None] Replacement if the condition is False.

**Returns**

pandas.Index A copy of self with values replaced from other where the condition is False.

**See also:**

- **Series.where** Same method for Series.
- **DataFrame.where** Same method for DataFrame.

**Examples**

```python
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')
>>> idx.where(idx.isin(['car', 'train']), 'other')
Index(['car', 'other', 'train', 'other'], dtype='object')
```
## Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Index.values</code></td>
<td>Return an array representing the data in the Index.</td>
</tr>
<tr>
<td><code>Index.is_monotonic</code></td>
<td>Alias for <code>is_monotonic_increasing</code>.</td>
</tr>
<tr>
<td><code>Index.is_monotonic_increasing</code></td>
<td>Return if the index is monotonic increasing (only equal or increasing) values.</td>
</tr>
<tr>
<td><code>Index.is_monotonic_decreasing</code></td>
<td>Return if the index is monotonic decreasing (only equal or decreasing) values.</td>

<tr>
<td><code>Index.is_unique</code></td>
<td>Return if the index has unique values.</td>
</tr>
<tr>
<td><code>Index.has_duplicates</code></td>
<td>Check if the Index has duplicate values.</td>
</tr>
<tr>
<td><code>Index.hasnans</code></td>
<td>Return True if there are any NaNs.</td>
</tr>
<tr>
<td><code>Index.dtype</code></td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td><code>Index.inferred_type</code></td>
<td>Return a string of the type inferred from the values.</td>
</tr>
<tr>
<td><code>Index.is_all_dates</code></td>
<td>Whether or not the index values only consist of dates.</td>
</tr>
<tr>
<td><code>Index.shape</code></td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td><code>Index.name</code></td>
<td>Return Index or MultiIndex name.</td>
</tr>
<tr>
<td><code>Index.names</code></td>
<td></td>
</tr>
<tr>
<td><code>Index.nbytes</code></td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td><code>Index.ndim</code></td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td><code>Index.size</code></td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td><code>Index.empty</code></td>
<td></td>
</tr>
<tr>
<td><code>Index.T</code></td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td><code>Index.memory_usage</code></td>
<td>Memory usage of the values.</td>
</tr>

</tr>
<tr>
<td><code>Index.get_slice_bound(label, side[, kind])</code></td>
<td>Calculate slice bound that corresponds to given label.</td>
</tr>
<tr>
<td><code>Index.isin(values[, level])</code></td>
<td>Return a boolean array where the index values are in values.</td>
</tr>
<tr>
<td><code>Index.slice_indexer([start, end, step, kind])</code></td>
<td>Compute the slice indexer for input labels and step.</td>
</tr>
<tr>
<td><code>Index.slice_locs([start, end, step, kind])</code></td>
<td>Compute slice locations for input labels.</td>
</tr>
</tbody>
</table>

### 3.6.2 Numeric Index

- **`RangeIndex([start, stop, step, dtype, copy, ...])`**
  Immutable Index implementing a monotonic integer range.
  RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

  This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

  **Parameters**
  - `start` [int (default: 0), range, or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.
  - `stop` [int (default: 0)]
  - `step` [int (default: 1)]
  - `dtype` [np.int64] Unused, accepted for homogeneity with other index types.
  - `copy` [bool, default False] Unused, accepted for homogeneity with other index types.
  - `name` [object, optional] Name to be stored in the index.

---

`pandas.RangeIndex`

**class pandas.RangeIndex(start=None, stop=None, step=None, dtype=None, copy=False, name=None)**

Immutable Index implementing a monotonic integer range.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

**Parameters**

- `start` [int (default: 0), range, or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.
- `stop` [int (default: 0)]
- `step` [int (default: 1)]
- `dtype` [np.int64] Unused, accepted for homogeneity with other index types.
- `copy` [bool, default False] Unused, accepted for homogeneity with other index types.
- `name` [object, optional] Name to be stored in the index.
See also:

**Index**  The base pandas Index type.
**Int64Index**  Index of int64 data.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>start</strong></td>
<td>The value of the <code>start</code> parameter (0 if this was not supplied).</td>
</tr>
<tr>
<td><strong>stop</strong></td>
<td>The value of the <code>stop</code> parameter.</td>
</tr>
<tr>
<td><strong>step</strong></td>
<td>The value of the <code>step</code> parameter (1 if this was not supplied).</td>
</tr>
</tbody>
</table>

**pandas.RangeIndex.start**

**property**  `RangeIndex.start`

The value of the `start` parameter (0 if this was not supplied).

**pandas.RangeIndex.stop**

**property**  `RangeIndex.stop`

The value of the `stop` parameter.

**pandas.RangeIndex.step**

**property**  `RangeIndex.step`

The value of the `step` parameter (1 if this was not supplied).

Methods

**from_range(data[, name, dtype])**

Create RangeIndex from a range object.

**classmethod**  `RangeIndex.from_range(data, name=None, dtype=None)`

Create RangeIndex from a range object.

**Returns**

```
RangeIndex
```
pandas.Int64Index

class pandas.Int64Index(data=None, dtype=None, copy=False, name=None)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Int64Index is a special case of Index with purely integer labels.

Deprecated since version 1.4.0: In pandas v2.0 Int64Index will be removed and NumericIndex used instead. Int64Index will remain fully functional for the duration of pandas 1.x.

Parameters

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: int64)]
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.

See also:

- **Index** The base pandas Index type.
- **NumericIndex** Index of numpy int/uint/float data.

Notes

An Index instance can only contain hashable objects.

Attributes

- None

Methods

- None

pandas.UInt64Index

class pandas.UInt64Index(data=None, dtype=None, copy=False, name=None)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of Index with purely unsigned integer labels.

Deprecated since version 1.4.0: In pandas v2.0 UInt64Index will be removed and NumericIndex used instead. UInt64Index will remain fully functional for the duration of pandas 1.x.

Parameters

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: uint64)]
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.

See also:

- **Index** The base pandas Index type.
- **NumericIndex** Index of numpy int/uint/float data.
Notes

An Index instance can only contain hashable objects.

Attributes

Methods

pandas.Float64Index

class pandas.Float64Index(data=None, dtype=None, copy=False, name=None)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Float64Index is a special case of Index with purely float labels.

Deprecated since version 1.4.0: In pandas v2.0 Float64Index will be removed and NumericIndex used instead. Float64Index will remain fully functional for the duration of pandas 1.x.

Parameters

- data [array-like (1-dimensional)]
- dtype [NumPy dtype (default: float64)]
- copy [bool] Make a copy of input ndarray.
- name [object] Name to be stored in the index.

See also:

- Index The base pandas Index type.
- NumericIndex Index of numpy int/uint/float data.

Notes

An Index instance can only contain hashable objects.

3.6.3 CategoricalIndex

CategoricalIndex([data, categories, ...]) Index based on an underlying Categorical.

pandas.CategoricalIndex

class pandas.CategoricalIndex(data=None, categories=None, ordered=None, dtype=None, copy=False, name=None)

Index based on an underlying Categorical.

CategoricalIndex, like Categorical, can only take on a limited, and usually fixed, number of possible values (categories). Also, like Categorical, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

Parameters

- **data** [array-like (1-dimensional)] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.
- **categories** [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here (and also not in dtype), they will be inferred from the data.
- **ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in dtype, the resulting categorical will be unordered.
- **dtype** [CategoricalDtype or “category”, optional] If CategoricalDtype, cannot be used together with categories or ordered.
- **copy** [bool, default False] Make a copy of input ndarray.
- **name** [object, optional] Name to be stored in the index.

Raises

- **ValueError** If the categories do not validate.
- **TypeError** If an explicit ordered=True is given but no categories and the values are not sortable.

See also:

- Index The base pandas Index type.
- Categorical A categorical array.
- CategoricalDtype Type for categorical data.

3.6. Index objects
Notes

See the user guide for more.

Examples

```python
>>> pd.CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'])
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')

CategoricalIndex can also be instantiated from a Categorical:

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')

Ordered CategoricalIndex can have a min and max value.

```python
>>> ci = pd.CategoricalIndex(
...     ['a', 'b', 'c', 'a', 'b', 'c'], ordered=True, categories=['c', 'b', 'a']
... )
>>> ci
CategoricalIndex(['a', 'b', 'c'], categories=['c', 'b', 'a'], ordered=True, dtype='category')
>>> ci.min()
'c'
```

Attributes

- `codes` The category codes of this categorical.
- `categories` The categories of this categorical.
- `ordered` Whether the categories have an ordered relationship.

`pandas.CategoricalIndex.codes` property

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns

pandas.CategoricalIndex.categories

**property** CategoricalIndex.categories

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to categories is a inplace operation!

**Raises**

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.ordered

**property** CategoricalIndex.ordered

Whether the categories have an ordered relationship.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rename_categories(*args, **kwargs)</td>
<td>Rename categories.</td>
</tr>
<tr>
<td>reorder_categories(*args, **kwargs)</td>
<td>Reorder categories as specified in new_categories.</td>
</tr>
<tr>
<td>add_categories(*args, **kwargs)</td>
<td>Add new categories.</td>
</tr>
<tr>
<td>remove_categories(*args, **kwargs)</td>
<td>Remove the specified categories.</td>
</tr>
<tr>

</tr>
<tr>
<td>set_categories(*args, **kwargs)</td>
<td>Set the categories to the specified new_categories.</td>
</tr>
<tr>
<td>as_ordered(*args, **kwargs)</td>
<td>Set the Categorical to be ordered.</td>
</tr>
<tr>
<td>as_unordered(*args, **kwargs)</td>
<td>Set the Categorical to be unordered.</td>
</tr>
<tr>
<td>map(mapper)</td>
<td>Map values using input an input mapping or function.</td>
</tr>
</tbody>
</table>
pandas.CategoricalIndex.rename_categories

CategoricalIndex.rename_categories(*args, **kwargs)

Rename categories.

Parameters

- **new_categories** [list-like, dict-like or callable] New categories which will replace old categories.
  - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
  - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
  - callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

- **inplace** [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Returns

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

 Raises

- **ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through.

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```
You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

### pandas.CategoricalIndex.reorder_categories

CategoricalIndex.reorder_categories(*args, **kwargs)

Reorder categories as specified in new_categories.

*new_categories* need to include all old categories and no new category items.

**Parameters**

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- **inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**

- **ValueError** If the new categories do not contain all old category items or any new ones

**See also:**

- rename_categories Rename categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

### pandas.CategoricalIndex.add_categories

CategoricalIndex.add_categories(*args, **kwargs)

Add new categories.

*new_categories* will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- **new_categories** [category or list-like of category] The new categories to be included.
inplace  [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Deprecated since version 1.3.0.

Returns

- **cat**  [Categorical or None] Categorical with new categories added or None if inplace=True.

Raises

- **ValueError**  If the new categories include old categories or do not validate as categories.

See also:

- **rename_categories**  Rename categories.
- **reorder_categories**  Reorder categories.
- **remove_categories**  Remove the specified categories.
- **remove_unused_categories**  Remove categories which are not used.
- **set_categories**  Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(["c", "b", "c"])
"'c', 'b', 'c']
Categories (2, object): ['b', 'c']

>>> c.add_categories(['d', 'a'])
['c', 'b', 'c', 'd', 'a']
Categories (6, object): ['b', 'c', 'd', 'a']
```

---

**pandas.CategoricalIndex.remove_categories**

```
CategoricalIndex.remove_categories(*args, **kwargs)
```

Remove the specified categories.

- **removals**  must be included in the old categories. Values which were in the removed categories will be set to NaN.

Parameters

- **removals**  [category or list of categories] The categories which should be removed.

- **inplace**  [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Deprecated since version 1.3.0.

Returns

- **cat**  [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

---
**ValueError** If the removals are not contained in the categories

See also:

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

**Examples**

```python
>>> c = pd.Categorical(['a', 'c', 'b', 'c', 'd'])
>>> c
['a', 'c', 'b', 'c', 'd']
Categories (4, object): ['a', 'b', 'c', 'd']

>>> c.remove_categories(['d', 'a'])
[NaN, 'c', 'b', 'c', NaN]
Categories (2, object): ['b', 'c']
```

`pandas.CategoricalIndex.remove_unused_categories`

CategoricalIndex.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

**Parameters**

- `inplace` [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.
  
  Deprecated since version 1.2.0.

**Returns**

- `cat` [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `set_categories` Set the categories to the specified ones.
Examples

```python
>>> c = pd.Categorical(['a', 'c', 'b', 'c', 'd'])
>>> c
['a', 'c', 'b', 'c', 'd']
Categories (4, object): ['a', 'b', 'c', 'd']

>>> c[2] = 'a'
>>> c[4] = 'c'
>>> c
['a', 'c', 'a', 'c', 'c']
Categories (4, object): ['a', 'b', 'c', 'd']

>>> c.remove_unused_categories()
['a', 'c', 'a', 'c', 'c']
Categories (2, object): ['a', 'c']
```

`pandas.CategoricalIndex.set_categories`

`CategoricalIndex.set_categories(*args, **kwargs)`

Set the categories to the specified new_categories.

`new_categories` can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If `rename==True`, the categories will simple be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

**Parameters**

- `new_categories` [Index-like] The categories in new order.
- `ordered` [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- `rename` [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.
- `inplace` [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

**Returns**

- Categorical with reordered categories or None if inplace.

**Raises**

- `ValueError` If `new_categories` does not validate as categories

**See also:**
rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.

pandas.CategoricalIndex.as_ordered

CategoricalIndex.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical or None Ordered Categorical or None if inplace=True.

pandas.CategoricalIndex.as_unordered

CategoricalIndex.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical or None Unordered Categorical or None if inplace=True.

pandas.CategoricalIndex.map

CategoricalIndex.map(mapper)
Map values using input an input mapping or function.
Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a CategoricalIndex which has the same order property as the original, otherwise an Index is returned.

If a dict or Series is used any unmapped category is mapped to NaN. Note that if this happens an Index will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.

Returns

pandas.CategoricalIndex or pandas.Index Mapped index.

See also:
**Index.map**  Apply a mapping correspondence on an Index.

**Series.map**  Apply a mapping correspondence on a Series.

**Series.apply**  Apply more complex functions on a Series.

### Examples

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

```python
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'], ordered=False, dtype='category')
```

```python
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first', 'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=True, dtype='category')
```

```python
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True, dtype='category')
```

If the mapping is not one-to-one an Index is returned:

```python
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a dict is used, all unmapped categories are mapped to NaN and the result is an Index:

```python
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```
Categorical components

- `CategoricalIndex.codes`: The category codes of this categorical.
- `CategoricalIndex.categories`: The categories of this categorical.
- `CategoricalIndex.ordered`: Whether the categories have an ordered relationship.
- `CategoricalIndex.rename_categories(*args, ...)`: Rename categories.
- `CategoricalIndex.reorder_categories(*args, ...)` : Reorder categories as specified in new_categories.
- `CategoricalIndex.add_categories(*args, **kwargs)`: Add new categories.
- `CategoricalIndex.remove_categories(*args, ...)`: Remove the specified categories.
- `CategoricalIndex.remove_unused_categories(...)` : Remove categories which are not used.
- `CategoricalIndex.set_categories(*args, **kwargs)`: Set the categories to the specified new_categories.
- `CategoricalIndex.as_ordered(*args, **kwargs)`: Set the Categorical to be ordered.
- `CategoricalIndex.as_unordered(*args, **kwargs)`: Set the Categorical to be unordered.

Modifying and computations

- `CategoricalIndex.map(mapper)` : Map values using input an input mapping or function.
- `CategoricalIndex.equals(other)` : Determine if two CategoricalIndex objects contain the same elements.

**pandas.CategoricalIndex.equals**

CategoricalIndex.**equals**(other)

Determine if two CategoricalIndex objects contain the same elements.

**Returns**

- bool: If two CategoricalIndex objects have equal elements True, otherwise False.

### 3.6.4 IntervalIndex

```
IntervalIndex(data[, closed, dtype, copy, ...])
```

Immutable index of intervals that are closed on the same side.

**pandas.IntervalIndex**

class pandas.IntervalIndex(data, closed=None, dtype=None, copy=False, name=None, verify_integrity=True)

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

**Parameters**

- **data** [array-like (1-dimensional)]: Array-like containing Interval objects from which to build the IntervalIndex.
**closed**  [['left', 'right', 'both', 'neither'], default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**dtype**  [dtype or None, default None] If None, dtype will be inferred.

**copy**  [bool, default False] Copy the input data.

**name**  [object, optional] Name to be stored in the index.

**verify_integrity**  [bool, default True] Verify that the IntervalIndex is valid.

See also:

**Index**  The base pandas Index type.

**Interval**  A bounded slice-like interval; the elements of an IntervalIndex.

**interval_range**  Function to create a fixed frequency IntervalIndex.

**cut**  Bin values into discrete Intervals.

**qcut**  Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the user guide for more.

Examples

A new IntervalIndex is typically constructed using `interval_range()`:

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
dtype='interval[int64, right]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>closed</strong></td>
<td>Whether the intervals are closed on the left-side, right-side, both or neither.</td>
</tr>
<tr>
<td><strong>is_empty</strong></td>
<td>Indicates if an interval is empty, meaning it contains no points.</td>
</tr>
<tr>
<td><strong>is_non_overlapping_monotonic</strong></td>
<td>Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.</td>
</tr>
<tr>
<td><strong>is_overlapping</strong></td>
<td>Return True if the IntervalIndex has overlapping intervals, else False.</td>
</tr>
<tr>
<td><strong>values</strong></td>
<td>Return an array representing the data in the Index.</td>
</tr>
</tbody>
</table>
**pandas.IntervalIndex.closed**

IntervalIndex.closed
Whether the intervals are closed on the left-side, right-side, both or neither.

**pandas.IntervalIndex.is_empty**

property IntervalIndex.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.

Returns
bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

Examples
An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
           pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```
pandas.IntervalIndex.is_non_overlapping_monotonic

IntervalIndex.is_non_overlapping_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

pandas.IntervalIndex.is_overlapping

property IntervalIndex.is_overlapping

Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Returns

bool Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

Interval.overlaps Check whether two Interval objects overlap.
IntervalIndex.overlaps Check an IntervalIndex elementwise for overlaps.

Examples

```python
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]],
   dtype='interval[int64, right]')
>>> index.is_overlapping
True
```

Intervals that share closed endpoints overlap:

```python
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([0, 1], [1, 2], [2, 3]],
   dtype='interval[int64, both]')
>>> index.is_overlapping
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([0, 1), [1, 2), [2, 3)),
   dtype='interval[int64, left]')
>>> index.is_overlapping
False
```
**pandas.IntervalIndex.values**

**property IntervalIndex.values**

Return an array representing the data in the Index.

**Warning:** We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

**Returns**

array: `numpy.ndarray` or ExtensionArray

**See also:**

`Index.array` Reference to the underlying data.

`Index.to_numpy` A NumPy array representing the underlying data.

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>mid</th>
<th>length</th>
</tr>
</thead>
</table>

**Methods**

- `from_arrays(left, right[, closed, name, ...])` Construct from two arrays defining the left and right bounds.
- `from_tuples(data[, closed, name, copy, dtype])` Construct an IntervalIndex from an array-like of tuples.
- `from_breaks(breaks[, closed, name, copy, dtype])` Construct an IntervalIndex from an array of splits.
- `contains(*args, **kwargs)` Check elementwise if the Intervals contain the value.
- `overlaps(*args, **kwargs)` Check elementwise if an Interval overlaps the values in the IntervalArray.
- `set_closed(*args, **kwargs)` Return an IntervalArray identical to the current one, but closed on the specified side.
- `to_tuples(*args, **kwargs)` Return an ndarray of tuples of the form (left, right).

**pandas.IntervalIndex.from_arrays**

**classmethod IntervalIndex.from_arrays**(left, right, closed='right', name=None, copy=False, dtype=None)

Construct from two arrays defining the left and right bounds.

**Parameters**

- `left` [array-like (1-dimensional)] Left bounds for each interval.
- `right` [array-like (1-dimensional)] Right bounds for each interval.
- `closed` ['left', 'right', 'both', 'neither'], default 'right' Whether the intervals are closed on the left-side, right-side, both or neither.
copy  [bool, default False] Copy the data.
dtype  [dtype, optional] If None, dtype will be inferred.

Returns
IntervalIndex

Raises

ValueError  When a value is missing in only one of left or right. When a value in left is greater than the corresponding value in right.

See also:

interval_range  Function to create a fixed frequency IntervalIndex.
IntervalIndex.from_breaks  Construct an IntervalIndex from an array of splits.
IntervalIndex.from_tuples  Construct an IntervalIndex from an array-like of tuples.

Notes

Each element of left must be less than or equal to the right element at the same position. If an element is missing, it must be missing in both left and right. A TypeError is raised when using an unsupported type for left or right. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

Examples

```python
>>> pd.IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([(0, 1), (1, 2), (2, 3)],
        dtype='interval[int64, right]')
```

pandas.IntervalIndex.from_tuples

classmethod  IntervalIndex.from_tuples(data, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array-like of tuples.

Parameters

data  [array-like (1-dimensional)] Array of tuples.
closed  [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
copy  [bool, default False] By-default copy the data, this is compat only and ignored.
dtype  [dtype or None, default None] If None, dtype will be inferred.

Returns
IntervalIndex

See also:

interval_range  Function to create a fixed frequency IntervalIndex.
IntervalIndex.from_arrays  Construct an IntervalIndex from a left and right array.
IntervalIndex.from_breaks  Construct an IntervalIndex from an array of splits.
Examples

```python
>>> pd.IntervalIndex.from_tuples(((0, 1), (1, 2)))
IntervalIndex(((0, 1], (1, 2]],
dtype='interval[int64, right]')
```

pandas.IntervalIndex.from_breaks

```python
classmethod IntervalIndex.from_breaks(breaks, closed='right', name=None, copy=False, dtype=None)
```

Construct an IntervalIndex from an array of splits.

Parameters

- **breaks** `[array-like (1-dimensional)]` Left and right bounds for each interval.
- **closed** `['left', 'right', 'both', 'neither'], default 'right'` Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** `[bool, default False]` Copy the data.
- **dtype** `[dtype or None, default None]` If None, dtype will be inferred.

Returns

- `IntervalIndex`

See also:

- `interval_range` Function to create a fixed frequency IntervalIndex.
- `IntervalIndex.from_arrays` Construct from a left and right array.
- `IntervalIndex.from_tuples` Construct from a sequence of tuples.

Examples

```python
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex(((0, 1], (1, 2], (2, 3]],
dtype='interval[int64, right]')
```

pandas.IntervalIndex.contains

```python
IntervalIndex.contains(*args, **kwargs)
```

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

Parameters

- **other** `[scalar]` The value to check whether it is contained in the Intervals.

Returns

- `boolean array`
See also:

**Interval.contains** Check whether Interval object contains value.

**IntervalArray.overlaps** Check if an Interval overlaps the values in the IntervalArray.

**Examples**

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray> [
[(0, 1], (1, 3], (2, 4]
Length: 3, dtype: interval[int64, right]

>>> intervals.contains(0.5)
array([ True, False, False])
```

**pandas.IntervalIndex.overlaps**

`IntervalIndex.overlaps(*args, **kwargs)`

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have
an open endpoint in common do not overlap.

**Parameters**

- **other** [IntervalArray] Interval to check against for an overlap.

**Returns**

- **ndarray** Boolean array positionally indicating where an overlap occurs.

See also:

**Interval.overlaps** Check whether two Interval objects overlap.

**Examples**

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray> [
[(0, 1], (1, 3], (2, 4]
Length: 3, dtype: interval[int64, right]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True, True, False])
```

Intervals that share closed endpoints overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True, True, True])
```
Intervals that only have an open endpoint in common do not overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

**pandas.IntervalIndex.set_closed**

`IntervalIndex.set_closed(*args, **kwargs)`

Return an IntervalArray identical to the current one, but closed on the specified side.

- **Parameters**
  - `closed` [{‘left’, ‘right’, ‘both’, ‘neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

- **Returns**
  - `new_index` [IntervalArray]

**Examples**

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]
```

**pandas.IntervalIndex.to_tuples**

`IntervalIndex.to_tuples(*args, **kwargs)`

Return an ndarray of tuples of the form (left, right).

- **Parameters**
  - `na_tuple` [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

- **Returns**
  - `tuples: ndarray`
IntervalIndex components

</tbody>
</table>

`pandas.IntervalIndex.left`

IntervalIndex.left
pandas.IntervalIndex.right

IntervalIndex.right

pandas.IntervalIndex.mid

IntervalIndex.mid

pandas.IntervalIndex.length

property IntervalIndex.length

pandas.IntervalIndex.get_loc

IntervalIndex.get_loc(key, method=\None, tolerance=\None)

Get integer location, slice or boolean mask for requested label.

Parameters

type: key [label]

method [{\None}, optional]

• default: matches where the label is within an interval only.

Returns

int if unique index, slice if monotonic index, else mask

Examples

>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0

You can also supply a point inside an interval.

>>> index.get_loc(1.5)
1

If a label is in several intervals, you get the locations of all the relevant intervals.

>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])

Only exact matches will be returned if an interval is provided.

>>> index.get_loc(pd.Interval(0, 1))
0

3.6. Index objects
pandas.IntervalIndex.get_indexer

IntervalIndex.get_indexer(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

- **target** [Index]
- **method** [{None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation \( \text{abs(index[indexer] - target)} \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

- **indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Notes

Returns -1 for unmatched values, for further explanation see the example below.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.
3.6.5 MultiIndex

MultiIndex([levels, codes, sortorder, ...])  
A multi-level, or hierarchical, index object for pandas objects.

pandas.MultiIndex

class pandas.MultiIndex(levels=None, codes=None, sortorder=None, names=None, dtype=None, copy=False, name=None, verify_integrity=True)

A multi-level, or hierarchical, index object for pandas objects.

Parameters

levels  [sequence of arrays] The unique labels for each level.
codes  [sequence of arrays] Integers for each level designating which label at each location.
sortorder  [optional int] Level of sortedness (must be lexicographically sorted by that level).
names  [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).
copy  [bool, default False] Copy the meta-data.
verify_integrity  [bool, default True] Check that the levels/codes are consistent and valid.

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.
MultiIndex.from_product Create a MultiIndex from the cartesian product of iterables.
MultiIndex.from_tuples Convert list of tuples to a MultiIndex.
MultiIndex.from_frame Make a MultiIndex from a DataFrame.
Index The base pandas Index type.

Notes

See the user guide for more.

Examples

A new MultiIndex is typically constructed using one of the helper methods MultiIndex.from_arrays(), MultiIndex.from_product() and MultiIndex.from_tuples(). For example (using .from_arrays):

>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'), (1, 'blue'), (2, 'red'), (2, 'blue')], names=['number', 'color'])

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.
Attributes

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>names</td>
<td>Names of levels in MultiIndex.</td>
</tr>
<tr>
<td>nlevels</td>
<td>Integer number of levels in this MultiIndex.</td>
</tr>
<tr>
<td>levshape</td>
<td>A tuple with the length of each level.</td>
</tr>
</tbody>
</table>

pandas.MultiIndex.names

property MultiIndex.names
Names of levels in MultiIndex.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
           names=['x', 'y', 'z'])
>>> mi.names
FrozenList(['x', 'y', 'z'])
```

pandas.MultiIndex.nlevels

property MultiIndex.nlevels
Integer number of levels in this MultiIndex.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([('a', 'b', 'c')],
           )
>>> mi.nlevels
3
```

pandas.MultiIndex.levshape

property MultiIndex.levshape
A tuple with the length of each level.
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([('a', 'b', 'c')],
            )
>>> mi.levshape
(1, 1, 1)
```

Methods

- `from_arrays(arrays[, sortorder, names])` Convert arrays to MultiIndex.
- `from_tuples(tuples[, sortorder, names])` Convert list of tuples to MultiIndex.
- `from_product(iterables[, sortorder, names])` Make a MultiIndex from the cartesian product of multiple iterables.
- `from_frame(df[, sortorder, names])` Make a MultiIndex from a DataFrame.
- `set_levels(levels[, level, inplace, ...])` Set new levels on MultiIndex.
- `set_codes(codes[, level, inplace, ...])` Set new codes on MultiIndex.
- `to_frame([index, name])` Create a DataFrame with the levels of the MultiIndex as columns.
- `to_flat_index()` Convert a MultiIndex to an Index of Tuples containing the level values.
- `sortlevel([level, ascending, sort_remaining])` Sort MultiIndex at the requested level.
- `droplevel([level])` Return index with requested level(s) removed.
- `swaplevel([i, j])` Swap level i with level j.
- `reorder_levels(order)` Rearrange levels using input order.
- `remove_unused_levels()` Create new MultiIndex from current that removes unused levels.
- `get_locs(seq)` Get location for a sequence of labels.

**pandas.MultiIndex.from_arrays**

**classmethod** `MultiIndex.from_arrays(arrays, sortorder=None, names=NoDefault.no_default)` Convert arrays to MultiIndex.

**Parameters**

- `arrays` [list / sequence of array-likes] Each array-like gives one level’s value for each data point. len(arrays) is the number of levels.
- `sortorder` [int or None] Level of sortedness (must be lexicographically sorted by that level).
- `names` [list / sequence of str, optional] Names for the levels in the index.

**Returns**

MultiIndex

**See also:**
**MultiIndex.from_tuples** Convert list of tuples to MultiIndex.

**MultiIndex.from_product** Make a MultiIndex from cartesian product of iterables.

**MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

**Examples**

```python
>>> arrays = 
[[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex((1, 'red'),
(1, 'blue'),
(2, 'red'),
(2, 'blue'),
names=['number', 'color'])
```

**pandas.MultiIndex.from_tuples**

classmethod MultiIndex.from_tuples(tuples, sortorder=None, names=None)

Convert list of tuples to MultiIndex.

**Parameters**

- **tuples** [list / sequence of tuple-likes] Each tuple is the index of one row/column.
- **sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list / sequence of str, optional] Names for the levels in the index.

**Returns**

MultiIndex

See also:

- **MultiIndex.from_arrays** Convert list of arrays to MultiIndex.
- **MultiIndex.from_product** Make a MultiIndex from cartesian product of iterables.
- **MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

**Examples**

```python
>>> tuples = 
[(1, 'red'), (1, 'blue'),
...
(2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex((1, 'red'),
(1, 'blue'),
(2, 'red'),
(2, 'blue'),
names=['number', 'color'])
```
**pandas.MultiIndex.from_product**

**classmethod MultiIndex.from_product(iterables, sortorder=None, names=NoDefault.no_default)**

Make a MultiIndex from the cartesian product of multiple iterables.

**Parameters**

- **iterables** [list / sequence of iterables] Each iterable has unique labels for each level of the index.
- **sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from the elements of iterables if an element has a name attribute

**Returns**

MultiIndex

See also:

- **MultiIndex.from_arrays** Convert list of arrays to MultiIndex.
- **MultiIndex.from_tuples** Convert list of tuples to MultiIndex.
- **MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

**Examples**

```python
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
...                             names=['number', 'color'])
MultiIndex([(0, 'green'),
            (0, 'purple'),
            (1, 'green'),
            (1, 'purple'),
            (2, 'green'),
            (2, 'purple')],
           names=['number', 'color'])
```

**pandas.MultiIndex.from_frame**

**classmethod MultiIndex.from_frame(df, sortorder=None, names=None)**

Make a MultiIndex from a DataFrame.

**Parameters**

- **df** [DataFrame] DataFrame to be converted to MultiIndex.
- **sortorder** [int, optional] Level of sortedness (must be lexicographically sorted by that level).
names [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

Returns

MultiIndex The MultiIndex representation of the given DataFrame.

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.
MultiIndex.from_tuples Convert list of tuples to MultiIndex.
MultiIndex.from_product Make a MultiIndex from cartesian product of iterables.

Examples

```python
>>> df = pd.DataFrame([[['HI', 'Temp'], ['HI', 'Precip']], ...
...                     [[‘NJ’, ‘Temp’], [‘NJ’, ‘Precip’]], ...
...                     columns=['a', 'b'])
```

```python
>>> df
   a   b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip
```

```python
>>> pd.MultiIndex.from_frame(df)
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['a', 'b'])
```

Using explicit names, instead of the column names

```python
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['state', 'observation'])
```

pandas.MultiIndex.set_levels

MultiIndex.set_levels(levels, level=None, inplace=None, verify_integrity=True)

Set new levels on MultiIndex. Defaults to returning new index.

Parameters

levels [sequence or list of sequence] New level(s) to apply.

level [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
inplace  [bool] If True, mutates in place.

Deprecated since version 1.2.0.

verify_integrity  [bool, default True] If True, checks that levels and codes are compatible.

Returns

new index (of same type and class...etc) or None  The same type as the caller or None if inplace=True.

Examples

```python
>>> idx = pd.MultiIndex.from_tuples(
...     [(1, "one"), (1, "two"), (2, "one"), (2, "two"),
...      (3, "one"), (3, "two")],
...     names=['foo', 'bar'])
>>> idx
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two'),
            (3, 'one'),
            (3, 'two')],
           names=['foo', 'bar'])

>>> idx.set_levels([['a', 'b', 'c'], [1, 2]])
MultiIndex([['a', 1], ['b', 2], ['c', 1],
            ('a', 2), ('b', 1), ('c', 2)],
           names=['foo', 'bar'])

>>> idx.set_levels(['a', 'b', 'c'], level=0)
MultiIndex([['a', 'one'],
            ('a', 'two'),
            ('b', 'one'),
            ('b', 'two'),
            ('c', 'one'),
            ('c', 'two')],
           names=['foo', 'bar'])

>>> idx.set_levels(['a', 'b'], level='bar')
MultiIndex([(1, 'a'), (2, 'a'), (1, 'b')],
            names=['foo', 'bar'])
```

(continues on next page)
If any of the levels passed to `set_levels()` exceeds the existing length, all of the values from that argument will be stored in the MultiIndex levels, though the values will be truncated in the MultiIndex output.

```python
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1])
MultiIndex([('a', 1), ('b', 2), ('b', 2), ('c', 1), ('c', 2)],
           names=['foo', 'bar'])
```

```python
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1]).levels
FrozenList([['a', 'b', 'c'], [1, 2, 3, 4]])
```

---

### pandas.MultiIndex.set_codes

`MultiIndex.set_codes(codes, level=None, inplace=None, verify_integrity=True)`

Set new codes on MultiIndex. Defaults to returning new index.

**Parameters**

- **codes** [sequence or list of sequence] New codes to apply.
- **level** [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
- **inplace** [bool] If True, mutates in place.
  
  Deprecated since version 1.2.0.

- **verify_integrity** [bool, default True] If True, checks that levels and codes are compatible.

**Returns**

- **new index (of same type and class...etc) or None** The same type as the caller or None if inplace=True.

**Examples**

```python
>>> idx = pd.MultiIndex.from_tuples(
...     [(1, 'one'), (1, 'two'), (2, 'one'), (2, 'two')], names=['foo', 'bar']
... )
>>> idx
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['foo', 'bar'])
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([[2, 'one'],
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
           names=['foo', 'bar'])

>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([[2, 'one'],
            (1, 'two'),
            (2, 'one'),
            (1, 'two')],
           names=['foo', 'bar'])

>>> idx.set_codes([[0, 0, 1, 1], level='bar')
MultiIndex([[1, 'one'],
            (1, 'one'),
            (2, 'two'),
            (2, 'two')],
           names=['foo', 'bar'])

>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1], level=[0, 1])
MultiIndex([[2, 'one'],
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
           names=['foo', 'bar'])
```

**pandas.MultiIndex.to_frame**

MultiIndex.to_frame(index=True, name=NoDefault.no_default)

Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

**Parameters**

- **index** [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.

- **name** [list / sequence of str, optional] The passed names should substitute index level names.

**Returns**

- **DataFrame** [a DataFrame containing the original MultiIndex data.]

**See also:**

- **DataFrame** Two-dimensional, size-mutable, potentially heterogeneous tabular data.
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a', 'b'], ['c', 'd']])
>>> mi
MultiIndex([('a', 'c'),
             ('b', 'd')],
            )

>>> df = mi.to_frame()
>>> df
   0  1
0 a c
1 b d

>>> df = mi.to_frame(index=False)
>>> df
   0  1
0 a c
1 b d

>>> df = mi.to_frame(name=['x', 'y'])
>>> df
   x  y
0 a c
1 b d
```

**pandas.MultiIndex.to_flat_index**

MultiIndex.to_flat_index()

Convert a MultiIndex to an Index of Tuples containing the level values.

Returns

pd.Index  Index with the MultiIndex data represented in Tuples.

See also:

MultiIndex.from_tuples  Convert flat index back to MultiIndex.

Notes

This method will simply return the caller if called by anything other than a MultiIndex.
Examples

```python
>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index(['foo', 'baz'], 'foo', 'qux'),
('bar', 'baz'), ('bar', 'qux')]
```

```
pandas: powerful Python data analysis toolkit, Release 1.4.3
```

```
Examples

>>> index = pd.MultiIndex.from_product(  ...
...     [['foo', 'bar'], ['baz', 'qux']],  ...
...     names=['a', 'b'])
>>> index.to_flat_index()
Index(['foo', 'baz'], 'foo', 'qux'),
('bar', 'baz'), ('bar', 'qux')]
```

```
pandas: powerful Python data analysis toolkit, Release 1.4.3
```

```
Examples

>>> index = pd.MultiIndex.from_product(  ...
...     [['foo', 'bar'], ['baz', 'qux']],  ...
...     names=['a', 'b'])
>>> index.to_flat_index()
Index(['foo', 'baz'], 'foo', 'qux'),
('bar', 'baz'), ('bar', 'qux')]
```

```
pandas: powerful Python data analysis toolkit, Release 1.4.3
```

```
Examples

>>> index = pd.MultiIndex.from_product(  ...
...     [['foo', 'bar'], ['baz', 'qux']],  ...
...     names=['a', 'b'])
>>> index.to_flat_index()
Index(['foo', 'baz'], 'foo', 'qux'),
('bar', 'baz'), ('bar', 'qux')]
```

```
pandas: powerful Python data analysis toolkit, Release 1.4.3
```

```
Examples

>>> index = pd.MultiIndex.from_product(  ...
...     [['foo', 'bar'], ['baz', 'qux']],  ...
...     names=['a', 'b'])
>>> index.to_flat_index()
Index(['foo', 'baz'], 'foo', 'qux'),
('bar', 'baz'), ('bar', 'qux')]
```

```
pandas: powerful Python data analysis toolkit, Release 1.4.3
```

```
Examples

>>> index = pd.MultiIndex.from_product(  ...
...     [['foo', 'bar'], ['baz', 'qux']],  ...
...     names=['a', 'b'])
>>> index.to_flat_index()
Index(['foo', 'baz'], 'foo', 'qux'),
('bar', 'baz'), ('bar', 'qux')]
```

```
pandas: powerful Python data analysis toolkit, Release 1.4.3
```

```
Examples

>>> index = pd.MultiIndex.from_product(  ...
...     [['foo', 'bar'], ['baz', 'qux']],  ...
...     names=['a', 'b'])

(continued from previous page)

>>> mi.sortlevel(1, ascending=False)
(MultiIndex(((0, 2),
          (0, 1)),
          array([0, 1])))

pandas.MultiIndex.droplevel

MultiIndex.droplevel(level=0)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a level If
list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex

Examples

>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]],
... names=['x', 'y', 'z'])

>>> mi
MultiIndex([[1, 3, 5],
          (2, 4, 6)],
          names=['x', 'y', 'z'])

>>> mi.droplevel()
MultiIndex([[3, 5],
          (4, 6)],
          names=['y', 'z'])

>>> mi.droplevel(2)
MultiIndex([[1, 3],
          (2, 4)],
          names=['x', 'y'])

>>> mi.droplevel('z')
MultiIndex([[1, 3],
          (2, 4)],
          names=['x', 'y'])

>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')
pandas.MultiIndex.swaplevel

MultiIndex.swaplevel(i=-2, j=-1)

Swap level i with level j.

Calling this method does not change the ordering of the values.

Parameters

i [int, str, default -2] First level of index to be swapped. Can pass level name as string.
   Type of parameters can be mixed.

j [int, str, default -1] Second level of index to be swapped. Can pass level name as string.
   Type of parameters can be mixed.

Returns

MultiIndex A new MultiIndex.

See also:

Series.swaplevel Swap levels i and j in a MultiIndex.

Dataframe.swaplevel Swap levels i and j in a MultiIndex on a particular axis.

Examples

```python
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([('a', 'bb'),
            ('a', 'aa'),
            ('b', 'bb'),
            ('b', 'aa')],
           )
>>> mi.swaplevel(0, 1)
MultiIndex([('bb', 'a'),
            ('aa', 'a'),
            ('bb', 'b'),
            ('aa', 'b')],
           )
```

pandas.MultiIndex.reorder_levels

MultiIndex.reorder_levels(order)

Rearrange levels using input order. May not drop or duplicate levels.

Parameters

order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

Returns

MultiIndex
Examples

```python
>>> mi = pd.MultiIndex.from_arrays(([1, 2], [3, 4]), names=['x', 'y'])
>>> mi
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])

>>> mi.reorder_levels(order=[1, 0])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])

>>> mi.reorder_levels(order=['y', 'x'])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])
```

`pandas.MultiIndex.remove_unused_levels`

`MultiIndex.remove_unused_levels()`

Create new `MultiIndex` from current that removes unused levels.

Unused level(s) means levels that are not expressed in the labels. The resulting `MultiIndex` will have the same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

Returns

`MultiIndex`

Examples

```python
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')])
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )

>>> mi[2:]
MultiIndex([(1, 'a'),
            (1, 'b')],
           )

The 0 from the first level is not represented and can be removed

>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[1], ['a', 'b']])
```
pandas.MultiIndex.get_locs

MultiIndex.get_locs(seq)

Get location for a sequence of labels.

Parameters

seq [label, slice, list, mask or a sequence of such] You should use one of the above for each level. If a level should not be used, set it to slice(None).

Returns

numpy.ndarray NumPy array of integers suitable for passing to iloc.

See also:

MultiIndex.get_loc Get location for a label or a tuple of labels.

MultiIndex.slice_locs Get slice location given start label(s) and end label(s).

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_locs('b')
array([1, 2], dtype=int64)

>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)

>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

IndexSlice

Create an object to more easily perform multi-index slicing.

pandas.IndexSlice

pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>

Create an object to more easily perform multi-index slicing.

See also:

MultiIndex.remove_unused_levels New MultiIndex with no unused levels.
Notes

See Defined Levels for further info on slicing a MultiIndex.

Examples

```python
>>> midx = pd.MultiIndex.from_product([['A0', 'A1'], ['B0', 'B1', 'B2', 'B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
                       index=midx, columns=columns)
```

Using the default slice command:

```python
>>> dfmi.loc[(slice(None), slice('B0', 'B1'))], :]
foo   bar
A0  0   1
B1  2   3
A1  8   9
B1 10  11
```

Using the IndexSlice class for a more intuitive command:

```python
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, slice('B0': 'B1')], :]
foo   bar
A0  0   1
B1  2   3
A1  8   9
B1 10  11
```

MultiIndex constructors

| MultiIndex.from_arrays(arrays[, sortorder, ...]) | Convert arrays to MultiIndex. |
| MultiIndex.from_tuples(tuples[, sortorder, ...]) | Convert list of tuples to MultiIndex. |
| MultiIndex.from_product(iterables[, ...]) | Make a MultiIndex from the cartesian product of multiple iterables. |
| MultiIndex.from_frame(df[, sortorder, names]) | Make a MultiIndex from a DataFrame. |

MultiIndex properties

| MultiIndex.names | Names of levels in MultiIndex. |
| MultiIndex.levels |
| MultiIndex.codes |
| MultiIndex.nlevels | Integer number of levels in this MultiIndex. |
| MultiIndex.levshape | A tuple with the length of each level. |
| MultiIndex.dtypes | Return the dtypes as a Series for the underlying MultiIndex. |
**pandas.MultiIndex.levels**

**MultiIndex.levels**

**pandas.MultiIndex.codes**

**property MultiIndex.codes**

**pandas.MultiIndex.dtypes**

**MultiIndex.dtypes**

Return the dtypes as a Series for the underlying MultiIndex.

</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.MultiIndex.get_loc

MultiIndex.get_loc(key, method=None)

Get location for a label or a tuple of labels.

The location is returned as an integer/slice or boolean mask.

Parameters

key [label or tuple of labels (one for each level)]

method [None]

Returns

loc [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

See also:

Index.get_loc The get_loc method for (single-level) index.
MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.

Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use MultiIndex.get_locs() instead.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```python
>>> mi.get_loc('b')
slice(1, 3, None)
```

```python
>>> mi.get_loc(('b', 'e'))
1
```

pandas.MultiIndex.get_loc_level

MultiIndex.get_loc_level(key, level=0, drop_level=True)

Get location and sliced index for requested label(s)/level(s).

Parameters

key [label or sequence of labels]

level [int/level name or list thereof, optional]

drop_level [bool, default True] If False, the resulting index will not drop any level.

Returns

loc [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be None.

See also:
**MultiIndex.get_loc** Get location for a label or a tuple of labels.

**MultiIndex.get_locs** Get location for a label/slice/list/mask or a sequence of such.

### Examples

```python
df = pd.DataFrame(data={'A': [1, 2, 3], 'B': [4, 5, 6]}, index=['a', 'b', 'c'])
print(df)
```

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')], names=['A', 'B'])

>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))

>>> mi.get_loc_level('e', level='B')
(array([False, True, False]), Index(['b'], dtype='object', name='A'))

>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

### pandas.MultiIndex.get_indexer

**MultiIndex.get_indexer** *(target, method=None, limit=None, tolerance=None)*

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

- **target** [Index]
- **method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

**Tolerance** may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

- **indexer** [np.ndarray[np.intp]] Integers from 0 to n-1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.
Notes

Returns -1 for unmatched values, for further explanation see the example below.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

`pandas.MultiIndex.get_level_values`

`MultiIndex.get_level_values(level)`

Return vector of label values for requested level.

Length of returned vector is equal to the length of the index.

Parameters

- `level` [int or str] `level` is either the integer position of the level in the MultiIndex, or the name of the level.

Returns

- `values` [Index] Values is a level of this MultiIndex converted to a single `Index` (or subclass thereof).

Notes

If the level contains missing values, the result may be casted to `float` with missing values specified as `NaN`. This is because the level is converted to a regular `Index`.

Examples

Create a MultiIndex:

```python
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```python
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

If a level contains missing values, the return type of the level maybe casted to `float`.

```python
>>> pd.MultiIndex.from_arrays([[1, None, 2], [3, 4, 5]]).dtypes
level_0    int64
level_1    int64
```

(continues on next page)
3.6.6 DatetimeIndex

**DatetimeIndex**([data, freq, tz, normalize, ...])  Immutable ndarray-like of datetime64 data.

**pandas.DatetimeIndex**

class pandas.DatetimeIndex(data=None, freq=NoDefault.no_default, tz=None, normalize=False, closed=None, ambiguous='infer', dayfirst=False, yearfirst=False, dtype=None, copy=False, name=None)

Immutable ndarray-like of datetime64 data.

Represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata.

**Parameters**

- **data** [array-like (1-dimensional), optional] Optional datetime-like data to construct index with.
- **freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- **tz** [pytz.timezone or dateutil.tz.tzfile or datetime.tzinfo or str] Set the Timezone of the data.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **closed** [[‘left’, ‘right’], optional] Set whether to include start and end that are on the boundary. The default includes boundary points on either end.
- **ambiguous** [‘infer’, bool-n.ndarray, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-n.ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- **dayfirst** [bool, default False] If True, parse dates in data with the day first order.
- **yearfirst** [bool, default False] If True parse dates in data with the year first order.
- **dtype** [numpy.dtype or DatetimeTZDtype or str, default None] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.
- **copy** [bool, default False] Make a copy of input ndarray.
name  [label, default None] Name to be stored in the index.

See also:

- **Index**  The base pandas Index type.
- **TimedeltaIndex**  Index of timedelta64 data.
- **PeriodIndex**  Index of Period data.
- **to_datetime**  Convert argument to datetime.
- **date_range**  Create a fixed-frequency DatetimeIndex.

Notes

To learn more about the frequency strings, please see [this link](#).

</table>
pandas.DatetimeIndex.year

**property** DatetimeIndex.year
The year of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="Y")
... )
>>> datetime_series
0 2000-12-31
1 2001-12-31
2 2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0 2000
1 2001
2 2002
dtype: int64
```

pandas.DatetimeIndex.month

**property** DatetimeIndex.month
The month as January=1, December=12.

**Examples**

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0 2000-01-31
1 2000-02-29
2 2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0 1
1 2
2 3
dtype: int64
```
pandas.DatetimeIndex.day

**property** DatetimeIndex.day

The day of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0 2000-01-01
1 2000-01-02
2 2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0 1
1 2
2 3
dtype: int64
```

pandas.DatetimeIndex.hour

**property** DatetimeIndex.hour

The hours of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0 0
1 1
2 2
dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.DatetimeIndex.minute

property DatetimeIndex.minute
The minutes of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 00:01:00
2  2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0  0
1  1
2  2
dtype: int64
```

pandas.DatetimeIndex.second

property DatetimeIndex.second
The seconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 00:00:01
2  2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0  0
1  1
2  2
dtype: int64
```
pandas.DatetimeIndex.microsecond

**property** DatetimeIndex.microsecond

The microseconds of the datetime.

**Examples**

```python
g>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="us")
... )
g>>> datetime_series
datetime_series
0  2000-01-01 00:00:00.000000
1  2000-01-01 00:00:00.000001
2  2000-01-01 00:00:00.000002
dtype: datetime64[ns]

g>>> datetime_series.dt.microsecond
datetime_series.dt.microsecond
0    0
1    1
2    2
dtype: int64
```

pandas.DatetimeIndex.nanosecond

**property** DatetimeIndex.nanosecond

The nanoseconds of the datetime.

**Examples**

```python
g>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="ns")
... )
g>>> datetime_series
datetime_series
0  2000-01-01 00:00:00.000000000
1  2000-01-01 00:00:00.000000001
2  2000-01-01 00:00:00.000000002
dtype: datetime64[ns]

g>>> datetime_series.dt.nanosecond
datetime_series.dt.nanosecond
0    0
1    1
2    2
dtype: int64
```
pandas.DatetimeIndex.date

property DatetimeIndex.date
Returns numpy array of python \texttt{datetime.date} objects.
Namely, the date part of Timestamps without time and timezone information.

pandas.DatetimeIndex.time

property DatetimeIndex.time
Returns numpy array of \texttt{datetime.time} objects.
The time part of the Timestamps.

pandas.DatetimeIndex.timetz

property DatetimeIndex.timetz
Returns numpy array of \texttt{datetime.time} objects with timezone information.
The time part of the Timestamps.

pandas.DatetimeIndex.dayofyear

property DatetimeIndex.dayofyear
The ordinal day of the year.

pandas.DatetimeIndex.day_of_year

property DatetimeIndex.day_of_year
The ordinal day of the year.

pandas.DatetimeIndex.weekofyear

property DatetimeIndex.weekofyear
The week ordinal of the year.
Deprecated since version 1.1.0.
weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.
**pandas.DatetimeIndex.week**

**property** `DatetimeIndex.week`

The week ordinal of the year.

Deprecated since version 1.1.0.

`weekofyear` and `week` have been deprecated. Please use `DatetimeIndex.isocalendar().week` instead.

**pandas.DatetimeIndex.dayofweek**

**property** `DatetimeIndex.dayofweek`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the `dt` accessor) or DatetimeIndex.

**Returns**

- **Series or Index** Containing integers indicating the day number.

**See also:**

- `Series.dt.dayofweek` Alias.
- `Series.dt.weekday` Alias.
- `Series.dt.day_name` Returns the name of the day of the week.

**Examples**

```python
generate_code_snippet()
```
**pandas.DatetimeIndex.day_of_week**

**property DatetimeIndex.day_of_week**

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the \texttt{dt} accessor) or DatetimeIndex.

**Returns**

**Series or Index** Containing integers indicating the day number.

**See also:**

\texttt{Series.dt.dayofweek} Alias.

\texttt{Series.dt.weekday} Alias.

\texttt{Series.dt.day_name} Returns the name of the day of the week.

**Examples**

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

**pandas.DatetimeIndex.weekday**

**property DatetimeIndex.weekday**

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the \texttt{dt} accessor) or DatetimeIndex.

**Returns**

**Series or Index** Containing integers indicating the day number.

**See also:**

\texttt{Series.dt.dayofweek} Alias.

\texttt{Series.dt.weekday} Alias.

\texttt{Series.dt.day_name} Returns the name of the day of the week.
Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.quarter

**property** DatetimeIndex.quarter

The quarter of the date.

pandas.DatetimeIndex.tz

**property** DatetimeIndex.tz

Return the timezone.

Returns

- `datetime.tzinfo`, `pytz.tzinfo.BaseTZInfo`, `dateutil.tz.tz.tzfile`, or `None` Returns None when the array is tz-naive.

pandas.DatetimeIndex.freq

**property** DatetimeIndex.freq

Return the frequency object if it is set, otherwise None.

pandas.DatetimeIndex.freqstr

**property** DatetimeIndex.freqstr

Return the frequency object as a string if its set, otherwise None.
pandas.DataFrame.is_month_start

property DataFrame.is_month_start
Indicates whether the date is the first day of the month.

Returns

Series or array  For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start  Return a boolean indicating whether the date is the first day of the month.

is_month_end  Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0  False
1  False
2  True
dtype: bool
>>> s.dt.is_month_end
0  False
1  True
2  False
dtype: bool

>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```
pandas.DatetimeIndex.is_month_end

property DatetimeIndex.is_month_end
Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.
is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0   False
1   False
2    True
dtype: bool
>>> s.dt.is_month_end
0   False
1    True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.DatetimeIndex.is_quarter_start

property DatetimeIndex.is_quarter_start
Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
is_quarter_end Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range('2017-03-30', ...
...     periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...     is_quarter_start=df.dates.dt.is_quarter_start)
     dates    quarter  is_quarter_start
0 2017-03-30      1            False
1 2017-03-31      1            False
2 2017-04-01      2             True
3 2017-04-02      2            False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_start
array([False, False,  True, False])
```

pandas.DatetimeIndex.is_quarter_end

property DatetimeIndex.is_quarter_end
Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
**is_quarter_start** Similar property indicating the quarter start.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range('2017-03-30', periods=4))
... df.assign(quarter=df.dates.dt.quarter,
...     is_quarter_end=df.dates.dt.is_quarter_end)
   dates  quarter  is_quarter_end
0 2017-03-30      1        False
1 2017-03-31      1        True
2 2017-04-01      2        False
3 2017-04-02      2        False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx.is_quarter_end
array([False, True, False, False])
```

**pandas.DatetimeIndex.is_year_start**

**property** `DatetimeIndex.is_year_start`

Indicate whether the date is the first day of a year.

**Returns**

- **Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- **is_year_end** Similar property indicating the last day of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range('2017-12-30', periods=3))
>>> dates
0  2017-12-30
1  2017-12-31
2  2018-01-01
```

3.6. Index objects
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> dates.dt.is_year_start
0   False
1   False
2    True
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_year_start
array([False, False, True])
```

### pandas.DatetimeIndex.is_year_end

**property** `DatetimeIndex.is_year_end`

Indicate whether the date is the last day of the year.

**Returns**

- **Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- `is_year_start` Similar property indicating the start of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```python
>>> dates.dt.is_year_end
0   False
1    True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

>>> idx.is_year_end
array([False, True, False])

pandas.DatetimeIndex.is_leap_year

property DatetimeIndex.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray  Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")

>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'], dtype='datetime64[ns]', freq='A-DEC')

>>> idx.is_leap_year
array([ True, False, False])

>>> dates_series = pd.Series(idx)

>>> dates_series
0  2012-12-31
1  2013-12-31
2  2014-12-31
dtype: datetime64[ns]

>>> dates_series.dt.is_leap_year
0   True
1   False
2   False
dtype: bool

pandas.DatetimeIndex.inferred_freq

DatetimeIndex.inferred_freq

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

3.6. Index objects
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>normalize(*args, **kwargs)</code></td>
<td>Convert times to midnight. The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.</td>
</tr>

<tr>
<td><code>day_name(*args, **kwargs)</code></td>
<td>Return the day names of the Series or DatetimeIndex with specified locale.</td>
</tr>
<tr>
<td><code>mean(*args, **kwargs)</code></td>
<td>Return the mean value of the Array.</td>
</tr>
<tr>
<td><code>std(*args, **kwargs)</code></td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
</tbody>
</table>

**pandas.DatetimeIndex.normalize**

`DatetimeIndex.normalize(*args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

**Returns**

- **DatetimeArray, DatetimeIndex or Series** The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- `floor` Floor the datetimes to the specified freq.
ceil  Ceil the datetimes to the specified freq.
round  Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...         periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
                '2014-08-01 11:00:00+05:30',
                '2014-08-01 12:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
                '2014-08-01 00:00:00+05:30',
                '2014-08-01 00:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.DatetimeIndex.strftime

```python
DatetimeIndex.strftime(*args, **kwargs)
```
Convert to Index using specified date_format.
Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

**Parameters**

- `date_format` [str] Date format string (e.g. “Y-%m-%d”).

**Returns**

- `ndarray[object]` NumPy ndarray of formatted strings.

See also:

to_datetime  Convert the given argument to datetime.
DatetimeIndex.normalize  Return DatetimeIndex with times to midnight.
DatetimeIndex.round  Round the DatetimeIndex to the specified freq.
DatetimeIndex.floor  Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...         periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
       dtype='object')
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.DatetimeIndex.snap

DatetimeIndex.<code>snap</code>(freq='S')
Snap time stamps to nearest occurring frequency.

Returns

DatetimeIndex

pandas.DatetimeIndex.tz_convert

DatetimeIndex.<code>tz_convert</code>(tz)
Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding
timestamps would be converted to this time zone of the Datetime Array/Index. A
tz of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.<code>tz</code> A timezone that has a variable offset from UTC.

DatetimeIndex.<code>tz_localize</code> Localize tz-naive DatetimeIndex to a given time zone, or remove time-
zone from a tz-aware DatetimeIndex.

Examples

With the <code>tz</code> parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
                      freq='H', periods=3, tz='Europe/Berlin')

>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the <code>tz=None</code>, we can remove the timezone (after converting to UTC if necessary):
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H', periods=3, tz='Europe/Berlin')
...```

```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
             dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

**pandas.DatetimeIndex.tz_localize**

`DatetimeIndex.tz_localize(tz, ambiguous='raise', nonexistent='raise')`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass `tz=None`.

**Parameters**

- **tz** `[str, pytz.timezone, dateutil.tzfile or None]` Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

- **ambiguous** `['infer', ‘NaT’, bool array, default ‘raise’]` When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- **nonexistent** `['shift_forward', ‘shift_backward, ‘NaT’, timedelta, default ‘raise’]` A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times

3.6. Index objects 2261
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Same type as self  Array/Index converted to the specified time zone.

Raises

TypeError  If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert  Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                                '2018-10-28 02:00:00',
                                '2018-10-28 02:30:00',
                                '2018-10-28 02:00:00',
                                '2018-10-28 02:30:00',
                                '2018-10-28 03:00:00',
                                '2018-10-28 03:30:00']))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0  2018-10-28 01:30:00+02:00
1  2018-10-28 02:00:00+02:00
2  2018-10-28 02:30:00+02:00
3  2018-10-28 02:00:00+01:00
4  2018-10-28 02:30:00+01:00
...  ...
(continues on next page)
In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
                                '2018-10-28 02:36:00',
                                '2018-10-28 03:46:00']))
```

```python
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or 'shift_forward' or 'shift_backwards'.

```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
                                '2015-03-29 03:30:00']))
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
```

### pandas.DatetimeIndex.round

`DatetimeIndex.round(*args, **kwargs)`

Perform round operation on the data to the specified `freq`.

**Parameters**

- **freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See `frequency aliases` for a list of possible `freq` values.

- **ambiguous** ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

**nonexistent** ['shift_forward', 'shift_backward', 'NaT', timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

**ValueError if the freq cannot be converted.**

**Notes**

If the timestamps have a timezone, rounding will take place relative to the local (“wall”) time and re-localized to the same timezone. When rounding near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.round("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> rng_tz = pd.DatetimeIndex(["2021-10-31 03:30:00"], tz="Europe/Amsterdam")
```

```python
>>> rng_tz.floor("2H", ambiguous=False)
DatetimeIndex(['2021-10-31 02:00:00+01:00'],
dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```

```python
>>> rng_tz.floor("2H", ambiguous=True)
DatetimeIndex(['2021-10-31 02:00:00+02:00'],
dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```

### pandas.DatetimeIndex.floor

**DatetimeIndex.floor**(*args, **kwargs*)

Perform floor operation on the data to the specified freq.

**Parameters**

- **freq**  [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

- **ambiguous**  [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- **nonexistent**  [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- **DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

- **ValueError** if the freq cannot be converted.
Notes

If the timestamps have a timezone, flooring will take place relative to the local ("wall") time and re-localized to the same timezone. When flooring near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

```python
>>> rng_tz = pd.DatetimeIndex(['2021-10-31 03:30:00'], tz="Europe/Amsterdam")
>>> rng_tz.floor("2H", ambiguous=False)
DatetimeIndex(['2021-10-31 02:00:00+01:00'],
               dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
>>> rng_tz.floor("2H", ambiguous=True)
DatetimeIndex(['2021-10-31 02:00:00+02:00'],
               dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```

pandas.DatetimeIndex.ceil

`DatetimeIndex.ceil(*args, **kwargs)`

Perform ceil operation on the data to the specified `freq`.

Parameters

- `freq` [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See `frequency aliases` for a list of possible `freq` values.
ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

**ValueError if the freq cannot be converted.**

Notes

If the timestamps have a timezone, ceiling will take place relative to the local (“wall”) time and re-localized to the same timezone. When ceiling near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

Examples

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
 DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
                 '2018-01-01 12:01:00'],
                dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
 DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
                 '2018-01-01 13:00:00'],
                dtype='datetime64[ns]', freq=None)
```

**Series**
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> pd.Series(rng).dt.ceil("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 13:00:00
dtype: datetime64[ns]
```

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

```python
>>> rng_tz = pd.DatetimeIndex(["2021-10-31 01:30:00"], tz="Europe/Amsterdam")

>>> rng_tz.ceil("H", ambiguous=False)
DatetimeIndex(['2021-10-31 02:00:00+01:00'],
                dtype='datetime64[ns, Europe/Amsterdam]', freq=None)

>>> rng_tz.ceil("H", ambiguous=True)
DatetimeIndex(['2021-10-31 02:00:00+02:00'],
                dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```

**pandas.DatetimeIndex.to_period**

DatetimeIndex.to_period(*args, **kwargs)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

**Parameters**

- **freq** [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

**Returns**

- PeriodArray/Index

**Raises**

- ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

**See also**

- PeriodIndex Immutable ndarray holding ordinal values.
- DatetimeIndex.to_pydatetime Return DatetimeIndex as object.
Examples

```python
>>> df = pd.DataFrame({"y": [1, 2, 3]},
                    index=pd.to_datetime(["2000-03-31 00:00:00",
                                          "2000-05-31 00:00:00",
                                          "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(["2000-03", '2000-05', '2000-08'],
dtype='period[M]')

Infer the daily frequency

```python
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(["2017-01-01", '2017-01-02'],
dtype='period[D]')
```
Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.

If keep_tz is False:

Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

**Parameters**

- `index` [Index, optional] Index of resulting Series. If None, defaults to original index.
- `name` [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

- `Series`

**pandas.DatetimeIndex.to_frame**

`DatetimeIndex.to_frame(index=True, name=NoDefault.no_default)`

Create a DataFrame with a column containing the Index.

**Parameters**

- `index` [bool, default True] Set the index of the returned DataFrame as the original Index.
- `name` [object, default None] The passed name should substitute for the index name (if it has one).

**Returns**

- `DataFrame` DataFrame containing the original Index data.

**See also:**

- `Index.to_series` Convert an Index to a Series.
- `Series.to_frame` Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
animal
    animal
   Ant    Ant
  Bear   Bear
 Cow     Cow

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
animal
    animal
   Ant     Ant
  Bear   Bear
 Cow    Cow
```

(continues on next page)
To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
zoo
0  Ant
1  Bear
2  Cow
```

### pandas.DatetimeIndex.month_name

**pandas.DatetimeIndex.month_name**(*args, **kwargs*)

Return the month names of the `Series` or `DatetimeIndex` with specified locale.

**Parameters**

- **locale** [str, optional] Locale determining the language in which to return the month name. Default is English locale.

**Returns**

- **Series** or **Index** Series or Index of month names.

**Examples**

```python
>>> s = pd.Series(pd.date_range(start='2018-01', freq='M', periods=3))
>>> s
0  2018-01-31
1  2018-02-28
2  2018-03-31
dtype: datetime64[ns]
```

```python
>>> s.dt.month_name()
0  January
1  February
2  March
dtype: object
```

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
```

```python
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
```

```python
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```
pandas.DatetimeIndex.day_name

DatetimeIndex.day_name(*args, **kwargs)

Return the day names of the Series or DatetimeIndex with specified locale.

Parameters

locale [str, optional] Locale determining the language in which to return the day name.
Default is English locale.

Returns

Series or Index Series or Index of day names.

Examples

```python
>>> s = pd.Series(pd.date_range(start='2018-01-01', freq='D', periods=3))
>>> s
datetime[ns]
0 2018-01-01
1 2018-01-02
2 2018-01-03
dtype: datetime64[ns]
>>> s.dt.day_name()
0 Monday
1 Tuesday
2 Wednesday
dtype: object
```

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
datetime[ns]
2018-01-01
2018-01-02
2018-01-03
freq='D'
```

```python
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

pandas.DatetimeIndex.mean

DatetimeIndex.mean(*args, **kwargs)

Return the mean value of the Array.

New in version 0.25.0.

Parameters

skipna [bool, default True] Whether to ignore any NaT elements.
axis [int, optional, default 0]

Returns

scalar Timestamp or Timedelta.

See also:

numpy.ndarray.mean Returns the average of array elements along a given axis.
Series.mean Return the mean value in a Series.
Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

**pandas.DatetimeIndex.std**

`DatetimeIndex.std(*args, **kwargs)`

Return sample standard deviation over requested axis.
Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- **axis** [int optional, default None] Axis for the function to be applied on.
- **ddof** [int, default 1] Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

Timedelta
Time/date components

<table>

Selecting

| DatetimeIndex.indexer_at_time(time[, asof]) | Return index locations of values at particular time of day (e.g.). |
| DatetimeIndex.indexer_between_time(...[, ...]) | Return index locations of values between particular times of day (e.g., 9:00-9:30AM). |
**pandas.DatetimeIndex.indexer_at_time**

**DatetimeIndex.indexer_at_time**(time, asof=False)

Return index locations of values at particular time of day (e.g. 9:30AM).

**Parameters**

- **time** [datetime.time or str] Time passed in either as object (datetime.time) or as string in appropriate format ("%H:%M", "%H%M", "%I:%M%p", "%I%M%p", "%H:%M:%S", "%H%M%S", "%I:%M%S%p", "%I%M%S%p").

**Returns**

np.ndarray[np.intp]

See also:

- **indexer_between_time** Get index locations of values between particular times of day.
- **DataFrame.at_time** Select values at particular time of day.

**pandas.DatetimeIndex.indexer_between_time**

**DatetimeIndex.indexer_between_time**(start_time, end_time, include_start=True, include_end=True)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

**Parameters**

- **start_time**, **end_time** [datetime.time, str] Time passed either as object (datetime.time) or as string in appropriate format ("%H:%M", "%H%M", "%I:%M%p", "%I%M%p", "%H:%M:%S", "%H%M%S", "%I:%M%S%p", "%I%M%S%p").
- **include_start** [bool, default True]
- **include_end** [bool, default True]

**Returns**

np.ndarray[np.intp]

See also:

- **indexer_at_time** Get index locations of values at particular time of day.
- **DataFrame.between_time** Select values between particular times of day.

**Time-specific operations**

- **DatetimeIndex.normalize**(args, **kwargs) Convert times to midnight.
- **DatetimeIndex.strftime**(args, **kwargs) Convert to Index using specified date_format.
- **DatetimeIndex.snap**(freq) Snap time stamps to nearest occurring frequency.
- **DatetimeIndex.tz_convert**(tz) Convert tz-aware Datetime Array/Index from one time zone to another.
- **DatetimeIndex.tz_localize**(tz[, ambiguous, ...]) Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
- **DatetimeIndex.round**(args, **kwargs) Perform round operation on the data to the specified freq.
- **DatetimeIndex.floor**(args, **kwargs) Perform floor operation on the data to the specified freq.
- **DatetimeIndex.ceil**(args, **kwargs) Perform ceil operation on the data to the specified freq.
- **DatetimeIndex.month_name**(args, **kwargs) Return the month names of the Series or DatetimeIndex with specified locale.
- **DatetimeIndex.day_name**(args, **kwargs) Return the day names of the Series or DatetimeIndex with specified locale.
Conversion

**DatetimeIndex.to_period**(*args, **kwargs)  
Cast to PeriodArray/Index at a particular frequency.

**DatetimeIndex.to_perioddelta**(freq)  
Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq.

**DatetimeIndex.to_pydatetime**(*args, **kwargs)  
Return Datetime Array/Index as object ndarray of datetime.datetime objects.

**DatetimeIndex.to_series**([keep_tz, index, name])  
Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

**DatetimeIndex.to_frame**([index, name])  
Create a DataFrame with a column containing the Index.

Methods

**DatetimeIndex.mean**(*args, **kwargs)  
Return the mean value of the Array.

**DatetimeIndex.std**(*args, **kwargs)  
Return sample standard deviation over requested axis.

3.6.7 TimedeltaIndex

**TimedeltaIndex**([data, unit, freq, closed, ...])  
Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

**pandas.TimedeltaIndex**

```python
class pandas.TimedeltaIndex(data=None, unit=None, freq=None, closed=None, dtype=dtype('<m8[ns]'), copy=False, name=None)
```

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

- **data**  [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with.
- **unit**  [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.
- **freq**  [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string `infer` can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- **copy**  [bool] Make a copy of input ndarray.
- **name**  [object] Name to be stored in the index.

See also:
- **Index**  The base pandas Index type.
- **Timedelta**  Represents a duration between two dates or times.
- **DatetimeIndex**  Index of datetime64 data.
- **PeriodIndex**  Index of Period data.
**timedelta_range**  Create a fixed-frequency TimedeltaIndex.

**Notes**
To learn more about the frequency strings, please see [this link](#).

**Attributes**

<table>
<thead>
<tr>

</tbody>
</table>

**pandas.TimedeltaIndex.days**

**property**  TimedeltaIndex.days
    Number of days for each element.

**pandas.TimedeltaIndex.seconds**

**property**  TimedeltaIndex.seconds
    Number of seconds (>= 0 and less than 1 day) for each element.

**pandas.TimedeltaIndex.microseconds**

**property**  TimedeltaIndex.microseconds
    Number of microseconds (>= 0 and less than 1 second) for each element.

**pandas.TimedeltaIndex.nanoseconds**

**property**  TimedeltaIndex.nanoseconds
    Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
**pandas.TimedeltaIndex.components**

**property TimedeltaIndex.components**

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

**Returns**

DataFrame

**pandas.TimedeltaIndex.inferred_freq**

**TimedeltaIndex.inferred_freq**

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can't autodetect the frequency.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_pytimedelta(*args, **kwags)</td>
<td>Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.</td>

<tr>
<td>mean(*args, **kwags)</td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

**pandas.TimedeltaIndex.to_pytimedelta**

**TimedeltaIndex.to_pytimedelta(*args, **kwargs)**

Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

**Returns**

timedeltas [ndarray[object]]
pandas.TimedeltaIndex.to_series

TimedeltaIndex.to_series(index=None, name=None)
Create a Series with both index and values equal to the index keys.
Useful with map for returning an indexer based on an index.

Parameters

index [Index, optional] Index of resulting Series. If None, defaults to original index.
name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

Index.to_frame Convert an Index to a DataFrame.
Series.to_frame Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
Ant   Ant
Bear  Bear
Cow   Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to `index`:

```python
>>> idx.to_series(index=[0, 1, 2])
0   Ant
1   Bear
2   Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_series(name='zoo')
animal
Ant   Ant
Bear  Bear
Cow   Cow
Name: zoo, dtype: object
```
pandas.TimedeltaIndex.round

TimedeltaIndex.round(*args, **kwargs)
Perform round operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Notes

If the timestamps have a timezone, rounding will take place relative to the local (‘wall’) time and re-localized to the same timezone. When rounding near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.
Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.round("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

```python
>>> rng_tz = pd.DatetimeIndex(["2021-10-31 03:30:00"], tz="Europe/Amsterdam")
```

```python
>>> rng_tz.floor("2H", ambiguous=False)
DatetimeIndex(["2021-10-31 02:00:00+01:00"],
               dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```

```python
>>> rng_tz.floor("2H", ambiguous=True)
DatetimeIndex(["2021-10-31 02:00:00+02:00"],
               dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```

pandas.TimedeltaIndex.floor

TimedeltaIndex.floor(*args, **kwargs)

Perform floor operation on the data to the specified freq.

Parameters

- **freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.
- **ambiguous** ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times

3.6. Index objects
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

**nonexistent** ['shift_forward', 'shift_backward', 'NaT', timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time

• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time

• ‘NaT’ will return NaT where there are nonexistent times

• timedelta objects will shift nonexistent times by the timedelta

• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- **DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

- **ValueError if the freq cannot be converted.**

**Notes**

If the timestamps have a timezone, flooring will take place relative to the local (“wall”) time and re-localized to the same timezone. When flooring near daylight savings time, use **nonexistent** and **ambiguous** to control the re-localization behavior.

**Examples**

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
 DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
                dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
 DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00', '2018-01-01 12:00:00'],
                dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

When rounding near a daylight savings time transition, use **ambiguous** or **nonexistent** to control how the timestamp should be re-localized.
```python
>>> rng_tz = pd.DatetimeIndex(['2021-10-31 03:30:00'], tz="Europe/Amsterdam")
>>> rng_tz.floor("2H", ambiguous=False)
```

```
DatetimeIndex(['2021-10-31 02:00:00+01:00'],
dtype='datetime64[ns, Europe/Amsterdam]', freq=None)
```
Notes

If the timestamps have a timezone, ceiling will take place relative to the local (“wall”) time and re-localized to the same timezone. When ceiling near daylight savings time, use nonexistent and ambiguous to control the re-localization behavior.

Examples

DatetimeIndex

>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)

Series

>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]

When rounding near a daylight savings time transition, use ambiguous or nonexistent to control how the timestamp should be re-localized.

>>> rng_tz = pd.DatetimeIndex(['2021-10-31 01:30:00'], tz="Europe/Amsterdam")

>>> rng_tz.ceil("H", ambiguous=False)
DatetimeIndex(['2021-10-31 02:00:00+01:00'],
              dtype='datetime64[ns, Europe/Amsterdam]', freq=None)

>>> rng_tz.ceil("H", ambiguous=True)
DatetimeIndex(['2021-10-31 02:00:00+02:00'],
              dtype='datetime64[ns, Europe/Amsterdam]', freq=None)

pandas.TimedeltaIndex.to_frame

TimedeltaIndex.to_frame(index=True, name=NoDefault.no_default)

Create a DataFrame with a column containing the Index.

Parameters

- **index** [bool, default True] Set the index of the returned DataFrame as the original Index.
- **name** [object, default None] The passed name should substitute for the index name (if it has one).

Returns
DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.
Series.to_frame Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
0   Ant
1   Bear
2   Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
0   Ant
1   Bear
2   Cow
```

To override the name of the resulting column, specify name:

```python
>>> idx.to_frame(index=False, name='zoo')
   zoo
0   Ant
1   Bear
2   Cow
```

pandas.TimedeltaIndex.mean

TimedeltaIndex.mean(*args, **kwargs)
Return the mean value of the Array.
New in version 0.25.0.

Parameters

- skipna [bool, default True] Whether to ignore any NaT elements.
- axis [int, optional, default 0]

Returns

- scalar Timestamp or Timedelta.

See also:

numpy.ndarray.mean Returns the average of array elements along a given axis.
Series.mean Return the mean value in a Series.
Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

Components

- **TimedeltaIndex.days**
  Number of days for each element.

- **TimedeltaIndex.seconds**
  Number of seconds (>= 0 and less than 1 day) for each element.

- **TimedeltaIndex.microseconds**
  Number of microseconds (>= 0 and less than 1 second) for each element.

- **TimedeltaIndex.nanoseconds**
  Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

- **TimedeltaIndex.components**
  Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

- **TimedeltaIndex.inferred_freq**
  Tries to return a string representing a frequency guess, generated by infer_freq.

Conversion

- **TimedeltaIndex.to_pytimedelta(**args, **kwargs)**
  Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

- **TimedeltaIndex.to_series([index, name])**
  Create a Series with both index and values equal to the index keys.

- **TimedeltaIndex.round(**args, **kwargs)**
  Perform round operation on the data to the specified freq.

- **TimedeltaIndex.floor(**args, **kwargs)**
  Perform floor operation on the data to the specified freq.

- **TimedeltaIndex.ceil(**args, **kwargs)**
  Perform ceil operation on the data to the specified freq.

- **TimedeltaIndex.to_frame([index, name])**
  Create a DataFrame with a column containing the Index.

Methods

- **TimedeltaIndex.mean(**args, **kwargs)**
  Return the mean value of the Array.

3.6.8 PeriodIndex

- **PeriodIndex([data, ordinal, freq, dtype, ...])**
  Immutable ndarray holding ordinal values indicating regular periods in time.
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.PeriodIndex

class pandas.PeriodIndex(
    data=None,
    ordinal=None,
    freq=None,
    dtype=None,
    copy=False,
    name=None,
    **fields
)

Immutable ndarray holding ordinal values indicating regular periods in time.
Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

Parameters

- **data** [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.
- **copy** [bool] Make a copy of input ndarray.
- **freq** [str or period object, optional] One of pandas period strings or corresponding objects.
- **year** [int, array, or Series, default None]
- **month** [int, array, or Series, default None]
- **quarter** [int, array, or Series, default None]
- **day** [int, array, or Series, default None]
- **hour** [int, array, or Series, default None]
- **minute** [int, array, or Series, default None]
- **second** [int, array, or Series, default None]
- **dtype** [str or PeriodDtype, default None]

See also:

- Index The base pandas Index type.
- Period Represents a period of time.
- DatetimeIndex Index with datetime64 data.
- TimedeltaIndex Index of timedelta64 data.
- period_range Create a fixed-frequency PeriodIndex.

Examples

```python
>>> idx = pd.PeriodIndex(year=[2000, 2002], quarter=[1, 3])
>>> idx
PeriodIndex(['2000Q1', '2002Q3'], dtype='period[Q-DEC]')
```

**pandas.PeriodIndex.day**

**property** `PeriodIndex.day`

The days of the period.

**pandas.PeriodIndex.dayofweek**

**property** `PeriodIndex.dayofweek`

The day of the week with Monday=0, Sunday=6.

**pandas.PeriodIndex.day_of_week**

**property** `PeriodIndex.day_of_week`

The day of the week with Monday=0, Sunday=6.
pandas.PeriodIndex.dayofyear

property PeriodIndex.dayofyear
    The ordinal day of the year.

pandas.PeriodIndex.day_of_year

property PeriodIndex.day_of_year
    The ordinal day of the year.

pandas.PeriodIndex.days_in_month

property PeriodIndex.days_in_month
    The number of days in the month.

pandas.PeriodIndex.daysinmonth

property PeriodIndex.daysinmonth
    The number of days in the month.

pandas.PeriodIndex.freq

property PeriodIndex.freq
    Return the frequency object if it is set, otherwise None.

pandas.PeriodIndex.freqstr

property PeriodIndex.freqstr
    Return the frequency object as a string if its set, otherwise None.

pandas.PeriodIndex.hour

property PeriodIndex.hour
    The hour of the period.

pandas.PeriodIndex.is_leap_year

property PeriodIndex.is_leap_year
    Logical indicating if the date belongs to a leap year.
**pandas.PeriodIndex.minute**

**property** PeriodIndex.minute
The minute of the period.

**pandas.PeriodIndex.month**

**property** PeriodIndex.month
The month as January=1, December=12.

**pandas.PeriodIndex.quarter**

**property** PeriodIndex.quarter
The quarter of the date.

**pandas.PeriodIndex.second**

**property** PeriodIndex.second
The second of the period.

**pandas.PeriodIndex.week**

**property** PeriodIndex.week
The week ordinal of the year.

**pandas.PeriodIndex.weekday**

**property** PeriodIndex.weekday
The day of the week with Monday=0, Sunday=6.

**pandas.PeriodIndex.weekofyear**

**property** PeriodIndex.weekofyear
The week ordinal of the year.

**pandas.PeriodIndex.year**

**property** PeriodIndex.year
The year of the period.
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>asfreq(freq, how)</code></td>
<td>Convert the PeriodArray to the specified frequency <code>freq</code>.</td>
</tr>
<tr>
<td><code>strftime(*args, **kwargs)</code></td>
<td>Convert to Index using specified date_format.</td>
</tr>
<tr>
<td><code>to_timestamp(freq, how)</code></td>
<td>Cast to DatetimeArray/Index.</td>
</tr>
</tbody>
</table>

`pandas.PeriodIndex.asfreq`

`PeriodIndex.asfreq(freq=None, how='E')`

Convert the PeriodArray to the specified frequency `freq`. Equivalent to applying `pandas.Period.asfreq()` with the given arguments to each `Period` in this PeriodArray.

Parameters

- `freq` [str] A frequency.
- `how` [str {'E', 'S'}, default 'E'] Whether the elements should be aligned to the end or start within a period.
  
  - 'E', 'END', or 'FINISH' for end,
  - 'S', 'START', or 'BEGIN' for start.

  January 31st ('END') vs. January 1st ('START') for example.

Returns

- `PeriodArray` The transformed PeriodArray with the new frequency.

See also:

- `pandas.arrays.PeriodArray.asfreq` Convert each Period in a PeriodArray to the given frequency.

- `Period.asfreq` Convert a Period object to the given frequency.

Examples

```python
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx

>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12', '2015-12'], dtype='period[M]')

>>> pidx.asfreq('M', how='S')
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.PeriodIndex.strftime

PeriodIndex.strftime(*args, **kwargs)
Convert to Index using specified date_format.
Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

- **date_format** (str) Date format string (e.g. “%Y-%m-%d”).

Returns

- ndarray[object] NumPy ndarray of formatted strings.

See also:

to_datetime Convert the given argument to datetime.
DatetimeIndex.normalize Return DatetimeIndex with times to midnight.
DatetimeIndex.round Round the DatetimeIndex to the specified freq.
DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.PeriodIndex.to_timestamp

PeriodIndex.to_timestamp(freq=None, how='start')
Cast to DatetimeArray/Index.

Parameters

- **freq** (str or DateOffset, optional) Target frequency. The default is ‘D’ for week or longer, ‘S’ otherwise.

- **how** [{‘s’, ‘e’, ‘start’, ‘end’}] Whether to use the start or end of the time period being converted.

Returns

- DatetimeArray/Index

3.7 Date offsets

3.7.1 DateOffset

DateOffset

Standard kind of date increment used for a date range.

pandas.tseries.offsets.DateOffset
class pandas.tseries.offsets.DateOffset

Standard kind of date increment used for a date range.

Works exactly like the keyword argument form of relativedelta. Note that the positional argument form of relativedelta is not supported. Use of the keyword n is discouraged— you would be better off specifying n in the keywords you use, but regardless it is there for you. n is needed for DateOffset subclasses.

DateOffset works as follows. Each offset specify a set of dates that conform to the DateOffset. For example, Bday defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a DateOffset dateOffset we can use the is_on_offset method: dateOffset.is_on_offset(date).

If a date is not on a valid date, the rollback and rollforward methods can be used to roll the date to the nearest valid date before/after the date.

DateOffsets can be created to move dates forward a given number of valid dates. For example, Bday(2) can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

def __add__(date):
date = rollback(date)  # does nothing if date is valid return date + <n number of periods>

When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

def __add__(date):
date = rollforward(date)  # does nothing if date is valid return date + <n number of periods>

Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

date + BDay(0) == BDay.rollforward(date)

Since 0 is a bit weird, we suggest avoiding its use.

Parameters

- n [int, default 1] The number of time periods the offset represents. If specified without a temporal pattern, defaults to n days.

- normalize [bool, default False] Whether to round the result of a DateOffset addition down to the previous midnight.

- **kwds Temporal parameter that add to or replace the offset value.

Parameters that add to the offset (like Timedelta):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that replace the offset value:
- year
- month
- day
- weekday
- hour
- minute
- second
- microsecond
- nanosecond.

See also:

dateutil.relativedelta.relativedelta The relativedelta type is designed to be applied to an existing
datetime and can replace specific components of that datetime, or represents an interval of time.

Examples

```python
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')

>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```

Attributes

| base | Returns a copy of the calling offset object with n=1 and all other attributes equal. |
**pandas.tseries.offsets.DateOffset.base**

DateOffset.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

<table>
<thead>
<tr>
<th>CustomBusinessDay</th>
<th>DateOffset subclass representing custom business days excluding holidays.</th>
</tr>
</thead>
</table>

**pandas.tseries.offsets.CustomBusinessDay**

**class pandas.tseries.offsets.CustomBusinessDay**

DateOffset subclass representing custom business days excluding holidays.

**Parameters**

- **n** [int, default 1]
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **weekmask** [str, Default ‘Mon Tue Wed Thu Fri’] Weekmask of valid business days, passed to numpy.busdaycalendar.
- **holidays** [list] List/array of dates to exclude from the set of valid business days, passed to numpy.busdaycalendar.
- **calendar** [pd.HolidayCalendar or np.busdaycalendar]
- **offset** [timedelta, default timedelta(0)]
Attributes

<table>
<thead>
<tr>
<th>base</th>
<th>Returns a copy of the calling offset object with n=1 and all other attributes equal.</th>

<table>
<thead>
<tr>
<th>Class Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomBusinessHour</td>
<td>DateOffset subclass representing possibly n custom business days.</td>
</tr>
</tbody>
</table>

**class pandas.tseries.offsets.CustomBusinessHour**

DateOffset subclass representing possibly n custom business days.

**Parameters**

- **n** [int, default 1] The number of months represented.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **weekmask** [str, Default ‘Mon Tue Wed Thu Fri’] Weekmask of valid business days, passed to numpy.busdaycalendar.
- **start** [str, default “09:00”] Start time of your custom business hour in 24h format.
- **end** [str, default: “17:00”] End time of your custom business hour in 24h format.

**Attributes**

<table>

### 3.7.9 BusinessMonthBegin

**BusinessMonthBegin**

DateOffset of one month at the first business day.

**pandas.tseries.offsets.BusinessMonthBegin**

```python
class pandas.tseries.offsets.BusinessMonthBegin
    DateOffset of one month at the first business day.
```

**Examples**

```python
>>> from pandas.tseries.offsets import BMonthBegin
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BMonthBegin()
Timestamp('2020-06-01 05:01:15')
>>> ts + BMonthBegin(2)
Timestamp('2020-07-01 05:01:15')
>>> ts + BMonthBegin(-3)
Timestamp('2020-03-02 05:01:15')
```

**Attributes**

```python
base
    Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

**pandas.tseries.offsets.BusinessMonthBegin.base**

```python
BusinessMonthBegin.base
    Returns a copy of the calling offset object with n=1 and all other attributes equal.
```
Methods

</tbody>
</table>

**pandas.tseries.offsets.BusinessMonthBegin.**

`__call__`

BusinessMonthBegin.**__call__**(args, **kwargs)
Call self as a function.

`rollback`

BusinessMonthBegin.**rollback**()
Roll provided date backward to next offset only if not on offset.

Returns

**TimeStamp**  Rolled timestamp if not on offset, otherwise unchanged timestamp.

`rollforward`

BusinessMonthBegin.**rollforward**()
Roll provided date forward to next offset only if not on offset.

Returns

**TimeStamp**  Rolled timestamp if not on offset, otherwise unchanged timestamp.

</thead>
<tbody>
<tr>
<td>Weekly offset.</td>
<td></td>
</tr>
</tbody>
</table>

    Parameters
    
    weekday [int or None, default None] Always generate specific day of week. 0 for Monday.

Attributes

    base
    Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.Week.base

    Week.base
    Returns a copy of the calling offset object with n=1 and all other attributes equal.

Methods

    __call__(*args, **kwargs)  Call self as a function.
    
    rollback
    Roll provided date backward to next offset only if not on offset.
    
    rollforward
    Roll provided date forward to next offset only if not on offset.
pandas.tseries.offsets.Week.__call__

Week.__call__(*args, **kwargs)
    Call self as a function.

pandas.tseries.offsets.Week.rollback

Week.rollback()
    Roll provided date backward to next offset only if not on offset.
    Returns

    TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.Week.rollforward

Week.rollforward()
    Roll provided date forward to next offset only if not on offset.
    Returns

    TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

</tr>
</thead>
</table>

pandas.tseries.offsets.WeekOfMonth

class pandas.tseries.offsets.WeekOfMonth

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

Parameters

- n [int]
- week [int {0, 1, 2, 3, ...}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.
- weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.
  - 0 is Monday
  - 1 is Tuesday
  - 2 is Wednesday
  - 3 is Thursday
  - 4 is Friday
  - 5 is Saturday
  - 6 is Sunday.
Attributes

| base          | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

pandas.tseries.offsets.WeekOfMonth.base

WeekOfMonth.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

</thead>
</table>

pandas.tseries.offsets.LastWeekOfMonth

class pandas.tseries.offsets.LastWeekOfMonth

Describes monthly dates in last week of month like “the last Tuesday of each month”.

**Parameters**

- **n** [int, default 1]
- **weekday** [int {0, 1, …, 6}, default 0] A specific integer for the day of the week.
  
  - 0 is Monday
  - 1 is Tuesday
  - 2 is Wednesday
  - 3 is Thursday
  - 4 is Friday
  - 5 is Saturday
  - 6 is Sunday.
Attributes

| base       | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

pandas.tseries.offsets.LastWeekOfMonth.base

LastWeekOfMonth.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

**3.7.17 BQuarterEnd**

**BQuarterEnd**

DateOffset increments between the last business day of each Quarter.

**class pandas.tseries.offsets.BQuarterEnd**

DateOffset increments between the last business day of each Quarter.

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

**Examples**

```python
>>> from pandas.tseries.offsets import BQuarterEnd
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterEnd()
Timestamp('2020-06-30 05:01:15')
>>> ts + BQuarterEnd(2)
Timestamp('2020-09-30 05:01:15')
>>> ts + BQuarterEnd(1, startingMonth=2)
Timestamp('2020-05-29 05:01:15')
>>> ts + BQuarterEnd(startingMonth=2)
Timestamp('2020-05-29 05:01:15')
```

**Attributes**

**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

**pandas.tseries.offsets.BQuarterEnd.base**

BQuarterEnd.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

___call___(*args, **kwargs) Call self as a function.

rollback
Roll provided date backward to next offset only if not on offset.

rollforward
Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.BQuarterEnd.__call__

BQuarterEnd.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.BQuarterEnd.rollback

BQuarterEnd.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BQuarterEnd.rollforward

BQuarterEnd.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

BQuarterEnd.is_year_end()

### 3.7.18 BQuarterBegin

**BQuarterBegin**

DateOffset increments between the first business day of each Quarter.

*startingMonth = 1 corresponds to dates like 1/01/2007, 4/01/2007, … startingMonth = 2 corresponds to dates like 2/01/2007, 5/01/2007, … startingMonth = 3 corresponds to dates like 3/01/2007, 6/01/2007, …*

#### Examples

```python
>>> from pandas.tseries.offsets import BQuarterBegin
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterBegin()  # startingMonth = 1 by default
Timestamp('2020-06-01 05:01:15')

>>> ts + BQuarterBegin(2)  # startingMonth = 2
Timestamp('2020-09-01 05:01:15')

>>> ts + BQuarterBegin(startingMonth=2)
Timestamp('2020-08-03 05:01:15')

>>> ts + BQuarterBegin(-1)
Timestamp('2020-03-02 05:01:15')
```

#### Attributes

**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

**pandas.tseries.offsets.BQuarterBegin.base**

BQuarterBegin.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

<table>
<thead>
<tr>
<th>freqstr</th>
<th>kwds</th>
<th>n</th>
<th>name</th>
<th>nanos</th>
<th>normalize</th>
<th>rule_code</th>

</tr>
</thead>
</table>

pandas.tseries.offsets.BQuarterBegin.__call__

BQuarterBegin.__call__(*args, **kwargs*)
Call self as a function.

pandas.tseries.offsets.BQuarterBegin.rollback

BQuarterBegin.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BQuarterBegin.rollforward

BQuarterBegin.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.25 FY5253

| FY5253 | Describes 52-53 week fiscal year. |

pandas.tseries.offsets.FY5253

class pandas.tseries.offsets.FY5253

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.
It is used by companies that desire that their fiscal year always end on the same day of the week.
It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.
For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:
• end on the last X day of the Y month.
• end on the last X day closest to the last day of the Y month.
X is a specific day of the week. Y is a certain month of the year

Parameters

n [int]

weekday [int {0, 1, …, 6}, default 0] A specific integer for the day of the week.
• 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday

3.7. Date offsets 2433
• 6 is Sunday.

startingMonth [int {1, 2, … 12}, default 1] The month in which the fiscal year ends.

variation [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:

• “nearest” means year end is weekday closest to last day of month in year.
• “last” means year end is final weekday of the final month in fiscal year.

Attributes

| FY5253Quarter | DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar). |

**pandas.tseries.offsets.FY5253Quarter**

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:

- end on the last X day of the Y month.
- end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

**Parameters**

- n [int]
**weekday** [int \{0, 1, …, 6\}, default 0] A specific integer for the day of the week.
- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

**startingMonth** [int \{1, 2, …, 12\}, default 1] The month in which fiscal years end.

**qtr_with_extra_week** [int \{1, 2, 3, 4\}, default 1] The quarter number that has the leap or 14 week when needed.

**variation** [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:
- “nearest” means year end is **weekday** closest to last day of month in year.
- “last” means year end is final **weekday** of the final month in fiscal year.

Day

Attributes

pandas.tseries.offsets.Day

class pandas.tseries.offsets.Day

Attributes

base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.Day.base

Day.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

__call__(*args, **kwargs)  
Call self as a function.

rollback
Roll provided date backward to next offset only if not on offset.

rollforward
Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.Day.__call__

Day.__call__(*args, **kwargs)  
Call self as a function.

pandas.tseries.offsets.Day.rollback

Day.rollback()  
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.Day.rollforward

Day.rollforward()  
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.8 Frequencies

<table>
<thead>
<tr>
<th>to_offset</th>
<th>Return DateOffset object from string or tuple representation or datetime.timedelta object.</th>
</tr>
</thead>
</table>

3.8.1 pandas.tseries.frequencies.to_offset

pandas.tseries.frequencies.to_offset()

Return DateOffset object from string or tuple representation or datetime.timedelta object.

Parameters

freq [str, datetime.timedelta, BaseOffset or None]

Returns

DateOffset or None

Raises

ValueError If freq is an invalid frequency

See also:

BaseOffset Standard kind of date increment used for a date range.

Examples

```python
>>> to_offset("5min")
<5 * Minutes>

>>> to_offset("1D1H")
<25 * Hours>

>>> to_offset("2W")
<2 * Weeks: weekday=6>

>>> to_offset("2B")
<2 * BusinessDays>

>>> to_offset(pd.Timedelta(days=1))
<Day>

>>> to_offset(Hour())
<Hour>
```
3.9 Window

Rolling objects are returned by `.rolling` calls: `pandas.DataFrame.rolling()`, `pandas.Series.rolling()`, etc. Expanding objects are returned by `.expanding` calls: `pandas.DataFrame.expanding()`, `pandas.Series.expanding()`, etc. ExponentialMovingWindow objects are returned by `.ewm` calls: `pandas.DataFrame.ewm()`, `pandas.Series.ewm()`, etc.

3.9.1 Rolling window functions

</tbody>
</table>

pandas.core.window.rolling.Rolling.count

Rolling.count()

Calculate the rolling count of non NaN observations.

Returns

Series or DataFrame  Return type is the same as the original object with np. float64 dtype.

See also:

pandas.Series.rolling  Calling rolling with Series data.
pandas.DataFrame.rolling  Calling rolling with DataFrames.
pandas.Series.count  Aggregating count for Series.
pandas.DataFrame.count  Aggregating count for DataFrame.
Examples

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0   1.0
1   2.0
2   1.0
3   1.0
dtype: float64
>>> s.rolling(3).count()
0   1.0
1   2.0
2   2.0
3   2.0
dtype: float64
>>> s.rolling(4).count()
0   1.0
1   2.0
2   2.0
3   3.0
dtype: float64
```

**pandas.core.window.rolling.Rolling.sum**

`Rolling.sum(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the rolling sum.

**Parameters**

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]
- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwargs [dict, default None]
- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

- `pandas.Series.rolling` Calling rolling with Series data.
**pandas.DataFrame.rolling** Calling rolling with DataFrames.

**pandas.Series.sum** Aggregating sum for Series.

**pandas.DataFrame.sum** Aggregating sum for DataFrame.

**Notes**

See [Numba engine](#) and [Numba (JIT compilation)](#) for extended documentation and performance considerations for the Numba engine.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0   1
1   2
2   3
3   4
4   5
dtype: int64

>>> s.rolling(3).sum()
0   NaN
1   NaN
2   6.0
3   9.0
4   12.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0   NaN
1   6.0
2   9.0
3   12.0
4   NaN
dtype: float64
```

For DataFrame, each sum is computed column-wise.

```python
>>> df = pd.DataFrame({'A': s, 'B': s ** 2})
>>> df
   A     B
0  1     1
1  2     4
2  3     9
3  4   16
4  5   25

>>> df.rolling(3).sum()
   A     B
0  NaN   NaN
1  NaN   NaN
```

(continues on next page)
Rolling.mean(*args, engine=None, engine_kwars=None, **kwargs)

Calculate the rolling mean.

Parameters

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]
- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba
  New in version 1.3.0.

engine_kwars [dict, default None]
- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
  New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.mean Aggregating mean for Series.
pandas.DataFrame.mean Aggregating mean for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.
Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0     NaN
1  1.500
2  2.500
3  3.500
dtype: float64

>>> s.rolling(3).mean()
0     NaN
1     NaN
2  2.000
3  3.000
dtype: float64
```

pandas.core.window.rolling.Rolling.median

Rolling.median(engine=None, engine_kwargs=None, **kwargs)

Calculate the rolling median.

Parameters

- **engine** [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba
    New in version 1.3.0.

- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
    New in version 1.3.0.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

- Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

- pandas.Series.rolling Calling rolling with Series data.
- pandas.DataFrame.rolling Calling rolling with DataFrames.
- pandas.Series.median Aggregating median for Series.
- pandas.DataFrame.median Aggregating median for DataFrame.
Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

Examples

Compute the rolling median of a series with a window size of 3.

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

**pandas.core.window.rolling.Rolling.var**

Rolling.var(ddof=1, *args, engine=None, engine_kwargs=None, **kwargs)

Calculate the rolling variance.

**Parameters**

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **args** For NumPy compatibility and will not have an effect on the result.
- **engine** [str, default None]
  - 'cython' : Runs the operation through C-extensions from cython.
  - 'numba' : Runs the operation through JIT compiled code from numba.
  - None : Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.4.0.

- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

  New in version 1.4.0.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

- **Series or DataFrame** Return type is the same as the original object with np.float64 dtype.

See also:

- numpy.var Equivalent method for NumPy array.
- pandas.Series.rolling Calling rolling with Series data.
**pandas.DataFrame.rolling** Calling rolling with DataFrames.

**pandas.Series.var** Aggregating var for Series.

**pandas.DataFrame.var** Aggregating var for DataFrame.

**Notes**

The default \( \text{ddof} \) of 1 used in \( \text{Series.var()} \) is different than the default \( \text{ddof} \) of 0 in \( \text{numpy.var()} \).

A minimum of one period is required for the rolling calculation.

The implementation is susceptible to floating point imprecision as shown in the example below.

**Examples**

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0   NaN
1   NaN
2  3.333333e-01
3  1.000000e+00
4  1.000000e+00
5  1.333333e+00
6  6.661338e-16
dtype: float64
```

**pandas.core.window.rolling.Rolling.std**

Rolling.std\((\text{ddof}=1, *\text{args}, \text{engine}=\text{None}, \text{engine_kwargs}=\text{None}, **\text{kwargs})\)

Calculate the rolling standard deviation.

**Parameters**

- \text{ddof} [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - \text{ddof} \), where \( N \) represents the number of elements.
- \*\text{args} For NumPy compatibility and will not have an effect on the result.
- \text{engine} [str, default None]
  - 'cython' : Runs the operation through C-extensions from cython.
  - 'numba' : Runs the operation through JIT compiled code from numba.
  - None : Defaults to 'cython' or globally setting compute.use_numba
    
    New in version 1.4.0.
- \text{engine_kwargs} [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
    
    New in version 1.4.0.
- **\text{kwargs}** For NumPy compatibility and will not have an effect on the result.
Returns

Series or DataFrame  Return type is the same as the original object with np.float64 dtype.

See also:

numpy.std  Equivalent method for NumPy array.
pandas.Series.rolling  Calling rolling with Series data.
pandas.DataFrame.rolling  Calling rolling with DataFrames.
pandas.Series.std  Aggregating std for Series.
pandas.DataFrame.std  Aggregating std for DataFrame.

Notes

The default ddof of 1 used in Series.std() is different than the default ddof of 0 in numpy.std().
A minimum of one period is required for the rolling calculation.
The implementation is susceptible to floating point imprecision as shown in the example below.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0    NaN
1    NaN
2  5.773503e-01
3    1.000000e+00
4    1.000000e+00
5    1.154701e+00
6  2.580957e-08
dtype: float64
```

pandas.core.window.rolling.Rolling.min

Rolling.min(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the rolling minimum.

Parameters

*args  For NumPy compatibility and will not have an effect on the result.

engine  [str, default None]
- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwargs  [dict, default None]
- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nonpython, nogil and parallel
dictionary keys. The values must either be True or False. The default
engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.min Aggregating min for Series.
pandas.DataFrame.min Aggregating min for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

Examples

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0  NaN
1  NaN
2  3.0
3  2.0
4  2.0
dtype: float64
```

pandas.core.window.rolling.Rolling.max

Rolling.max(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the rolling maximum.

Parameters

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs
• For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.max Aggregating max for Series.
pandas.DataFrame.max Aggregating max for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.rolling.Rolling.corr

Rolling.corr(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the rolling correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N – ddof, where N represents the number of elements.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson's correlation calculation.
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.corr Aggregating corr for Series.
pandas.DataFrame.corr Aggregating corr for DataFrame.
Notes

This function uses Pearson's definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1's), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using numpy.corrcoef().

```python
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}\n")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}\n")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0    NaN
1    NaN
2    NaN
3  0.333333
4  0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```python
>>> print(np.corrcoef(matrix[:1,0], matrix[:1,1]).round(7))
[[1.  0.6263001]
 [0.6263001  1.]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.  0.5553681]
 [0.5553681  1.]]
>>> df = pd.DataFrame(matrix, columns=['X', 'Y'])
>>> df
    X    Y
0  51.0  35.0
1  49.0  30.0
```

(continues on next page)
2  47.0  32.0
3  46.0  31.0
4  50.0  36.0

```python
>>> df.rolling(4).corr(pairwise=True)
X       Y
0  NaN    NaN
  NaN    NaN
1  NaN    NaN
  NaN    NaN
2  NaN    NaN
  NaN    NaN
3  1.000000  0.626300
  0.626300  1.000000
4  1.000000  0.555368
  0.555368  1.000000
```

**pandas.core.window.rolling.Rolling.cov**

Rolling.cov(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the rolling sample covariance.

**Parameters**

- **other** [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.
- **pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

- pandas.Series.rolling Calling rolling with Series data.
- pandas.DataFrame.rolling Calling rolling with DataFrames.
- pandas.Series.cov Aggregating cov for Series.
- pandas.DataFrame.cov Aggregating cov for DataFrame.
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.core.window.rolling.Rolling.skew

Rolling.skew(**kwargs)

Calculate the rolling unbiased skewness.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

scipy.stats.skew Third moment of a probability density.
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.skew Aggregating skew for Series.
pandas.DataFrame.skew Aggregating skew for DataFrame.

Notes

A minimum of three periods is required for the rolling calculation.

pandas.core.window.rolling.Rolling.kurt

Rolling.kurt(**kwargs)

Calculate the rolling Fisher's definition of kurtosis without bias.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.kurt Aggregating kurt for Series.
pandas.DataFrame.kurt Aggregating kurt for DataFrame.

Notes

A minimum of four periods is required for the calculation.
Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using scipy.stats.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats

>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}"
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr[1:], bias=False):.6f}")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0    NaN
1    NaN
2    NaN
3 -1.200000
4      3.999946
dtype: float64
```

pandas.core.window.rolling.Rolling.apply

Rolling.apply(func, raw=False, engine=None, engine_kwargs=None, args=None, kwargs=None)

Calculate the rolling custom aggregation function.

Parameters

- **func** [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.
  
  Changed in version 1.0.0.

- **raw** [bool, default False]
  
  - False : passes each row or column as a Series to the function.
  
  - True : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

- **engine** [str, default None]
  
  - 'cython' : Runs rolling apply through C-extensions from cython.
  
  - 'numba' : Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
  
  - None : Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.0.0.

- **engine_kwargs** [dict, default None]
  
  For 'cython' engine, there are no accepted engine_kwargs

  For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.
New in version 1.0.0.

```
args  [tuple, default None] Positional arguments to be passed into func.
kwargs [dict, default None] Keyword arguments to be passed into func.
```

**Returns**

```
Series or DataFrame  Return type is the same as the original object with np.float64 dtype.
```

**See also:**

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.apply` Aggregating apply for Series.
- `pandas.DataFrame.apply` Aggregating apply for DataFrame.

---

### pandas.core.window.rolling.Rolling.aggregate

**Rolling.aggregate(func, *args, **kwargs)**

Aggregate using one or more operations over the specified axis.

**Parameters**

```
func  [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.
```

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

```
*args  Positional arguments to pass to func.
**kwargs  Keyword arguments to pass to func.
```

**Returns**

```
scalar, Series or DataFrame  The return can be:
```

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**

- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrame data.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See `Mutating with User Defined Function (UDF) methods` for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> df.rolling(2).sum()
   A  B  C
0  NaN NaN NaN
1  3.0  9.0  15.0
2  5.0  11.0  17.0

>>> df.rolling(2).agg({'A': 'sum', 'B': 'min'})
   A  B
0  NaN NaN
1  3.0  4.0
2  5.0  5.0
```

`pandas.core.window.rolling.Rolling.quantile`

Rolling.quantile(quantile, interpolation='linear', **kwargs)

Calculate the rolling quantile.

Parameters

- `quantile` [float] Quantile to compute. 0 <= quantile <= 1.
- `interpolation` [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points \( i \) and \( j \):
  - linear: \( i + (j - i) \times \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
  - lower: \( i \).
  - higher: \( j \).
  - nearest: \( i \) or \( j \) whichever is nearest.
  - midpoint: \( (i + j) / 2 \).
- **kwargs For NumPy compatibility and will not have an effect on the result.

Returns
Series or DataFrame  Return type is the same as the original object with \texttt{np.float64} dtype.

See also:

\texttt{pandas.Series.rolling} Calling rolling with Series data.
\texttt{pandas.DataFrame.rolling} Calling rolling with DataFrames.
\texttt{pandas.Series.quantile} Aggregating quantile for Series.
\texttt{pandas.DataFrame.quantile} Aggregating quantile for DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
\begin{verbatim}
0  NaN
1  1.0
2  2.0
3  3.0
dtype: float64
\end{verbatim}

>>> s.rolling(2).quantile(.4, interpolation='midpoint')
\begin{verbatim}
0  NaN
1  1.5
2  2.5
3  3.5
dtype: float64
\end{verbatim}
```

\texttt{pandas.core.window.rolling.Rolling.sem}

\texttt{Rolling.sem}(\texttt{ddof=1, *args, **kwargs})

Calculate the rolling standard error of mean.

Parameters

\begin{itemize}
  \item \texttt{ddof} [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \(N - ddof\), where \(N\) represents the number of elements.
  \item \texttt{*args} For NumPy compatibility and will not have an effect on the result.
  \item \texttt{**kwargs} For NumPy compatibility and will not have an effect on the result.
\end{itemize}

Returns

Series or DataFrame  Return type is the same as the original object with \texttt{np.float64} dtype.

See also:

\texttt{pandas.Series.rolling} Calling rolling with Series data.
\texttt{pandas.DataFrame.rolling} Calling rolling with DataFrames.
\texttt{pandas.Series.sem} Aggregating sem for Series.
\texttt{pandas.DataFrame.sem} Aggregating sem for DataFrame.
Notes

A minimum of one period is required for the calculation.

Examples

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> s.rolling(2, min_periods=1).sem()
0   NaN
1   0.707107
2   0.707107
3   0.707107
dtype: float64
```

pandas.core.window.rolling.Rolling.rank

Rolling.rank(method='average', ascending=True, pct=False, **kwargs)

Calculate the rolling rank.

New in version 1.4.0.

Parameters

- **method** ['average', 'min', 'max', default 'average'] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group

- **ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.

- **pct** [bool, default False] Whether or not to display the returned rankings in percentile form.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

- pandas.Series.rolling Calling rolling with Series data.
- pandas.DataFrame.rolling Calling rolling with DataFrames.
- pandas.Series.rank Aggregating rank for Series.
- pandas.DataFrame.rank Aggregating rank for DataFrame.
Examples

```python
>>> s = pd.Series([1, 4, 2, 3, 5, 3])
>>> s.rolling(3).rank()
0    NaN
1    NaN
2    2.0
3    2.0
4    3.0
5    1.5
dtype: float64

>>> s.rolling(3).rank(method="max")
0    NaN
1    NaN
2    2.0
3    2.0
4    3.0
5    2.0
dtype: float64

>>> s.rolling(3).rank(method="min")
0    NaN
1    NaN
2    2.0
3    2.0
4    3.0
5    1.0
dtype: float64
```

3.9.2 Weighted window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window.mean(*args, **kwargs)</td>
<td>Calculate the rolling weighted window mean.</td>
</tr>
<tr>
<td>Window.sum(*args, **kwargs)</td>
<td>Calculate the rolling weighted window sum.</td>
</tr>
<tr>
<td>Window.var(ddof)</td>
<td>Calculate the rolling weighted window variance.</td>
</tr>
<tr>
<td>Window.std(ddof)</td>
<td>Calculate the rolling weighted window standard deviation.</td>
</tr>
</tbody>
</table>

**pandas.core.window.rolling.Window.mean**

Window.mean(*args, **kwargs)

Calculate the rolling weighted window mean.

**Parameters**

**kwargs Keyword arguments to configure the SciPy weighted window type.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

tSeries.rolling Calling rolling with Series data.
**pandas.DataFrame.rolling** Calling rolling with DataFrames.
**pandas.Series.mean** Aggregating mean for Series.
**pandas.DataFrame.mean** Aggregating mean for DataFrame.

**pandas.core.window.rolling.Window.sum**

Window.sum(*args, **kwargs)
Calculate the rolling weighted window sum.

**Parameters**

**kwargs** Keyword arguments to configure the SciPy weighted window type.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:
**pandas.Series.rolling** Calling rolling with Series data.
**pandas.DataFrame.rolling** Calling rolling with DataFrames.
**pandas.Series.sum** Aggregating sum for Series.
**pandas.DataFrame.sum** Aggregating sum for DataFrame.

**pandas.core.window.rolling.Window.var**

Window.var(ddof=1, *args, **kwargs)
Calculate the rolling weighted window variance.

New in version 1.0.0.

**Parameters**

**kwargs** Keyword arguments to configure the SciPy weighted window type.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:
**pandas.Series.rolling** Calling rolling with Series data.
**pandas.DataFrame.rolling** Calling rolling with DataFrames.
**pandas.Series.var** Aggregating var for Series.
**pandas.DataFrame.var** Aggregating var for DataFrame.

**pandas.core.window.rolling.Window.std**

Window.std(ddof=1, *args, **kwargs)
Calculate the rolling weighted window standard deviation.

New in version 1.0.0.

**Parameters**

**kwargs** Keyword arguments to configure the SciPy weighted window type.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:
**pandas.Series.rolling** Calling rolling with Series data.
pandas: powerful Python data analysis toolkit, Release 1.4.3

*pandas.DataFrame.rolling* Calling rolling with DataFrames.
*pandas.Series.std* Aggregating std for Series.
*pandas.DataFrame.std* Aggregating std for DataFrame.

### 3.9.3 Expanding window functions

<table>

</table>

#### pandas.core.window.expanding.Expanding.count

**Expanding.count()**

Calculate the expanding count of non NaN observations.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

**See also:**

*pandas.Series.expanding* Calling expanding with Series data.
*pandas.DataFrame.expanding* Calling expanding with DataFrames.
*pandas.Series.count* Aggregating count for Series.
*pandas.DataFrame.count* Aggregating count for DataFrame.

#### pandas.core.window.expanding.Expanding.sum

**Expanding.sum(*args, engine=None, engine_kwargs=None, **kwargs)**

Calculate the expanding sum.

**Parameters**

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
pandas: powerful Python data analysis toolkit, Release 1.4.3

- None : Defaults to 'cython' or globally setting compute.use_numba
  New in version 1.3.0.

**kwargs : For NumPy compatibility and will not have an effect on the result.

Returns

**Series or DataFrame**  Return type is the same as the original object with np.float64 dtype.

See also:

- pandas.Series.expanding  Calling expanding with Series data.
- pandas.DataFrame.expanding  Calling expanding with DataFrames.
- pandas.Series.sum  Aggregating sum for Series.
- pandas.DataFrame.sum  Aggregating sum for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.mean

Expanding.mean(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the expanding mean.

Parameters

**args**  For NumPy compatibility and will not have an effect on the result.

**engine** [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting compute.use_numba
  New in version 1.3.0.

**engine_kwargs** [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
  New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.
pandas: powerful Python data analysis toolkit, Release 1.4.3

Returns

Series or DataFrame  Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.expanding  Calling expanding with Series data.
pandas.DataFrame.expanding  Calling expanding with DataFrames.
pandas.Series.mean  Aggregating mean for Series.
pandas.DataFrame.mean  Aggregating mean for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.median

Expanding.median(engine=None, engine_kwars=None, **kwargs)

Calculate the expanding median.

Parameters

engine  [str, default None]

• 'cython' : Runs the operation through C-extensions from cython.
• 'numba' : Runs the operation through JIT compiled code from numba.
• None : Defaults to 'cython' or globally setting compute.use_numba
  New in version 1.3.0.

engine_kwars  [dict, default None]

• For 'cython' engine, there are no accepted engine_kwars
• For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
  New in version 1.3.0.

**kwargs  For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame  Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.expanding  Calling expanding with Series data.
pandas.DataFrame.expanding  Calling expanding with DataFrames.
pandas.Series.median  Aggregating median for Series.
pandas.DataFrame.median  Aggregating median for DataFrame.
Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.var

Expanding.var(ddof=1, *args, engine=None, engine_kwags=None, **kwargs)

Calculate the expanding variance.

Parameters

ddf [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddf \), where \( N \) represents the number of elements.

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.4.0.

engine_kwags [dict, default None]

- For 'cython' engine, there are no accepted engine_kwags
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwags for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.4.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

numpy.var Equivalent method for NumPy array.
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.var Aggregating var for Series.
pandas.DataFrame.var Aggregating var for DataFrame.
Notes

The default \texttt{ddof} of 1 used in \texttt{Series.var()} is different than the default \texttt{ddof} of 0 in \texttt{numpy.var()}. A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])

>>> s.expanding(3).var()
0    NaN
1    NaN
2  0.333333
3  0.916667
4  0.800000
5  0.700000
6  0.619048
dtype: float64
```

### pandas.core.window.expanding.Expanding.std

\texttt{Expanding.std}(\texttt{ddof=1, *args, engine=None, engine_kwargs=None, **kwargs})

Calculate the expanding standard deviation.

**Parameters**

- \texttt{ddof} [\texttt{int}, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where $N$ represents the number of elements.
- \texttt{*args} For NumPy compatibility and will not have an effect on the result.
- \texttt{engine} [\texttt{str}, default \texttt{None}]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - \texttt{None}: Defaults to 'cython' or globally setting \texttt{compute.use_numba}
  - New in version 1.4.0.
- \texttt{engine_kwargs} [\texttt{dict}, default \texttt{None}]
  - For 'cython' engine, there are no accepted \texttt{engine_kwargs}
  - For 'numba' engine, the engine can accept \texttt{nopython}, \texttt{nogil} and \texttt{parallel} dictionary keys. The values must either be \texttt{True} or \texttt{False}. The default \texttt{engine_kwargs} for the 'numba' engine is \{'nopython': True, 'nogil': False, 'parallel': False\}
  - New in version 1.4.0.
- \texttt{**kwargs} For NumPy compatibility and will not have an effect on the result.

**Returns**

- \texttt{Series or DataFrame}: Return type is the same as the original object with \texttt{np.float64} dtype.

See also:
**Notes**

The default `ddof` of 1 used in `Series.std()` is different than the default `ddof` of 0 in `numpy.std()`.

A minimum of one period is required for the rolling calculation.

**Examples**

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])

>>> s.expanding(3).std()
0    NaN
1    NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

**pandas.core.window.expanding.Expanding.min**

`Expanding.min(*args, engine=None, engine_kwars=None, **kwargs)`

Calculate the expanding minimum.

**Parameters**

- `args` For NumPy compatibility and will not have an effect on the result.
- `engine` [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting `compute.use_numba`
    New in version 1.3.0.
- `engine_kwars` [dict, default None]
  - For 'cython' engine, there are no accepted `engine_kwars`
  - For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwars` for the 'numba' engine is `{ 'nopython': True, 'nogil': False, 'parallel': False}`
    New in version 1.3.0.
- `**kwargs` For NumPy compatibility and will not have an effect on the result.
Returns

Series or DataFrame  Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.expanding  Calling expanding with Series data.
pandas.DataFrame.expanding  Calling expanding with DataFrames.
pandas.Series.min  Aggregating min for Series.
pandas.DataFrame.min  Aggregating min for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.max

Expanding.max(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the expanding maximum.

Parameters

*args  For NumPy compatibility and will not have an effect on the result.

engine  [str, default None]
  • 'cython' : Runs the operation through C-extensions from cython.
  • 'numba' : Runs the operation through JIT compiled code from numba.
  • None : Defaults to 'cython' or globally setting compute.use_numba
    New in version 1.3.0.

engine_kwargs  [dict, default None]
  • For 'cython' engine, there are no accepted engine_kwargs
  • For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default
engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False,'parallel': False}
    New in version 1.3.0.

**kwargs  For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame  Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.expanding  Calling expanding with Series data.
pandas.DataFrame.expanding  Calling expanding with DataFrames.
pandas.Series.max  Aggregating max for Series.
pandas.DataFrame.max  Aggregating max for DataFrame.
Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.corr

Expanding.cor(r(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the expanding correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson’s correlation calculation.
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.corr Aggregating corr for Series.
pandas.DataFrame.corr Aggregating corr for DataFrame.

Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.
pandas.core.window.expanding.Expanding.cov

Expanding.cov(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the expanding sample covariance.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddf [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.cov Aggregating cov for Series.
pandas.DataFrame.cov Aggregating cov for DataFrame.

pandas.core.window.expanding.Expanding.skew

Expanding.skew(**kwargs)

Calculate the expanding unbiased skewness.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

scipy.stats.skew Third moment of a probability density.
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.skew Aggregating skew for Series.
pandas.DataFrame.skew Aggregating skew for DataFrame.
Notes

A minimum of three periods is required for the rolling calculation.

pandas.core.window.expanding.Expanding.kurt

Expanding.kurt(**kwargs)

Calculate the expanding Fisher’s definition of kurtosis without bias.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.kurt Aggregating kurt for Series.
pandas.DataFrame.kurt Aggregating kurt for DataFrame.

Notes

A minimum of four periods is required for the calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using scipy.stats.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr, bias=False):.6f}")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
          0     1     2     3     4
dtype: float64
   0   NaN   NaN   NaN -1.200000
   1   NaN   NaN   NaN   4.999874
```

3.9. Window
Expanding.apply(func, raw=False, engine=None, engine_kwags=None, args=None, kwags=None)

Calculate the expanding custom aggregation function.

**Parameters**

- **func** [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.

  Changed in version 1.0.0.

- **raw** [bool, default False]
  - False: passes each row or column as a Series to the function.
  - True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

- **engine** [str, default None]
  - 'cython': Runs rolling apply through C-extensions from cython.
  - 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
  - None: Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.0.0.

- **engine_kwags** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwags
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwags for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

  New in version 1.0.0.

- **args** [tuple, default None] Positional arguments to be passed into func.

- **kwags** [dict, default None] Keyword arguments to be passed into func.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

- pandas.Series.expanding Calling expanding with Series data.
- pandas.DataFrame.expanding Calling expanding with DataFrames.
- pandas.Series.apply Aggregating apply for Series.
- pandas.DataFrame.apply Aggregating apply for DataFrame.
pandas.core.window.expanding.Expanding.aggregate

Expanding.aggregate(func, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

**Returns**

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

- pandas.DataFrame.aggregate Similar DataFrame method.
- pandas.Series.aggregate Similar Series method.

**Notes**

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
  A  B  C
0 1  4  7
1 2  5  8
2 3  6  9
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> df.ewm(alpha=0.5).mean()
   A       B       C
0 1.000000 4.000000 7.000000
1 1.666667 4.666667 7.666667
2 2.428571 5.428571 8.428571
```

### pandas.core.window.expanding.Expanding.quantile

**`Expanding.quantile(quantile, interpolation='linear', **kwargs)`**

Calculate the expanding quantile.

**Parameters**

- **quantile** [float] Quantile to compute. 0 <= quantile <= 1.
- **interpolation** [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points $i$ and $j$:
  - linear: $i + (j - i) \times fraction$, where $fraction$ is the fractional part of the index surrounded by $i$ and $j$.
  - lower: $i$.
  - higher: $j$.
  - nearest: $i$ or $j$ whichever is nearest.
  - midpoint: $(i + j) / 2$.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

- **Series or DataFrame** Return type is the same as the original object with np.float64 dtype.

See also:

- `pandas.Series.expanding` Calling expanding with Series data.
- `pandas.DataFrame.expanding` Calling expanding with DataFrames.
- `pandas.Series.quantile` Aggregating quantile for Series.
- `pandas.DataFrame.quantile` Aggregating quantile for DataFrame.

### pandas.core.window.expanding.Expanding.sem

**`Expanding.sem(ddof=1, *args, **kwargs)`**

Calculate the expanding standard error of mean.

**Parameters**

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.
- **args** For NumPy compatibility and will not have an effect on the result.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

- **Series or DataFrame** Return type is the same as the original object with np.float64 dtype.

See also:
**pandas.Series.expanding** Calling expanding with Series data.
**pandas.DataFrame.expanding** Calling expanding with DataFrames.
**pandas.Series.sem** Aggregating sem for Series.
**pandas.DataFrame.sem** Aggregating sem for DataFrame.

**Notes**

A minimum of one period is required for the calculation.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])

>>> s.expanding().sem()
0    NaN
1    0.707107
2    0.707107
3    0.745356
dtype: float64
```

**pandas.core.window.expanding.Expanding.rank**

Expanding .rank *(method='average', ascending=True, pct=False, **kwargs)*

Calculate the expanding rank.

New in version 1.4.0.

**Parameters**

- **method** [‘average’, ‘min’, ‘max’], default ‘average’ How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group

- **ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.

- **pct** [bool, default False] Whether or not to display the returned rankings in percentile form.

- ****kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

**See also:**

- **pandas.Series.expanding** Calling expanding with Series data.
- **pandas.DataFrame.expanding** Calling expanding with DataFrames.
- **pandas.Series.rank** Aggregating rank for Series.
- **pandas.DataFrame.rank** Aggregating rank for DataFrame.
Examples

```python
>>> s = pd.Series([1, 4, 2, 3, 5, 3])
>>> s.expanding().rank()
0   1.0
1   2.0
2   2.0
3   3.0
4   5.0
5   3.5
dtype: float64
```

```python
>>> s.expanding().rank(method="max")
0   1.0
1   2.0
2   2.0
3   3.0
4   5.0
5   4.0
dtype: float64
```

```python
>>> s.expanding().rank(method="min")
0   1.0
1   2.0
2   2.0
3   3.0
4   5.0
5   3.0
dtype: float64
```

3.9.4 Exponentially-weighted window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ExponentialMovingWindow.mean(*args[, ...])</code></td>
<td>Calculate the ewm (exponential weighted moment) mean.</td>
</tr>
<tr>

<tr>
<td><code>ExponentialMovingWindow.cov([other, ...])</code></td>
<td>Calculate the ewm (exponential weighted moment) sample covariance.</td>
</tr>
</tbody>
</table>
pandas.core.window.ewm.ExponentialMovingWindow.mean

ExponentialMovingWindow.mean(*args, engine=None, engine_kwars=None, **kwargs)

Calculate the ewm (exponential weighted moment) mean.

Parameters

*args  For NumPy compatibility and will not have an effect on the result.
engine  [str, default None]
    • 'cython': Runs the operation through C-extensions from cython.
    • 'numba': Runs the operation through JIT compiled code from numba.
    • None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwars  [dict, default None]
    • For 'cython' engine, there are no accepted engine_kwars
    • For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs  For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame  Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.ewm  Calling ewm with Series data.
pandas.DataFrame.ewm  Calling ewm with DataFrames.
pandas.Series.mean  Aggregating mean for Series.
pandas.DataFrame.mean  Aggregating mean for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.ewm.ExponentialMovingWindow.sum

ExponentialMovingWindow.sum(*args, engine=None, engine_kwars=None, **kwargs)

Calculate the ewm (exponential weighted moment) sum.

Parameters

*args  For NumPy compatibility and will not have an effect on the result.
engine  [str, default None]
    • 'cython': Runs the operation through C-extensions from cython.
    • 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting `compute.use_numba`  
  New in version 1.3.0.

**engine_kwargs** (dict, default None)
- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil`, and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{‘nopython’: True, ‘nogil’: False, ‘parallel’: False}`  
  New in version 1.3.0.

**kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**
- **Series or DataFrame** Return type is the same as the original object with np.float64 dtype.

See also:
- `pandas.Series.ewm` Calling ewm with Series data.
- `pandas.DataFrame.ewm` Calling ewm with DataFrames.
- `pandas.Series.sum` Aggregating sum for Series.
- `pandas.DataFrame.sum` Aggregating sum for DataFrame.

**Notes**
See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

**pandas.core.window.ewm.ExponentialMovingWindow.std**

`ExponentialMovingWindow.std(bias=False, *args, **kwargs)`
Calculate the ewm (exponential weighted moment) standard deviation.

**Parameters**
- `bias` [bool, default False] Use a standard estimation bias correction.
- `*args` For NumPy compatibility and will not have an effect on the result.
- `**kwargs` For NumPy compatibility and will not have an effect on the result.

**Returns**
- **Series or DataFrame** Return type is the same as the original object with np.float64 dtype.

See also:
- `pandas.Series.ewm` Calling ewm with Series data.
- `pandas.DataFrame.ewm` Calling ewm with DataFrames.
- `pandas.Series.std` Aggregating std for Series.
- `pandas.DataFrame.std` Aggregating std for DataFrame.
pandas.core.window.ewm.ExponentialMovingWindow.var

ExponentialMovingWindow.var(bias=False, *args, **kwargs)

Calculate the ewm (exponential weighted moment) variance.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

*args For NumPy compatibility and will not have an effect on the result.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.ewm Calling ewm with Series data.
pandas.DataFrame.ewm Calling ewm with DataFrames.
pandas.Series.var Aggregating var for Series.
pandas.DataFrame.var Aggregating var for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.corr

ExponentialMovingWindow.corr(other=None, pairwise=None, **kwargs)

Calculate the ewm (exponential weighted moment) sample correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

pandas.Series.ewm Calling ewm with Series data.
pandas.DataFrame.ewm Calling ewm with DataFrames.
pandas.Series.corr Aggregating corr for Series.
pandas.DataFrame.corr Aggregating corr for DataFrame.
pandas.core.window.ewm.ExponentialMovingWindow.cov

ExponentialMovingWindow.cov(other=None, pairwise=None, bias=False, **kwargs)

Calculate the ewm (exponential weighted moment) sample covariance.

Parameters

- **other** [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.
- **pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- **bias** [bool, default False] Use a standard estimation bias correction.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

- **Series** or DataFrame Return type is the same as the original object with np.float64 dtype.

See also:

- pandas.Series.ewm Calling ewm with Series data.
- pandas.DataFrame.ewm Calling ewm with DataFrames.
- pandas.Series.cov Aggregating cov for Series.
- pandas.DataFrame.cov Aggregating cov for DataFrame.

3.9.5 Window indexer

Base class for defining custom window boundaries.

| api.indexers.BaseIndexer([index_array, ...]) | Base class for window bounds calculations. |
| api.indexers.FixedForwardWindowIndexer([...]) | Creates window boundaries for fixed-length windows that include the current row. |
| api.indexers.VariableOffsetWindowIndexer([...]) | Calculate window boundaries based on a non-fixed offset such as a BusinessDay. |

pandas.api.indexers.BaseIndexer

class pandas.api.indexers.BaseIndexer(index_array=None, window_size=0, **kwargs)

Base class for window bounds calculations.

Methods

- get_window_bounds([num_values, min_periods, ...]) Computes the bounds of a window.
pandas.api.indexers.BaseIndexer.get_window_bounds

BaseIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)
Computes the bounds of a window.

Parameters

- num_values [int, default 0] number of values that will be aggregated over
- window_size [int, default 0] the number of rows in a window
- min_periods [int, default None] min_periods passed from the top level rolling API
- center [bool, default None] center passed from the top level rolling API
- closed [str, default None] closed passed from the top level rolling API
- win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64], indicating the boundaries of each window

pandas.api.indexers.FixedForwardWindowIndexer

class pandas.api.indexers.FixedForwardWindowIndexer(index_array=None, window_size=0, **kwargs)
Creates window boundaries for fixed-length windows that include the current row.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
   B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```
Methods

```
get_window_bounds([num_values, min_periods, ...])
```

```
pandas.api.indexers.FixedForwardWindowIndexer.get_window_bounds
```

FixedForwardWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

Parameters

- **num_values** [int, default 0] number of values that will be aggregated over window_size
- **window_size** [int, default 0] the number of rows in a window
- **min_periods** [int, default None] min_periods passed from the top level rolling API
- **center** [bool, default None] center passed from the top level rolling API
- **closed** [str, default None] closed passed from the top level rolling API
- **win_type** [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64], indicating the boundaries of each window

```
pandas.api.indexers.VariableOffsetWindowIndexer
```

class pandas.api.indexers.VariableOffsetWindowIndexer(index_array=None, window_size=0, index=None, offset=None, **kwargs)

Calculate window boundaries based on a non-fixed offset such as a BusinessDay.

Methods

```
get_window_bounds([num_values, min_periods, ...])
```

```
pandas.api.indexers.VariableOffsetWindowIndexer.get_window_bounds
```

VariableOffsetWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

Parameters

- **num_values** [int, default 0] number of values that will be aggregated over window_size
- **window_size** [int, default 0] the number of rows in a window
**min_periods** [int, default None] min_periods passed from the top level rolling API

**center** [bool, default None] center passed from the top level rolling API

**closed** [str, default None] closed passed from the top level rolling API

**win_type** [str, default None] win_type passed from the top level rolling API

**Returns**

A tuple of ndarray[int64]s, indicating the boundaries of each window

### 3.10 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.

#### 3.10.1 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GroupBy.<strong>iter</strong>()</strong></td>
<td>Groupby iterator.</td>
</tr>
<tr>
<td><strong>GroupBy.groups</strong></td>
<td>Dict {group name -&gt; group labels}.</td>
</tr>
<tr>
<td><strong>GroupBy.indices</strong></td>
<td>Dict {group name -&gt; group indices}.</td>
</tr>
<tr>
<td><strong>GroupBy.get_group(name[, obj])</strong></td>
<td>Construct DataFrame from group with provided name.</td>
</tr>
</tbody>
</table>

#### pandas.core.groupby.GroupBy.__iter__

GroupBy.__iter__()

Groupby iterator.

Returns

Generator yielding sequence of (name, subsetted object) for each group

#### pandas.core.groupby.GroupBy.groups

**property GroupBy.groups**

Dict {group name -> group labels}.

#### pandas.core.groupby.GroupBy.indices

**property GroupBy.indices**

Dict {group name -> group indices}.
**pandas.core.groupby.GroupBy.get_group**

GroupBy.get_group(name, obj=None)

Construct DataFrame from group with provided name.

**Parameters**

- **name** [object] The name of the group to get as a DataFrame.
- **obj** [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

**Returns**

- **group** [same type as obj]

---

**pandas.Grouper**

class pandas.Grouper(*args, **kwargs)

A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If axis and/or level are passed as keywords to both Grouper and groupby, the values passed to Grouper take precedence.

**Parameters**

- **key** [str, defaults to None] Groupby key, which selects the grouping column of the target.
- **level** [name/number, defaults to None] The level for the target index.
- **freq** [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of available frequencies, please see here.
- **axis** [str, int, defaults to 0] Number/name of the axis.
- **sort** [bool, default to False] Whether to sort the resulting labels.
- **closed** [‘left’ or ‘right’] Closed end of interval. Only when freq parameter is passed.
- **label** [‘left’ or ‘right’) Interval boundary to use for labeling. Only when freq parameter is passed.
- **convention** [‘start’, ‘end’, ‘e’, ‘s’] If grouper is PeriodIndex and freq parameter is passed.
- **base** [int, default 0] Only when freq parameter is passed. For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

- **loffset** [str, DateOffset, timedelta object] Only when freq parameter is passed.

Deprecated since version 1.1.0: loffset is only working for .resample(...) and not for Grouper (GH28302). However, loffset is also deprecated for .resample(...) See: DataFrame.resample
**origin** [Timestamp or str, default ‘start_day’] The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If string, must be one of the following:

- `epoch`: origin is 1970-01-01
- `start`: origin is the first value of the timeseries
- `start_day`: origin is the first day at midnight of the timeseries

New in version 1.1.0.

- `end`: origin is the last value of the timeseries
- `end_day`: origin is the ceiling midnight of the last day

New in version 1.3.0.

**offset** [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

**dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

New in version 1.2.0.

**Returns**

A specification for a groupby instruction

**Examples**

Syntactic sugar for `df.groupby('A')`

```python
>>> df = pd.DataFrame(
...     
...     { 
...         "Animal": ["Falcon", "Parrot", "Falcon", "Falcon", "Parrot"],
...         "Speed": [100, 5, 200, 300, 15],
...     }
... )
... 
>>> df
Animal  Speed
0  Falcon  100
1  Parrot   5
2  Falcon  200
3  Falcon  300
4  Parrot   5

>>> df.groupby(pd.Grouper(key="Animal")).mean()
Speed
Animal
Falcon  200.0
Parrot  10.0
```

Specify a resample operation on the column ‘Publish date’

```python
>>> df = pd.DataFrame(
...     
...     { 
...     }
... )
... 
>>> df
Animal  Publish date
0  Falcon  2021-01-01
1  Parrot  2021-01-03
2  Falcon  2021-01-04
3  Falcon  2021-01-08
4  Parrot  2021-01-15
```

(continues on next page)
... "Publish date": [
...   pd.Timestamp("2000-01-02"),
...   pd.Timestamp("2000-01-02"),
...   pd.Timestamp("2000-01-09"),
...   pd.Timestamp("2000-01-16"),
... ],
... "ID": [0, 1, 2, 3],
... "Price": [10, 20, 30, 40]
... }

>>> df

<table>
<thead>
<tr>
<th>Publish date</th>
<th>ID</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts

2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64

>>> ts.groupby(pd.Grouper(freq='17min')).sum()

2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64

>>> ts.groupby(pd.Grouper(freq='17min', origin='epoch')).sum()

2000-10-01 23:18:00    0
2000-10-01 23:35:00   18
2000-10-01 23:52:00   27
```
>>> df.groupby('date').sum()  
2000-10-01 23:24:00 3  
2000-10-01 23:41:00 15  
2000-10-01 23:58:00 45  
2000-10-02 00:15:00 45  
Freq: 17T, dtype: int64

If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

>>> df.groupby(pd.Grouper(freq='17min', offset='23h30min')).sum()  
2000-10-01 23:30:00 9  
2000-10-01 23:47:00 21  
2000-10-02 00:04:00 54  
2000-10-02 00:21:00 24  
Freq: 17T, dtype: int64

To replace the use of the deprecated base argument, you can now use offset, in this example it is equivalent to have base=2:

>>> df.groupby(pd.Grouper(freq='17min', offset='2min')).sum()  
2000-10-01 23:16:00 0  
2000-10-01 23:33:00 9  
2000-10-01 23:50:00 36  
2000-10-02 00:07:00 39  
2000-10-02 00:24:00 24  
Freq: 17T, dtype: int64

<td>Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values.</td>
</tr>
<tr>
<td><code>GroupBy.pipe(func, *args, **kwargs)</code></td>
<td>Apply a function <code>func</code> with arguments to this GroupBy object and return the function’s result.</td>
</tr>
</tbody>
</table>

**pandas.core.groupby.GroupBy.apply**

The function passed to `apply` must take a dataframe as its first argument and return a DataFrame, Series or scalar. `apply` will then take care of combining the results back together into a single dataframe or series. `apply` is therefore a highly flexible grouping method.

While `apply` is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like `agg` or `transform`. Pandas offers a wide range of method that will be much faster than using `apply` for their specific purposes, so try to use them before reaching for `apply`.

**Parameters**

- **func** [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.
- **args, kwargs** [tuple and dict] Optional positional and keyword arguments to pass to `func`.

**Returns**

- **applied** [Series or DataFrame]

**See also:**

- `pipe` Apply function to the full GroupBy object instead of to each group.
- `aggregate` Apply aggregate function to the GroupBy object.
- `transform` Apply function column-by-column to the GroupBy object.
- `Series.apply` Apply a function to a Series.
**DataFrame.apply**  Apply a function to each row or column of a DataFrame.

**Notes**

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

**Examples**

```python
>>> df = pd.DataFrame({'A': 'a a b'.split(),
                     'B': [1,2,3],
                     'C': [4,6,5]})
```

Notice that `g` has two groups, `a` and `b`. Calling `apply` in various ways, we can get different grouping results:

**Example 1:** below the function passed to `apply` takes a DataFrame as its argument and returns a DataFrame. `apply` combines the result for each group together into a new DataFrame:

```python
>>> g[['B', 'C']].apply(lambda x: x / x.sum())
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.333333</td>
<td>0.4</td>
</tr>
<tr>
<td>1</td>
<td>0.666667</td>
<td>0.6</td>
</tr>
<tr>
<td>2</td>
<td>1.000000</td>
<td>1.0</td>
</tr>
</tbody>
</table>

**Example 2:** The function passed to `apply` takes a DataFrame as its argument and returns a Series. `apply` combines the result for each group together into a new DataFrame.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`.

```python
>>> g[['B', 'C']].apply(lambda x: x.astype(float).max() - x.min())
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>a</td>
<td>1.0 2.0</td>
</tr>
<tr>
<td></td>
<td>b</td>
<td>0.0 0.0</td>
</tr>
</tbody>
</table>

**Example 3:** The function passed to `apply` takes a DataFrame as its argument and returns a scalar. `apply` combines the result for each group together into a Series, including setting the index as appropriate:

```python
>>> g.apply(lambda x: x.C.max() - x.B.min())
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>5</td>
</tr>
<tr>
<td>b</td>
<td>2</td>
</tr>
</tbody>
</table>

dtype: int64
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.core.groupby.GroupBy.agg

GroupBy.agg(func, *args, **kwargs)

pandas.core.groupby.SeriesGroupBy.aggregate

SeriesGroupBy.aggregate(func=None, *args, engine=None, engine_kwargs=None, **kwargs)

Aggregate using one or more operations over the specified axis.

Parameters

  func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

  Accepted combinations are:
  • function
  • string function name
  • list of functions and/or function names, e.g. [np.sum, 'mean']
  • dict of axis labels -> functions, function names or list of such.

  Can also accept a Numba JIT function with engine='numba' specified. Only passing a single function is supported with this engine.

  If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

  *args Positional arguments to pass to func.

  engine [str, default None]
  • 'cython' : Runs the function through C-extensions from cython.
  • 'numba' : Runs the function through JIT compiled code from numba.
  • None : Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.1.0.

  engine_kwargs [dict, default None]
  • For 'cython' engine, there are no accepted engine_kwargs
  • For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

  New in version 1.1.0.

  **kwargs Keyword arguments to be passed into func.

Returns

  Series

  See also:

  Series.groupby.apply Apply function func group-wise and combine the results together.
**Series.groupby.transform** Aggregate using one or more operations over the specified axis.

**Series.aggregate** Transforms the Series on each group based on the given function.

**Notes**

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])

>>> s
0 1
1 2
2 3
3 4
dtype: int64

>>> s.groupby([1, 1, 2, 2]).min()
1 1
2 3
dtype: int64

>>> s.groupby([1, 1, 2, 2]).agg('min')
1 1
2 3
dtype: int64

>>> s.groupby([1, 1, 2, 2]).agg(['min', 'max'])
min  max
1  1  2
2  3  4
```

The output column names can be controlled by passing the desired column names and aggregations as keyword arguments.

```python
>>> s.groupby([1, 1, 2, 2]).agg(
...     minimum='min',
...     maximum='max',
... )
minimum  maximum
1  1  2
2  3  4
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

Changed in version 1.3.0: The resulting dtype will reflect the return value of the aggregating function.

```python
>>> s.groupby([1, 1, 2, 2]).agg(lambda x: x.astype(float).min())
1  1.0
2  3.0
dtype: float64
```

**pandas.core.groupby.DataFrameGroupBy.aggregate**

`DataFrameGroupBy.aggregate(func=None, *args, engine=None, engine_kwargs=None, **kwargs)`

Aggregate using one or more operations over the specified axis.

**Parameters**

- `func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. `[np.sum, 'mean']`
  - dict of axis labels -> functions, function names or list of such.

Can also accept a Numba JIT function with `engine='numba'` specified. Only passing a single function is supported with this engine.

If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

- `*args` Positional arguments to pass to `func`.

- `engine` [str, default None]
  
  - 'cython' : Runs the function through C-extensions from cython.
  - 'numba' : Runs the function through JIT compiled code from numba.
  - None : Defaults to 'cython' or globally setting `compute.use_numba`

  New in version 1.1.0.

- `engine_kwargs` [dict, default None]
  
  - For 'cython' engine, there are no accepted `engine_kwargs`
  
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

  New in version 1.1.0.

- `**kwargs` Keyword arguments to be passed into `func`.

**Returns**

- `DataFrame`
See also:

- **DataFrame.groupby.apply** Apply function func group-wise and combine the results together.
- **DataFrame.groupby.transform** Aggregate using one or more operations over the specified axis.
- **DataFrame.aggregate** Transforms the Series on each group based on the given function.

### Notes

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function (UDF) methods](#) for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

### Examples

```python
>>> df = pd.DataFrame(
...     
...     {
...         "A": [1, 1, 2, 2],
...         "B": [1, 2, 3, 4],
...         "C": [0.362838, 0.227877, 1.267767, -0.562860],
...     }
... )

>>> df
   A  B         C
0  1  1  0.362838
1  1  2  0.227877
2  2  3  1.267767
3  2  4 -0.562860

The aggregation is for each column.

```python
>>> df.groupby('A').agg('min')
   B
A
  1  1  0.227877
  2  3 -0.562860

Multiple aggregations

```python
>>> df.groupby('A').agg(['min', 'max'])
   B         C
min max
A
  1  1  2  0.227877  0.362838
  2  3  4 -0.562860  1.267767

Select a column for aggregation
Different aggregations per column

```python
>>> df.groupby('A').agg([('min', 'max')])

    min  max
A
  1    1    2
  2    3    4
```

To control the output names with different aggregations per column, pandas supports “named aggregation”

```python
>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})

   B     C
A
  1  1  0.590715
  2  3  0.704907
```

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields ['column', 'aggfunc'] to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

See Named aggregation for more.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the aggregating function.

```python
>>> df.groupby('A')[['B']].agg(lambda x: x.astype(float).min())

    B
A
  1  1.0
  2  3.0
```

---

**pandas.core.groupby.SeriesGroupBy.transform**

`SeriesGroupBy.transform(func, *args, engine=None, engine_kwargs=None, **kwargs)`

Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values.

**Parameters**

- `f` [function] Function to apply to each group.

  Can also accept a Numba JIT function with `engine='numba'` specified.

  If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function sig-
nature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

*args Positional arguments to pass to func.

engine [str, default None]

- 'cython' : Runs the function through C-extensions from cython.
- 'numba' : Runs the function through JIT compiled code from numba.
- None : Defaults to 'cython' or the global setting compute.use_numba

New in version 1.1.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

New in version 1.1.0.

**kwargs Keyword arguments to be passed into func.

Returns

Series

See also:

Series.groupby.apply Apply function func group-wise and combine the results together.
Series.groupby.aggregate Aggregate using one or more operations over the specified axis.
Series.transform Call func on self producing a Series with the same axis shape as self.

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

- f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the input subframe.
- if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- f must not mutate groups. Mutation is not supported and may produce unexpected results. See Mutating with User Defined Function (UDF) methods for more details.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, see the examples below.
Examples

```python
>>> df = pd.DataFrame({
    'A': ['foo', 'bar', 'foo', 'bar',
          'foo', 'bar'],
    'B': ['one', 'one', 'two', 'three',
          'two', 'two'],
    'C': [1, 5, 5, 2, 5, 5],
    'D': [2.0, 5., 8., 1., 2., 9.])

>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())

<table>
<thead>
<tr>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.000000</td>
<td>1.000000</td>
</tr>
<tr>
<td>0.577350</td>
<td>1.000000</td>
</tr>
<tr>
<td>0.577350</td>
<td>1.000000</td>
</tr>
<tr>
<td>0.577350</td>
<td>1.000000</td>
</tr>
<tr>
<td>0.577350</td>
<td>1.000000</td>
</tr>
<tr>
<td>0.577350</td>
<td>1.000000</td>
</tr>
</tbody>
</table>
```

Broadcast result of the transformation

```python
>>> grouped.transform(lambda x: x.max() - x.min())

<table>
<thead>
<tr>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, for example:

```python
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())

<table>
<thead>
<tr>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
</tr>
</tbody>
</table>
```

**pandas.core.groupby.DataFrameGroupBy.transform**

`DataFrameGroupBy.transform(func, *args, engine=None, engine_kwargs=None, **kwargs)`

Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values.

**Parameters**

- `f` [function] Function to apply to each group.

  Can also accept a Numba JIT function with `engine='numba'` specified.

  If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function sig-
nature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

*args  Positional arguments to pass to func.

engine  [str, default None]

- 'cython': Runs the function through C-extensions from cython.
- 'numba': Runs the function through JIT compiled code from numba.
- None: Defaults to 'cython' or the global setting compute.use_numba

New in version 1.1.0.

engine_kwargs  [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

New in version 1.1.0.

**kwargs  Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply  Apply function func group-wise and combine the results together.
DataFrame.groupby.aggregate  Aggregate using one or more operations over the specified axis.
DataFrame.transform  Call func on self producing a DataFrame with the same axis shape as self.

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

- f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the input subframe.
- if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- f must not mutate groups. Mutation is not supported and may produce unexpected results. See Mutating with User Defined Function (UDF) methods for more details.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, see the examples below.
Examples

```python
>>> df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
    ...                      'foo', 'bar'],
    ... 'B': ['one', 'one', 'two', 'three',
    ...        'two', 'two'],
    ... 'C': [1, 5, 5, 2, 5, 5],
    ... 'D': [2.0, 5., 8., 1., 2., 9.]})

>>> grouped = df.groupby('A')

>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
      C     D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000

Broadcast result of the transformation

``` python
>>> grouped.transform(lambda x: x.max() - x.min())
      C     D
0   4  6.0
1   3  8.0
2   4  6.0
3   3  8.0
4   4  6.0
5   3  8.0

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, for example:

```python
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())
      C     D
0   5   8
1   5   9
2   5   8
3   5   9
4   5   8
5   5   9
```

```
pandas.core.groupby.GroupBy.pipe

`.pipe(func, *args, **kwargs)`

Apply a function `func` with arguments to this GroupBy object and return the function’s result.

Use `.pipe` when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write
```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- **func** [callable or tuple of (callable, str)] Function to apply to this GroupBy object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the GroupBy object.
- **args** [iterable, optional] Positional arguments passed into func.
- **kwargs** [dict, optional] A dictionary of keyword arguments passed into func.

**Returns**

object [the return type of func.]

**See also:**

- `Series.pipe` Apply a function with arguments to a series.
- `DataFrame.pipe` Apply a function with arguments to a dataframe.
- `apply` Apply function to each group instead of to the full GroupBy object.

**Notes**

See more here

**Examples**

```python
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
  A B
0 a 1
1 b 2
2 a 3
3 b 4

To get the difference between each groups maximum and minimum value in one pass, you can do

```python
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
```

### 3.10.3 Computations / descriptive stats

</tbody>
</table>
**pandas.core.groupby.GroupBy.all**

```python
final GroupBy.all(skipna=True)
```

Return True if all values in the group are truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- **Series or DataFrame** DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**
- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.any**

```python
final GroupBy.any(skipna=True)
```

Return True if any value in the group is truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- **Series or DataFrame** DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

**See also:**
- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.bfill**

```python
final GroupBy.bfill(limit=None)
```

Backward fill the values.

**Parameters**

- `limit` [int, optional] Limit of how many values to fill.

**Returns**

- **Series or DataFrame** Object with missing values filled.

**See also:**
- `Series.bfill` Backward fill the missing values in the dataset.
- `DataFrame.bfill` Backward fill the missing values in the dataset.
- `Series.fillna` Fill NaN values of a Series.
- `DataFrame.fillna` Fill NaN values of a DataFrame.
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.core.groupby.GroupBy.backfill

GroupBy.backfill(limit=None)
Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:
Series.bfill Backward fill the missing values in the dataset.
DataFrame.bfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.count

final GroupBy.count()
Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumcount

final GroupBy.cumcount(ascending=True)
Number each item in each group from 0 to the length of that group - 1.
Essentially this is equivalent to

```python
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:
ngroup Number the groups themselves.
Examples

```python
>>> df = pd.DataFrame([[a], [a], [a], [b], [b], [a]],
                    columns=['A'])
```

```python
>>> df
  A
0 a
1 a
2 a
3 b
4 b
5 a
```

```python
>>> df.groupby('A').cumcount()
0 0
1 1
2 2
3 0
4 1
5 3
dtype: int64
```

```python
>>> df.groupby('A').cumcount(ascending=False)
0 3
1 2
2 1
3 1
4 0
5 0
dtype: int64
```

**pandas.core.groupby.GroupBy.cummax**

**final** GroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.

**Returns**

Series or DataFrame

**See also:**

.Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.cummin**

**final** GroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.

**Returns**

Series or DataFrame

**See also:**

.Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.cumprod

**final** GroupBy.cumprod(*axis=0, *args, **kwargs*)
Cumulative product for each group.

**Returns**

Series or DataFrame

**See also:**

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumsum

**final** GroupBy.cumsum(*axis=0, *args, **kwargs*)
Cumulative sum for each group.

**Returns**

Series or DataFrame

**See also:**

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.ffill

**final** GroupBy.ffill(*limit=None*)
Forward fill the values.

**Parameters**

limit [int, optional] Limit of how many values to fill.

**Returns**

Series or DataFrame Object with missing values filled.

**See also:**

Series.fill Returns Series with minimum number of char in object.
DataFrame.fill Object with missing values filled or None if inplace=True.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.first

**final** GroupBy.first(*numeric_only=False, min_count=-1*)
Compute first of group values.

**Parameters**

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

Series or DataFrame Computed first of values within each group.
pandas.core.groupby.GroupBy.head

**final** GroupBy.head(n=5)

Return first n rows of each group.

Similar to .apply(lambda x: x.head(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

**Parameters**

n [int] If positive: number of entries to include from start of each group. If negative: number of entries to exclude from end of each group.

**Returns**

Series or DataFrame Subset of original Series or DataFrame as determined by n.

**See also:**

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**Examples**

```python
>>> df = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
                    columns=['A', 'B'])
>>> df.groupby('A').head(1)
  A  B
0 1 2
2 5 6

>>> df.groupby('A').head(-1)
  A  B
0 1 2
```

pandas.core.groupby.GroupBy.last

**final** GroupBy.last(numeric_only=False, min_count=-1)

Compute last of group values.

**Parameters**

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

Series or DataFrame Computed last of values within each group.
**pandas.core.groupby.GroupBy.max**

**final GroupBy.max**(numeric_only=False, min_count=-1)

Compute max of group values.

**Parameters**

- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame** Computed max of values within each group.

**pandas.core.groupby.GroupBy.mean**

**final GroupBy.mean**(numeric_only=None, engine='cython', engine_kwargs=None)

Compute mean of groups, excluding missing values.

**Parameters**

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- **engine** [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.4.0.

- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {{'nopython': True, 'nogil': False, 'parallel': False}}

New in version 1.4.0.

**Returns**

- **pandas.Series or pandas.DataFrame**

See also:

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
Examples

```python
df = pd.DataFrame({'A': [1, 1, 2, 1, 2], 'B': [np.nan, 2, 3, 4, 5], 'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```python
df.groupby('A').mean()
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>3.0</td>
<td>1.333333</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
<td>1.500000</td>
</tr>
</tbody>
</table>

Groupby two columns and return the mean of the remaining column.

```python
df.groupby(['A', 'B']).mean()
```

<table>
<thead>
<tr>
<th></th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>2.0</td>
</tr>
<tr>
<td></td>
<td>1.0</td>
</tr>
<tr>
<td>2</td>
<td>3.0</td>
</tr>
<tr>
<td></td>
<td>2.0</td>
</tr>
</tbody>
</table>

Groupby one column and return the mean of only particular column in the group.

```python
df.groupby('A')['B'].mean()
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>3.0</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
</tr>
</tbody>
</table>

Name: B, dtype: float64

### pandas.core.groupby.GroupBy.median

**final GroupBy.median(numeric_only=NoDefault.no_default)**

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

- `numeric_only` [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- `Series` or `DataFrame` Median of values within each group.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
**pandas.core.groupby.GroupBy.min**

**final** GroupBy.min(numeric_only=False, min_count=-1)

Compute min of group values.

**Parameters**

- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

Series or DataFrame  Computed min of values within each group.

**pandas.core.groupby.GroupBy.ngroup**

**final** GroupBy.ngroup(ascending=True)

Number each group from 0 to the number of groups - 1.

This is the enumerative complement of cumcount. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

**Parameters**

- **ascending** [bool, default True] If False, number in reverse, from number of group - 1 to 0.

**Returns**

Series  Unique numbers for each group.

**See also:**

cumcount  Number the rows in each group.

**Examples**

```python
>>> df = pd.DataFrame({'A': list('aabba')})
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
0  0
1  0
2  0
3  1
4  1
5  0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0  1
```

(continues on next page)
```python
1 1
2 1
3 0
4 0
5 1
dtype: int64
```
Index notation may also be used

```python
>>> g.nth([0, 1])
   B
   A
   1  NaN
   1  2.0
   2  3.0
   2  5.0
```  
Specifying `dropna` allows count ignoring NaN

```python
>>> g.nth(0, dropna='any')
   B
   A
   1  2.0
   2  3.0
```  
NaNs denote group exhausted when using dropna

```python
>>> g.nth(3, dropna='any')
   B
   A
```
Specifying `as_index=False` in `groupby` keeps the original index.

```python
>>> df.groupby('A', as_index=False).nth(1)
   A  B
1  1  2.0
4  2  5.0
```

### pandas.core.groupby.GroupBy.ohlc

**final** GroupBy.ohlc()  
Compute open, high, low and close values of a group, excluding missing values.  
For multiple groupings, the result index will be a **MultiIndex**  
**Returns**  
- **DataFrame** Open, high, low and close values within each group.  
**See also:**  
- Series.groupby Apply a function groupby to a Series.  
- DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

### pandas.core.groupby.GroupBy.pad

**GroupBy.pad(limit=None)**  
Forward fill the values.  
**Parameters**  
- limit [int, optional] Limit of how many values to fill.  
**Returns**  
- Series or DataFrame Object with missing values filled.  
**See also:**  
- Series.ffill Returns Series with minimum number of char in object.  
- DataFrame.ffill Object with missing values filled or None if inplace=True.  
- Seriesfillna Fill NaN values of a Series.  
- DataFramefillna Fill NaN values of a DataFrame.

### pandas.core.groupby.GroupBy.prod

**final** GroupBy.prod(**numeric_only=None, min_count=0**)  
Compute prod of group values.  
**Parameters**  
- numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.  
- min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.  
**Returns**
Series or DataFrame  Computed prod of values within each group.

pandas.core.groupby.GroupBy.rank

**final** GroupBy.rank *(method='average', ascending=True, na_option='keep', pct=False, axis=0)*

Provide the rank of values within each group.

**Parameters**

- **method** [{’average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’]
  - average: average rank of group.
  - min: lowest rank in group.
  - max: highest rank in group.
  - first: ranks assigned in order they appear in the array.
  - dense: like ‘min’, but rank always increases by 1 between groups.

- **ascending** [bool, default True] False for ranks by high (1) to low (N).

- **na_option** [{’keep’, ‘top’, ‘bottom’}, default ‘keep’]
  - keep: leave NA values where they are.
  - top: smallest rank if ascending.
  - bottom: smallest rank if descending.

- **pct** [bool, default False] Compute percentage rank of data within each group.

- **axis** [int, default 0] The axis of the object over which to compute the rank.

**Returns**

DataFrame with ranking of values within each group

**See also:**

- Series.groupby  Apply a function groupby to a Series.
- DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

**Examples**

```python
>>> df = pd.DataFrame(
... {  
...   "group": ["a", "a", "a", "a", "b", "b", "b", "b"],
...   "value": [2, 4, 2, 3, 1, 2, 4, 1, 5],
...  }
... )
>>> df
   group  value
0    a      2
1    a      4
2    a      2
3    a      3
4    a      5
5    b      1
6    b      2
```

(continues on next page)
```python
>>> for method in ['average', 'min', 'max', 'dense', 'first']:
...     df[f'{method}_rank'] = df.groupby('group')['value'].rank(method)
```

```
<table>
<thead>
<tr>
<th>group</th>
<th>value</th>
<th>average_rank</th>
<th>min_rank</th>
<th>max_rank</th>
<th>dense_rank</th>
<th>first_rank</th>

</tr>
</tbody>
</table>
```
pandas.core.groupby.GroupBy.sem

**final** GroupBy.sem(ddof=1)

Compute standard error of the mean of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex.

**Parameters**
- **ddof** [int, default 1] Degrees of freedom.

**Returns**
- **Series or DataFrame** Standard error of the mean of values within each group.

**See also:**
- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.std

**final** GroupBy.std(ddof=1, engine=None, engine_kwargs=None)

Compute standard deviation of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex.

**Parameters**
- **ddof** [int, default 1] Degrees of freedom.
- **engine** [str, default None]
  - 'cython' : Runs the operation through C-extensions from cython.
  - 'numba' : Runs the operation through JIT compiled code from numba.
  - None : Defaults to 'cython' or globally setting compute.use_numba

New in version 1.4.0.

- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {{'nopython': True, 'nogil': False, 'parallel': False}}

New in version 1.4.0.

**Returns**
- **Series or DataFrame** Standard deviation of values within each group.

**See also:**
- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
pandas: powerful Python data analysis toolkit, Release 1.4.3

**pandas.core.groupby.GroupBy.sum**

```
final GroupBy.sum(numeric_only=NoDefault.no_default, min_count=0, engine=None, engine_kwars=NoDefault.no_default)
```

Compute sum of group values.

**Parameters**

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame** Computed sum of values within each group.

**pandas.core.groupby.GroupBy.var**

```
final GroupBy.var(ddof=1, engine=None, engine_kwars=NoDefault.no_default)
```

Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

- **ddof** [int, default 1] Degrees of freedom.

- **engine** [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.4.0.

- **engine_kwars** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwars
  - For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {{'nopython': True, 'nogil': False, 'parallel': False}}

New in version 1.4.0.

**Returns**

- **Series or DataFrame** Variance of values within each group.

**See also:**

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.core.groupby.GroupBy.tail

final GroupBy.tail(n=5)

Return last n rows of each group.

Similar to .apply(lambda x: x.tail(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Parameters

n [int] If positive: number of entries to include from end of each group. If negative: number of entries to exclude from start of each group.

Returns

Series or DataFrame Subset of original Series or DataFrame as determined by n.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```python
>>> df = pd.DataFrame([[a, 1], [a, 2], [b, 1], [b, 2]], columns=[A, B])
```

```python
>>> df.groupby(A).tail(1)
   A B
1 a 2
3 b 2
```

```python
>>> df.groupby(A).tail(-1)
   A B
1 a 2
3 b 2
```

The following methods are available in both SeriesGroupBy and DataFrameGroupBy objects, but may differ slightly, usually in that the DataFrameGroupBy version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

<table>

---

**pandas.core.groupby.DataFrameGroupBy.all**

`DataFrameGroupBy.all(skipna=True)`

Return True if all values in the group are truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- `Series or DataFrame` DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.any

DataFrameGroupBy.any(skipna=True)
Return True if any value in the group is truthful, else False.

Parameters

    skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

    Series or DataFrame  DataFrame or Series of boolean values, where a value is True if any
                        element is True within its respective group, False otherwise.

See also:

    Series.groupby  Apply a function groupby to a Series.
    DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.backfill

DataFrameGroupBy.backfill(limit=None)
Backward fill the values.

Parameters

    limit [int, optional] Limit of how many values to fill.

Returns

    Series or DataFrame  Object with missing values filled.

See also:

    Series.bfill  Backward fill the missing values in the dataset.
    DataFrame.bfill  Backward fill the missing values in the dataset.
    Series.fillna  Fill NaN values of a Series.
    DataFrame.fillna  Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.bfill(limit=None)
Backward fill the values.

Parameters

    limit [int, optional] Limit of how many values to fill.

Returns

    Series or DataFrame  Object with missing values filled.

See also:

    Series.bfill  Backward fill the missing values in the dataset.
    DataFrame.bfill  Backward fill the missing values in the dataset.
    Series.fillna  Fill NaN values of a Series.
    DataFrame.fillna  Fill NaN values of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.corr

property DataFrameGroupBy.corr

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method  ['pearson', 'kendall', 'spearman'] or callable  Method of correlation:
- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- callable : callable with input two 1d ndarrays and returning a float. Note that
  the returned matrix from corr will have 1 along the diagonals and will be sym-
  metric regardless of the callable’s behavior.

min_periods  [int, optional] Minimum number of observations required per pair of columns
to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns

DataFrame  Correlation matrix.

See also:

DataFrame.corrwith  Compute pairwise correlation with another DataFrame or Series.
Series.corr  Compute the correlation between two Series.

Examples

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
```
```python
>>> df = pd.DataFrame([(12, .3), (0, .6), (12, .0), (.2, .1)],
...                    columns=['dogs', 'cats'])
```
```python
>>> df.corr(method=histogram_intersection)
```
<table>
<thead>
<tr>
<th></th>
<th>dogs</th>
<th>cats</th>
</tr>
</thead>
<tbody>
<tr>
<td>dogs</td>
<td>1.0</td>
<td>0.3</td>
</tr>
<tr>
<td>cats</td>
<td>0.3</td>
<td>1.0</td>
</tr>
</tbody>
</table>
```

pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.count()

Compute count of group, excluding missing values.

Returns

Series or DataFrame  Count of values within each group.

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.
property DataFrameGroupBy.cov

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

ddf [int, default 1] Delta degrees of freedom. The divisor used in calculations is N - ddf, where N represents the number of elements.

New in version 1.1.0.

Returns

DataFrame The covariance matrix of the series of the DataFrame.

See also:

Series.cov Compute covariance with another Series.
core.window.ExponentialMovingWindow.cov Exponential weighted sample covariance.
core.window.Expanding.cov Expanding sample covariance.
core.window.Rolling.cov Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

Examples

```python
>>> df = pd.DataFrame([[1, 2], [0, 3], [2, 0], [1, 1]],
                  columns=['dogs', 'cats'])
>>> df.cov()
dogs    cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                   columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.998438</td>
<td>-0.020161</td>
<td>0.059277</td>
<td>-0.008943</td>
<td>0.014144</td>
</tr>
<tr>
<td>b</td>
<td>-0.020161</td>
<td>1.059352</td>
<td>-0.008543</td>
<td>-0.024738</td>
<td>0.009826</td>
</tr>
<tr>
<td>c</td>
<td>0.059277</td>
<td>-0.008543</td>
<td>1.010670</td>
<td>-0.001486</td>
<td>-0.000271</td>
</tr>
<tr>
<td>d</td>
<td>-0.008943</td>
<td>-0.024738</td>
<td>-0.001486</td>
<td>0.921297</td>
<td>-0.013692</td>
</tr>
<tr>
<td>e</td>
<td>0.014144</td>
<td>0.009826</td>
<td>-0.000271</td>
<td>-0.013692</td>
<td>0.977795</td>
</tr>
</tbody>
</table>

**Minimum number of periods**

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.316741</td>
<td>NaN</td>
<td>-0.150812</td>
</tr>
<tr>
<td>b</td>
<td>NaN</td>
<td>1.248003</td>
<td>0.191417</td>
</tr>
<tr>
<td>c</td>
<td>-0.150812</td>
<td>0.191417</td>
<td>0.895202</td>
</tr>
</tbody>
</table>
```

**pandas.core.groupby.DataFrameGroupBy.cumcount**

DataFrameGroupBy.cumcount(ascending=True)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```python
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

**Parameters**

- `ascending` [bool, default True] If False, number in reverse, from length of group - 1 to 0.

**Returns**

- `Series` Sequence number of each element within each group.

**See also:**

- `ngroup` Number the groups themselves.
Examples

```python
>>> df = pd.DataFrame([[a], [a], [a], [b], [b], [a]],
                    columns=['A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
0  0
1  1
2  2
3  0
4  1
5  3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0  3
1  2
2  1
3  1
4  0
5  0
dtype: int64
```

`pandas.core.groupby.DataFrameGroupBy.cummax`

DataFrameGroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.

**Returns**

Series or DataFrame

See also:

- Series.groupby Apply a function groupby to a Series.
- DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

`pandas.core.groupby.DataFrameGroupBy.cummin`

DataFrameGroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.

**Returns**

Series or DataFrame

See also:

- Series.groupby Apply a function groupby to a Series.
- DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.cumprod(*args, **kwargs)

Cumulative product for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.cumsum(*args, **kwargs)

Cumulative sum for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.describe

DataFrameGroupBy.describe(**kwargs)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

• 'all': All columns of the input will be included in the output.
• A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
• None (default): The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
• A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(exclude=['O'])`). To exclude pandas categorical columns, use `'category'`

• None (default): The result will exclude nothing.

`datetime_is_numeric` [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.
DataFrame.max Maximum of the values in the object.
DataFrame.min Minimum of the values in the object.
DataFrame.mean Mean of the values.
DataFrame.std Standard deviation of the observations.
DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
```
25%  1.5  
50%  2.0  
75%  2.5  
max  3.0  
dtype: float64

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
    count  4
    unique 3
top     a
freq    2
```

describe():

Describing a timestamp Series.

```python
>>> s = pd.Series([... np.datetime64("2000-01-01"),
                   ... np.datetime64("2010-01-01"),
                   ... np.datetime64("2010-01-01")
                   ... ])
>>> s.describe(datetime_is_numeric=True)
    count    3
mean 2006-09-01 08:00:00
min 2000-01-01 00:00:00
25% 2004-12-31 12:00:00
50% 2010-01-01 00:00:00
75% 2010-01-01 00:00:00
max 2010-01-01 00:00:00
```

describe():

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({
                      'categorical': pd.Categorical(['d', 'e', 'f']),
                      'numeric': [1, 2, 3],
                      'object': ['a', 'b', 'c']
                      })
>>> df.describe()
    numeric
    count   3.0
    mean    2.0
    std     1.0
    min     1.0
    25%     1.5
    50%     2.0
    75%     2.5
    max     3.0
```

describe():

Describing all columns of a DataFrame regardless of data type.

```python
```
>>> df.describe(include='all')
categorical   numeric   object
count         3          3.0        3
unique        3          NaN        3
top           f          NaN        a
freq          1          NaN        1
mean          NaN        2.0        NaN
std           NaN        1.0        NaN
min           NaN        1.0        NaN
25%           NaN        1.5        NaN
50%           NaN        2.0        NaN
75%           NaN        2.5        NaN
max           NaN        3.0        NaN

Describing a column from a DataFrame by accessing it as an attribute.

>>> df.numeric.describe()
count        3.0
mean         2.0
std          1.0
min          1.0
25%          1.5
50%          2.0
75%          2.5
max          3.0
Name: numeric, dtype: float64

Including only numeric columns in a DataFrame description.

>>> df.describe(include=[np.number])
numeric
count        3.0
mean         2.0
std          1.0
min          1.0
25%          1.5
50%          2.0
75%          2.5
max          3.0

Including only string columns in a DataFrame description.

>>> df.describe(include=[object])
object
count        3
unique       3
top          a
freq         1

Including only categorical columns from a DataFrame description.

>>> df.describe(include=['category'])
categorical
Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])

categorical object
    count     3   3
    unique    3   3
    top       f   a
    freq      1   1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])

categorical numeric
    count     3   3.0
    unique    3   NaN
    top       f   NaN
    freq      1   NaN
    mean      NaN  2.0
    std       NaN  1.0
    min       NaN  1.0
    25%       NaN  1.5
    50%       NaN  2.0
    75%       NaN  2.5
    max       NaN  3.0
```

**pandas.core.groupby.DataFrameGroupBy.diff**

**property DataFrameGroupBy.diff**

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is element in previous row).

**Parameters**

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [[0 or ‘index’, 1 or ‘columns’,] default 0] Take difference over rows (0) or columns (1).

**Returns**

- **DataFrame** First differences of the Series.

**See also:**

- **Dataframe.pct_change** Percent change over given number of periods.
- **Dataframe.shift** Shift index by desired number of periods with an optional time freq.
- **Series.diff** First discrete difference of object.
Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```python
In [2]: df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
                      'b': [1, 1, 2, 3, 5, 8],
                      'c': [1, 4, 9, 16, 25, 36]})

In [3]: df
Out[3]:
      a  b  c
0    1  1  1
1    2  1  4
2    3  2  9
3    4  3 16
4    5  5 25
5    6  8 36

In [4]: df.diff()
Out[4]:
      a    b    c
0  NaN  NaN  NaN
1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

Difference with previous column

```python
In [5]: df.diff(axis=1)
Out[5]:
      a    b    c
0  NaN  0.0  NaN
1  NaN -1.0  3.0
2  NaN -1.0  7.0
3  NaN -1.0 13.0
4  NaN  2.0  20.0
5  NaN  2.0  28.0
```

Difference with 3rd previous row

```python
In [6]: df.diff(periods=3)
Out[6]:
      a    b    c
0  NaN  NaN  NaN
1  NaN  NaN  NaN
2  NaN  NaN  NaN
3  3.0  2.0 15.0
4  3.0  4.0 21.0
5  3.0  6.0 27.0
```

Difference with following row
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
a
0  NaN
1  255.0

Overflow in input dtype

pandas.core.groupby.DataFrameGroupBy.ffill

DataFrameGroupBy.ffill(limit=None)
Forward fill the values.

Parameters

   limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.ffill Returns Series with minimum number of char in object.
DataFrame.ffill Object with missing values filled or None if inplace=True.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.fillna

property DataFrameGroupBy.fillna
Fill NA/NaN values using the specified method.

Parameters

   value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a
dict/Series/DataFrame of values specifying which value to use for each index (for a Se-
ries) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be
filled. This value cannot be a list.

   method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes
in reindexed Series pad / ffill: propagate last valid observation forward to next valid
backfill / bfill: use next valid observation to fill gap.

   axis [{0 or 'index', 1 or 'columns'}] Axis along which to fill missing values.

   inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on
this object (e.g., a no-copy slice for a column in a DataFrame).
limit  [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast  [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None  Object with missing values filled or None if inplace=True.

See also:

interpolate  Fill NaN values using interpolation.
reindex  Conform object to new index.
asfreq  Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
                        [3, 4, np.nan, 1],
                        [np.nan, np.nan, np.nan, np.nan],
                        [np.nan, 3, np.nan, 4]],
                        columns=list("ABCD"))
>>> df
   A    B    C    D
0  NaN  2.0  NaN  0.0
1  3.0  4.0  NaN  1.0
2  NaN  NaN  NaN  NaN
3  NaN  3.0  NaN  4.0

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0.0
1  3.0  4.0  0.0  1.0
2  0.0  0.0  0.0  0.0
3  0.0  3.0  0.0  4.0
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method="ffill")
   A    B    C    D
0  NaN  2.0  NaN  0.0
1  3.0  4.0  NaN  1.0
2  3.0  4.0  NaN  1.0
3  3.0  3.0  NaN  4.0
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
```

(continues on next page)
A B C D
0 0.0 2.0 2.0 0.0
1 3.0 4.0 2.0 1.0
2 0.0 1.0 2.0 3.0
3 0.0 3.0 2.0 4.0

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
   A   B   C   D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  NaN  1.0
2  NaN  1.0  NaN  3.0
3  NaN  3.0  NaN  4.0
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```python
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
   A   B   C   D
0  0.0  2.0  0.0  0.0
1  3.0  4.0  0.0  1.0
2  NaN  1.0  NaN  3.0
3  NaN  3.0  NaN  4.0
```

Note that column D is not affected since it is not present in df2.

**pandas.core.groupby.DataFrameGroupBy.filter**

`DataFrameGroupBy.filter(func, dropna=True, *args, **kwargs)`

Return a copy of a DataFrame excluding filtered elements.

Elements from groups are filtered if they do not satisfy the boolean criterion specified by func.

**Parameters**

- `func` [function] Function to apply to each subframe. Should return True or False.
- `dropna` [Drop groups that do not pass the filter. True by default;] If False, groups that evaluate False are filled with NaNs.

**Returns**

- `filtered` [DataFrame]

**Notes**

Each subframe is endowed the attribute ‘name’ in case you need to know which group you are working on.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.
Examples

```python
>>> df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
...             'foo', 'bar'],
...            'B': [1, 2, 3, 4, 5, 6],
...            'C': [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
   A  B  C
1  bar 2  5.0
3  bar 4  1.0
5  bar 6  9.0
```

pandas.core.groupby.DataFrameGroupBy.hist

**property DataFrameGroupBy.hist**

Make a histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

- **data** [DataFrame] The pandas object holding the data.
- **column** [str or sequence, optional] If passed, will be used to limit data to a subset of columns.
- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- **ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
- **sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- **sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
- **figsize** [tuple, optional] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.
- **layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
- **bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
**backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend.`

New in version 1.0.0.

**legend** [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

`matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

**Examples**

This example draws a histogram based on the length and width of some animals, displayed in three bins.

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

**pandas.core.groupby.DataFrameGroupBy.idxmax**

`DataFrameGroupBy.idxmax(axis=0, skipna=True)`

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

**Parameters**

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- `Series` Indexes of maxima along the specified axis.

**Raises**

- `ValueError`

  - If the row/column is empty

**See also:**

- `Series.idxmax` Return index of the maximum element.
Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
                      'co2_emissions': [37.2, 19.66, 1712],
                      'index': ['Pork', 'Wheat Products', 'Beef']})
```

```plaintext
<table>
<thead>
<tr>
<th></th>
<th>consumption</th>
<th>co2_emissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pork</td>
<td>10.51</td>
<td>37.20</td>
</tr>
<tr>
<td>Wheat Products</td>
<td>103.11</td>
<td>19.66</td>
</tr>
<tr>
<td>Beef</td>
<td>55.48</td>
<td>1712.00</td>
</tr>
</tbody>
</table>
```

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption    Wheat Products
co2_emissions  Beef
```

To return the index for the maximum value in each row, use `axis="columns"`.

```python
>>> df.idxmax(axis="columns")
Pork            co2_emissions
Wheat Products  consumption
Beef            co2_emissions
```

`pandas.core.groupby.DataFrameGroupBy.idxmin`

DataFrameGroupBy.\texttt{idxmin}(\texttt{axis=0}, \texttt{skipna=True})

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

- **Series** Indexes of minima along the specified axis.

Raises

- **ValueError**
  - If the row/column is empty
See also:

**Series.idxmin** Return index of the minimum element.

**Notes**

This method is the DataFrame version of `ndarray.argmin`.

**Examples**

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
                     'co2_emissions': [37.2, 19.66, 1712],
                     'index': ['Pork', 'Wheat Products', 'Beef'])
```

```py
<table>
<thead>
<tr>
<th></th>
<th>consumption</th>
<th>co2_emissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pork</td>
<td>10.51</td>
<td>37.20</td>
</tr>
<tr>
<td>Wheat Products</td>
<td>103.11</td>
<td>19.66</td>
</tr>
<tr>
<td>Beef</td>
<td>55.48</td>
<td>1712.00</td>
</tr>
</tbody>
</table>
```

By default, it returns the index for the minimum value in each column.

```python
>>> df.idxmin()
consumption  Pork
co2_emissions Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```python
>>> df.idxmin(axis="columns")
Pork  consumption
Wheat Products  co2_emissions
Beef  consumption
dtype: object
```

**pandas.core.groupby.DataFrameGroupBy.mad**

**property** `DataFrameGroupBy.mad`

Return the mean absolute deviation of the values over the requested axis.

**Parameters**

- `axis` ([index (0), columns (1)]) Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**Returns**

Series or DataFrame (if level specified)
DataFrameGroupBy.nunique
dropna=True

Return DataFrame with counts of unique elements in each position.

Parameters

dropna [bool, default True] Don’t include NaN in the counts.

Returns

nunique: DataFrame

Examples

```python
>>> df = pd.DataFrame({'id': ['spam', 'egg', 'egg', 'spam', 'ham', 'ham'],
                    'value1': [1, 5, 5, 2, 5, 5],
                    'value2': list('abbaxy'))

>>> df
   id  value1  value2
0  spam     1      a
1   egg     5      b
2   egg     5      b
3  spam     2      a
4   ham     5      x
5   ham     5      y

>>> df.groupby('id').nunique()
   value1  value2
id
egg    1     1
ham    1     2
spam   2     1

Check for rows with the same id but conflicting values:

```python
>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())
   id  value1  value2
0  spam     1      a
3  spam     2      a
4   ham     5      x
5   ham     5      y

pandas.core.groupby.DataFrameGroupBy.pad

DataFrameGroupBy.pad(limit=None)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.
See also:

- `Series.ffill` Returns Series with minimum number of char in object.
- `DataFrame.ffill` Object with missing values filled or None if inplace=True.
- `Series.fillna` Fill NaN values of a Series.
- `DataFrame.fillna` Fill NaN values of a DataFrame.

**pandas.core.groupby.DataFrameGroupBy.pct_change**

DataFrameGroupBy.pct_change(periods=1, fill_method='ffill', limit=None, freq=None, axis=0)

Calculate pct_change of each value to previous entry in group.

Returns

- `Series` or `DataFrame` Percentage changes within each group.

See also:

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.DataFrameGroupBy.plot**

property DataFrameGroupBy.plot

Class implementing the .plot attribute for groupby objects.

**pandas.core.groupby.DataFrameGroupBy.quantile**

DataFrameGroupBy.quantile(q=0.5, interpolation='linear')

Return group values at the given quantile, a la numpy.percentile.

Parameters

- `q` [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.

- `interpolation` [['linear', 'lower', 'higher', 'midpoint', 'nearest']] Method to use when the desired quantile falls between two points.

Returns

- `Series` or `DataFrame` Return type determined by caller of GroupBy object.

See also:

- `Series.quantile` Similar method for Series.
- `DataFrame.quantile` Similar method for DataFrame.
- `numpy.percentile` NumPy method to compute qth percentile.
Examples

```python
>>> df = pd.DataFrame([['a', 1], ['a', 2], ['a', 3],
                    ['b', 1], ['b', 3], ['b', 5]],
                   columns=['key', 'val'])
>>> df.groupby('key').quantile()
   key
  a  2.0
  b  3.0
```

`pandas.core.groupby.DataFrameGroupBy.rank`

`DataFrameGroupBy.rank(method='average', ascending=True, na_option='keep', pct=False, axis=0)`

Provide the rank of values within each group.

**Parameters**

- `method` ([{'average', 'min', 'max', 'first', 'dense'}, default 'average']
  - `average`: average rank of group.
  - `min`: lowest rank in group.
  - `max`: highest rank in group.
  - `first`: ranks assigned in order they appear in the array.
  - `dense`: like ‘min’, but rank always increases by 1 between groups.

- `ascending` [bool, default True] False for ranks by high (1) to low (N).

- `na_option` [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]
  - `keep`: leave NA values where they are.
  - `top`: smallest rank if ascending.
  - `bottom`: smallest rank if descending.

- `pct` [bool, default False] Compute percentage rank of data within each group.

- `axis` [int, default 0] The axis of the object over which to compute the rank.

**Returns**

`DataFrame with ranking of values within each group`

See also:

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame({
...     "group": ["a", "a", "a", "a", "b", "b", "b", "b"],
...     "value": [2, 4, 2, 3, 1, 2, 4, 1],
... })
... >>> df
   group value
  0    a     2
  1    a     4
  2    a     2
  3    a     3
  4    a     5
  5    b     1
  6    b     2
  7    b     4
  8    b     1
  9    b     5
>>> for method in ['average', 'min', 'max', 'dense', 'first']:
...     df[f'{method}_rank'] = df.groupby('group')['value'].rank(method)
... >>> df
   group value average_rank  min_rank  max_rank  dense_rank  first_rank
  0    a     2     1.5         1.0     2.0         1.0   1.0
  1    a     4     4.0         4.0     4.0         3.0   4.0
  2    a     2     1.5         1.0     2.0         1.0   2.0
  3    a     3     3.0         3.0     3.0         2.0   3.0
  4    a     5     5.0         5.0     5.0         4.0   5.0
  5    b     1     1.5         1.0     2.0         1.0   1.0
  6    b     2     3.0         3.0     3.0         2.0   3.0
  7    b     4     4.0         4.0     4.0         3.0   4.0
  8    b     1     1.5         1.0     2.0         1.0   2.0
  9    b     5     5.0         5.0     5.0         4.0   5.0
```

pandas.core.groupby.DataFrameGroupBy.resample

DataFrameGroupBy.resample(rule, *args, **kwargs)

Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string “string” -> “frequency”.

See the frequency aliases documentation for more details.

Parameters

- **rule** [str or DateOffset] The offset string or object representing target grouper conversion.
- ***args, **kwargs** Possible arguments are how, fill_method, limit, kind and on, and other arguments of TimeGrouper.

Returns

- Grouper Return a new grouper with our resampler appended.

See also:

- Grouper Specify a frequency to resample with when grouping by a key.
**DatetimeIndex.resample** Frequency conversion and resampling of time series.

### Examples

```python
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
   a    b
0 0 1
1 0 1
2 5 1
3 0 1

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> df.groupby('a').resample('3T').sum()
   a    b
   a
0 0 1
1 0 1
2 5 1
```

Upsample the series into 30 second bins.

```python
>>> df.groupby('a').resample('30S').sum()
   a    b
   a
0 0 1
1 0 1
2 0 1
3 0 1
4 0 1
5 5 1
```

Resample by month. Values are assigned to the month of the period.

```python
>>> df.groupby('a').resample('M').sum()
   a    b
   a
0 0 3
5 5 1
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> df.groupby('a').resample('3T', closed='right').sum()
   a    b
   a
0 1999-12-31 23:57:00 0 1
```
Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using
the right edge instead of the left.

```python
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
   a  b
0 0 2000-01-01 00:00:00  0  1
   5 2000-01-01 00:03:00  5  1
```

**pandas.core.groupby.DataFrameGroupBy.sample**

**DataFrameGroupBy.sample**(n=None, frac=None, replace=False, weights=None, random_state=None)

Return a random sample of items from each group.

You can use random_state for reproducibility.

New in version 1.1.0.

**Parameters**

- **n** [int, optional] Number of items to return for each group. Cannot be used with frac and must be no larger than the smallest group unless replace is True. Default is one if frac is None.
- **frac** [float, optional] Fraction of items to return. Cannot be used with n.
- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights** [list-like, optional] Default None results in equal probability weighting. If passed a list-like then values must have the same length as the underlying DataFrame or Series object and will be used as sampling probabilities after normalization within each group. Values must be non-negative with at least one positive element within each group.
- **random_state** [int, array-like, BitGenerator, np.random.RandomState, np.random.Generator, optional] If int, array-like, or BitGenerator, seed for random number generator. If np.random.RandomState or np.random.Generator, use as given.

Changed in version 1.4.0: np.random.Generator objects now accepted

**Returns**

- **Series or DataFrame** A new object of same type as caller containing items randomly sampled within each group from the caller object.

**See also:**

- DataFrame.sample Generate random samples from a DataFrame object.
- numpy.random.choice Generate a random sample from a given 1-D numpy array.
Examples

```python
>>> df = pd.DataFrame(
...     {
...         "a": ["red"] * 2 + ["blue"] * 2 + ["black"] * 2,  
...         "b": range(6)
...     }
... )
>>> df
  a   b
0 red 0
1 red 1
2 blue 2
3 blue 3
4 black 4
5 black 5
```

Select one row at random for each distinct value in column a. The `random_state` argument can be used to guarantee reproducibility:

```python
>>> df.groupby("a").sample(n=1, random_state=1)
  a   b
4 black 4
2 blue 2
1 red 1
```

Set `frac` to sample fixed proportions rather than counts:

```python
>>> df.groupby("a")["b"].sample(frac=0.5, random_state=2)
  5  5
  2  2
  0  0
Name: b, dtype: int64
```

Control sample probabilities within groups by setting weights:

```python
>>> df.groupby("a").sample(
...     n=1,
...     weights=[1, 1, 1, 0, 0, 1],
...     random_state=1,
... )
  a   b
5 black 5
2 blue 2
0 red 0
```

`pandas.core.groupby.DataFrameGroupBy.shift`

`DataFrameGroupBy.shift(periods=1, freq=None, axis=0, fill_value=None)`

Shift each group by periods observations.

If `freq` is passed, the index will be increased using the periods and the freq.

**Parameters**

- `periods` [int, default 1] Number of periods to shift.
- `freq` [str, optional] Frequency string.
axis  [axis to shift, default 0] Shift direction.

fill_value  [optional] The scalar value to use for newly introduced missing values.

Returns

Series or DataFrame  Object shifted within each group.

See also:

Index.shift  Shift values of Index.
tshift  Shift the time index, using the index’s frequency if available.

pandas.core.groupby.DataFrameGroupBy.size

DataFrameGroupBy.size()

Compute group sizes.

Returns

DataFrame or Series  Number of rows in each group as a Series if as_index is True or a
                      DataFrame if as_index is False.

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.skew

property DataFrameGroupBy.skew

Return unbiased skew over requested axis.

Normalized by N-1.

Parameters

axis  [[index (0), columns (1)]] Axis for the function to be applied on.

skipna  [bool, default True] Exclude NA/null values when computing the result.

level  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along
         a particular level, collapsing into a Series.

numeric_only  [bool, default None] Include only float, int, boolean columns. If None, will
              attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs  Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)
pandas.core.groupby.DataFrameGroupBy.take

**property** DataFrameGroupBy.take

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- **indices** *(array-like)* An array of ints indicating which positions to take.
- **axis** *
  - 0 or ‘index’,
  - 1 or ‘columns’,
  - None, default 0*
  The axis on which to select elements.
  
  0 means that we are selecting rows, 1 means that we are selecting columns.

- **is_copy** *(bool)* Before pandas 1.0, **is_copy=False** can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, **take** always returns a copy, and the keyword is therefore deprecated.

  Deprecated since version 1.0.0.

- **** **kwargs** For compatibility with **numpy.take()**. Has no effect on the output.

**Returns**

- **taken** *(same type as caller)* An array-like containing the elements taken from the object.

**See also:**

- **DataFrame.loc** Select a subset of a DataFrame by labels.
- **DataFrame.iloc** Select a subset of a DataFrame by positions.
- **numpy.take** Take elements from an array along an axis.

**Examples**

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                   ('parrot', 'bird', 24.0),
...                   ('lion', 'mammal', 80.5),
...                   ('monkey', 'mammal', np.nan)],
...                   columns=['name', 'class', 'max_speed'],
...                   index=[0, 2, 3, 1])
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
```

Take elements at indices 1 and 2 along the axis 1 (column selection).
We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
        name     class  max_speed
1   monkey  mammal         NaN
3    lion  mammal      80.5
```

---

**pandas.core.groupby.DataFrameGroupBy.tshift**

**property** DataFrameGroupBy.tshift

Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use shift instead.

**Parameters**

- `periods` [int] Number of periods to move, can be positive or negative.
- `freq` [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- `axis` [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Corresponds to the axis that contains the Index.

**Returns**

- `shifted` [Series/DataFrame]

**Notes**

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

**pandas.core.groupby.DataFrameGroupBy.value_counts**

DataFrameGroupBy.value_counts(subset=None, normalize=False, sort=True, ascending=False, dropna=True)

Return a Series or DataFrame containing counts of unique rows.

New in version 1.4.0.

**Parameters**

- `subset` [list-like, optional] Columns to use when counting unique combinations.
- `normalize` [bool, default False] Return proportions rather than frequencies.
- `sort` [bool, default True] Sort by frequencies.
- `ascending` [bool, default False] Sort in ascending order.
- `dropna` [bool, default True] Don’t include counts of rows that contain NA values.
Returns

**Series or DataFrame**  
Series if the groupby as_index is True, otherwise DataFrame.

See also:

- `DataFrame.value_counts`  
  Equivalent method on DataFrame.
- `SeriesGroupBy.value_counts`  
  Equivalent method on SeriesGroupBy.

Notes

- If the groupby as_index is True then the returned Series will have a MultiIndex with one level per input column.
- If the groupby as_index is False then the returned DataFrame will have an additional column with the `value_counts`. The column is labelled 'count' or 'proportion', depending on the `normalize` parameter.

By default, rows that contain any NA values are omitted from the result.

By default, the result will be in descending order so that the first element of each group is the most frequently-occurring row.

Examples

```python
>>> df = pd.DataFrame({
...     'gender': ['male', 'male', 'female', 'male', 'female', 'male'],
...     'education': ['low', 'medium', 'high', 'low', 'high', 'low'],
...     'country': ['US', 'FR', 'US', 'FR', 'FR', 'FR']
... })
```

```python
>>> df
   gender  education  country
0   male      low     US
1   male  medium     FR
2  female    high     US
3   male      low     FR
4  female    high     FR
5   male      low     FR
```

```python
>>> df.groupby('gender').value_counts()
   education  country
female      high    FR  1
              US  1
male        low    FR  2
             US  1
             medium    FR  1
dtype: int64
```

```python
>>> df.groupby('gender').value_counts(ascending=True)
   education  country
female      high    FR  1
              US  1
male        low    US  1
            medium    FR  1
```

(continues on next page)
>>> df.groupby('gender').value_counts(normalize=True)
gender          education  country  proportion
female          high        FR    0.50
              US          0.50
male            low         FR    0.50
              US          0.25
              medium     FR    0.25
dtype: float64

The following methods are available only for SeriesGroupBy objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SeriesGroupBy.hist</td>
<td>Draw histogram of the input series using matplotlib.</td>
</tr>
<tr>

<tr>
<td>SeriesGroupBy.value_counts(keepna)</td>
<td></td>
</tr>
</tbody>
</table>

SeriesGroupBy.is_monotonic_increasing
SeriesGroupBy.is_monotonic_decreasing

Return boolean if values in the object are monotonic_increasing or monotonic_decreasing.
**pandas.core.groupby.SeriesGroupBy.hist**

**property SeriesGroupBy.hist**

Draw histogram of the input series using matplotlib.

**Parameters**

- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **ax** [matplotlib axis object] If not passed, uses gca().
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels.
- **figsize** [tuple, default None] Figure size in inches by default.
- **bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- **backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

- **legend** [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs To be passed to the actual plotting function.

**Returns**

- **matplotlib.AxesSubplot** A histogram plot.

See also:

- `matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

**pandas.core.groupby.SeriesGroupBy.nlargest**

**SeriesGroupBy.nlargest**(n=5, keep=’first’)

Return the largest n elements.

**Parameters**

- **n** [int, default 5] Return this many descending sorted values.
- **keep** [{’first’, ’last’, ’all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of n elements:
  - **first**: return the first n occurrences in order of appearance.
  - **last**: return the last n occurrences in reverse order of appearance.
  - **all**: keep all occurrences. This can result in a Series of size larger than n.

**Returns**

- **Series**
Series  The \( n \) largest values in the Series, sorted in decreasing order.

See also:

Series.nsmallest  Get the \( n \) smallest elements.
Series.sort_values  Sort Series by values.
Series.head  Return the first \( n \) rows.

Notes

Faster than \( \text{.sort_values(ascending=False).head(n)} \) for small \( n \) relative to the size of the Series object.

Examples

```python
>>> countries_population = {
    "Italy": 59000000,
    "France": 65000000,
    "Malta": 4340000,
    "Maldives": 434000,
    "Brunei": 434000,
    "Iceland": 337000,
    "Nauru": 11300,
    "Tuvalu": 11300,
    "Anguilla": 11300,
    "Montserrat": 5200
}

>>> s = pd.Series(countries_population)
```

The \( n \) largest elements where \( n=5 \) by default.

```python
>>> s.nlargest()
France  65000000
Italy   59000000
Malta   4340000
Maldives 434000
Brunei  434000
Iceland 337000
Nauru   11300
Tuvalu  11300
Anguilla 11300
Montserrat 5200
dtype: int64
```

The \( n \) largest elements where \( n=3 \). Default keep value is ‘first’ so Malta will be kept.

```python
>>> s.nlargest(3)
France  65000000
Italy   59000000
Malta   4340000
Maldives 434000
Brunei  434000
Iceland 337000
Nauru   11300
Tuvalu  11300
Anguilla 11300
Montserrat 5200
dtype: int64
```

The \( n \) largest elements where \( n=3 \) and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.
>>> s.nlargest(3, keep='last')
France    65000000
Italy     59000000
Brunei    434000
dtype: int64

The $n$ largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

>>> s.nlargest(3, keep='all')
France    65000000
Italy     59000000
Malta     434000
Maldives  434000
Brunei    434000
dtype: int64

pandas.core.groupby.SeriesGroupBy.nsmallest

SeriesGroupBy.nsmallest($n=5$, keep='first')
Return the smallest $n$ elements.

Parameters

- $n$ [int, default 5] Return this many ascending sorted values.
- keep [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of $n$ elements:
  - first: return the first $n$ occurrences in order of appearance.
  - last: return the last $n$ occurrences in reverse order of appearance.
  - all: keep all occurrences. This can result in a Series of size larger than $n$.

Returns

Series The $n$ smallest values in the Series, sorted in increasing order.

See also:

Series.nlargest Get the $n$ largest elements.
Series.sort_values Sort Series by values.
Series.head Return the first $n$ rows.

Notes

Faster than .sort_values().head($n$) for small $n$ relative to the size of the Series object.
Examples

```python
>>> countries_population = {
    "Italy": 59000000, "France": 65000000,
    "Brunei": 434000, "Malta": 434000,
    "Maldives": 434000, "Iceland": 337000,
    "Nauru": 11300, "Tuvalu": 11300,
    "Anguilla": 11300, "Montserrat": 5200
}

>>> s = pd.Series(countries_population)

s

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Italy</td>
<td>59000000</td>
</tr>
<tr>
<td>France</td>
<td>65000000</td>
</tr>
<tr>
<td>Brunei</td>
<td>434000</td>
</tr>
<tr>
<td>Malta</td>
<td>434000</td>
</tr>
<tr>
<td>Maldives</td>
<td>434000</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
</tr>
<tr>
<td>Nauru</td>
<td>11300</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
</tr>
<tr>
<td>Montserrat</td>
<td>5200</td>
</tr>
</tbody>
</table>

The `n` smallest elements where `n=5` by default.

```python
>>> s.nsmallest()

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Montserrat</td>
<td>5200</td>
</tr>
<tr>
<td>Nauru</td>
<td>11300</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
</tr>
</tbody>
</table>

The `n` smallest elements where `n=3`. Default `keep` value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Montserrat</td>
<td>5200</td>
</tr>
<tr>
<td>Nauru</td>
<td>11300</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
</tr>
</tbody>
</table>

The `n` smallest elements where `n=3` and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Montserrat</td>
<td>5200</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
</tr>
</tbody>
</table>

The `n` smallest elements where `n=3` with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest(3, keep='all')

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Montserrat</td>
<td>5200</td>
</tr>
<tr>
<td>Nauru</td>
<td>11300</td>
</tr>
</tbody>
</table>

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.4.3

Tuvalu 11300
Anguilla 11300
dtype: int64

pandas.core.groupby.SeriesGroupBy.nunique

SeriesGroupBy.nunique(dropna=True)
Return number of unique elements in the group.

Returns
Series Number of unique values within each group.

pandas.core.groupby.SeriesGroupBy.unique

property SeriesGroupBy.unique
Return unique values of Series object.
Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns
ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:
unique Top-level unique method for any 1-d array-like object.
Index.unique Return Index with unique values from an Index object.

Notes
Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new
ExtensionArray of that type with just the unique values is returned. This includes
• Categorical
• Period
• Datetime with Timezone
• Interval
• Sparse
• IntegerNA
See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
... for _ in range(3)]).unique()
<DatetimeArray>
```

(continues on next page)
An Categorical will return categories in the order of appearance and with the same dtype.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'), ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

### pandas.core.groupby.SeriesGroupBy.value_counts

`SeriesGroupBy.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)`

### pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing

`property SeriesGroupBy.is_monotonic_increasing`

Alias for `is_monotonic`.

### pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing

`property SeriesGroupBy.is_monotonic_decreasing`

Return boolean if values in the object are monotonic_decreasing.

**Returns**

`bool`

The following methods are available only for `DataFrameGroupBy` objects:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrameGroupBy.corrwith</code></td>
<td>Compute pairwise correlation.</td>
</tr>
<tr>
<td><code>DataFrameGroupBy.boxplot</code></td>
<td>Make box plots from <code>DataFrameGroupBy</code> data.</td>
</tr>
</tbody>
</table>

### pandas.core.groupby.DataFrameGroupBy.corrwith

`property DataFrameGroupBy.corrwith`

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters**

- `other` [DataFrame, Series] Object with which to compute correlations.
- `axis` [[0 or ‘index’, 1 or ‘columns’], default 0] The axis to use. 0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise.
- `drop` [bool, default False] Drop missing indices from result.
- `method` [['pearson', ‘kendall’, ‘spearman’] or callable] Method of correlation:
• pearson : standard correlation coefficient
• kendall : Kendall Tau correlation coefficient
• spearman : Spearman rank correlation

• callable: callable with input two 1d ndarrays and returning a float.

Returns
Series Pairwise correlations.

See also:
DataFrame.corr Compute pairwise correlation of columns.

pandas.core.groupby.DataFrameGroupBy.boxplot

DataFrameGroupBy.boxplot(subplots=True, column=None, fontsize=None, rot=0, grid=True, ax=None, figsize=None, layout=None, sharex=False, sharey=True, backend=None, **kwargs)

Make box plots from DataFrameGroupBy data.

Parameters

grouped [Grouped DataFrame]
subplots [bool]
  • False - no subplots will be used
  • True - create a subplot for each group.
column [column name or list of names, or vector] Can be any valid input to groupby.
fontsize [int or str]
rot [label rotation angle]
grid [Setting this to True will show the grid]
ax [Matplotlib axis object, default None]
figsize [A tuple (width, height) in inches]
layout [tuple (optional)] The layout of the plot: (rows, columns).
sharex [bool, default False] Whether x-axes will be shared among subplots.
sharey [bool, default True] Whether y-axes will be shared among subplots.
backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib’s boxplot function.

Returns
dict of key/value = group key/DataFrame.boxplot return value
or DataFrame.boxplot return value in case subplots=figures=False
Examples

You can create boxplots for grouped data and show them as separate subplots:

```python
>>> import itertools
>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])
>>> data = np.random.randn(len(index),4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>> grouped = df.groupby(level='lvl1')
>>> grouped.boxplot(rot=45, fontsize=12, figsize=(8,10))
```

The subplots=False option shows the boxplots in a single figure.

```python
>>> grouped.boxplot(subplots=False, rot=45, fontsize=12)
```

3.11 Resampling

Resampler objects are returned by resample calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

3.11.1 Indexing, iteration

```
Resampler.__iter__()  Groupby iterator.
Resampler.groups  Dict {group name -> group labels}.
Resampler.indices  Dict {group name -> group indices}.
Resampler.get_group(name[, obj])  Construct DataFrame from group with provided name.
```

```python
pandas.core.resample.Resampler.__iter__

Resampler.__iter__()

Groupby iterator.

Returns

Generator yielding sequence of (name, subsetted object)
for each group

pandas.core.resample.Resampler.groups

property Resampler.groups

Dict {group name -> group labels}.
```
pandas.core.resample.Resampler.indices

property Resampler.indices
   Dict {group name -> group indices}.

pandas.core.resample.Resampler.get_group

Resampler.get_group(name, obj=None)
   Construct DataFrame from group with provided name.

   Parameters
      name [object] The name of the group to get as a DataFrame.
      obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

   Returns
      group [same type as obj]

3.11.2 Function application

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resampler.apply(func)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>Resampler.aggregate(func)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>Resampler.transform(arg, *args, **kwargs)</td>
<td>Call function producing a like-indexed Series on each group and return a Series with the transformed values.</td>
</tr>
<tr>
<td>Resampler.pipe(func, *args, **kwargs)</td>
<td>Apply a function func with arguments to this Resampler object and return the function's result.</td>
</tr>
</tbody>
</table>

pandas.core.resample.Resampler.apply

Resampler.apply(func=None, *args, **kwargs)
   Aggregate using one or more operations over the specified axis.

   Parameters
      func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

      Accepted combinations are:
      • function
      • string function name
      • list of functions and/or function names, e.g. [np.sum, 'mean']
      • dict of axis labels -> functions, function names or list of such.

      *args Positional arguments to pass to func.

      **kwargs Keyword arguments to pass to func.

   Returns
      scalar, Series or DataFrame The return can be:
• scalar: when Series.agg is called with single function
• Series: when DataFrame.agg is called with a single function
• DataFrame: when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:
DataFrame.groupby.aggregate Aggregate using callable, string, dict, or list of string/callables.
DataFrame.resample.transform Transforms the Series on each group based on the given function.
DataFrame.aggregate Aggregate using one or more operations over the specified axis.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5],
                 index=pd.date_range('20130101', periods=5, freq='s'))
>>> s
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64

>>> r = s.resample('2s')

>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64

>>> r.agg(['sum', 'mean', 'max'])
sum  mean  max
2013-01-01 00:00:00 3.0 1.5 2
2013-01-01 00:00:02 7.0 3.5 4
2013-01-01 00:00:04 5.0 5.0 5

>>> r.agg({'result': lambda x: x.mean() / x.std(),
          'total': np.sum})
result  total
2013-01-01 00:00:00 2.121320 3
2013-01-01 00:00:02 4.949747 7
2013-01-01 00:00:04 NaN 5
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> r.agg(average="mean", total="sum")
   average  total
2013-01-01 00:00:00   1.5   3
2013-01-01 00:00:02   3.5   7
2013-01-01 00:00:04   5.0   5
```

```python
import pandas as pd
r = pd.Series([1.5, 3.5, 5.0], index=[pd.Timestamp('2013-01-01 00:00:00'),
                                     pd.Timestamp('2013-01-01 00:00:02'),
                                     pd.Timestamp('2013-01-01 00:00:04')])
```

```python
pandas.core.resample.Resampler.aggregate

Resampler.aggregate(func=None, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

    Accepted combinations are:
    - function
    - string function name
    - list of functions and/or function names, e.g. `[np.sum, 'mean']`
    - dict of axis labels -> functions, function names or list of such.

- **args** Positional arguments to pass to `func`.

- **kwargs** Keyword arguments to pass to `func`.

**Returns**

- **scalar, Series or DataFrame** The return can be:
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**

- `DataFrame.groupby.aggregate` Aggregate using callable, string, dict, or list of string/callables.
- `DataFrame.resample.transform` Transforms the Series on each group based on the given function.
- `DataFrame.aggregate` Aggregate using one or more operations over the specified axis.

**Notes**

- `agg` is an alias for `aggregate`. Use the alias.

- Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

- A passed user-defined-function will be passed a Series for evaluation.

---

3.11. Resampling 2617
Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5],
                 index=pd.date_range('20130101', periods=5, freq='S'))
>>> s
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64

>>> r = s.resample('2S')
```

```python
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum', 'mean', 'max'])
         sum  mean  max
2013-01-01 00:00:00    3  1.5   2
2013-01-01 00:00:02    7  3.5   4
2013-01-01 00:00:04    5  5.0   5
```

```python
>>> r.agg({'result': lambda x: x.mean() / x.std(),
          'total': np.sum})
                      result  total
2013-01-01 00:00:00 2.121320   3
2013-01-01 00:00:02 4.949747   7
2013-01-01 00:00:04   NaN    5
```

```python
>>> r.agg(average="mean", total="sum")
         average  total
2013-01-01 00:00:00     1.5    3
2013-01-01 00:00:02     3.5    7
2013-01-01 00:00:04     5.0    5
```

**pandas.core.resample.Resampler.transform**

Resampler.transform(arg, *args, **kwargs)

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

**Parameters**

- **arg** [function] To apply to each group. Should return a Series with the same index.

**Returns**

- **transformed** [Series]
Examples

```python
>>> s = pd.Series([1, 2],
...                index=pd.date_range('20180101',
...                                    periods=2,
...                                    freq='1h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
Freq: H, dtype: int64

>>> resampled = s.resample('15min')
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
2018-01-01 00:00:00    NaN
2018-01-01 01:00:00    NaN
Freq: H, dtype: float64
```

dataframe

```python
pandas.core.resample.Resampler.pipe

Resampler.pipe(func, *args, **kwargs)

Apply a function func with arguments to this Resampler object and return the function’s result.

Use .pipe when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group'))), arg1=a, arg2=b, arg3=c)
```n
You can write

```python
>>> (df.groupby('group')
...     .pipe(f)
...     .pipe(g, arg1=a)
...     .pipe(h, arg2=b, arg3=c))

which is much more readable.

Parameters

- **func** [callable or tuple of (callable, str)] Function to apply to this Resampler object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Resampler object.
- **args** [iterable, optional] Positional arguments passed into func.
- **kwargs** [dict, optional] A dictionary of keyword arguments passed into func.

Returns

- **object** [the return type of func.]

See also:

- Series.pipe Apply a function with arguments to a series.
- DataFrame.pipe Apply a function with arguments to a dataframe.
- apply Apply function to each group instead of to the full Resampler object.
Notes

See more here

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
                   index=pd.date_range('2012-08-02', periods=4))
>>> df
   A
2012-08-02    1
2012-08-03    2
2012-08-04    3
2012-08-05    4

To get the difference between each 2-day period’s maximum and minimum value in one pass, you can do

```python
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
   A
2012-08-02    1
2012-08-04    1
```

3.11.3 Upsampling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resampler.ffill([limit])</td>
<td>Forward fill the values.</td>
</tr>
<tr>
<td>Resampler.backfill([limit])</td>
<td>Backward fill the new missing values in the resampled data.</td>
</tr>
<tr>
<td>Resampler.bfill([limit])</td>
<td>Backward fill the new missing values in the resampled data.</td>
</tr>
<tr>
<td>Resampler.pad([limit])</td>
<td>Forward fill the values.</td>
</tr>
<tr>
<td>Resampler.nearest([limit])</td>
<td>Resample by using the nearest value.</td>
</tr>
<tr>
<td>Resampler.fillna(method[, limit])</td>
<td>Fill missing values introduced by upsampling.</td>
</tr>
<tr>
<td>Resampler.asfreq([fill_value])</td>
<td>Return the values at the new freq, essentially a reindex.</td>
</tr>
<tr>
<td>Resampler.interpolate([method, axis, limit, ...])</td>
<td>Interpolate values according to different methods.</td>
</tr>
</tbody>
</table>

**pandas.core.resample.Resampler.ffill**

Resampler.ffill(limit=None)

Forward fill the values.

**Parameters**

- limit [int, optional] Limit of how many values to fill.

**Returns**

An upsampled Series.

See also:

- Series.fillna Fill NA/NaN values using the specified method.
- DataFrame.fillna Fill NA/NaN values using the specified method.
pandas.core.resample.Resampler.backfill

Resampler.backfill(limit=None)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

- **limit** [int, optional] Limit of how many values to fill.

Returns

- **Series, DataFrame** An upsampled Series or DataFrame with backward filled NaN values.

See also:

- **bfill** Alias of backfill.
- **fillna** Fill NaN values using the specified method, which can be ‘backfill’.
- **nearest** Fill NaN values with nearest neighbor starting from center.
- **ffill** Forward fill NaN values.
- **Series.fillna** Fill NaN values in the Series using the specified method, which can be ‘backfill’.
- **DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```python
>>> s.resample('30min').bfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').bfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00   NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
```

(continues on next page)
Resampling a DataFrame that has missing values:

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
>>> df
          a  b
2018-01-01 2.0 1
2018-01-01 NaN 3
2018-01-01 6.0 5

>>> df.resample('30min').bfill()
          a  b
2018-01-01 2.0 1
2018-01-01 NaN 3
2018-01-01 6.0 5
2018-01-01 6.0 5

>>> df.resample('15min').bfill(limit=2)
          a  b
2018-01-01 2.0 1.0
2018-01-01 NaN NaN
2018-01-01 NaN 3.0
2018-01-01 NaN 3.0
2018-01-01 NaN 3.0
2018-01-01 NaN 5.0
2018-01-01 NaN 5.0
2018-01-01 6.0 5.0
2018-01-01 6.0 5.0
2018-01-01 6.0 5.0
```

`pandas.core.resample.Resampler.bfill`

Resampler.bfill(limit=None)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

**Parameters**

- **limit** [int, optional] Limit of how many values to fill.

**Returns**
Series, DataFrame  An upsampled Series or DataFrame with backward filled NaN values.

See also:

bfill  Alias of backfill.
fillna  Fill NaN values using the specified method, which can be ‘backfill’.
nearest  Fill NaN values with nearest neighbor starting from center.
ffill  Forward fill NaN values.
Series.fillna  Fill NaN values in the Series using the specified method, which can be ‘backfill’.
DataFrame.fillna  Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

2018-01-01 02:00:00 6.0 5.0
```

**pandas.core.resample.Resampler.pad**

Resampler.pad(limit=None)

Forward fill the values.

Parameters

- **limit** [int, optional] Limit of how many values to fill.

Returns

An upsampled Series.

See also:

- **Seriesfillna** Fill NA/NaN values using the specified method.
- **DataFramefillna** Fill NA/NaN values using the specified method.

**pandas.core.resample.Resampler.nearest**

Resampler.nearest(limit=None)

Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The nearest method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If limit is given, fill only this many values in each direction for each of the original values.

Parameters
limit  [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame  An upsampled Series or DataFrame with NaN values filled with their nearest value.

See also:

backfill  Backward fill the new missing values in the resampled data.

pad  Forward fill NaN values.

Examples

```python
>>> s = pd.Series([1, 2],
...                 index=pd.date_range('20180101',
...                                        periods=2,
...                                        freq='1h'))
>>> s
2018-01-01 00:00:00  1
2018-01-01 01:00:00  2
Freq: H, dtype: int64

>>> s.resample('15min').nearest()
2018-01-01 00:00:00  1
2018-01-01 00:15:00  1
2018-01-01 00:30:00  2
2018-01-01 00:45:00  2
2018-01-01 01:00:00  2
Freq: 15T, dtype: int64
```

Limit the number of upsampled values imputed by the nearest:

```python
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00  1.0
2018-01-01 00:15:00  1.0
2018-01-01 00:30:00  NaN
2018-01-01 00:45:00  2.0
2018-01-01 01:00:00  2.0
Freq: 15T, dtype: float64
```

pandas.core.resample.Resampler.fillna

Resampler.fillna(method, limit=None)

Fill missing values introduced by up sampling.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

Parameters

method  [{'pad', 'backfill', 'ffill', 'bfill', 'nearest'}] Method to use for filling holes in resampled data

- 'pad' or 'ffill': use previous valid observation to fill gap (forward fill).
• ‘backfill’ or ‘bfill’: use next valid observation to fill gap.
• ‘nearest’: use nearest valid observation to fill gap.

**limit** [int, optional] Limit of how many consecutive missing values to fill.

**Returns**

Series or DataFrame An upsampled Series or DataFrame with missing values filled.

**See also:**

*bfill* Backward fill NaN values in the resampled data.
*ffill* Forward fill NaN values in the resampled data.
*nearest* Fill NaN values in the resampled data with nearest neighbor starting from center.
*interpolate* Fill NaN values using interpolation.
*Series.fillna* Fill NaN values in the Series using the specified method, which can be ‘bfill’ and ‘ffill’.
*DataFrame.fillna* Fill NaN values in the DataFrame using the specified method, which can be ‘bfill’ and ‘ffill’.

**References**

[1]

**Examples**

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00  1
2018-01-01 01:00:00  2
2018-01-01 02:00:00  3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```python
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 2.0
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 NaN
2018-01-01 00:30:00 2.0
2018-01-01 00:45:00 2.0
2018-01-01 01:00:00 2.0
2018-01-01 01:15:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 01:45:00 3.0
2018-01-01 02:00:00 3.0
Freq: 15T, dtype: float64

>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 1
2018-01-01 01:00:00 2
2018-01-01 01:30:00 2
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64

>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64

Missing values present before the upsampling are not affected.

>>> sm = pd.Series([1, None, 3],
... index=pd.date_range('20180101', periods=3, freq='h'))
>>> sm
2018-01-01 00:00:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 02:00:00 3.0
Freq: H, dtype: float64

>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64

>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0

(continues on next page)
Freq: 30T, dtype: float64

```
sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00  1.0
2018-01-01 00:30:00  NaN
2018-01-01 01:00:00  NaN
2018-01-01 01:30:00  3.0
2018-01-01 02:00:00  3.0
Freq: 30T, dtype: float64
```

Dataframe resampling is done column-wise. All the same options are available.

```python
df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                  index=pd.date_range('20180101', periods=3,
                                       freq='h'))
```

```python
df.resample('30min').fillna("bfill")
a  b
2018-01-01 00:00:00 2.0 1
2018-01-01 00:30:00 NaN 3
2018-01-01 01:00:00 6.0 5
2018-01-01 01:30:00 6.0 5
```

```
pandas.core.resample.Resampler.asfreq
Resampler.asfreq(fill_value=None)
Return the values at the new freq, essentially a reindex.
Parameters
    fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note
                this does not fill NaNs that already were present).
Returns
    DataFrame or Series Values at the specified freq.
See also:
    Series.asfreq Convert TimeSeries to specified frequency.
    DataFrame.asfreq Convert TimeSeries to specified frequency.
```
**pandas.core.resample.Resampler.interpolate**

**Resampler.interpolate**(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)

Interpolate values according to different methods.

Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

**Parameters**

- **method** [str, default ‘linear’] Interpolation technique to use. One of:
  - ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
  - ‘index’, ‘values’: use the actual numerical values of the index.
  - ‘pad’: Fill in NaNs using existing values.
  - ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method=’polynomial’, order=5).
  - ‘from_derivatives’: Refers to scipy.interpolate.BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

- **limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

- **inplace** [bool, default False] Update the data in place if possible.

- **limit_direction** [{‘forward’, ‘backward’, ‘both’}, Optional] Consecutive NaNs will be filled in this direction.

**If limit is specified:**

- If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
  - If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

**If ‘limit’ is not specified:**

- If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
  - else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

- **limit_area** [{None, ‘inside’, ‘outside’}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.
  - None: No fill restriction.
  - ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).

**downcast** [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

````**kwargs```` [optional] Keyword arguments to pass on to the interpolating function.

**Returns**

Series or DataFrame or None  Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

**See also:**

fillna   Fill missing values using different methods.
scipy.interpolate.Akima1DInterpolator   Piecewise cubic polynomials (Akima interpolator).
scipy.interpolate.BPoly.from_derivatives   Piecewise polynomial in the Bernstein basis.
scipy.interpolate.interp1d   Interpolate a 1-D function.
scipy.interpolate.KroghInterpolator   Interpolate polynomial (Krogh interpolator).
scipy.interpolate.PchipInterpolator   PCHIP 1-d monotonic cubic interpolation.
scipy.interpolate.CubicSpline   Cubic spline data interpolator.

**Notes**

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

**Examples**

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0 0.0
1 1.0
2 NaN
3 3.0
dtype: float64
>>> s.interpolate()
0 0.0
1 1.0
2 2.0
3 3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ...
                   "fill_two_more", np.nan, np.nan, np.nan,
                   ... 4.71, np.nan])
>>> s
0   NaN
1   single_one
2   NaN
3   fill_two_more
4   NaN
```

(continues on next page)
Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).

```python
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```python
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
                     ...                   (np.nan, 2.0, np.nan, np.nan),
                     ...                   (2.0, 3.0, np.nan, 9.0),
                     ...                   (np.nan, 4.0, -4.0, 16.0)],
                     ... columns=list('abcd'))
>>> df
   a     b     c     d
0  0.0  NaN  -1.0   1.0
1  NaN   2.0  NaN  NaN
2  2.0   3.0  NaN   9.0
3  NaN   4.0 -4.0  16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a     b     c     d
0  0.0  NaN  -1.0   1.0
1  1.0  2.0  -2.0   5.0
2  2.0  3.0  -3.0   9.0
3  2.0  4.0 -4.0  16.0
```

Using polynomial interpolation.
```python
>>> df['d'].interpolate(method='polynomial', order=2)
0   1.0
1   4.0
2   9.0
3  16.0
Name: d, dtype: float64
```

#### pandas.core.resample.Resampler.count

`Resampler.count()`  
Compute count of group, excluding missing values.  

**Returns**  
Series or DataFrame  Count of values within each group.

**See also:**  
Series.groupby  Apply a function groupby to a Series.  
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.
pandas.core.resample.Resampler.nunique

Resampler.nunique(_method='nunique')

Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.resample.Resampler.first

Resampler.first(_method='first', min_count=0, *args, **kwargs)

Compute first of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.resample.Resampler.last

Resampler.last(_method='last', min_count=0, *args, **kwargs)

Compute last of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed last of values within each group.

pandas.core.resample.Resampler.max

Resampler.max(_method='max', min_count=0, *args, **kwargs)

Compute max of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed max of values within each group.
pandas.core.resample.Resampler.mean

Resampler.mean(_method='mean', *args, **kwargs)

Compute mean of groups, excluding missing values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting compute.use_numba

New in version 1.4.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.4.0.

Returns

pandas.Series or pandas.DataFrame

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5],
...                    'C': [1, 2, 1, 1, 2], columns=['A', 'B', 'C'])

Groupby one column and return the mean of the remaining columns in each group.

>>> df.groupby('A').mean()
   B   C
A
1  3.0  1.333333
2  4.0  1.500000

Groupby two columns and return the mean of the remaining column.

>>> df.groupby(['A', 'B']).mean()
   C
   A B
1  2.0  2.0
2  4.0  1.0

(continues on next page)
Groupby one column and return the mean of only particular column in the group.

```python
>>> df.groupby('A')['B'].mean()
A  
1  3.0  
2  4.0  
Name: B, dtype: float64
```

**pandas.core.resample.Resampler.median**

`Resampler.median(_method='median', *args, **kwargs)`

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Parameters**

- `numeric_only` [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- Series or DataFrame Median of values within each group.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.resample.Resampler.min**

`Resampler.min(_method='min', min_count=0, *args, **kwargs)`

Compute min of group values.

**Parameters**

- `numeric_only` [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- `min_count` [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

- Series or DataFrame Computed min of values within each group.
pandas.core.resample.Resampler.ohlc

Resampler.ohlc(_method='ohlc', *args, **kwargs)

Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame  Open, high, low and close values within each group.

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.prod

Resampler.prod(_method='prod', min_count=0, *args, **kwargs)

Compute prod of group values.

Parameters

numeric_only  [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count  [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed prod of values within each group.

pandas.core.resample.Resampler.size

Resampler.size()

Compute group sizes.

Returns

DataFrame or Series  Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.sem

Resampler.sem(_method='sem', *args, **kwargs)

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof  [int, default 1] Degrees of freedom.

Returns

Series or DataFrame  Standard error of the mean of values within each group.

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.std

Resampler.std(ddof=1, *args, **kwargs)
Compute standard deviation of groups, excluding missing values.
Parameters
ddof [int, default 1] Degrees of freedom.
Returns
Dataframe or Series Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

Resampler.sum(_method='sum', min_count=0, *args, **kwargs)
Compute sum of group values.
Parameters
numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
Returns
Series or DataFrame Computed sum of values within each group.

pandas.core.resample.Resampler.var

Resampler.var(ddof=1, *args, **kwargs)
Compute variance of groups, excluding missing values.
Parameters
ddof [int, default 1] Degrees of freedom.
Returns
Dataframe or Series Variance of values within each group.

pandas.core.resample.Resampler.quantile

Resampler.quantile(q=0.5, **kwargs)
Return value at the given quantile.
Parameters
q [float or array-like, default 0.5 (50% quantile)]
Returns
Dataframe or Series Quantile of values within each group.
See also:
Series.quantile Return a series, where the index is q and the values are the quantiles.
DataFrame.quantile  Return a DataFrame, where the columns are the columns of self, and the values are the quantiles.

DataFrameGroupBy.quantile  Return a DataFrame, where the columns are groupby columns, and the values are its quantiles.

3.12 Style

Styler objects are returned by pandas.DataFrame.style.

3.12.1 Styler constructor

Styler(data[, precision, table_styles, ...])  Helps style a DataFrame or Series according to the data with HTML and CSS.

Styler.from_custom_template(searchpath[, ...])  Factory function for creating a subclass of Styler.

pandas.io.formats.style.Styler

class pandas.io.formats.style.Styler(data, precision=None, table_styles=None, uuid=None, caption=None, table_attributes=None, cell_ids=True, na_rep=None, uuid_len=5, decimal=None, thousands=None, escape=None, formatter=None)

Helps style a DataFrame or Series according to the data with HTML and CSS.

Parameters

  data  [Series or DataFrame] Data to be styled - either a Series or DataFrame.

  precision  [int, optional] Precision to round floats to. If not given defaults to pandas.options.styler.format.precision.

  Changed in version 1.4.0.

  table_styles  [list-like, default None] List of {selector: (attr, value)} dicts; see Notes.

  uuid  [str, default None] A unique identifier to avoid CSS collisions; generated automatically.

  caption  [str, tuple, default None] String caption to attach to the table. Tuple only used for LaTeX dual captions.

  table_attributes  [str, default None] Items that show up in the opening <table> tag in addition to automatic (by default) id.

  cell_ids  [bool, default True] If True, each cell will have an id attribute in their HTML tag.

  The id takes the form T_<uuid>_<row><num_row>_<col><num_col> where <uuid> is the unique identifier, <num_row> is the row number and <num_col> is the column number.

  na_rep  [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied, and falls back to pandas.options.styler.format.na_rep.

  New in version 1.0.0.

  uuid_len  [int, default 5] If uuid is not specified, the length of the uuid to randomly generate expressed in hex characters, in range [0, 32].

  New in version 1.2.0.
decimal  [str, optional] Character used as decimal separator for floats, complex and integers. If not given uses pandas.options.styler.format.decimal. New in version 1.3.0.

thousands  [str, optional, default None] Character used as thousands separator for floats, complex and integers. If not given uses pandas.options.styler.format.thousands. New in version 1.3.0.

escape  [str, optional] Use ‘html’ to replace the characters &, <, >, ' , and " in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters & , %, $, #, _, { }, ~, ^, and \ in the cell display string with LaTeX-safe sequences. If not given uses pandas.options.styler.format.escape. New in version 1.3.0.

formatter  [str, callable, dict, optional] Object to define how values are displayed. See Styler.format. If not given uses pandas.options.styler.format.formatter. New in version 1.4.0.

See also:

DataFrame.style Return a Styler object containing methods for building a styled HTML representation for the DataFrame.

Notes

Most styling will be done by passing style functions into Styler.apply or Styler.applymap. Style functions should return values with strings containing CSS ‘attr: value’ that will be applied to the indicated cells.

If using in the Jupyter notebook, Styler has defined a _repr_html_ to automatically render itself. Otherwise call Styler.to_html to get the generated HTML.

CSS classes are attached to the generated HTML

• Index and Column names include index_name and level<k> where k is its level in a MultiIndex
• Index label cells include
  – row_heading
  – row<n> where n is the numeric position of the row
  – level<k> where k is the level in a MultiIndex
• Column label cells include * col_heading * col<n> where n is the numeric position of the column *
  level<k> where k is the level in a MultiIndex
• Blank cells include blank
• Data cells include data
• Trimmed cells include col_trim or row_trim.

Any, or all, or these classes can be renamed by using the css_class_names argument in Styler.

set_table_classes, giving a value such as {"row": "MY_ROW_CLASS", "col Trim": "", "row Trim": ""}.

Methods

apply(func[, axis, subset])

Apply a CSS-styling function column-wise, row-wise, or table-wise.

apply_index(func[, axis, level])

Apply a CSS-styling function to the index or column headers, level-wise.

applymap(func[, subset])

Apply a CSS-styling function elementwise.

applymap_index(func[, axis, level])

Apply a CSS-styling function to the index or column headers, elementwise.

background_gradient([cmap, low, high, axis, ...])

Color the background in a gradient style.

bar([subset, axis, color, cmap, width, ...])

Draw bar chart in the cell backgrounds.

clear()

Reset the Styler, removing any previously applied styles.

export()

Export the styles applied to the current Styler.

format([formatter, subset, na_rep, ...])

Format the text display value of cells.

format_index([formatter, axis, level, ...])

Format the text display value of index labels or column headers.

from_custom_template(searchpath[,...])

Factory function for creating a subclass of Styler.

hide([subset, axis, level, names])

Hide the entire index / column headers, or specific rows / columns from display.

hide_columns([subset, level, names])

Hide the column headers or specific keys in the columns from rendering.

hide_index([subset, level, names])

(DEPRECATED) Hide the entire index, or specific keys in the index from rendering.

highlight_between([subset, color, axis, ...])

Highlight a defined range with a style.

highlight_max([subset, color, axis, props])

Highlight the maximum with a style.

highlight_min([subset, color, axis, props])

Highlight the minimum with a style.

highlight_null([null_color, subset, props])

Highlight missing values with a style.

highlight_quantile([subset, color, axis, ...])

Highlight values defined by a quantile with a style.

pipe(func, *args, **kwargs)

Apply func(self, *args, **kwargs), and return the result.

render([sparse_index, sparse_columns])

(DEPRECATED) Render the Styler including all applied styles to HTML.

set_caption(caption)

Set the text added to a <caption> HTML element.

set_na_rep(na_rep)

(DEPRECATED) Set the missing data representation on a Styler.

set_precision(precision)

(DEPRECATED) Set the precision used to display values.

set_properties([subset])

Set defined CSS-properties to each <td> HTML element within the given subset.

---

**pandas.io.formats.style.Styler.apply**

`Styler.apply(func, axis=0, subset=None, **kwargs)`

Apply a CSS-styling function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

**Parameters**

- `func` [function] `func` should take a Series if `axis` in [0,1] and return a list-like object of same length, or a Series, not necessarily of same length, with valid index labels considering `subset`. `func` should take a DataFrame if `axis` is `None` and return either an ndarray with the same shape or a DataFrame, not necessarily of the same shape, with valid index and columns labels considering `subset`.

  Changed in version 1.3.0.

  Changed in version 1.4.0.

- `axis` [0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- `**kwargs` [dict] Pass along to `func`.

**Returns**

- `self` [Styler]

See also:
Styler.applymap_index  Apply a CSS-styling function to headers elementwise.
Styler.apply_index  Apply a CSS-styling function to headers level-wise.
Styler.applymap  Apply a CSS-styling function elementwise.

Notes

The elements of the output of func should be CSS styles as strings, in the format 'attribute: value; attribute2: value2; ...' or, if nothing is to be applied to that element, an empty string or None.

This is similar to DataFrame.apply, except that axis=None applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

Examples

```python
>>> def highlight_max(x, color):
...     return np.where(x == np.nanmax(x.to_numpy()), f"color: {color};", None)

>>> df = pd.DataFrame(np.random.randn(5, 2), columns=['A', 'B'])
>>> df.style.apply(highlight_max, color='red')
>>> df.style.apply(highlight_max, color='blue', axis=1)
>>> df.style.apply(highlight_max, color='green', axis=None)

Using subset to restrict application to a single column or multiple columns

```python
>>> df.style.apply(highlight_max, color='red', subset="A")
...
```python
>>> df.style.apply(highlight_max, color='red', subset=["A", "B"], axis=1)
...

Using a 2d input to subset to select rows in addition to columns

```python
>>> df.style.apply(highlight_max, color='red', subset=(slice(0,5,2), "A"))
...
```

Using a function which returns a Series / DataFrame of unequal length but containing valid index labels

```python
>>> df = pd.DataFrame([[1, 2], [3, 4], [4, 6]], index=['A1', 'A2', 'Total'])
>>> total_style = pd.Series("font-weight: bold;", index=['Total'])
>>> df.style.apply(lambda s: total_style)
```

See Table Visualization user guide for more details.
**Styler.apply_index**

Apply a CSS-styling function to the index or column headers, level-wise.

Updates the HTML representation with the result.

New in version 1.4.0.

**Parameters**

- **func** [function] func should take a Series and return a string array of the same length.
- **axis** [{0, 1, "index", "columns"}] The headers over which to apply the function.
- **level** [int, str, list, optional] If index is MultiIndex the level(s) over which to apply the function.
- **kwargs** [dict] Pass along to func.

**Returns**

self [Styler]

**See also:**

- **Styler.applymap_index** Apply a CSS-styling function to headers elementwise.
- **Styler.apply** Apply a CSS-styling function column-wise, row-wise, or table-wise.
- **Styler.applymap** Apply a CSS-styling function elementwise.

**Notes**

Each input to func will be the index as a Series, if an Index, or a level of a MultiIndex. The output of func should be an identically sized array of CSS styles as strings, in the format ‘attribute: value; attribute2: value2; …’ or, if nothing is to be applied to that element, an empty string or None.

**Examples**

Basic usage to conditionally highlight values in the index.

```python
>>> df = pd.DataFrame([[1,2], [3,4]], index=["A", "B"])
>>> def color_b(s):
...     return np.where(s == "B", "background-color: yellow;", ")
>>> df.style.apply_index(color_b)
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>B</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

Selectively applying to specific levels of MultiIndex columns.
```python
>>> midx = pd.MultiIndex.from_product([['ix', 'jy'], [0, 1], ['x3', 'z4']])
>>> df = pd.DataFrame([np.arange(8)], columns=midx)
>>> def highlight_x(s):
...     return "background-color: yellow;" if "x" in v else "" for v in s
>>> df.style.apply_index(highlight_x, axis="columns", level=[0, 2])
```

<p>| | | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ix</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>x3</td>
<td>z4</td>
<td>x3</td>
<td>z4</td>
<td>x3</td>
<td>z4</td>
<td>z4</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>

*pandas.io.formats.style.Styler.applymap*

`Styler.applymap(func, subset=None, **kwargs)`

Apply a CSS-styling function elementwise.

Updates the HTML representation with the result.

**Parameters**

- `func` [function] func should take a scalar and return a string.
- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.
- `**kwargs` [dict] Pass along to func.

**Returns**

- `self` [Styler]

See also:

- `Styler.applymap_index` Apply a CSS-styling function to headers elementwise.
- `Styler.apply_index` Apply a CSS-styling function to headers level-wise.
- `Styler.apply` Apply a CSS-styling function column-wise, row-wise, or table-wise.

**Notes**

The elements of the output of func should be CSS styles as strings, in the format ‘attribute: value; attribute2: value2; …’ or, if nothing is to be applied to that element, an empty string or None.
Examples

```python
>>> def color_negative(v, color):
...     return f"color: {color};" if v < 0 else None

>>> df = pd.DataFrame(np.random.randn(5, 2), columns=['A', 'B'])
```

```python
>>> df.style.applymap(color_negative, color='red')
```

Using subset to restrict application to a single column or multiple columns

```python
>>> df.style.applymap(color_negative, color='red', subset="A")
... >>> df.style.applymap(color_negative, color='red', subset=["A", "B"])
```

Using a 2d input to subset to select rows in addition to columns

```python
>>> df.style.applymap(color_negative, color='red',
...                    subset=([0,1,2], slice(None)))
>>> df.style.applymap(color_negative, color='red',
...                    subset=(slice(0,5,2), 'A'))
```

See Table Visualization user guide for more details.

pandas.io.formats.style.Styler.applymap_index

**Styler.applymap_index** *(func, axis=0, level=None, **kwargs)*

Apply a CSS-styling function to the index or column headers, elementwise.

Updates the HTML representation with the result.

New in version 1.4.0.

**Parameters**

- **func** [function] func should take a scalar and return a string.
- **axis** [{0, 1, "index", "columns"}] The headers over which to apply the function.
- **level** [int, str, list, optional] If index is MultiIndex the level(s) over which to apply the function.
- ****kwargs** [dict] Pass along to func.

**Returns**

- **self** [Styler]

See also:

- **Styler.apply_index** Apply a CSS-styling function to headers level-wise.
- **Styler.apply** Apply a CSS-styling function column-wise, row-wise, or table-wise.
- **Styler.applymap** Apply a CSS-styling function elementwise.
Notes

Each input to func will be an index value, if an Index, or a level value of a MultiIndex. The output of func should be CSS styles as a string, in the format ‘attribute: value; attribute2: value2; ...’ or, if nothing is to be applied to that element, an empty string or None.

Examples

Basic usage to conditionally highlight values in the index.

```python
def color_b(s):
    ... return "background-color: yellow;" if v == "B" else None
>>>
df.style.applymap_index(color_b)
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>B</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

Selectively applying to specific levels of MultiIndex columns.

```python
midx = pd.MultiIndex.from_product([["ix", "jy"], [0, 1], ['x3', 'z4']])
df = pd.DataFrame([np.arange(8)], columns=midx)
def highlight_x(v):
    ... return "background-color: yellow;" if "x" in v else None
df.style.applymap_index(highlight_x, axis="columns", level=[0, 2])
```

pandas.io.formats.style.Styler.background_gradient

Styler.**background_gradient**(cmap='PuBu', low=0, high=0, axis=0, subset=None, text_color_threshold=0.408, vmin=None, vmax=None, gmap=None)

Color the background in a gradient style.

The background color is determined according to the data in each column, row or frame, or by a given gradient map. Requires matplotlib.

Parameters

- `cmap` [str or colormap] Matplotlib colormap.
**low** [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.

**high** [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.

**axis** [(0 or 'index', 1 or 'columns', None), default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

**subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

**text_color_threshold** [float or int] Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.

**vmin** [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

New in version 1.0.0.

**vmax** [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

New in version 1.0.0.

**gmap** [array-like, optional] Gradient map for determining the background colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering axis and subset. If given as DataFrame or Series must have same index and column labels considering axis and subset. If supplied, vmin and vmax should be given relative to this gradient map.

New in version 1.3.0.

**Returns**

**self** [Styler]

**See also:**

*Styler.text_gradient* Color the text in a gradient style.

**Notes**

When using low and high the range of the gradient, given by the data if gmap is not given or by gmap, is extended at the low end effectively by \(map.min - low \times map.range\) and at the high end by \(map.max + high \times map.range\) before the colors are normalized and determined.

If combining with vmin and vmax the map.min, map.max and map.range are replaced by values according to the values derived from vmin and vmax.

This method will preselect numeric columns and ignore non-numeric columns unless a gmap is supplied in which case no preselection occurs.
Examples

```python
>>> df = pd.DataFrame(columns=["City", "Temp (c)", "Rain (mm)", "Wind (m/s)"],
...                   data=[["Stockholm", 21.6, 5.0, 3.2],
...                      ["Oslo", 22.4, 13.3, 3.1],
...                      ["Copenhagen", 24.5, 0.0, 6.7]])
```

Shading the values column-wise, with `axis=0`, preselecting numeric columns

```python
>>> df.style.background_gradient(axis=0)
```

```
<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stockholm</td>
<td>21.60000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>Oslo</td>
<td>22.40000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>Copenhagen</td>
<td>24.50000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>
```

Shading all values collectively using `axis=None`

```python
>>> df.style.background_gradient(axis=None)
```

```
<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stockholm</td>
<td>21.60000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>Oslo</td>
<td>22.40000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>Copenhagen</td>
<td>24.50000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>
```

Compress the color map from the both low and high ends

```python
>>> df.style.background_gradient(axis=None, low=0.75, high=1.0)
```

```
<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stockholm</td>
<td>21.60000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>Oslo</td>
<td>22.40000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>Copenhagen</td>
<td>24.50000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>
```

Manually setting `vmin` and `vmax` gradient thresholds

```python
>>> df.style.background_gradient(axis=None, vmin=6.7, vmax=21.6)
```

Setting a `gmap` and applying to all columns with another `cmap`

```python
>>> df.style.background_gradient(axis=0, gmap=df['Temp (c)'], cmap='YlOrRd')
```

Setting the gradient map for a dataframe (i.e. `axis=None`), we need to explicitly state subset to match the gmap shape
```python
>>> gmap = np.array([[1,2,3], [2,3,4], [3,4,5]])
>>> df.style.background_gradient(axis=None, gmap=gmap, ...
...   cmap='YlOrRd', subset=['Temp (c)', 'Rain (mm)', 'Wind (m/s)'])
...
```

```
<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>
```

### pandas.io.formats.style.Styler.bar

**Styler.bar**

```python
Styler.bar(subset=None, axis=0, *, color=None, cmap=None, width=100, height=100, align='mid', vmin=None, vmax=None, props='width: 10em;')
```

Draw bar chart in the cell backgrounds.

Changed in version 1.4.0.

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[[<subset>]]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- **axis** [[0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

- **color** [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the color_negative and the second is the color_positive (eg: ['#d65f5f', '#5fba7d']).

- **cmap** [str, matplotlib.cm.ColorMap] A string name of a matplotlib Colormap, or a Colormap object. Cannot be used together with color.

New in version 1.4.0.
width  [float, default 100] The percentage of the cell, measured from the left, in which to draw the bars, in [0, 100].

height [float, default 100] The percentage height of the bar in the cell, centrally aligned, in [0,100].

New in version 1.4.0.

align [str, int, float, callable, default ‘mid’] How to align the bars within the cells relative to a width adjusted center. If string must be one of:

• ‘left’ : bars are drawn rightwards from the minimum data value.
• ‘right’ : bars are drawn leftwards from the maximum data value.
• ‘zero’ : a value of zero is located at the center of the cell.
• ‘mid’ : a value of (max-min)/2 is located at the center of the cell, or if all values are negative (positive) the zero is aligned at the right (left) of the cell.
• ‘mean’ : the mean value of the data is located at the center of the cell.

If a float or integer is given this will indicate the center of the cell.
If a callable should take a 1d or 2d array and return a scalar.

Changed in version 1.4.0.

vmin   [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to vmin. When None (default): the minimum value of the data will be used.

vmax   [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to vmax. When None (default): the maximum value of the data will be used.

props  [str, optional] The base CSS of the cell that is extended to add the bar chart. Defaults to “width: 10em;”.

New in version 1.4.0.

Returns

self   [Styler]

Notes

This section of the user guide: Table Visualization gives a number of examples for different settings and color coordination.

pandas.io.formats.style.Styler.clear

Styler.clear()

Reset the Styler, removing any previously applied styles.

Returns None.
**pandas.io.formats.style.Styler.export**

**Styler.export()**

Export the styles applied to the current Styler.

Can be applied to a second Styler with Styler.use.

**Returns**

- *styles* [dict]

**See also:**

- **Styler.use** Set the styles on the current Styler.
- **Styler.copy** Create a copy of the current Styler.

**Notes**

This method is designed to copy non-data dependent attributes of one Styler to another. It differs from Styler.copy where data and data dependent attributes are also copied.

The following items are exported since they are not generally data dependent:

- Styling functions added by the apply and applymap
- Whether axes and names are hidden from the display, if unambiguous.
- Table attributes
- Table styles

The following attributes are considered data dependent and therefore not exported:

- Caption
- UUID
- Tooltips
- Any hidden rows or columns identified by Index labels
- Any formatting applied using Styler.format
- Any CSS classes added using Styler.set_td_classes

**Examples**

```python
>>> styler = DataFrame([[1, 2], [3, 4]]).style
>>> styler2 = DataFrame([[9, 9, 9]]).style
>>> styler.hide(axis=0).highlight_max(axis=1)
>>> export = styler.export()
>>> styler2.use(export)
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.io.formats.style.Styler.format

Styler.format(formatter=None, subset=None, na_rep=None, precision=None, decimal='.', thousands=None, escape=None, hyperlinks=None)

Format the text display value of cells.

Parameters

- **formatter** [str, callable, dict or None] Object to define how values are displayed. See notes.
- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.
- **na_rep** [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.
  New in version 1.0.0.
- **precision** [int, optional] Floating point precision to use for display purposes, if not determined by the specified formatter.
  New in version 1.3.0.
- **decimal** [str, default “.”] Character used as decimal separator for floats, complex and integers.
  New in version 1.3.0.
- **thousands** [str, optional, default None] Character used as thousands separator for floats, complex and integers.
  New in version 1.3.0.
- **escape** [str, optional] Use ‘html’ to replace the characters & < > , and ” in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters &, %, $, #, _, { }, ~, ^, and \ in the cell display string with LaTeX-safe sequences. Escaping is done before formatter.
  New in version 1.3.0.
- **hyperlinks** [{“html”, “latex”}, optional] Convert string patterns containing https://, http://, ftp:// or www. to HTML <a> tags as clickable URL hyperlinks if “html”, or LaTeX href commands if “latex”.
  New in version 1.4.0.

Returns

- **self** [Styler]

See also:

Styler.format_index Format the text display value of index labels.
Notes

This method assigns a formatting function, `formatter`, to each cell in the DataFrame. If `formatter` is `None`, then the default formatter is used. If a callable then that function should take a data value as input and return a displayable representation, such as a string. If `formatter` is given as a string this is assumed to be a valid Python format specification and is wrapped to a callable as `str.format(x)`. If a dict is given, keys should correspond to column names, and values should be string or callable, as above.

The default formatter currently expresses floats and complex numbers with the pandas display precision unless using the `precision` argument here. The default formatter does not adjust the representation of missing values unless the `na_rep` argument is used.

The `subset` argument defines which region to apply the formatting function to. If the `formatter` argument is given in dict form but does not include all columns within the subset then these columns will have the default formatter applied. Any columns in the formatter dict excluded from the subset will be ignored.

When using a `formatter` string the dtypes must be compatible, otherwise a `ValueError` will be raised.

When instantiating a Styler, default formatting can be applied by setting the `pandas.options`:

- `styler.format.formatter`: default `None`.
- `styler.format.na_rep`: default `None`.
- `styler.format.decimal`: default `"."`.
- `styler.format.thousands`: default `None`.
- `styler.format.escape`: default `None`.

**Warning:** `Styler.format` is ignored when using the output format `Styler.to_excel`, since Excel and Python have inherently different formatting structures. However, it is possible to use the `number-format` pseudo CSS attribute to force Excel permissible formatting. See examples.

Examples

Using `na_rep` and precision with the default formatter

```python
>>> df = pd.DataFrame([[np.nan, 1.0, 'A'], [2.0, np.nan, 3.0]])
>>> df.style.format(na_rep='MISS', precision=3)
0     1     2
0  MISS  1.000  A
1    2.00  MISS  3.00
```

Using a `formatter` specification on consistent column dtypes

```python
>>> df.style.format('{:.2f}', na_rep='MISS', subset=[0,1])
0     1     2
0  MISS  1.00  A
1    2.00  MISS  3.00
```

Using the default `formatter` for unspecified columns
>>> df.style.format({0: '{:.2f}', 1: '£ {:.1f}'}, na_rep='MISS', precision=1)
...
    0 1 2
0  MISS £ 1.0  A
1  2.00  MISS  3.0

Multiple `na_rep` or precision specifications under the default formatter.

>>> df.style.format(na_rep='MISS', precision=1, subset=[0])
...
    0 1 2
0  MISS 1.00  A
1  2.0  MISS  FLOAT

Using a callable `formatter` function.

```python
>>> func = lambda s: 'STRING' if isinstance(s, str) else 'FLOAT'
>>> df.style.format({0: '{:.1f}', 2: func}, precision=4, na_rep='MISS')
...
    0 1 2
0  MISS 1.0000  STRING
1  2.0  MISS  FLOAT
```

Using a `formatter` with HTML escape and `na_rep`.

```python
>>> df = pd.DataFrame([[<div></div>', 'A&B', None]])
>>> s = df.style.format(
...    '<a href="a.com/\{0\}\">\{0\}\</a>', escape="html", na_rep="NA"
... )
>>> s.to_html()
...
    <td .. ><a href="a.com/&lt;div&gt;&lt;/div&gt;">&lt;div&gt;&lt;/div&gt;</a></td>
    <td .. ><a href="a.com/"A&B"">"A&B"</a></td>
    <td .. >NA</td>
...
```

Using a `formatter` with LaTeX escape.

```python
>>> df = pd.DataFrame([['123'], ['~ ^'], ['$%#']])
>>> df.style.format("\textbf{\{0\}}", escape="latex").to_latex()
...
\begin{tabular}{ll}
{} & {0} \\
0 & textbf\{123\} \\
1 & textbf\{$\%\#$}\ \\
2 & textbf\{$\%\#$}\ \\
\end{tabular}
```

Pandas defines a `number-format` pseudo CSS attribute instead of the `.format` method to create `to_excel` permissible formatting. Note that semi-colons are CSS protected characters but used as separators in Excel’s format string. Replace semi-colons with the section separator character (ASCII-245) when defining the formatting here.
```python
>>> df = pd.DataFrame({"A": [1, 0, -1]})
>>> pseudo_css = "number-format: 0§[Red](0)§-§@;"
>>> df.style.applymap(lambda v: css).to_excel("formatted_file.xlsx")
```

### pandas.io.formats.style.Styler.format_index

**Styler.format_index** (formatter=None, axis=0, level=None, na_rep=None, precision=None, decimal=\',\', thousands=None, escape=None, hyperlinks=None)

Format the text display value of index labels or column headers.

New in version 1.4.0.

**Parameters**

- **formatter** ([str, callable, dict or None]) Object to define how values are displayed. See notes.
- **axis** ([0, “index”, 1, “columns”]) Whether to apply the formatter to the index or column headers.
- **level** [int, str, list] The level(s) over which to apply the generic formatter.
- **na_rep** [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.
- **precision** [int, optional] Floating point precision to use for display purposes, if not determined by the specified formatter.
- **decimal** [str, default ‘.’] Character used as decimal separator for floats, complex and integers.
- **thousands** [str, optional, default None] Character used as thousands separator for floats, complex and integers.
- **escape** [str, optional] Use ‘html’ to replace the characters &<, >', and " in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters &%, $, #, _, { }, ~, ^, and \ in the cell display string with LaTeX-safe sequences. Escaping is done before formatter.
- **hyperlinks** ["html", "latex"], optional] Convert string patterns containing https://, http://, ftp:// or www. to HTML <a> tags as clickable URL hyperlinks if “html”, or LaTeX href commands if “latex”.

**Returns**
self [Styler]

See also:

Styler.format Format the text display value of data cells.

Notes

This method assigns a formatting function, formatter, to each level label in the DataFrame’s index or column headers. If formatter is None, then the default formatter is used. If a callable then that function should take a label value as input and return a displayable representation, such as a string. If formatter is given as a string this is assumed to be a valid Python format specification and is wrapped to a callable as string.format(x). If a dict is given, keys should correspond to MultiIndex level numbers or names, and values should be string or callable, as above.

The default formatter currently expresses floats and complex numbers with the pandas display precision unless using the precision argument here. The default formatter does not adjust the representation of missing values unless the na_rep argument is used.

The level argument defines which levels of a MultiIndex to apply the method to. If the formatter argument is given in dict form but does not include all levels within the level argument then these unspecified levels will have the default formatter applied. Any levels in the formatter dict specifically excluded from the level argument will be ignored.

When using a formatter string the dtypes must be compatible, otherwise a ValueError will be raised.

Warning: Styler.format_index is ignored when using the output format Styler.to_excel, since Excel and Python have inherently different formatting structures. However, it is possible to use the number-format pseudo CSS attribute to force Excel permissible formatting. See documentation for Styler.format.

Examples

Using na_rep and precision with the default formatter

>>> df = pd.DataFrame([[1, 2, 3]], columns=[2.0, np.nan, 4.0])
>>> df.style.format_index(axis=1, na_rep='MISS', precision=3)
  2.000 MISS  4.000
0  1   2   3

Using a formatter specification on consistent dtypes in a level

>>> df.style.format_index('{:.2f}', axis=1, na_rep='MISS')
  2.00 MISS  4.00
0  1   2   3

Using the default formatter for unspecified levels

>>> df = pd.DataFrame([[1, 2, 3]],
...                   columns=pd.MultiIndex.from_arrays(["a", "a", "b"],[2, np.nan, 4]))
>>> df.style.format_index({0: lambda v: upper(v)}, axis=1, precision=1)
...  A  B
0  A  B
(continues on next page)
Using a callable formatter function.

```python
>>> func = lambda s: 'STRING' if isinstance(s, str) else 'FLOAT'
>>> df.style.format_index(func, axis=1, na_rep='MISS')
...  STRING  STRING
   FLOAT     MISS  FLOAT
0     1  2  3
```

Using a formatter with HTML escape and `na_rep`.

```python
>>> df = pd.DataFrame([[1, 2, 3]], columns=['A', 'A&B', None])
>>> s = df.style.format_index('$ {0}', axis=1, escape='html', na_rep='NA')
...
<th .. >$ A</th>
```

Using a formatter with LaTeX escape.

```python
>>> df = pd.DataFrame([[1, 2, 3]], columns=['123', '~', '$%#'])
>>> df.style.format_index('\textbf{\{\}}', escape='latex', axis=1).to_latex()
...
\begin{tabular}{llll}
{} & \textbf{123} & \textbf{\~} & \textbf{$\%\#$} \\
0 & 1 & 2 & 3 \\
\end{tabular}
```

### pandas.io.formats.style.Styler.from_custom_template

**class method** `Styler.from_custom_template(searchpath, html_table=None, html_style=None)`

Factory function for creating a subclass of `Styler`.

Uses custom templates and Jinja environment.

Changed in version 1.3.0.

**Parameters**

- `searchpath` [str or list] Path or paths of directories containing the templates.
- `html_table` [str] Name of your custom template to replace the `html_table` template.
  
  New in version 1.3.0.
- `html_style` [str] Name of your custom template to replace the `html_style` template.
  
  New in version 1.3.0.

**Returns**

pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.io.formats.style.Styler.hide

**Styler.hide***(subset=None, axis=0, level=None, names=False)**

Hide the entire index / column headers, or specific rows / columns from display.

New in version 1.4.0.

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 1d input or single key along the axis within DataFrame.loc[<subset>, :] or DataFrame.loc[:, <subset>] depending upon axis, to limit data to select hidden rows / columns.

- **axis** [[“index”, 0, “columns”, 1]] Apply to the index or columns.

- **level** [int, str, list] The level(s) to hide in a MultiIndex if hiding the entire index / column headers. Cannot be used simultaneously with subset.

- **names** [bool] Whether to hide the level name(s) of the index / columns headers in the case it (or at least one the levels) remains visible.

**Returns**

- **self** [Styler]

**Notes**

This method has multiple functionality depending upon the combination of the subset, level and names arguments (see examples). The axis argument is used only to control whether the method is applied to row or column headers:

<table>
<thead>
<tr>
<th>subset</th>
<th>level</th>
<th>names</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>False</td>
<td>The axis-Index is hidden entirely.</td>
</tr>
<tr>
<td>None</td>
<td>None</td>
<td>True</td>
<td>Only the axis-Index names are hidden.</td>
</tr>
<tr>
<td>None</td>
<td>Int, Str, List</td>
<td>False</td>
<td>Specified axis-MultiIndex levels are hidden entirely.</td>
</tr>
<tr>
<td>None</td>
<td>Int, Str, List</td>
<td>True</td>
<td>Specified axis-MultiIndex levels are hidden entirely and the names of remaining axis-MultiIndex levels.</td>
</tr>
<tr>
<td>Subset</td>
<td>None</td>
<td>False</td>
<td>The specified data rows/columns are hidden, but the axis-Index itself, and names, remain unchanged.</td>
</tr>
<tr>
<td>Subset</td>
<td>None</td>
<td>True</td>
<td>The specified data rows/columns and axis-Index names are hidden, but the axis-Index itself remains unchanged.</td>
</tr>
<tr>
<td>Subset</td>
<td>Int, Str, List</td>
<td>Boolean</td>
<td>ValueError: cannot supply subset and level simultaneously.</td>
</tr>
</tbody>
</table>

Note this method only hides the identified elements so can be chained to hide multiple elements in sequence.
Examples

Simple application hiding specific rows:

```python
>>> df = pd.DataFrame([[1,2], [3,4], [5,6]], index=['a', 'b', 'c'])
>>> df.style.hide(['a', 'b'])
    0  1
  c  5  6
```

Hide the index and retain the data values:

```python
>>> midx = pd.MultiIndex.from_product([['x', 'y'], ['a', 'b', 'c']])
>>> df = pd.DataFrame(np.random.randn(6,6), index=midx, columns=midx)
>>> df.style.format('"{:1f}"').hide()
      x    y
   a b c a b c
0.1 0.0 0.4 1.3 0.6 -1.4
0.7 1.0 1.3 1.5 -0.0 -0.2
1.4 -0.8 1.6 -0.2 -0.4 -0.3
0.4 1.0 -0.2 -0.8 -1.2 1.1
-0.6 1.2 1.8 1.9 0.3 0.3
0.8 0.5 -0.3 1.2 2.2 -0.8
```

Hide specific rows in a MultiIndex but retain the index:

```python
>>> df.style.format('"{:1f}"').hide(subset=(slice(None), ['a', 'c']))
...  x y
a b c a b c
0.1 0.0 0.4 1.3 0.6 -1.4
0.7 1.0 1.3 1.5 -0.0 -0.2
1.4 -0.8 1.6 -0.2 -0.4 -0.3
```

Hide specific rows and the index through chaining:

```python
>>> df.style.format('"{:1f}"').hide(subset=(slice(None), ['a', 'c'])).hide()
...  x y
   a b c a b c
x b 0.7 1.0 1.3 1.5 -0.0 -0.2
y b -0.6 1.2 1.8 1.9 0.3 0.3
```

Hide a specific level:

```python
>>> df.style.format('"{:1f}"').hide(level=1)
      x    y
   a b c a b c
x  0.1 0.0 0.4 1.3 0.6 -1.4
  0.7 1.0 1.3 1.5 -0.0 -0.2
  1.4 -0.8 1.6 -0.2 -0.4 -0.3
y  0.4 1.0 -0.2 -0.8 -1.2 1.1
  -0.6 1.2 1.8 1.9 0.3 0.3
  0.8 0.5 -0.3 1.2 2.2 -0.8
```

Hiding just the index level names:
pandas: powerful Python data analysis toolkit, Release 1.4.3

```python
>>> df.index.names = ['lev0', 'lev1']
>>> df.style.format("{:,.1f}").hide(names=True)

<table>
<thead>
<tr>
<th>x a</th>
<th>b</th>
<th>c</th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>0.1</td>
<td>0.0</td>
<td>0.4</td>
<td>1.3</td>
<td>0.6</td>
</tr>
<tr>
<td>b</td>
<td>0.7</td>
<td>1.0</td>
<td>1.3</td>
<td>1.5</td>
<td>-0.0</td>
</tr>
<tr>
<td>c</td>
<td>1.4</td>
<td>-0.8</td>
<td>1.6</td>
<td>-0.2</td>
<td>-0.4</td>
</tr>
<tr>
<td>y</td>
<td>0.4</td>
<td>1.0</td>
<td>-0.2</td>
<td>-0.8</td>
<td>-1.2</td>
</tr>
<tr>
<td>b</td>
<td>-0.6</td>
<td>1.2</td>
<td>1.8</td>
<td>1.9</td>
<td>0.3</td>
</tr>
<tr>
<td>c</td>
<td>0.8</td>
<td>0.5</td>
<td>-0.3</td>
<td>1.2</td>
<td>2.2</td>
</tr>
</tbody>
</table>

Examples all produce equivalently transposed effects with axis="columns".

**pandas.io.formats.style.Styler.hide_columns**

**Styler.hide_columns** *(subset=None, level=None, names=False)*

Hide the column headers or specific keys in the columns from rendering.

This method has dual functionality:

- if *subset* is *None* then the entire column headers row, or specific levels, will be hidden whilst the data-values remain visible.
- if a *subset* is given then those specific columns, including the data-values will be hidden, whilst the column headers row remains visible.

Changed in version 1.3.0.

.. deprecated:: 1.4.0  This method should be replaced by hide(axis="columns", **kwargs)

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 1d input or single key along the columns axis within `DataFrame.loc[:, <subset>]`, to limit data to before applying the function.

- **level** [int, str, list] The level(s) to hide in a MultiIndex if hiding the entire column headers row. Cannot be used simultaneously with *subset*.

  New in version 1.4.0.

- **names** [bool] Whether to hide the column index name(s), in the case all column headers, or some levels, are visible.

  New in version 1.4.0.

**Returns**

- **self** [Styler]

**See also:**

**Styler.hide** Hide the entire index / columns, or specific rows / columns.
**Styler.hide_index**

Hide the entire index, or specific keys in the index from rendering.

This method has dual functionality:

- if `subset` is `None` then the entire index, or specified levels, will be hidden whilst displaying all data-rows.
- if a `subset` is given then those specific rows will be hidden whilst the index itself remains visible.

Changed in version 1.3.0.

Deprecated since version 1.4.0: This method should be replaced by `hide(axis="index", **kwargs)`

**Parameters**

- `subset` [label, array-like, IndexSlice, optional] A valid 1d input or single key along the index axis within `DataFrame.loc[]`, to limit data to before applying the function.
- `level` [int, str, list] The level(s) to hide in a MultiIndex if hiding the entire index. Cannot be used simultaneously with `subset`.
  
  New in version 1.4.0.
- `names` [bool] Whether to hide the index name(s), in the case the index or part of it remains visible.
  
  New in version 1.4.0.

**Returns**

- `self` [Styler]

See also:

- **Styler.hide** Hide the entire index / columns, or specific rows / columns.

**Styler.highlight_between**

Highlight a defined range with a style.

New in version 1.3.0.

**Parameters**

- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.
- `color` [str, default ‘yellow’] Background color to use for highlighting.
- `axis` [[0 or ‘index’, 1 or ‘columns’, None], default 0] If `left` or `right` given as sequence, axis along which to apply those boundaries. See examples.
- `left` [scalar or datetime-like, or sequence or array-like, default None] Left bound for defining the range.
right  [scalar or datetime-like, or sequence or array-like, default None] Right bound for defining the range.

inclusive  [{‘both’, ‘neither’, ‘left’, ‘right’}] Identify whether bounds are closed or open.

props  [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

Returns

self  [Styler]

See also:

Styler.highlight_null  Highlight missing values with a style.

Styler.highlight_max  Highlight the maximum with a style.

Styler.highlight_min  Highlight the minimum with a style.

Styler.highlight_quantile  Highlight values defined by a quantile with a style.

Notes

If left is None only the right bound is applied. If right is None only the left bound is applied. If both are None all values are highlighted.

axis is only needed if left or right are provided as a sequence or an array-like object for aligning the shapes. If left and right are both scalars then all axis inputs will give the same result.

This function only works with compatible dtypes. For example a datetime-like region can only use equivalent datetime-like left and right arguments. Use subset to control regions which have multiple dtypes.

Examples

Basic usage

>>> df = pd.DataFrame({
...     'One': [1.2, 1.6, 1.5],
...     'Two': [2.9, 2.1, 2.5],
...     'Three': [3.1, 3.2, 3.8],
... })

>>> df.style.highlight_between(left=2.1, right=2.9)

Using a range input sequence along an axis, in this case setting a left and right for each column individually

>>> df.style.highlight_between(left=[1.4, 2.4, 3.4], right=[1.6, 2.6, 3.6],
...     axis=1, color=“#ffe775")
Using `axis=None` and providing the `left` argument as an array that matches the input DataFrame, with a constant `right`

```python
>>> df.style.highlight_between(left=[[2,2,3],[2,2,3],[3,3,3]], right=3.5,
... axis=None, color="#fffd75")
```

```
0   1.2  2.9  3.1
1   1.6  2.1  3.2
2   1.5  2.5  3.8
```

Using `props` instead of default background coloring

```python
>>> df.style.highlight_between(left=1.5, right=3.5,
... props='font-weight:bold;color:#e83e8c')
```

```
0   1.2  2.9  3.1
1   1.6  2.1  3.2
2   1.5  2.5  3.8
```

**pandas.io.formats.style.Styler.highlight_max**

Styler.**highlight_max**(subset=None, color='yellow', axis=0, props=None)

Highlight the maximum with a style.

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to `Dataframe.loc[<subset>]`, or, in the case of a 1d input or single key, to `Dataframe.loc[.. <subset>..]` where the columns are prioritised, to limit data to before applying the function.

- **color** [str, default ‘yellow’] Background color to use for highlighting.

- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

- **props** [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

**Returns**
pandas: powerful Python data analysis toolkit, Release 1.4.3

self [Styler]

See also:

Styler.highlight_null  Highlight missing values with a style.
Styler.highlight_min  Highlight the minimum with a style.
Styler.highlight_between  Highlight a defined range with a style.
Styler.highlight_quantile  Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_min

Styler.highlight_min(subset=None, color='yellow', axis=0, props=None)

Highlight the minimum with a style.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

color [str, default 'yellow'] Background color to use for highlighting.

axis [[0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.highlight_null  Highlight missing values with a style.
Styler.highlight_max  Highlight the maximum with a style.
Styler.highlight_between  Highlight a defined range with a style.
Styler.highlight_quantile  Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_null

Styler.highlight_null(null_color='red', subset=None, props=None)

Highlight missing values with a style.

Parameters

null_color [str, default 'red']

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

New in version 1.1.0.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.highlight_max Highlight the maximum with a style.

Styler.highlight_min Highlight the minimum with a style.

Styler.highlight_between Highlight a defined range with a style.

Styler.highlight_quantile Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_quantile

Styler.highlight_quantile(subset=None, color='yellow', axis=0, q_left=0.0, q_right=1.0, interpolation='linear', inclusive='both', props=None)

Highlight values defined by a quantile with a style.

New in version 1.3.0.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

color [str, default ‘yellow’] Background color to use for highlighting.

axis [[0 or ‘index’, 1 or ‘columns’, None], default 0] Axis along which to determine and highlight quantiles. If None quantiles are measured over the entire DataFrame. See examples.

q_left [float, default 0] Left bound, in [0, q_right), for the target quantile range.

q_right [float, default 1] Right bound, in (q_left, 1], for the target quantile range.

inclusive [{‘both’, ‘neither’, ‘left’, ‘right’}] Identify whether quantile bounds are closed or open.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

Returns

self [Styler]
See also:

- `Styler.highlight_null` Highlight missing values with a style.
- `Styler.highlight_max` Highlight the maximum with a style.
- `Styler.highlight_min` Highlight the minimum with a style.
- `Styler.highlight_between` Highlight a defined range with a style.

Notes

This function does not work with `str` dtypes.

Examples

Using `axis=None` and apply a quantile to all collective data

```python
>>> df = pd.DataFrame(np.arange(10).reshape(2, 5) + 1)
>>> df.style.highlight_quantile(axis=None, q_left=0.8, color="#fffd75")

0 1 2 3 4
0  1  2  3  4  5
1  6  7  8  9 10
```

Or highlight quantiles row-wise or column-wise, in this case by row-wise

```python
>>> df.style.highlight_quantile(axis=1, q_left=0.8, color="#fffd75")

0 1 2 3 4
0 1 2 3 4 5
1 6 7 8 9 10
```

Use `props` instead of default background coloring

```python
>>> df.style.highlight_quantile(axis=None, q_left=0.2, q_right=0.8, props='font-weight:bold;color:#e83e8c')

0 1 2 3 4
0 1 2 3 4 5
1 6 7 8 9 10
```
Styler.pipe(func, *args, **kwargs)

Apply func(self, *args, **kwargs), and return the result.

Parameters

- **func** [function] Function to apply to the Styler. Alternatively, a (callable, keyword) tuple where keyword is a string indicating the keyword of callable that expects the Styler.
- **args** [optional] Arguments passed to func.
- **kwargs** [optional] A dictionary of keyword arguments passed into func.

Returns

- **object** : The value returned by func.

See also:

- **DataFrame.pipe** Analogous method for DataFrame.
- **Styler.apply** Apply a CSS-styling function column-wise, row-wise, or table-wise.

Notes

Like DataFrame.pipe(), this method can simplify the application of several user-defined functions to a styler. Instead of writing:

\[
\text{f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)}
\]

users can write:

\[
\text{(df.style.set_precision(3)}
\text{.pipe(g, arg1=a)}
\text{.pipe(f, arg2=b, arg3=c))}
\]

In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling *Styler.apply()* or *Styler.set_properties()*). Using .pipe, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.

Examples

```python
>>> def format_conversion(styler):
...     return (styler.set_properties(**{'text-align': 'right'}))
...     .format({'conversion': '{:.1%}'})
```

The user-defined format_conversion function above can be called within a sequence of other style modifications:

```python
>>> df = pd.DataFrame({
...     'trial': list(range(5)),
...     'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
>>> (df.style
```
... .highlight_min(subset=['conversion'], color='yellow')
... .pipe(format_conversion)
... .set_caption("Results with minimum conversion highlighted."))
...

```python
Results with minimum conversion highlighted.

<table>
<thead>
<tr>
<th>trial</th>
<th>conversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>75.0%</td>
</tr>
<tr>
<td>1</td>
<td>85.0%</td>
</tr>
<tr>
<td>2</td>
<td>nan%</td>
</tr>
<tr>
<td>3</td>
<td>70.0%</td>
</tr>
<tr>
<td>4</td>
<td>72.0%</td>
</tr>
</tbody>
</table>
```

**pandas.io.formats.style.Styler.render**

*Styler.render*(sparse_index=None, sparse_columns=None, **kwargs)

Render the Styler including all applied styles to HTML.

Deprecated since version 1.4.0.

**Parameters**

- **sparse_index** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.index` value.

- **sparse_columns** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.columns` value.

- **kwargs** Any additional keyword arguments are passed through to `self.template.render`. This is useful when you need to provide additional variables for a custom template.

**Returns**

- **rendered** [str] The rendered HTML.
Notes

This method is deprecated in favour of Styler.to_html.

Styler objects have defined the _repr_html_ method which automatically calls self.to_html() when it's the last item in a Notebook cell.

When calling Styler.render() directly, wrap the result in IPython.display.HTML to view the rendered HTML in the notebook.

Pandas uses the following keys in render. Arguments passed in **kwargs take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- table_styles
- caption
- table_attributes

pandas.io.formats.style.Styler.set_caption

Styler.set_caption(caption)

Set the text added to a <caption> HTML element.

Parameters

- caption [str, tuple] For HTML output either the string input is used or the first element of the tuple. For LaTeX the string input provides a caption and the additional tuple input allows for full captions and short captions, in that order.

Returns

- self [Styler]

pandas.io.formats.style.Styler.set_na_rep

Styler.set_na_rep(na_rep)

Set the missing data representation on a Styler.

New in version 1.0.0.

Deprecated since version 1.3.0.

Parameters

- na_rep [str]

Returns

- self [Styler]
Notes

This method is deprecated. See Styler.format()

pandas.io.formats.style.Styler.set_precision

Styler.set_precision(precision)

Set the precision used to display values.

Deprecated since version 1.3.0.

Parameters

precision [int]

Returns

self [Styler]

Notes

This method is deprecated see Styler.format.

pandas.io.formats.style.Styler.set_properties

Styler.set_properties(subset=None, **kwargs)

Set defined CSS-properties to each <td> HTML element within the given subset.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

**kwargs [dict] A dictionary of property, value pairs to be set for each cell.

Returns

self [Styler]

Notes

This is a convenience methods which wraps the Styler.applymap() calling a function returning the CSS-properties independently of the data.
Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{"background-color": 'yellow'})
```

See Table Visualization user guide for more details.

### pandas.io.formats.style.Styler.set_sticky

**Styler.set_sticky**(axis=0, pixel_size=None, levels=None)

Add CSS to permanently display the index or column headers in a scrolling frame.

**Parameters**

- **axis** [0 or ‘index’, 1 or ‘columns’], default 0] Whether to make the index or column headers sticky.
- **pixel_size** [int, optional] Required to configure the width of index cells or the height of column header cells when sticking a MultiIndex (or with a named Index). Defaults to 75 and 25 respectively.
- **levels** [int, str, list, optional] If axis is a MultiIndex the specific levels to stick. If None will stick all levels.

**Returns**

- **self** [Styler]

**Notes**

This method uses the CSS ‘position: sticky;’ property to display. It is designed to work with visible axes, therefore both:

- `styler.set_sticky(axis="index").hide(axis="index")`
- `styler.set_sticky(axis="columns").hide(axis="columns")`

may produce strange behaviour due to CSS controls with missing elements.

### pandas.io.formats.style.Styler.set_table_attributes

**Styler.set_table_attributes**(attributes)

Set the table attributes added to the <table> HTML element.

These are items in addition to automatic (by default) id attribute.

**Parameters**

- **attributes** [str]

**Returns**

- **self** [Styler]

**See also**: 

**Styler.set_table_styles** Set the table styles included within the <style> HTML element.
Styler.set_td_classes Set the DataFrame of strings added to the class attribute of <td> HTML elements.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

pandas.io.formats.style.Styler.set_table_styles

Styler.set_table_styles(table_styles=None, axis=0, overwrite=True, css_class_names=None)
Set the table styles included within the <style> HTML element.

This function can be used to style the entire table, columns, rows or specific HTML selectors.

Parameters

- **table_styles** [list or dict] If supplying a list, each individual table_style should be a dictionary with selector and props keys. selector should be a CSS selector that the style will be applied to (automatically prefixed by the table’s UUID) and props should be a list of tuples with (attribute, value). If supplying a dict, the dict keys should correspond to column names or index values, depending upon the specified axis argument. These will be mapped to row or col CSS selectors. MultiIndex values as dict keys should be in their respective tuple form. The dict values should be a list as specified in the form with CSS selectors and props that will be applied to the specified row or column.

  Changed in version 1.2.0.

- **axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'). Only used if table_styles is dict.

  New in version 1.2.0.

- **overwrite** [bool, default True] Styles are replaced if True, or extended if False. CSS rules are preserved so most recent styles set will dominate if selectors intersect.

  New in version 1.2.0.

- **css_class_names** [dict, optional] A dict of strings used to replace the default CSS classes described below.

  New in version 1.4.0.

Returns

- **self** [Styler]

See also:

- **Styler.set_td_classes** Set the DataFrame of strings added to the class attribute of <td> HTML elements.

- **Styler.set_table_attributes** Set the table attributes added to the <table> HTML element.
Notes

The default CSS classes dict, whose values can be replaced is as follows:

css_class_names = {
    "row_heading": "row_heading",
    "col_heading": "col_heading",
    "index_name": "index_name",
    "col": "col",
    "col_trim": "col_trim",
    "row_trim": "row_trim",
    "level": "level",
    "data": "data",
    "blank": "blank"
}

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                     columns=['A', 'B', 'C', 'D'])
>>> df.style.set_table_styles(
...     [{
...         'selector': 'tr:hover',
...         'props': [{
...             'background-color': 'yellow'}]
...     }]
```

Or with CSS strings

```python
>>> df.style.set_table_styles(
...     [{
...         'selector': 'tr:hover',
...         'props': 'background-color: yellow; font-size: 1em;'}]
```

Adding column styling by name

```python
>>> df.style.set_table_styles({
...     'A': [{
...         'selector': '',
...         'props': [{
...             'color': 'red'}]},
...     'B': [{
...         'selector': 'td',
...         'props': 'color: blue;'}]
... }, overwrite=False)
```

Adding row styling

```python
>>> df.style.set_table_styles({
...     0: [{
...         'selector': 'td:hover',
...         'props': [{
...             'font-size': '25px'}]}
... }, axis=1, overwrite=False)
```

See Table Visualization user guide for more details.
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.io.formats.style.Styler.set_td_classes

Styler.set_td_classes(classes)
Set the DataFrame of strings added to the class attribute of <td> HTML elements.

Parameters

- classes [DataFrame] DataFrame containing strings that will be translated to CSS classes, mapped by identical column and index key values that must exist on the underlying Styler data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

Returns

- self [Styler]

See also:

Styler.set_table_styles Set the table styles included within the <style> HTML element.
Styler.set_table_attributes Set the table attributes added to the <table> HTML element.

Notes

Can be used in combination with Styler.set_table_styles to define an internal CSS solution without reference to external CSS files.

Examples

```python
>>> df = pd.DataFrame(data=[[1, 2], [3, 4]], index=["a", "b"], columns=["level0", "level1b"], columns=["level0", ["a", "b", "c", "d"]])
>>> classes = pd.DataFrame(["min-val", "max-val"], index=["b", "c"], columns=["level0", ["a", "b", "c", "d"]])
>>> df.style.set_td_classes(classes)
```

Using MultiIndex columns and a classes DataFrame as a subset of the underlying.

```python
>>> df = pd.DataFrame(data=[[1, 2], [3, 4]], index=["a", "b"], columns=["level0", ["a", "b", "c", "d"]])
>>> classes = pd.DataFrame(["min-val", "max-val"], index=["a", "b"], columns=["level0", ["a", "b", "c", "d"]])
>>> df.style.set_td_classes(classes)
```

Form of the output with new additional css classes,

```python
>>> df = pd.DataFrame(data=[[1]])
>>> css = pd.DataFrame(["other-class"], index=["other-class"], columns=["other-class"])
>>> s = Styler(df, uuid="_", cell_ids=False).set_td_classes(css)
>>> s.hide(axis=0).to_html()
'<style type="text/css"></style>'
'<table id="T__">
  <thead>
    <tr><th class="col_heading level0 col0" >0</th></tr>
(continues on next page)
```
pandas.io.formats.style.Styler.set_tooltips

**Styler.set_tooltips**(*ttips*, *props*=*None*, *css_class*=*None*)

Set the DataFrame of strings on *Styler* generating :hover tooltips.

These string based tooltips are only applicable to `<td>` HTML elements, and cannot be used for column or index headers.

New in version 1.3.0.

**Parameters**

- **ttips** [DataFrame] DataFrame containing strings that will be translated to tooltips, mapped by identical column and index values that must exist on the underlying *Styler* data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

- **props** [list-like or str, optional] List of (attr, value) tuples or a valid CSS string. If *None* adopts the internal default values described in notes.

- **css_class** [str, optional] Name of the tooltip class used in CSS, should conform to HTML standards. Only useful if integrating tooltips with external CSS. If *None* uses the internal default value ‘pd-t’.

**Returns**

- **self** [Styler]

**Notes**

Tooltips are created by adding `<span class="pd-t">` to each data cell and then manipulating the table level CSS to attach pseudo hover and pseudo after selectors to produce the required results.

The default properties for the tooltip CSS class are:

- visibility: hidden
- position: absolute
- z-index: 1
- background-color: black
- color: white
- transform: translate(-20px, -20px)

The property ‘visibility: hidden;’ is a key prerequisite to the hover functionality, and should always be included in any manual properties specification, using the *props* argument.

Tooltips are not designed to be efficient, and can add large amounts of additional HTML for larger tables, since they also require that *cell_ids* is forced to True.
Examples

Basic application

```python
>>> df = pd.DataFrame(data=[[0, 1], [2, 3]])
>>> ttips = pd.DataFrame(
...     data=[['Min', ''], [np.nan, 'Max']], columns=df.columns, index=df.index
... )
>>> s = df.style.set_tooltips(ttips).to_html()
```

Optionally controlling the tooltip visual display

```python
>>> df.style.set_tooltips(ttips, css_class='tt-add', props=[
...     ('visibility', 'hidden'),
...     ('position', 'absolute'),
...     ('z-index', 1)]
>>> df.style.set_tooltips(ttips, css_class='tt-add',
...     props='visibility:hidden; position:absolute; z-index:1;')
```

**pandas.io.formats.style.Styler.set_uuid**

`Styler.set_uuid(uuid)`

Set the uuid applied to id attributes of HTML elements.

- **Parameters**
  - `uuid` [str]

- **Returns**
  - `self` [Styler]

- **Notes**
  - Almost all HTML elements within the table, and including the `<table>` element are assigned id attributes. The format is T_uuid_<extra> where <extra> is typically a more specific identifier, such as row1_col2.

**pandas.io.formats.style.Styler.text_gradient**

`Styler.text_gradient(cmap='PuBu', low=0, high=0, axis=0, subset=None, vmin=None, vmax=None, gmap=None)`

Color the text in a gradient style.

- **Parameters**
  - `cmap` [str or colormap] Matplotlib colormap.
  - `low` [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.
**high** [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.

**axis** [([0 or ‘index’, 1 or ‘columns’, None], default 0)] Apply to each column (axis=0 or ‘index’), to each row (axis=1 or ‘columns’), or to the entire DataFrame at once with axis=None.

**subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

**text_color_threshold** [float or int] This argument is ignored (only used in background_gradient). Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.

**vmin** [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

New in version 1.0.0.

**vmax** [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

New in version 1.0.0.

**gmap** [array-like, optional] Gradient map for determining the text colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering axis and subset. If given as DataFrame or Series must have same index and column labels considering axis and subset. If supplied, vmin and vmax should be given relative to this gradient map.

New in version 1.3.0.

**Returns**

self [Styler]

**See also:**

*Styler.background_gradient* Color the background in a gradient style.

**Notes**

When using low and high the range of the gradient, given by the data if gmap is not given or by gmap, is extended at the low end effectively by \( \text{map.min} - \text{low} \times \text{map.range} \) and at the high end by \( \text{map.max} + \text{high} \times \text{map.range} \) before the colors are normalized and determined.

If combining with vmin and vmax the map.min, map.max and map.range are replaced by values according to the values derived from vmin and vmax.

This method will preselect numeric columns and ignore non-numeric columns unless a gmap is supplied in which case no preselection occurs.
Examples

```python
>>> df = pd.DataFrame(columns=["City", "Temp (c)", "Rain (mm)", "Wind (m/s)"],
                    data=[["Stockholm", 21.6, 5.0, 3.2],
                         ["Oslo", 22.4, 13.3, 3.1],
                         ["Copenhagen", 24.5, 0.0, 6.7]])

Shading the values column-wise, with `axis=0`, preselecting numeric columns

```python
>>> df.style.text_gradient(axis=0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2 Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Shading all values collectively using `axis=None`

```python
>>> df.style.text_gradient(axis=None)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2 Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Compress the color map from the both low and high ends

```python
>>> df.style.text_gradient(axis=None, low=0.75, high=1.0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>

</tbody>
</table>

Manually setting `vmin` and `vmax` gradient thresholds

```python
>>> df.style.text_gradient(axis=None, vmin=6.7, vmax=21.6)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2 Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Setting a gmap and applying to all columns with another cmap

```python
>>> df.style.text_gradient(axis=0, gmap=df["Temp (c)"], cmap='YlOrRd')
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2 Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Setting the gradient map for a dataframe (i.e. `axis=None`), we need to explicitly state subset to match the gmap shape
>>> gmap = np.array([[1,2,3], [2,3,4], [3,4,5]])
>>> df.style.text_gradient(axis=None, gmap=gmap, cmap='YlOrRd', subset=['Temp (c)', 'Rain (mm)', 'Wind (m/s)'])

pandas.io.formats.style.Styler.use

Styler.use(styles)

Set the styles on the current Styler.

Possibly uses styles from Styler.export.

Parameters

styles [dict(str, Any)]

List of attributes to add to Styler. Dict keys should contain only:

- “apply”: list of styler functions, typically added with apply or applymap.
- “table_attributes”: HTML attributes, typically added with set_table_attributes.
- “table_styles”: CSS selectors and properties, typically added with set_table_styles.
- “hide_index”: whether the index is hidden, typically added with hide_index, or a boolean list for hidden levels.
- “hide_columns”: whether column headers are hidden, typically added with hide_columns, or a boolean list for hidden levels.
- “hide_index_names”: whether index names are hidden.
- “hide_column_names”: whether column header names are hidden.
• “css”: the css class names used.

Returns

self [Styler]

See also:

Styler.export  Export the non data dependent attributes to the current Styler.

Examples

```python
>>> styler = DataFrame([[1, 2], [3, 4]]).style
>>> styler2 = DataFrame([[9, 9, 9]]).style
>>> styler.hide(axis=0).highlight_max(axis=1)
>>> export = styler.export()
>>> styler2.use(export)
```

pandas.io.formats.style.Styler.where

Styler.where(cond, value, other=None, subset=None, **kwargs)

Apply CSS-styles based on a conditional function elementwise.

Deprecated since version 1.3.0.

Updates the HTML representation with a style which is selected in accordance with the return value of a function.

Parameters

cond [callable] cond should take a scalar, and optional keyword arguments, and return a boolean.

value [str] Applied when cond returns true.

other [str] Applied when cond returns false.

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

**kwargs [dict] Pass along to cond.

Returns

self [Styler]

See also:

Styler.applymap  Apply a CSS-styling function elementwise.

Styler.apply  Apply a CSS-styling function column-wise, row-wise, or table-wise.
Notes

This method is deprecated.

This method is a convenience wrapper for `Styler.applymap()`, which we recommend using instead.

The example:

```python
def cond(v, limit=4):
    return v > 1 and v != limit

def style_func(v, value, other, limit=4):
    cond = v > 1 and v != limit
    return value if cond else other

>>> df = pd.DataFrame([[1, 2], [3, 4]])
>>> def cond(v, limit=4):
...     return v > 1 and v != limit
...     return value if cond else other

    >>> df.style.where(cond, value='color:green;', other='color:red;')
...     >>> df.style.applymap(style_func, value='color:green;', other='color:red;')
```

should be refactored to:

```python
def style_func(v, value, other, limit=4):
    cond = v > 1 and v != limit
    return value if cond else other

>>> df.style.applymap(style_func, value='color:green;', other='color:red;')
```

</tr>
<tr>
<td><code>table()</code></td>
<td>Helper function to convert DataFrame and Series to matplotlib table.</td>
</tr>
</tbody>
</table>
3.13.1 pandas.plotting.andrews_curves

pandas.plotting.andrews_curves(frame, class_column, ax=None, samples=200, color=None, colormap=None, **kwargs)

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:
\[ f(t) = \frac{x_1}{\sqrt{2}} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \ldots \]

Where x coefficients correspond to the values of each dimension and t is linearly spaced between -\pi and +\pi. Each row of frame then corresponds to a single curve.

**Parameters**

- **frame** [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0).
- **class_column** [Name of the column containing class names]
- **ax** [matplotlib axes object, default None]
- **samples** [Number of points to plot in each curve]
- **color** [list or tuple, optional] Colors to use for the different classes.
- **colormap** [str or matplotlib colormap object, default None] Colormap to select colors from.
  - If string, load colormap with that name from matplotlib.

**Returns**

class: :class:`matplotlib.axis.Axes`

**Examples**

```python

>>> pd.plotting.andrews_curves(df, 'Name')
<AxesSubplot:title={'center':'width'}>
```

3.13.2 pandas.plotting.autocorrelation_plot

pandas.plotting.autocorrelation_plot(series, ax=None, **kwargs)

Autocorrelation plot for time series.

**Parameters**

- **series** [Time series]
- **ax** [Matplotlib axis object, optional]

**Returns**

class: :class:`matplotlib.axis.Axes`

**Examples**

```python
>>> pd.plotting.autocorrelation_plot(series, ax=ax)
```
Examples

The horizontal lines in the plot correspond to 95% and 99% confidence bands.
The dashed line is 99% confidence band.

```python
>>> spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
>>> s = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
>>> pd.plotting.autocorrelation_plot(s)
<AxesSubplot:title={'center': 'width'}, xlabel='Lag', ylabel='Autocorrelation'>
```

3.13.3 pandas.plotting.bootstrap_plot

```python
pandas.plotting.bootstrap_plot(series, fig=None, size=50, samples=500, **kwds)
```

Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relaying on random sampling with replacement [1]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

**Parameters**

- **series** [pandas.Series] Series from where to get the samplings for the bootstrapping.
fig [matplotlib.figure.Figure, default None] If given, it will use the fig reference for plotting instead of creating a new one with default parameters.

size [int, default 50] Number of data points to consider during each sampling. It must be less than or equal to the length of the series.

samples [int, default 500] Number of times the bootstrap procedure is performed.

**kwds Options to pass to matplotlib plotting method.

Returns

matplotlib.figure.Figure Matplotlib figure.

See also:

DataFrame.plot Basic plotting for DataFrame objects.
Series.plot Basic plotting for Series objects.

Examples

This example draws a basic bootstrap plot for a Series.

```python
>>> s = pd.Series(np.random.uniform(size=100))
>>> pd.plotting.bootstrap_plot(s)
<Figure size 640x480 with 6 Axes>
```
3.13.4 pandas.plotting.boxplot

`pandas.plotting.boxplot(data=None, column=None, by=None, ax=None, figsize=None, layout=None, return_type=None, **kwargs)`

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than $1.5 \times IQR$ ($IQR = Q3 - Q1$) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia’s entry for boxplot.

**Parameters**

- `column` [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.

- `by` [str or array-like, optional] Column in the DataFrame to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in by.

- `ax` [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.

- `fontsize` [float or str] Tick label font size in points or as a string (e.g., large).

- `rot` [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

- `grid` [bool, default True] Setting this to True will show the grid.

- `figsize` [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

- `layout` [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

- `return_type` [{‘axes’, ‘dict’, ‘both’} or None, default ‘axes’] The kind of object to return. The default is `axes`.
  - ‘axes’ returns the matplotlib axes the boxplot is drawn on.
  - ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
  - ‘both’ returns a namedtuple with the axes and dict.
  - when grouping with by, a Series mapping columns to `return_type` is returned.

    If `return_type` is None, a NumPy array of axes with the same shape as `layout` is returned.

**kwargs All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

**Returns**

- `result` See Notes.

See also:

- `Series.plot.hist` Make a histogram.
- `matplotlib.pyplot.boxplot` Matplotlib equivalent plot.
Notes

The return type depends on the `return_type` parameter:
- 'axes': object of class matplotlib.axes.Axes
- 'dict': dict of matplotlib.lines.Line2D objects
- 'both': a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:
  - Series
  - array (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option by.
pandas: powerful Python data analysis toolkit, Release 1.4.3

For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
    ...                     columns=['Col1', 'Col2'])
    ...                     'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
    ...                     columns=['Col1', 'Col2', 'Col3'])
    ...                     'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
    ...                     'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
    ...                      layout=(2, 1))
```
Boxplot grouped by ["X", "Y"]

Col1

Col2

(A, A) (A, B) (B, A) (B, B)

[X, Y]
Additional formatting can be done to the boxplot, like suppressing the grid (grid=False), rotating the labels in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter return_type can be used to select the type of element returned by `boxplot`. When return_type='axes' is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with by, a Series mapping columns to return_type is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                        return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If return_type is None, a NumPy array of axes with the same shape as layout is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                        return_type=None)
```

(continues on next page)
3.13.5 pandas.plotting.deregister_matplotlib_converters

pandas.plotting.deregister_matplotlib_converters()

Remove pandas formatters and converters.

Removes the custom converters added by register(). This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas’ own types like Timestamp and Period are removed completely. Converters for types pandas overwrites, like datetime.datetime, are restored to their original value.

See also:

register_matplotlib_converters Register pandas formatters and converters with matplotlib.

3.13.6 pandas.plotting.lag_plot

pandas.plotting.lag_plot(series, lag=1, ax=None, **kwds)

Lag plot for time series.

Parameters

- series [Time series]
- lag [lag of the scatter plot, default 1]
- ax [Matplotlib axis object, optional]
- **kwds Matplotlib scatter method keyword arguments.

Returns

class: matplotlib.axis.Axes

Examples

Lag plots are most commonly used to look for patterns in time series data.

Given the following time series

```python
>>> np.random.seed(5)
>>> x = np.cumsum(np.random.normal(loc=1, scale=5, size=50))
>>> s = pd.Series(x)
>>> s.plot()
<AxesSubplot:xlabel='Midrange'>
```

A lag plot with lag=1 returns

```python
>>> pd.plotting.lag_plot(s, lag=1)
<AxesSubplot:xlabel='y(t)', ylabel='y(t + 1)'>
```
3.13.7 pandas.plotting.parallel_coordinates

```
pandas.plotting.parallel_coordinates(frame, class_column, cols=None, ax=None, color=None,
use_columns=False, xticks=None, colormap=None, axvlines=True,
axvlines_kws=None, sort_labels=False, **kwargs)
```

Parallel coordinates plotting.

**Parameters**
- **frame** [DataFrame]:
- **class_column** [str]: Column name containing class names.
- **cols** [list, optional]: A list of column names to use.
- **ax** [matplotlib.axis, optional]: Matplotlib axis object.
- **color** [list or tuple, optional]: Colors to use for the different classes.
- **use_columns** [bool, optional]: If true, columns will be used as xticks.
- **xticks** [list or tuple, optional]: A list of values to use for xticks.
- **colormap** [str or matplotlib colormap, default None]: Colormap to use for line colors.
- **axvlines** [bool, optional]: If true, vertical lines will be added at each xtick.
- **axvlines_kws** [keywords, optional]: Options to be passed to axvline method for vertical lines.
- **sort_labels** [bool, default False]: Sort class_column labels, useful when assigning colors.
- ****kwargs**: Options to pass to matplotlib plotting method.

**Returns**
- **class**: matplotlib.axis.Axes

**Examples**
```
>>> df = pd.read_csv(
...     'https://raw.github.com/pandas-dev/
p...     'pandas/main/pandas/tests/io/data/csv/iris.csv'
... )
```
```
>>> pd.plotting.parallel_coordinates(  
...     df, 'Name', color=('#556270', '#4ECDC4', '#C7F464')
... )
```
```
<AxesSubplot:xlabel='y(t)', ylabel='y(t + 1)'>
```

3.13.8 pandas.plotting.plot_params

```
pandas.plotting.plot_params = {'xaxis_compat': False}
```

Stores pandas plotting options.

Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.
3.13.9 pandas.plotting.radviz

```python
def radviz(frame, class_column, ax=None, color=None, colormap=None, **kwds):
    # Plot a multidimensional dataset in 2D.
    # Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated Series in the DataFrame are placed closer on the unit circle.
    # RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.
    # More info available at the original article describing RadViz.
    Parameters
    frame [DataFrame] Object holding the data.
    class_column [str] Column name containing the name of the data point category.
    ax [matplotlib.axes.Axes, optional] A plot instance to which to add the information.
    color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].
    colormap [str or matplotlib.colors.Colormap, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.
    **kwds Options to pass to matplotlib scatter plotting method.
    Returns
    class:matplotlib.axes.Axes
    See also:
    plotting.andrews_curves Plot clustering visualization.

    Examples

>>> df = pd.DataFrame(
    ...     {
    ...         'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
    ...         'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
    ...         'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
    ...         'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
    ...         'Category': ['virginica', 'virginica', 'setosa', 'virginica', 'virginica', 'versicolor', 'versicolor', 'setosa', 'virginica', 'setosa']
    ...     }
    ...)
```

(continues on next page)
3.13.10 pandas.plotting.register_matplotlib_converters

pandas.plotting.register_matplotlib_converters()

Register pandas formatters and converters with matplotlib.

This function modifies the global matplotlib.units.registry dictionary. pandas adds custom converters for

- pd.Timestamp
- pd.Period
- np.datetime64
- datetime.datetime
- datetime.date
- datetime.time

See also:

deregister_matplotlib_converters  Remove pandas formatters and converters.
3.13.11 pandas.plotting.scatter_matrix

pandas.plotting.scatter_matrix(frame, alpha=0.5, figsize=None, ax=None, grid=False, diagonal='hist', marker='.', density_kwds=None, hist_kwds=None, range_padding=0.05, **kwargs)

Draw a matrix of scatter plots.

**Parameters**

- **frame** [DataFrame] Amount of transparency applied.
- **alpha** [float, optional] A tuple (width, height) in inches.
- **figsize** [(float, float), optional] Matplotlib axis object, optional]
- **grid** [bool, optional] Setting this to True will show the grid.
- **diagonal** ['hist', 'kde'] Pick between ‘kde’ and ‘hist’ for either Kernel Density Estimation or Histogram plot in the diagonal.
- **marker** [str, optional] Matplotlib marker type, default ‘.’.
- **density_kwds** [keywords] Keyword arguments to be passed to kernel density estimate plot.
- **hist_kwds** [keywords] Keyword arguments to be passed to hist function.
- **range_padding** [float, default 0.05] Relative extension of axis range in x and y with respect to (x_max - x_min) or (y_max - y_min).

**Returns**

- **numpy.ndarray** A matrix of scatter plots.

**Examples**

```python
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A', 'B', 'C', 'D'])
>>> pd.plotting.scatter_matrix(df, alpha=0.2)
array([[[AxesSubplot:xlabel='A', ylabel='A'],
        AxesSubplot:xlabel='B', ylabel='A'],
       AxesSubplot:xlabel='C', ylabel='A'],
      AxesSubplot:xlabel='D', ylabel='A']),
      AxesSubplot:xlabel='A', ylabel='B'],
      AxesSubplot:xlabel='C', ylabel='B'],
      AxesSubplot:xlabel='D', ylabel='B']),
      AxesSubplot:xlabel='A', ylabel='C'],
      AxesSubplot:xlabel='B', ylabel='C'],
      AxesSubplot:xlabel='C', ylabel='C'],
      AxesSubplot:xlabel='D', ylabel='C'],
      AxesSubplot:xlabel='A', ylabel='D'],
      AxesSubplot:xlabel='B', ylabel='D'],
      AxesSubplot:xlabel='C', ylabel='D'],
      AxesSubplot:xlabel='D', ylabel='D']], dtype=object)
```
3.13.12 pandas.plotting.table

`pandas.plotting.table(ax, data, rowLabels=None, colLabels=None, **kwargs)`

Helper function to convert DataFrame and Series to matplotlib.table.

**Parameters**

- `ax` [Matplotlib axes object]
- `data` [DataFrame or Series] Data for table contents.
- `**kwargs` Keyword arguments to be passed to matplotlib.table.table. If `rowLabels` or `colLabels` is not specified, data index or column name will be used.

**Returns**

- `matplotlib table object`

3.14 General utility functions

3.14.1 Working with options

<table>
<thead>
<tr>
<th>function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>describe_option</code></td>
<td>Prints the description for one or more registered options.</td>
</tr>
<tr>
<td><code>reset_option</code></td>
<td>Reset one or more options to their default value.</td>
</tr>
<tr>
<td><code>get_option</code></td>
<td>Retrieves the value of the specified option.</td>
</tr>
<tr>
<td><code>set_option</code></td>
<td>Sets the value of the specified option.</td>
</tr>
<tr>
<td><code>option_context</code></td>
<td>Context manager to temporarily set options in the <code>with</code> statement context.</td>
</tr>
</tbody>
</table>

**pandas.describe_option**

`pandas.describe_option(pat, _print_desc=False) = <pandas._config.config.CallableDynamicDoc object>`

Prints the description for one or more registered options.

Call with no arguments to get a listing for all registered options.

Available options:

- `compute.[use_bottleneck, use_numba, use_numexpr]`
- `display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html.[border, table_schema, use_mathjax]`
- `display.[large_repr]`
- `display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display.[max_categories, max_columns, max_colwidth, max_dir_items, max_info_columns, max_info_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode.[ambiguous_as_wide, east_asian_width]`
- `display.[width]`
- `io.excel.ods.[reader, writer]`
- `io.excel.xls.[reader, writer]`
- `io.excel.xlsb.[reader]`
- `io.excel.xlsm.[reader, writer]`
- `io.excel.xlsx.[reader, writer]`
• io.hdf.[default_format, dropna_table]
• io.parquet.[engine]
• io.sql.[engine]
• mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
• plotting.[backend]
• plotting.matplotlib.[register_converters]
• styler.format.[decimal, escape, formatter, na_rep, precision, thousands]
• styler.html.[mathjax]
• styler.latex.[environment, hrules, multicol_align, multirow_align]
• styler.render.[encoding, max_columns, max_elements, max_rows, repr]
• styler.sparse.[columns, index]

Parameters

   pat  [str] Regexp pattern. All matching keys will have their description displayed.
   _print_desc  [bool, default True] If True (default) the description(s) will be printed to stdout.
   Otherwise, the description(s) will be returned as a unicode string (for testing).

Returns

None by default, the description(s) as a unicode string if _print_desc
is False

Notes

Please reference the User Guide for more information.

The available options with its descriptions:

compute.use_bottleneck  [bool] Use the bottleneck library to accelerate if it is installed, the default is True
Valid values: False,True [default: True] [currently: True]
compute.use_numba  [bool] Use the numba engine option for select operations if it is installed, the default is
False valid values: False,True [default: False] [currently: False]
compute.use_numexpr  [bool] Use the numexpr library to accelerate computation if it is installed, the default is
True valid values: False,True [default: True] [currently: True]
display.chop_threshold  [float or None] if set to a float value, all float values smaller then the given threshold
will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify  ['left'/'right'] Controls the justification of column headers. used by DataFrameFor-
matter. [default: right] [currently: right]
display.column_space  No description available. [default: 12] [currently: 12]
display.date_dayfirst  [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default:
False] [currently: False]
display.date_yearfirst  [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default:
False] [currently: False]
display.encoding  [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be
used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
display.expand_frame_repr  [boolean] Whether to print out the full DataFrame repr for wide DataFrames
across multiple lines, max_columns is still respected, but the output will wrap-around across multiple
“pages” if its width exceeds display.width. [default: True] [currently: True]
display.float_format  [callable] The callable should accept a floating point number and return a string with the
desired format of the number. This is used in some places like SeriesFormatter. See for-
mats.format.EngFormatter for an example. [default: None] [currently: None]
display.html.border  [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML
repr. [default: 1] [currently: 1]
**display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

**display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

**display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

**display.latex.escape** [bool] This specifies if the to_latex method of a DataFrame uses escapes special characters. Valid values: False,True [default: True] [currently: True]

**display.latex.longtable :bool** This specifies if the to_latex method of a DataFrame uses the longtable format. Valid values: False,True [default: False] [currently: False]

**display.latex.multicolumn** [bool] This specifies if the to_latex method of a DataFrame uses multicolumns to pretty-print MultiIndex columns. Valid values: True [default: True] [currently: True]

**display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a DataFrame uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

**display.latex.multirow** [bool] This specifies if the to_latex method of a DataFrame uses multirow to pretty-print MultiIndex rows. Valid values: True [default: False] [currently: False]

**display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for Jupyter environments that support it. (default: False) [default: False] [currently: False]

**display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

**display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

**display.max_colwidth** [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

**display.max_dir_items** [int] The number of items that will be added to dir(...). ‘None’ value means unlimited. Because dir is cached, changing this option will not immediately affect already existing dataframes until a column is deleted or added.

This is for instance used to suggest columns from a dataframe to tab completion. [default: 100] [currently: 100]

**display.max_info_categories** [int] max_info_categories is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

**display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

**display.max_rows** [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

**display.max_seq_items** [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string. If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

**display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]
display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]
display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy.set_printoptions() [default: 6] [currently: 6]
display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, the default is warn [default: warn] [currently: warn]
mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is
imported). [default: block] [currently: block]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False]
[currently: False]

mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way). False means None
and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version.
Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na
instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided
with pandas. Other backends can be specified by providing the name of the module that implements the
backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’] Whether to register converters with matplotlib’s units
registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring
any converters that pandas overwrote. [default: auto] [currently: auto]

styler.format.decimal [str] The character representation for the decimal separator for floats and complex. [de-
default: .] [currently: .]

styler.format.escape [str, optional] Whether to escape certain characters according to the given context: html
or latex. [default: None] [currently: None]

styler.format.formatter [str, callable, dict, optional] A formatter object to be used as default within Styler.
format. [default: None] [currently: None]

styler.format.na_rep [str, optional] The string representation for values identified as missing. [default: None]
[currently: None]

styler.format.precision [int] The precision for floats and complex numbers. [default: 6] [currently: 6]

styler.format.thousands [str, optional] The character representation for thousands separator for floats, int and
complex. [default: None] [currently: None]

styler.html.mathjax [bool] If False will render special CSS classes to table attributes that indicate Mathjax will
not be used in Jupyter Notebook. [default: True] [currently: True]

styler.latex.environment [str] The environment to replace \begin{table}. If “longtable” is used results in a
specific longtable environment format. [default: None] [currently: None]

styler.latex.hrules [bool] Whether to add horizontal rules on top and bottom and below the headers. [default:
False] [currently: False]

styler.latex.multicol_align [“r”, “c”, “l”, “naive-l”, “naive-r”] The specifier for horizontal alignment of spar-
sified LaTeX multicolumns. Pipe decorators can also be added to non-naive values to draw vertical rules,
e.g. “|r” will draw a rule on the left side of right aligned merged cells. [default: r] [currently: r]

styler.latex.multirow_align [“c”, “t”, “b”] The specifier for vertical alignment of sparsified LaTeX multirows.
[default: c] [currently: c]

styler.render.encoding [str] The encoding used for output HTML and LaTeX files. [default: utf-8] [currently:
utf-8]

styler.render.max_columns [int, optional] The maximum number of columns that will be rendered. May still
be reduced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

styler.render.max_elements [int] The maximum number of data-cell (<td>) elements that will be rendered
before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

styler.render.max_rows [int, optional] The maximum number of rows that will be rendered. May still be re-
duced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

styler.render.repr [str] Determine which output to use in Jupyter Notebook in {“html”, “latex”}. [default: html]
[currently: html]

styler.sparse.columns [bool] Whether to sparsify the display of hierarchical columns. Setting to False will
display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

styler.sparse.index [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display
each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

3.14. General utility functions
pandas: powerful Python data analysis toolkit, Release 1.4.3

pandas.reset_option

pandas.reset_option(pat) = <pandas._config.config.CallableDynamicDoc object>

Reset one or more options to their default value.

Pass “all” as argument to reset all options.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_dir_items, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
- mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]
- styler.format.[decimal, escape, formatter, na_rep, precision, thousands]
- styler.html.[mathjax]
- styler.latex.[environment, hrules, multicol_align, multirow_align]
- styler.render.[encoding, max_columns, max_elements, max_rows, repr]
- styler.sparse.[columns, index]

Parameters

pat [str/regex] If specified only options matching prefix* will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

None
Notes

Please reference the User Guide for more information.

The available options with its descriptions:
- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False. Valid values: False, True [default: False] [currently: False]
- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **display.chop_threshold** [float or None] If set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- **display.column_space** [int] No description available. [default: 12] [currently: 12]
- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, e.g., 20/01/2005. [default: False] [currently: False]
- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, e.g., 2005/01/20. [default: False] [currently: False]
- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. [default: False] [currently: False]
- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. [default: True] [currently: True]
- **display.large_repr** ['truncate'/’info’) For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]
- **display.latex.longtable** [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: False] [currently: False]
- **display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]
- **display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: False] [currently: False]
- **display.latex.multirow** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False, True [default: True] [currently: True]
- **display.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. [default: False] [currently: False]
- **display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
- **display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects
are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_dir_items [int] The number of items that will be added to dir(...). ‘None’ value means unlimited. Because dir is cached, changing this option will not immediately affect already existing dataframes until a column is deleted or added.

This is for instance used to suggest columns from a dataframe to tab completion. [default: 100] [currently: 100]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy.set_printoptions(). [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython
qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width.
[default: 80] [currently: 80]

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

styler.format.decimal [str] The character representation for the decimal separator for floats and complex. [default: .] [currently: .]

styler.format.escape [str, optional] Whether to escape certain characters according to the given context; html or latex. [default: None] [currently: None]

styler.format.formatter [str, callable, dict, optional] A formatter object to be used as default within Styler. [default: None] [currently: None]

styler.format.na_rep [str, optional] The string representation for values identified as missing. [default: None] [currently: None]
**pandas**—powerful Python data analysis toolkit, Release 1.4.3

**styler.format.precision** [int] The precision for floats and complex numbers. [default: 6] [currently: 6]

**styler.format.thousands** [str, optional] The character representation for thousands separator for floats, int and complex. [default: None] [currently: None]

**styler.html.mathjax** [bool] If False will render special CSS classes to table attributes that indicate Mathjax will not be used in Jupyter Notebook. [default: True] [currently: True]

**styler.latex.environment** [str] The environment to replace \begin{table}. If “longtable” is used results in a specific longtable environment format. [default: None] [currently: None]

**styler.latex.hrules** [bool] Whether to add horizontal rules on top and bottom and below the headers. [default: False] [currently: False]

**styler.latex.multicol_align** [“r”, “c”, “l”, “naive-l”, “naive-r”, “r”] The specifier for horizontal alignment of sparsified LaTeX multicolumns. Pipe decorators can also be added to non-naive values to draw vertical rules, e.g. “ir” will draw a rule on the left side of right aligned merged cells. [default: r] [currently: r]

**styler.latex.multirow_align** [“c”, “t”, “b”, “b”] The specifier for vertical alignment of sparsified LaTeX multirows. [default: c] [currently: c]

**styler.render.encoding** [str] The encoding used for output HTML and LaTeX files. [default: utf-8] [currently: utf-8]

**styler.render.max_columns** [int, optional] The maximum number of columns that will be rendered. May still be reduced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

**styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

**styler.render.max_rows** [int, optional] The maximum number of rows that will be rendered. May still be reduced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

**styler.render.repr** [str] Determine which output to use in Jupyter Notebook in {“html”, “latex”}. [default: html] [currently: html]

**styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

**styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

**pandas.get_option**

pandas.get_option(pat) = <pandas._config.config.CallableDynamicDoc object>

Retrieves the value of the specified option.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_dir_items, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multitabular, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsxm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
• mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
• plotting.[backend]
• plotting.matplotlib.[register_converters]
• styler.format.[decimal, escape, formatter, na_rep, precision, thousands]
• styler.html.[mathjax]
• styler.latex.[environment, hrules, multicol_align, multirow_align]
• styler.render.[encoding, max_columns, max_elements, max_rows, repr]
• styler.sparse.[columns, index]

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

result [the value of the option]

Raises

OptionError [if no such option exists]

Notes

Please reference the User Guide for more information.

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]
- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- **display.column_space** No description available. [default: 12] [currently: 12]
- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

3.14. General utility functions 2713
display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: False] [currently: True]
display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_dir_items [int] The number of items that will be added to dir(...). ‘None’ value means unlimited. Because dir is cached, changing this option will not immediately affect already existing dataframes until a column is deleted or added.

This is for instance used to suggest columns from a dataframe to tab completion. [default: 100] [currently: 100]
display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]
display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string. If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]
display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]
display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10]
display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy.set_printoptions(). [default: 6] [currently: 6]
display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, the default is warn [default: warn] [currently: warn]
mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]
mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
pandas: powerful Python data analysis toolkit, Release 1.4.3

[currently: False]

**mode.string_storage** [string] The default storage for StringDtype. [default: python] [currently: python]

**mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

**mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version.
Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

**plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

**plotting.matplotlib.register_converters** [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

**styler.format.decimal** [str] The character representation for the decimal separator for floats and complex. [default: .] [currently: .]

**styler.format.escape** [str, optional] Whether to escape certain characters according to the given context; html or latex. [default: None] [currently: None]

**styler.format.formatter** [str, callable, dict, optional] A formatter object to be used as default within Styler.
[default: None] [currently: None]

**styler.format.na_rep** [str, optional] The string representation for values identified as missing. [default: None] [currently: None]

**styler.format.precision** [int] The precision for floats and complex numbers. [default: 6] [currently: 6]

**styler.format.thousands** [str, optional] The character representation for thousands separator for floats, int and complex. [default: None] [currently: None]

**styler.html.mathjax** [bool] If False will render special CSS classes to table attributes that indicate Mathjax will not be used in Jupyter Notebook. [default: True] [currently: True]

**styler.latex.environment** [str] The environment to replace \begin{table}. If “longtable” is used results in a specific longtable environment format. [default: None] [currently: None]

**styler.latex.hrules** [bool] Whether to add horizontal rules on top and bottom and below the headers. [default: False] [currently: False]

**styler.latex.multicol_align** [“r”, “c”, “l”, “naive-l”, “naive-r”] The specifier for horizontal alignment of sparsified LaTeX multicolumns. Pipe decorators can also be added to non-naive values to draw vertical rules, e.g. “|r” will draw a rule on the left side of right aligned merged cells. [default: r] [currently: r]

**styler.latex.multirow_align** [“c”, “t”, “b”] The specifier for vertical alignment of sparsified LaTeX multirows. [default: c] [currently: c]

**styler.render.encoding** [str] The encoding used for output HTML and LaTeX files. [default: utf-8] [currently: utf-8]

**styler.render.max_columns** [int, optional] The maximum number of columns that will be rendered. May still be reduced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

**styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

**styler.render.max_rows** [int, optional] The maximum number of rows that will be rendered. May still be reduced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

**styler.render.repr** [str] Determine which output to use in Jupyter Notebook in {“html”, “latex”}. [default: html] [currently: html]

**styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

**styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]
pandas.set_option

pandas.set_option(pat, value) = <pandas._config.config.CallableDynamicDoc object>

Sets the value of the specified option.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_dir_items, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
- mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]
- styler.format.[decimal, escape, formatter, na_rep, precision, thousands]
- styler.html.[mathjax]
- styler.latex.[environment, hrules, multicol_align, multirow_align]
- styler.render.[encoding, max_columns, max_elements, max_rows, repr]
- styler.sparse.[columns, index]

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

value [object] New value of option.

Returns

None

Raises

OptionError if no such option exists
Notes

Please reference the User Guide for more information.

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False. Valid values: False, True [default: False] [currently: False]

- **display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: 1] [currently: 1]
- **display.latex.multitrow** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False, True [default: False] [currently: False]
- **display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
- **display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
- **display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects
are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_dir_items [int] The number of items that will be added to dir(...). ‘None’ value means unlimited. Because dir is cached, changing this option will not immediately affect already existing dataframes until a column is deleted or added.

This is for instance used to suggest columns from a dataframe to tab completion. [default: 100] [currently: 100]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string. If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True, False, ‘deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy.set_printoptions(). [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython

3.14. General utility functions 2719
qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width.  
[default: 80] [currently: 80]
[default: auto] [currently: auto]
[default: auto] [currently: auto]
[default: auto] [currently: auto]
[default: auto] [currently: auto] (Deprecated, use /\ instead.)
[default: auto] [currently: auto]
[default: auto] [currently: auto]
[default: auto] [currently: auto]
[default: auto] [currently: auto]
[default: auto] [currently: auto]
io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolor'auto'.] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]
mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]
mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
mode.use_inf_as_null [boolean] use_inf_as_null had been depreacted and will be removed in a future version. Use use_inf_as_nan instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)
plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
plotting.matplotlib.register_converters [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
styler.format.decimal [str] The character representation for the decimal separator for floats and complex.  
[default: .] [currently: .]
styler.format.escape [str, optional] Whether to escape certain characters according to the given context; html or latex. [default: None] [currently: None]
styler.format.formatter [str, callable, dict, optional] A formatter object to be used as default within Styler.  
format. [default: None] [currently: None]
styler.format.na_rep [str, optional] The string representation for values identified as missing. [default: None]  
[currently: None]
**pandas** : powerful Python data analysis toolkit, Release 1.4.3

**styler.format.precision** [int] The precision for floats and complex numbers. [default: 6] [currently: 6]

**styler.format.thousands** [str, optional] The character representation for thousands separator for floats, int and complex. [default: None] [currently: None]

**styler.html.mathjax** [bool] If False will render special CSS classes to table attributes that indicate Mathjax will not be used in Jupyter Notebook. [default: True] [currently: True]

**styler.latex.environment** [str] The environment to replace \begin{table}. If “longtable” is used results in a specific longtable environment format. [default: None] [currently: None]

**styler.latex.hrules** [bool] Whether to add horizontal rules on top and bottom and below the headers. [default: False] [currently: False]

**styler.latex.multicol_align** [{“r”, “c”, “l”, “naive-l”, “naive-r”}] The specifier for horizontal alignment of sparsified LaTeX multicolumns. Pipe decorators can also be added to non-naive values to draw vertical rules, e.g. “|r” will draw a rule on the left side of right aligned merged cells. [default: r] [currently: r]

**styler.latex.multirow_align** [{“c”, “t”, “b”}] The specifier for vertical alignment of sparsified LaTeX multirows. [default: c] [currently: c]

**styler.render.encoding** [str] The encoding used for output HTML and LaTeX files. [default: utf-8] [currently: utf-8]

**styler.render.max_columns** [int, optional] The maximum number of columns that will be rendered. May still be reduced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

**styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

**styler.render.max_rows** [int, optional] The maximum number of rows that will be rendered. May still be reduced to satisfy max_elements, which takes precedence. [default: None] [currently: None]

**styler.render.repr** [str] Determine which output to use in Jupyter Notebook in {“html”, “latex”}. [default: html] [currently: html]

**styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

**styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

---

**pandas.option_context**

**class pandas.option_context(*args)**

Context manager to temporarily set options in the with statement context.

You need to invoke as option_context(pat, val, [(pat, val), ...]).

**Examples**

```python
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...    pass
```

**Methods**

```python
__call__(func) Call self as a function.
```
### pandas.option_context.__call__

```python
option_context.__call__(func)
```

Call self as a function.

### 3.14.2 Testing functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>testing.assert_frame_equal(left, right[, ...])</code></td>
<td>Check that left and right DataFrame are equal.</td>

<td>Check that left and right Index are equal.</td>
</tr>
<tr>
<td><code>testing.assert_extension_array_equal(left, right)</code></td>
<td>Check that left and right ExtensionArrays are equal.</td>
</tr>
</tbody>
</table>

#### pandas.testing.assert_frame_equal

```python
pandas.testing.assert_frame_equal(left, right, check_dtype=True,
check_index_type='equiv',
check_column_type='equiv', check_frame_type=True,
check_less_precise=False, check_names=True,
by_blocks=False, check_exact=False,
check_datetimelike_compat=False, check_categorical=True,
check_like=False, check_freq=True, check_flags=True,
rtol=1e-05, atol=1e-08, obj='DataFrame')
```

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. Is is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

**Parameters**

- `left` [DataFrame] First DataFrame to compare.
- `right` [DataFrame] Second DataFrame to compare.
- `check_dtype` [bool, default True] Whether to check the DataFrame dtype is identical.
- `check_index_type` [bool or {‘equiv’}, default ‘equiv’] Whether to check the Index class, dtype and inferred_type are identical.
- `check_column_type` [bool or {‘equiv’}, default ‘equiv’] Whether to check the columns class, dtype and inferred_type are identical. Is passed as the exact argument of `assert_index_equal()`.
- `check_frame_type` [bool, default True] Whether to check the DataFrame class is identical.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
check_names [bool, default True] Whether to check that the names attribute for both the index and column attributes of the DataFrame is identical.

by_blocks [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_like [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.

click_freq [bool, default True] Whether to check the freq attribute on a DatetimeIndex or TimedeltaIndex.

New in version 1.1.0.

click_flags [bool, default True] Whether to check the flags attribute.

click [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

click [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default ‘DataFrame’] Specify object name being compared, internally used to show appropriate assertion message.

See also:

assert_series_equal Equivalent method for asserting Series equality.

DataFrame.equals Check DataFrame equality.

Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```python
>>> from pandas.testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```python
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column ‘b’ is of a different type.

```python
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
...
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute “dtype” are different [left]: int64 [right]: float64

Ignore differing dtypes in columns with check_dtypes.
assert_frame_equal(df1, df2, check_dtype=False)

pandas.testing.assert_series_equal
def pandas.testing.assert_series_equal(left, right, check_dtype=True, check_index_type='equiv',
check_series_type=True, check_less_precise=False, check_names=True, check_exact=False,
check_datetimelike_compat=False, check_categorical=True, check_category_order=True,
check_freq=True, check_flags=True, rtol=1e-05, atol=1e-08, obj='Series', *, check_index=True):

Check that left and right Series are equal.

Parameters

left [Series]
right [Series]
check_dtype [bool, default True] Whether to check the Series dtype is identical.
check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class,
dtype and inferred_type are identical.
check_series_type [bool, default True] Whether to check the Series class is identical.
check_less_precise [bool or int, default False] Specify comparison precision. Only used
when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are
compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we
compare the two numbers directly and check whether they are equivalent within the
specified precision. Otherwise, we compare the ratio of the second number to the first
number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute
tolerance, respectively. Similar to math.isclose().
check_names [bool, default True] Whether to check the Series and Index names attribute.
check_exact [bool, default False] Whether to compare number exactly.
check_datetimelike_compat [bool, default False] Compare datetime-like which is compa-
rable ignoring dtype.
check_categorical [bool, default True] Whether to compare internal Categorical exactly.
check_category_order [bool, default True] Whether to compare category order of internal
Categoricals.

New in version 1.0.2.
check_freq [bool, default True] Whether to check the freq attribute on a DatetimeIndex or
TimedeltaIndex.

New in version 1.1.0.
check_flags [bool, default True] Whether to check the flags attribute.

New in version 1.2.0.
rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.
atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.
New in version 1.1.0.

obj [str, default ‘Series’] Specify object name being compared, internally used to show appropriate assertion message.

check_index [bool, default True] Whether to check index equivalence. If False, then compare only values.
New in version 1.3.0.

Examples

```python
>>> from pandas import testing as tm
>>> a = pd.Series([1, 2, 3, 4])
>>> b = pd.Series([1, 2, 3, 4])
>>> tm.assert_series_equal(a, b)
```

pandas.testing.assert_index_equal

pandas.testing.assert_index_equal(left, right, exact='equiv', check_names=True,
check_less_precise=False, check_exact=True,
check_categorical=True, check_order=True, rtol=1e-05, atol=1e-08,
obj='Index')

Check that left and right Index are equal.

Parameters

left [Index]

right [Index]

exact [bool or {'equiv'}, default ‘equiv’] Whether to check the Index class, dtype and inferred_type are identical. If ‘equiv’, then RangeIndex can be substituted for Int64Index as well.

check_names [bool, default True] Whether to check the names attribute.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().

check_exact [bool, default True] Whether to compare number exactly.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_order [bool, default True] Whether to compare the order of index entries as well as their values. If True, both indexes must contain the same elements, in the same order. If False, both indexes must contain the same elements, but in any order.
New in version 1.2.0.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.
New in version 1.1.0.
**pandas: powerful Python data analysis toolkit, Release 1.4.3**

**atol** [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

**obj** [str, default ‘Index’] Specify object name being compared, internally used to show appropriate assertion message.

Examples

```python
>>> from pandas import testing as tm
>>> a = pd.Index([1, 2, 3])
>>> b = pd.Index([1, 2, 3])
>>> tm.assert_index_equal(a, b)
```

**pandas.testing.assert_extension_array_equal**

pandas.testing.assert_extension_array_equal(left, right, check_dtype=True, index_values=None, check_less_precise=NoDefault.no_default, check_exact=False, rtol=1e-05, atol=1e-08)

Check that left and right ExtensionArrays are equal.

**Parameters**

- **left, right** [ExtensionArray] The two arrays to compare.
- **check_dtype** [bool, default True] Whether to check if the ExtensionArray dtypes are identical.
- **index_values** [numpy.ndarray, default None] Optional index (shared by both left and right), used in output.
- **check_less_precise** [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare. Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().
- **check_exact** [bool, default False] Whether to compare number exactly.
- **rtol** [float, default 1e-5] Relative tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.
- **atol** [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.

**Notes**

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.
Examples

```python
>>> from pandas import testing as tm
>>> a = pd.Series([1, 2, 3, 4])
>>> b, c = a.array, a.array
>>> tm.assert_extension_array_equal(b, c)
```

### 3.14.3 Exceptions and warnings

</tr>
<tr>
<td><code>errors.UnsupportedFunctionCall</code></td>
<td>Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g.</td>
</tr>
</tbody>
</table>
pandas.errors(AbstractMethodError

**exception** pandas.errors.AbstractMethodError(*class_instance*, *methodtype='method')

Raise this error instead of NotImplementedError for abstract methods while keeping compatibility with Python 2 and Python 3.

pandas.errors.AccessorRegistrationWarning

**exception** pandas.errors.AccessorRegistrationWarning

Warning for attribute conflicts in accessor registration.

pandas.errors(DtypeWarning

**exception** pandas.errors.DtypeWarning

Warning raised when reading different dtypes in a column from a file.

Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

See also:

read_csv Read CSV (comma-separated) file into a DataFrame.
read_table Read general delimited file into a DataFrame.

Notes

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

Examples

This example creates and reads a large CSV file with a column that contains int and str.

```python
>>> df = pd.DataFrame({ 'a': ([1] * 100000 + ['X'] * 100000 + ...
... [1] * 100000),
... 'b': ['b'] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types
```

Important to notice that df2 will contain both str and int for the same input, '1'.

```python
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
```
One way to solve this issue is using the `dtype` parameter in the `read_csv` and `read_table` functions to explicit the conversion:

```python
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})
```

No warning was issued.

**pandas.errors.DuplicateLabelError**

**exception** pandas.errors.DuplicateLabelError

Error raised when an operation would introduce duplicate labels.

New in version 1.2.0.

**Examples**

```python
>>> s = pd.Series([0, 1, 2], index=['a', 'b', 'c']).set_flags(...
... allows_duplicate_labels=False
...)
>>> s.reindex(['a', 'a', 'b'])
Traceback (most recent call last):
  ...  
  duplicated: Index has duplicates.
  positions
  label
  a          [0, 1]
```

**pandas.errors.EmptyDataError**

**exception** pandas.errors.EmptyDataError

Exception that is thrown in `pd.read_csv` (by both the C and Python engines) when empty data or header is encountered.

**pandas.errors.InvalidIndexError**

**exception** pandas.errors.InvalidIndexError

Exception raised when attempting to use an invalid index key.

New in version 1.1.0.

**pandas.errors.IntCastingNaNError**

**exception** pandas.errors.IntCastingNaNError

Raised when attempting an astype operation on an array with NaN to an integer dtype.
pandas.errors.MergeError

`exception pandas.errors.MergeError`

Error raised when problems arise during merging due to problems with input data. Subclass of `ValueError`.

pandas.errors_NullFrequencyError

`exception pandas.errors_NullFrequencyError`

Error raised when a null `freq` attribute is used in an operation that needs a non-null frequency, particularly `DateTimeIndex.shift`, `TimedeltaIndex.shift`, `PeriodIndex.shift`.

pandas.errors.NumbaUtilError

`exception pandas.errors.NumbaUtilError`

Error raised for unsupported Numba engine routines.

pandas.errors.OptionError

`exception pandas.errors.OptionError`

Exception for pandas.options, backwards compatible with `KeyError` checks.

pandas.errorsOutOfBoundsDatetime

`exception pandas.errorsOutOfBoundsDatetime`

pandas.errorsOutOfBoundsTimedelta

`exception pandas.errorsOutOfBoundsTimedelta`

Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

pandas.errors.ParserError

`exception pandas.errors.ParserError`

Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like `read_csv` or `read_html` are parsing contents of a file.

See also:

- `read_csv` Read CSV (comma-separated) file into a DataFrame.
- `read_html` Read HTML table into a DataFrame.
exception pandas.errors.ParserWarning

Warning raised when reading a file that doesn’t use the default ‘c’ parser.

Raised by `pd.read_csv` and `pd.read_table` when it is necessary to change parsers, generally from the default ‘c’ parser to ‘python’.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, ‘c’ unsupported options include the following parameters:
   1. `sep` other than a single character (e.g. regex separators)
   2. `skipfooter` higher than 0
   3. `sep=None` with `delim_whitespace=False`

The warning can be avoided by adding `engine='python'` as a parameter in `pd.read_csv` and `pd.read_table` methods.

See also:

`pd.read_csv` Read CSV (comma-separated) file into DataFrame.
`pd.read_table` Read general delimited file into DataFrame.

Examples

Using a `sep` in `pd.read_csv` other than a single character:

```python
>>> import io
>>> csv = '''a;b;c
... 1;1,8
... 1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,,]')
... # ParserWarning: Falling back to the 'python' engine...
```

Adding `engine='python'` to `pd.read_csv` removes the Warning:

```python
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,,]', engine='python')
```

exception pandas.errors.PerformanceWarning

Warning raised when there is a possible performance impact.

exception pandas.errors.UnsortedIndexError

Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of `KeyError`.

3.14. General utility functions
pandas.errors.UnsupportedFunctionCall

**exception** pandas.errors.UnsupportedFunctionCall

Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)``

### 3.14.4 Data types related functionality

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api.types.union_categoricals(to_union[, ...])</code></td>
<td>Combine list-like of Categorical-like, unioning categories.</td>
</tr>
<tr>
<td><code>api.types.infer_dtype</code></td>
<td>Efficiently infer the type of a passed val, or list-like array of values.</td>
</tr>
<tr>
<td><code>api.types.pandas_dtype(dtype)</code></td>
<td>Convert input into a pandas only dtype object or a numpy dtype object.</td>
</tr>
</tbody>
</table>

**pandas.api.types.union_categoricals**

**pandas.api.types.union_categoricals(to_union, sort_categories=False, ignore_order=False)**

Combine list-like of Categorical-like, unioning categories.

All categories must have the same dtype.

**Parameters**

- `to_union` [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.
- `sort_categories` [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.
- `ignore_order` [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

**Returns**

Categorical

**Raises**

- **TypeError**
  - all inputs do not have the same dtype
  - all inputs do not have the same ordered property
  - all inputs are ordered and their categories are not identical
  - `sort_categories=True` and Categoricals are ordered

- **ValueError** Empty list of categoricals passed
Notes

To learn more about categories, see link

Examples

```python
>>> from pandas.api.types import union_categoricals

If you want to combine categoricals that do not necessarily have the same categories, `union_categoricals` will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python
>>> a = pd.Categorical(['b', 'c'])
>>> b = pd.Categorical(['a', 'b'])
```

```python
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the `categories` of the data. If you want the categories to be lexicographically sorted, use `sort_categories=True` argument.

```python
>>> union_categoricals([a, b], sort_categories=True)
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```python
>>> a = pd.Categorical(['a', 'b'], ordered=True)
>>> b = pd.Categorical(['a', 'b', 'a'], ordered=True)
```

```python
>>> union_categoricals([a, b])
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

Raises `TypeError` because the categories are ordered and not identical.

```python
>>> a = pd.Categorical(['a', 'b'], ordered=True)
>>> b = pd.Categorical(['a', 'b', 'c'], ordered=True)
```

```python
>>> union_categoricals([a, b])
Traceback (most recent call last):
...
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
>>> a = pd.Categorical(['a', 'b', 'c'], ordered=True)
>>> b = pd.Categorical(['c', 'b', 'a'], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`
>>> a = pd.Series(['b', 'c'], dtype='category')
>>> b = pd.Series(['a', 'b'], dtype='category')
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']

pandas.api.types.infer_dtype

pandas.api.types.infer_dtype()  
Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

Parameters

value [scalar, list, ndarray, or pandas type]

skipna [bool, default True] Ignore NaN values when inferring the type.

Returns

str Describing the common type of the input data.

Results can include:

• string
• bytes
• floating
• integer
• mixed-integer
• mixed-integer-float
• decimal
• complex
• categorical
• boolean
• datetime64
• datet ime
• date
• timedelta64
• timedelta
• time
• period
• mixed
• unknown-array

Raises

TypeError If ndarray-like but cannot infer the dtype
Notes

- ‘mixed’ is the catchall for anything that is not otherwise specialized
- ‘mixed-integer-float’ are floats and integers
- ‘mixed-integer’ are integers mixed with non-integers
- ‘unknown-array’ is the catchall for something that is an array (has a dtype attribute), but has a dtype unknown to pandas (e.g. external extension array)

Examples

```python
>>> import datetime
>>> infer_dtypes(['foo', 'bar'])
'string'
>>> infer_dtypes(['a', np.nan, 'b'], skipna=True)
'string'
>>> infer_dtypes(['a', np.nan, 'b'], skipna=False)
'mixed'
>>> infer_dtypes([b'foo', b'bar'])
'bytes'
>>> infer_dtypes([1, 2, 3])
'integer'
>>> infer_dtypes([1, 2, 3.5])
'mixed-integer-float'
>>> infer_dtypes([1.0, 2.0, 3.5])
'floating'
>>> infer_dtypes(['a', 1])
'mixed-integer'
>>> infer_dtypes([Decimal('1'), Decimal('2.0')])
<decimal'
>>> infer_dtypes([True, False])
'boolean'
>>> infer_dtypes([True, False, np.nan])
'boolean'
>>> infer_dtypes([pd.Timestamp('20130101')])
'datetime'
>>> infer_dtypes([datetime.date(2013, 1, 1)])
'date'
```
pandas: powerful Python data analysis toolkit, Release 1.4.3

>>> infer_dtype([np.datetime64('2013-01-01')])
'datetime64'

>>> infer_dtype([datetime.timedelta(0, 1, 1)])
'timedelta'

>>> infer_dtype(pd.Series(list('aabc')).astype('category'))
'categorical'

pandas.api.types.pandas_dtype

pandas.api.types.pandas_dtype(dtype)
Convert input into a pandas only dtype object or a numpy dtype object.

Parameters

dtype [object to be converted]

Returns

np.dtype or a pandas dtype

Raises

TypeError if not a dtype
Dtype introspection

- `api.types.is_bool_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of a boolean dtype.
- `api.types.is_categorical_dtype(arr_or_dtype)`: Check whether an array-like or dtype is of the Categorical dtype.
- `api.types.is_complex_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of a complex dtype.
- `api.types.is_datetime64_any_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of the datetime64 dtype.
- `api.types.is_datetime64_dtype(arr_or_dtype)`: Check whether an array-like or dtype is of the datetime64 dtype.
- `api.types.is_datetime64_ns_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of the datetime64[ns] dtype.
- `api.types.is_datetime64tz_dtype(arr_or_dtype)`: Check whether an array-like or dtype is of a DatetimeTZDtype dtype.
- `api.types.is_extension_type(arr)`: (DEPRECATED) Check whether an array-like is of a pandas extension class instance.
- `api.types.is_extension_array_dtype(arr_or_dtype)`: Check if an object is a pandas extension array type.
- `api.types.is_float_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of a float dtype.
- `api.types.is_int64_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of the int64 dtype.
- `api.types.is_integer_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of an integer dtype.
- `api.types.is_interval_dtype(arr_or_dtype)`: Check whether an array-like or dtype is of the Interval dtype.
- `api.types.is_numeric_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of a numeric dtype.
- `api.types.is_object_dtype(arr_or_dtype)`: Check whether an array-like or dtype is of the object dtype.
- `api.types.is_period_dtype(arr_or_dtype)`: Check whether an array-like or dtype is of the Period dtype.
- `api.types.is_signed_integer_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of a signed integer dtype.
- `api.types.is_string_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of the string dtype.
- `api.types.is_timedelta64_dtype(arr_or_dtype)`: Check whether an array-like or dtype is of the timedelta64 dtype.
- `api.types.is_timedelta64_ns_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of the timedelta64[ns] dtype.
- `api.types.is_unsigned_integer_dtype(arr_or_dtype)`: Check whether the provided array or dtype is of an unsigned integer dtype.
- `api.types.is_sparse(arr)`: Check whether an array-like is a 1-D pandas sparse array.
pandas.api.types.is_bool_dtype

pandas.api.types.is_bool_dtype(arr_or_dtype)

Check whether the provided array or dtype is of a boolean dtype.

Parameters

arr_or_dtype [array-like or dtype] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a boolean dtype.

Notes

An ExtensionArray is considered boolean when the _is_boolean attribute is set to True.

Examples

```python
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool_)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.arrays.SparseArray([True, False]))
True
```

pandas.api.types.is_categorical_dtype

pandas.api.types.is_categorical_dtype(arr_or_dtype)

Check whether an array-like or dtype is of the Categorical dtype.

Parameters

arr_or_dtype [array-like or dtype] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Categorical dtype.
Examples

```python
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex_dtype

```
pandas.api.types.is_complex_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a complex dtype.
Parameters
  arr_or_dtype  [array-like or dtype] The array or dtype to check.
Returns
  boolean      Whether or not the array or dtype is of a complex dtype.
```

Examples

```python
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex_)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

pandas.api.types.is_datetime64_any_dtype

```
pandas.api.types.is_datetime64_any_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64 dtype.
Parameters
  arr_or_dtype  [array-like or dtype] The array or dtype to check.
Returns
  bool         Whether or not the array or dtype is of the datetime64 dtype.
```
Examples

```python
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64)
# can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype="datetime64[ns]")
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]")
True
```

pandas.api.types.is_datetime64_dtype

pandas.api.types.is_datetime64_dtype(arr_or_dtype)

Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

- **arr_or_dtype** [array-like or dtype] The array-like or dtype to check.

Returns

- **boolean** Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

```python
>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False
```
pandas.api.types.is_datetime64_ns_dtype

pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype [array-like or dtype] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64[ns] dtype.

Examples

```python
>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64)  # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64"))  # no unit
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64[ps]"))  # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True
```

pandas.api.types.is_datetime64tz_dtype

pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)
Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

arr_or_dtype [array-like or dtype] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.
Examples

```python
>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3]))  # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
```

```python
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True
```

pandas.api.types.is_extension_type

pandas.api.types.is_extension_type(arr)
Check whether an array-like is of a pandas extension class instance.
Deprecated since version 1.0.0: Use is_extension_array_dtype instead.
Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

**Parameters**

- **arr** [array-like, scalar] The array-like to check.

**Returns**

- **boolean** Whether or not the array-like is of a pandas extension class instance.

Examples

```python
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>> cat = pd.Categorical([1, 2, 3])
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
```

(continues on next page)
is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
dtype = DatetimeTZDtype("ns", tz="US/Eastern")
s = pd.Series([], dtype=dtype)
is_extension_type(s)
True

pandas.api.types.is_extension_array_dtype

pandas.api.types.is_extension_array_dtype(arr_or_dtype)
Check if an object is a pandas extension array type.
See the Use Guide for more.
Parameters

arr_or_dtype [object] For array-like input, the .dtype attribute will be extracted.

Returns

bool Whether the arr_or_dtype is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:
• Categorical
• Sparse
• Interval
• Period
• DatetimeArray
• TimedeltaArray
Third-party libraries may implement arrays or types satisfying this interface as well.

Examples

>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True

>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False
pandas.api.types.is_float_dtype

pandas.api.types.is_float_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a float dtype.

Parameters

   arr_or_dtype  [array-like or dtype] The array or dtype to check.

Returns

   boolean  Whether or not the array or dtype is of a float dtype.

Examples

>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True

pandas.api.types.is_int64_dtype

pandas.api.types.is_int64_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the int64 dtype.

Parameters

   arr_or_dtype  [array-like or dtype] The array or dtype to check.

Returns

   boolean  Whether or not the array or dtype is of the int64 dtype.

Notes

Depending on system architecture, the return value of is_int64_dtype(int) will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.
### Examples

```python
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64)  # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.]))  # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

**pandas.api.types.is_integer_dtype**

**pandas.api.types.is_integer_dtype** *(arr_or_dtype)*

Check whether the provided array or dtype is of an integer dtype.

Unlike in *is_any_int_dtype*, timedelta64 instances will return False.

The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

**Parameters**

- **arr_or_dtype** [array-like or dtype] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of an integer dtype and not an instance of timedelta64.

**Examples**

```python
>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
```

(continues on next page)
True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.])) # float
False

pandas.api.types.is_interval_dtype

pandas.api.types.is_interval_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Interval dtype.
Parameters
    arr_or_dtype [array-like or dtype] The array-like or dtype to check.
Returns
    boolean Whether or not the array-like or dtype is of the Interval dtype.

Examples

>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
pandas.api.types.is_numeric_dtype

pandas.api.types.is_numeric_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a numeric dtype.

Parameters

arr_or_dtype [array-like or dtype] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a numeric dtype.

Examples

```python
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

pandas.api.types.is_object_dtype

pandas.api.types.is_object_dtypes(arr_or_dtype)
Check whether an array-like or dtype is of the object dtype.

Parameters

arr_or_dtype [array-like or dtype] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the object dtype.
Examples

```python
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

**pandas.api.types.is_period_dtype**

pandas.api.types.is_period_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Period dtype.

Parameters

- **arr_or_dtype** [array-like or dtype] The array-like or dtype to check.

Returns

- **boolean** Whether or not the array-like or dtype is of the Period dtype.

Examples

```python
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

**pandas.api.types.is_signed_integer_dtype**

pandas.api.types.is_signed_integer_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a signed integer dtype.

Unlike in is_any_int_dtype, timedelta64 instances will return False.

The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

Parameters

- **arr_or_dtype** [array-like or dtype] The array or dtype to check.

Returns

- **boolean** Whether or not the array or dtype is of a signed integer dtype and not an instance of timedelta64.
### Examples

given:

```python
given:

is_signed_integer_dtype(str)
False
is_signed_integer_dtype(int)
True
is_signed_integer_dtype(float)
False
is_signed_integer_dtype(np.uint64)  # unsigned
False
is_signed_integer_dtype('int8')
True
is_signed_integer_dtype('Int8')
True
is_signed_integer_dtype(pd.Int8Dtype)
True
is_signed_integer_dtype(np.datetime64)
False
is_signed_integer_dtype(np.timedelta64)
False
is_signed_integer_dtype(np.array(['a', 'b']))
False
is_signed_integer_dtype(pd.Series([1, 2]))
True
is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
is_signed_integer_dtype(pd.Index([1, 2.]))  # float
False
is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

#### pandas.api.types.is_string_dtype

**pandas.api.types.is_string_dtype(arr_or_dtype)**

Check whether the provided array or dtype is of the string dtype.

**Parameters**

- **arr_or_dtype** [array-like or dtype] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of the string dtype.
Examples

```python
>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>> is_string_dtype(np.array(['a', 'b']))
True
>>> is_string_dtype(pd.Series([1, 2]))
False
```

**pandas.api.types.is_timedelta64_dtype**

Check whether an array-like or dtype is of the timedelta64 dtype.

**Parameters**

- `arr_or_dtype` [array-like or dtype] The array-like or dtype to check.

**Returns**

- `boolean` Whether or not the array-like or dtype is of the timedelta64 dtype.

**Examples**

```python
>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False
```

**pandas.api.types.is_timedelta64_ns_dtype**

Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like `np.timedelta64` will return False if passed into this function.

**Parameters**

- `arr_or_dtype` [array-like or dtype] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of the timedelta64[ns] dtype.
Examples

```python
>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]'))  # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False
```

**pandas.api.types.is_unsigned_integer_dtype**

pandas.api.types.is_unsigned_integer_dtype(arr_or_dtype)

Check whether the provided array or dtype is of an unsigned integer dtype.

The nullable Integer dtypes (e.g. pandas.UInt64Dtype) are also considered as integer by this function.

Parameters

- **arr_or_dtype** [array-like or dtype] The array or dtype to check.

Returns

- boolean Whether or not the array or dtype is of an unsigned integer dtype.

Examples

```python
>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int)  # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2]))  # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True
```
pandas.api.types.is_sparse

pandas.api.types.is_sparse(arr)
Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

Parameters

arr [array-like] Array-like to check.

Returns

bool Whether or not the array-like is a pandas sparse array.

Examples

Returns True if the parameter is a 1-D pandas sparse array.

>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True

Returns False if the parameter is not sparse.

>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False

Returns False if the parameter is not a pandas sparse array.

>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False

Returns False if the parameter has more than one dimension.

Iterable introspection

| api.types.is_dict_like(obj) | Check if the object is dict-like. |
| api.types.is_file_like(obj) | Check if the object is a file-like object. |
| api.types.is_list_like | Check if the object is list-like. |
| api.types.is_named_tuple(obj) | Check if the object is a named tuple. |
| api.types.is_iterator | Check if the object is an iterator. |

**pandas.api.types.is_dict_like**

pandas.api.types.is_dict_like(obj)

Check if the object is dict-like.

**Parameters**

  - **obj** [The object to check]

**Returns**

  - **is_dict_like** [bool] Whether *obj* has dict-like properties.

**Examples**

```python
>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True
```

**pandas.api.types.is_file_like**

pandas.api.types.is_file_like(obj)

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a *read* and/or *write* method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

**Parameters**

  - **obj** [The object to check]

**Returns**

  - **is_file_like** [bool] Whether *obj* has file-like properties.

**Examples**

```python
>>> import io
>>> buffer = io.StringIO("data")
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```
pandas.api.types.is_list_like

pandas.api.types.is_list_like()  
Check if the object is list-like.
  
  Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series. Strings and datetime objects, however, are not considered list-like.

  Parameters
  
  *obj* [object] Object to check.

  *allow_sets* [bool, default True] If this parameter is False, sets will not be considered list-like.

  Returns

  *bool* Whether *obj* has list-like properties.

Examples

```python
>>> import datetime
>>> is_list_like([1, 2, 3])
True
>>> is_list_like({1, 2, 3})
True
>>> is_list_like(datetime.datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False
```

pandas.api.types.is_named_tuple

pandas.api.types.is_named_tuple(*obj*)  
Check if the object is a named tuple.

  Parameters

  *obj* [The object to check]

  Returns

  *is_named_tuple* [bool] Whether *obj* is a named tuple.
Examples

```python
>>> from collections import namedtuple
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False
```

**pandas.api.types.is_iterator**

pandas.api.types.is_iterator()

Check if the object is an iterator.

This is intended for generators, not list-like objects.

**Parameters**

- **obj** [The object to check]

**Returns**

- **is_iter** [bool] Whether *obj* is an iterator.

Examples

```python
>>> import datetime
>>> is_iterator((x for x in []))
True
>>> is_iterator([1, 2, 3])
False
>>> is_iterator(datetime.datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False
```
Scalar introspection

<table>

### pandas.api.types.is_bool

```python
pandas.api.types.is_bool()  
Return True if given object is boolean.

Returns

bool
```

### pandas.api.types.is_categorical

```python
pandas.api.types.is_categorical(arr)  
Check whether an array-like is a Categorical instance.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is of a Categorical instance.
```

#### Examples

```python
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```python
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```
pandas.api.types.is_complex

pandas.api.types.is_complex()
Return True if given object is complex.

Returns
bool

pandas.api.types.is_float

pandas.api.types.is_float()
Return True if given object is float.

Returns
bool

pandas.api.types.is_hashable

pandas.api.types.is_hashable(obj)
Return True if hash(obj) will succeed, False otherwise.

Some types will pass a test against collections.abc.Hashable but fail when they are actually hashed with hash().
Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.

Returns
bool

Examples

```python
>>> import collections
>>> a = ([],)
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```

pandas.api.types.is_integer

pandas.api.types.is_integer()
Return True if given object is integer.

Returns
bool
pandas.api.types.is_interval

pandas.api.types.is_interval()

pandas.api.types.is_number

pandas.api.types.is_number(obj)
Check if the object is a number.
Returns True when the object is a number, and False if is not.

Parameters

- obj [any type] The object to check if is a number.

Returns

- is_number [bool] Whether obj is a number or not.

See also:

api.types.is_integer Checks a subgroup of numbers.

Examples

```python
>>> from pandas.api.types import is_number
>>> is_number(1)
True
>>> is_number(7.15)
True

Booleans are valid because they are int subclass.

>>> is_number(False)
True

>>> is_number("foo")
False
>>> is_number("5")
False
```

pandas.api.types.is_re

pandas.api.types.is_re(obj)
Check if the object is a regex pattern instance.

Parameters

- obj [The object to check]

Returns

- is_regex [bool] Whether obj is a regex pattern.
Examples

```python
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

pandas.api.types.is_re_compilable

pandas.api.types.is_re_compilable(obj)

Check if the object can be compiled into a regex pattern instance.

Parameters

- **obj** [The object to check]

Returns

- **is_regex_compilable** [bool] Whether obj can be compiled as a regex pattern.

Examples

```python
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

pandas.api.types.is_scalar

pandas.api.types.is_scalar()

Return True if given object is scalar.

Parameters

- **val** [object] This includes:
  - numpy array scalar (e.g. np.int64)
  - Python builtin numerics
  - Python builtin byte arrays and strings
  - None
  - datetime.datetime
datetime.timedelta
  - Period
  - decimal.Decimal
  - Interval
  - DateOffset
  - Fraction
  - Number.
Returns

bool  Return True if given object is scalar.

Examples

>>> import datetime
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True

>>> pd.api.types.is_scalar([2, 3])
False

>>> pd.api.types.is_scalar({0: 1, 2: 3})
False

>>> pd.api.types.is_scalar((0, 2))
False

pandas supports PEP 3141 numbers:

>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True

3.14.5 Bug report function

show_versions([as_json])  Provide useful information, important for bug reports.

pandas.show_versions

pandas.show_versions(as_json=False)

Provide useful information, important for bug reports.

It comprises info about hosting operation system, pandas version, and versions of other installed relative packages.

Parameters

  as_json  [str or bool, default False]

  • If False, outputs info in a human readable form to the console.
  • If str, it will be considered as a path to a file. Info will be written to that file in JSON format.
  • If True, outputs info in JSON format to the console.
3.15 Extensions

These are primarily intended for library authors looking to extend pandas objects.

---

**api.extensions.register_extension_dtype**

This enables operations like `.astype(name)` for the name of the ExtensionDtype.

**Returns**

callable A class decorator.

**Examples**

```python
>>> from pandas.api.extensions import register_extension_dtype, ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     name = "myextension"
```

---

3.15.1 pandas.api.extensions.register_extension_dtype

3.15.2 pandas.api.extensions.register_dataframe_accessor

3.15.3 pandas.api.extensions.register_series_accessor

3.15.4 pandas.api.extensions.register_index_accessor
Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```python
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
                        "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```
3.15.3 pandas.api.extensions.register_series_accessor

pandas.api.extensions.register_series_accessor(name)

Register a custom accessor on Series objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this
name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:
register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the
signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
...```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your accessor
has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
... AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
```

(continues on next page)
Back in an interactive IPython session:

```python
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
...: "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

### 3.15.4 pandas.api.extensions.register_index_accessor

`pandas.api.extensions.register_index_accessor(name)`

Register a custom accessor on Index objects.

**Parameters**

- `name` [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

**Returns**

- `callable` A class decorator.

**See also:**

- `register_dataframe_accessor` Register a custom accessor on DataFrame objects.
- `register_series_accessor` Register a custom accessor on Series objects.
- `register_index_accessor` Register a custom accessor on Index objects.

**Notes**

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```
Examples

In your library code:

```python
import pandas as pd

def __init__(self, pandas_obj):
    self._obj = pandas_obj

def center(self):
    lat = self._obj.latitude
    lon = self._obj.longitude
    return (float(lon.mean()), float(lat.mean()))

def plot(self):
    # plot this array's data on a map, e.g., using Cartopy
    pass

Back in an interactive IPython session:

In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10), ...
                   "latitude": np.linspace(0, 20)})

In [2]: ds.geo.center
Out[2]: (5.0, 10.0)

In [3]: ds.geo.plot()  # plots data on a map

3.15.5 pandas.api.extensions.ExtensionDtype

class pandas.api.extensions.ExtensionDtype
    A custom data type, to be paired with an ExtensionArray.

See also:

extensions.register_extension_dtype Register an ExtensionType with pandas as class decorator.
extensions.ExtensionArray Abstract base class for custom 1-D array types.

Notes

The interface includes the following abstract methods that must be implemented by subclasses:
    • type
    • name
    • construct_array_type
The following attributes and methods influence the behavior of the dtype in pandas operations
    • _is_numeric
    • _is_boolean
    • _get_common_dtype
The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.
ExtensionDtypes are required to be hashable. The base class provides a default implementation, which relies on the _metadata class attribute. _metadata should be a tuple containing the strings that define your data type. For example, with PeriodDtype that’s the freq attribute.

**If you have a parametrized dtype you should set the \`_metadata\` class property.**

Ideally, the attributes in _metadata will match the parameters to your ExtensionDtype.__init__ (if any). If any of the attributes in _metadata don’t implement the standard __eq__ or __hash__, the default implementations here will not work.

For interaction with Apache Arrow (pyarrow), a __from_arrow__ method can be implemented: this method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:

```python
class ExtensionDtype:
    def __from_arrow__(self, array: Union[pyarrow.Array, pyarrow.ChunkedArray]) -> ExtensionArray:
        ...
```

This class does not inherit from ‘abc.ABCMeta’ for performance reasons. Methods and properties required by the interface raise pandas.errors(AbstractMethodError and no register method is provided for registering virtual subclasses.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>A character code (one of ‘biufcmMOSUV’), default ‘O’</td>
</tr>
<tr>
<td>na_value</td>
<td>Default NA value to use for this type.</td>
</tr>
<tr>
<td>name</td>
<td>A string identifying the data type.</td>
</tr>
<tr>
<td>names</td>
<td>Ordered list of field names, or None if there are no fields.</td>
</tr>
<tr>
<td>type</td>
<td>The scalar type for the array, e.g.</td>
</tr>
</tbody>
</table>

**pandas.api.extensions.ExtensionDtype.kind**

**property** ExtensionDtype.kind

A character code (one of ‘biufcmMOSUV’), default ‘O’

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably ‘O’ for object if the extension type cannot be represented as a built-in NumPy type.

**See also:**

**numpy.dtype.kind**
pandas.api.extensions.ExtensionDtype.na_value

**property ExtensionDtype.na_value**

Default NA value to use for this type.

This is used in e.g. ExtensionArray.take. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for JSONArray, this is an empty dictionary.

pandas.api.extensions.ExtensionDtype.name

**property ExtensionDtype.name**

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`

pandas.api.extensions.ExtensionDtype.names

**property ExtensionDtype.names**

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type

**property ExtensionDtype.type**

The scalar type for the array, e.g. `int`

It's expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of `type`.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>construct_array_type()</code></td>
<td>Return the array type associated with this dtype.</td>
</tr>
<tr>
<td><code>construct_from_string(string)</code></td>
<td>Construct this type from a string.</td>
</tr>
<tr>
<td><code>empty(shape)</code></td>
<td>Construct an ExtensionArray of this dtype with the given shape.</td>
</tr>
<tr>
<td><code>is_dtype(dtype)</code></td>
<td>Check if we match 'dtype'.</td>
</tr>
</tbody>
</table>

pandas.api.extensions.ExtensionDtype.construct_array_type

**classmethod ExtensionDtype.construct_array_type()**

Return the array type associated with this dtype.

**Returns**

`type`
pandas.api.extensions.ExtensionDtype.construct_from_string

classmethod ExtensionDtype.construct_from_string(string)

Construct this type from a string.

This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as period[H] (where H means hourly frequency).

By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

Parameters

   string [str] The name of the type, for example category.

Returns

   ExtensionDtype Instance of the dtype.

Raises

   TypeError If a class cannot be constructed from this 'string'.

Examples

For extension dtypes with arguments the following may be an adequate implementation.

```python
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"^my_type\[(?P<arg_name>.+)\]$")
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(f"Cannot construct a '{cls.__name__}' from '{string}'")
```

pandas.api.extensions.ExtensionDtype.empty

ExtensionDtype.empty(shape)

Construct an ExtensionArray of this dtype with the given shape.

Analogous to numpy.empty.

Parameters

   shape [int or tuple[int]]

Returns

   ExtensionArray
pandas.api.extensions.ExtensionDtype.is_dtype

classmethod ExtensionDtype.is_dtype(dtype)
    Check if we match 'dtype'.

    Parameters
    dtype [object] The object to check.

    Returns
    bool

Notes
The default implementation is True if
1. cls.construct_from_string(dtype) is an instance of cls.
2. dtype is an object and is an instance of cls
3. dtype has a dtype attribute, and any of the above conditions is true for dtype.dtype.

api.extensions.ExtensionArray() Abstract base class for custom 1-D array types.
arrays.PandasArray(values[, copy]) A pandas ExtensionArray for NumPy data.

3.15.6 pandas.api.extensions.ExtensionArray

class pandas.api.extensions.ExtensionArray
    Abstract base class for custom 1-D array types.

    pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a DataFrame or Series.

Notes
The interface includes the following abstract methods that must be implemented by subclasses:
• _from_sequence
• _from_factorized
• __getitem__
• __len__
• __eq__
• dtype
• nbytes
• isna
• take
• copy
• _concat_same_type
A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by by overriding:
• __repr__: A default repr for the ExtensionArray.
• _formatter: Print scalars inside a Series or DataFrame.
Some methods require casting the ExtensionArray to an ndarray of Python objects with self.astype(object), which may be expensive. When performance is a concern, we highly recommend overriding the following methods:
pandas: powerful Python data analysis toolkit, Release 1.4.3

- `fillna`
- `dropna`
- `unique`
- `factorize / _values_for_factorize`
- `argsort / _values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `_reduce`

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError)` and no `register` method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `.values` to ensure full compatibility with pandas internals. But other names as `.data`, `.data`, `.items`, ... can be freely used.

If implementing NumPy’s `_array_ufunc_` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in `inputs`. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See NumPy universal functions for more.

By default, ExtensionArrays are not hashable. Immutable subclasses may override this behavior.

**Attributes**

<table>
<thead>
<tr>
<th><code>dtype</code></th>
<th>An instance of 'ExtensionDtype'.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nbytes</code></td>
<td>The number of bytes needed to store this object in memory.</td>
</tr>
<tr>
<td><code>ndim</code></td>
<td>Extension Arrays are only allowed to be 1-dimensional.</td>
</tr>
<tr>
<td><code>shape</code></td>
<td>Return a tuple of the array dimensions.</td>
</tr>
</tbody>
</table>
pandas.api.extensions.ExtensionArray.dtype

property ExtensionArray.dtype
An instance of ‘ExtensionDtype’.

pandas.api.extensions.ExtensionArray.nbytes

property ExtensionArray.nbytes
The number of bytes needed to store this object in memory.

pandas.api.extensions.ExtensionArray.ndim

property ExtensionArray.ndim
Extension Arrays are only allowed to be 1-dimensional.

pandas.api.extensions.ExtensionArray.shape

property ExtensionArray.shape
Return a tuple of the array dimensions.
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>argsort()</code></td>
<td>Return the indices that would sort this array.</td>
</tr>
<tr>
<td><code>astype(dtype[, copy])</code></td>
<td>Cast to a NumPy array or ExtensionArray with 'dtype'.</td>
</tr>
<tr>
<td><code>copy()</code></td>
<td>Return a copy of the array.</td>
</tr>
<tr>
<td><code>dropna()</code></td>
<td>Return ExtensionArray without NA values.</td>
</tr>
<tr>
<td><code>factorize([na_sentinel])</code></td>
<td>Encode the extension array as an enumerated type.</td>
</tr>
<tr>
<td><code>fillna([value, method, limit])</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>equals(other)</code></td>
<td>Return if another array is equivalent to this array.</td>
</tr>
<tr>
<td><code>insert(loc, item)</code></td>
<td>Insert an item at the given position.</td>
</tr>
<tr>
<td><code>isin(values)</code></td>
<td>Pointwise comparison for set containment in the given values.</td>
</tr>
<tr>
<td><code>isna()</code></td>
<td>A 1-D array indicating if each value is missing.</td>
</tr>
<tr>
<td><code>ravel([order])</code></td>
<td>Return a flattened view on this array.</td>
</tr>
<tr>
<td><code>repeat(repeats[, axis])</code></td>
<td>Repeat elements of a ExtensionArray.</td>
</tr>
<tr>
<td><code>searchsorted(value[, side, sorter])</code></td>
<td>Find indices where elements should be inserted to maintain order.</td>
</tr>
<tr>
<td><code>shift([periods, fill_value])</code></td>
<td>Shift values by desired number.</td>
</tr>
<tr>
<td><code>take(indices, *[allow_fill, fill_value])</code></td>
<td>Take elements from an array.</td>
</tr>
<tr>
<td><code>tolist()</code></td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td><code>unique()</code></td>
<td>Compute the ExtensionArray of unique values.</td>
</tr>
<tr>
<td><code>view([dtype])</code></td>
<td>Return a view on the array.</td>
</tr>
<tr>
<td><code>_concat_same_type(to_concat)</code></td>
<td>Concatenate multiple array of this dtype.</td>
</tr>
<tr>
<td><code>_formatter([boxed])</code></td>
<td>Formatting function for scalar values.</td>
</tr>
<tr>
<td><code>_from_factorized(values, original)</code></td>
<td>Reconstruct an ExtensionArray after factorization.</td>
</tr>
<tr>
<td><code>_from_sequence(scalars, *[dtype, copy])</code></td>
<td>Construct a new ExtensionArray from a sequence of scalars.</td>
</tr>
<tr>
<td><code>_from_sequence_of_strings(strings, *[...])</code></td>
<td>Construct a new ExtensionArray from a sequence of strings.</td>
</tr>
<tr>
<td><code>_reduce(name, *[skipna])</code></td>
<td>Return a scalar result of performing the reduction operation.</td>
</tr>
<tr>
<td><code>_values_for_argsort()</code></td>
<td>Return values for sorting.</td>
</tr>
<tr>
<td><code>_values_for_factorize()</code></td>
<td>Return an array and missing value suitable for factorization.</td>
</tr>
</tbody>
</table>

pandas.api.extensions.ExtensionArray.argsort

ExtensionArray .argsort(ascending=True, kind='quicksort', na_position='last', *args, **kwargs)

Return the indices that would sort this array.

Parameters

- `ascending` [bool, default True] Whether the indices should result in an ascending or descending sort.
- `*args, **kwargs`: Passed through to `numpy.argsort()`.

Returns

- `np.ndarray[rt.intp]` Array of indices that sort self. If NaN values are contained, NaN values are placed at the end.
See also:

numpy.argsort  Sorting implementation used internally.

pandas.api.extensions.ExtensionArray.astype

ExtensionArray.astype(dtype, copy=True)
Cast to a NumPy array or ExtensionArray with ‘dtype’.

Parameters

dtype  [str or dtype] Typecode or data-type to which the array is cast.
copy  [bool, default True] Whether to copy the data, even if not necessary. If False, a
copy is made only if the old dtype does not match the new dtype.

Returns

array  [np.ndarray or ExtensionArray] An ExtensionArray if dtype is ExtensionDtype,
Otherwise a NumPy ndarray with ‘dtype’ for its dtype.

pandas.api.extensions.ExtensionArray.copy

ExtensionArray.copy()
Return a copy of the array.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

ExtensionArray.dropna()
Return ExtensionArray without NA values.

Returns

valid  [ExtensionArray]

pandas.api.extensions.ExtensionArray.factorize

ExtensionArray.factorize(na_sentinel=-1)
Encode the extension array as an enumerated type.

Parameters

na_sentinel  [int, default -1] Value to use in the codes array to indicate missing values.

Returns

codes  [ndarray] An integer NumPy array that’s an indexer into the original Extension-
Array.
uniques  [ExtensionArray] An ExtensionArray containing the unique values of self.

Note: uniques will not contain an entry for the NA value of the ExtensionArray if there are any missing values present in self.

See also:

factorize  Top-level factorize method that dispatches here.

Notes

pandas.factorize() offers a sort keyword as well.

pandas.api.extensions.ExtensionArray.fillna

ExtensionArray.fillna(value=None, method=None, limit=None)

Fill NA/NaN values using the specified method.

Parameters

value  [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like ‘value’ can be given. It’s expected that the array-like have the same length as ‘self’.

limit  [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

ExtensionArray  With NA/NaN filled.

pandas.api.extensions.ExtensionArray.equals

ExtensionArray.equals(other)

Return if another array is equivalent to this array.

Equivalent means that both arrays have the same shape and dtype, and all values compare equal. Missing values in the same location are considered equal (in contrast with normal equality).

Parameters

other  [ExtensionArray] Array to compare to this Array.

Returns

boolean  Whether the arrays are equivalent.
**pandas.api.extensions.ExtensionArray.insert**

ExtensionArray.insert(loc, item)

Insert an item at the given position.

**Parameters**

- loc [int]
- item [scalar-like]

**Returns**

same type as self

**Notes**

This method should be both type and dtype-preserving. If the item cannot be held in an array of this type/dtype, either ValueError or TypeError should be raised.

The default implementation relies on _from_sequence to raise on invalid items.

**pandas.api.extensions.ExtensionArray.isin**

ExtensionArray.isin(values)

Pointwise comparison for set containment in the given values.

Roughly equivalent to np.array([x in values for x in self])

**Parameters**

- values [Sequence]

**Returns**

np.ndarray[bool]

**pandas.api.extensions.ExtensionArray.isna**

ExtensionArray.isna()

A 1-D array indicating if each value is missing.

**Returns**

na_values [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like SparseArray, where returning an ndarray would be expensive, an ExtensionArray may be returned.
Notes

If returning an ExtensionArray, then

• `na_values._is_boolean` should be True

• `na_values` should implement `ExtensionArray._reduce()`

• `na_values.any` and `na_values.all` should be implemented

pandas.api.extensions.ExtensionArray.ravel

ExtensionArray.ravel(order='C')

Return a flattened view on this array.

Parameters

Returns

ExtensionArray

Notes

• Because ExtensionArrays are 1D-only, this is a no-op.
