pandas: powerful Python data analysis toolkit

Release 1.3.4

Wes McKinney and the Pandas Development Team
## CONTENTS

1 Getting started
   1.1 Installation .................................................. 3
   1.2 Intro to pandas ............................................ 3
   1.3 Coming from... ............................................ 5
   1.4 Tutorials .................................................. 5
      1.4.1 Installation .......................................... 6
      1.4.2 Package overview ..................................... 12
      1.4.3 Getting started tutorials ............................. 15
      1.4.4 Comparison with other tools ......................... 61
      1.4.5 Community tutorials ................................. 147

2 User Guide
   2.1 10 minutes to pandas ....................................... 149
      2.1.1 Object creation ...................................... 149
      2.1.2 Viewing data ........................................ 151
      2.1.3 Selection ............................................ 153
      2.1.4 Missing data ......................................... 158
      2.1.5 Operations ........................................... 159
      2.1.6 Merge ............................................... 161
      2.1.7 Grouping ............................................ 163
      2.1.8 Reshaping ............................................ 164
      2.1.9 Time series .......................................... 167
      2.1.10 Categoricals ......................................... 169
      2.1.11 Plotting ............................................ 170
      2.1.12 Getting data in/out ................................ 172
      2.1.13 Gotchas ............................................. 174
   2.2 Intro to data structures .................................... 174
      2.2.1 Series ............................................... 174
      2.2.2 DataFrame ........................................... 180
   2.3 Essential basic functionality ............................. 198
      2.3.1 Head and tail ......................................... 198
      2.3.2 Attributes and underlying data ...................... 199
      2.3.3 Accelerated operations ............................... 201
      2.3.4 Flexible binary operations .......................... 202
      2.3.5 Descriptive statistics ............................... 211
      2.3.6 Function application ................................ 220
      2.3.7 Reindexing and altering labels ...................... 233
      2.3.8 Iteration ............................................ 243
      2.3.9 dt accessor .......................................... 247
      2.3.10 Vectorized string methods ......................... 250

pandas: powerful Python data analysis toolkit, Release 1.3.4

**Date:** Oct 17, 2021  **Version:** 1.3.4

**Download documentation:** PDF Version | Zipped HTML

**Previous versions:** Documentation of previous pandas versions is available at pandas.pydata.org.

**Useful links:** Binary Installers | Source Repository | Issues & Ideas | Q&A Support | Mailing List

*pandas* is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the Python programming language.

---

**Getting started**

New to *pandas*? Check out the getting started guides. They contain an introduction to *pandas’* main concepts and links to additional tutorials.

*To the getting started guides*

**User guide**

The user guide provides in-depth information on the key concepts of *pandas* with useful background information and explanation.

*To the user guide*

**API reference**

The reference guide contains a detailed description of the *pandas* API. The reference describes how the methods work and which parameters can be used. It assumes that you have an understanding of the key concepts.

*To the reference guide*

**Developer guide**

Saw a typo in the documentation? Want to improve existing functionalities? The contributing guidelines will guide you through the process of improving *pandas*.

*To the development guide*
1.1 Installation

Working with conda?

pandas is part of the Anaconda distribution and can be installed with Anaconda or Miniconda:

```
conda install pandas
```

Prefer pip?

pandas can be installed via pip from PyPI.

```
pip install pandas
```

In-depth instructions?

Installing a specific version? Installing from source? Check the advanced installation page.

Learn more

1.2 Intro to pandas

*Straight to tutorial…*

When working with tabular data, such as data stored in spreadsheets or databases, pandas is the right tool for you. pandas will help you to explore, clean, and process your data. In pandas, a data table is called a **DataFrame**.

*To introduction tutorial*

*To user guide*

*Straight to tutorial…*

pandas supports the integration with many file formats or data sources out of the box (csv, excel, sql, json, parquet,…). Importing data from each of these data sources is provided by function with the prefix `read_*`. Similarly, the `to_*` methods are used to store data.

*To introduction tutorial*

*To user guide*

*Straight to tutorial…*
Selecting or filtering specific rows and/or columns? Filtering the data on a condition? Methods for slicing, selecting, and extracting the data you need are available in pandas.

pandas provides plotting your data out of the box, using the power of Matplotlib. You can pick the plot type (scatter, bar, boxplot,...) corresponding to your data.

There is no need to loop over all rows of your data table to do calculations. Data manipulations on a column work elementwise. Adding a column to a DataFrame based on existing data in other columns is straightforward.

Basic statistics (mean, median, min, max, counts...) are easily calculable. These or custom aggregations can be applied on the entire data set, a sliding window of the data, or grouped by categories. The latter is also known as the split-apply-combine approach.

Change the structure of your data table in multiple ways. You can melt your data table from wide to long/tidy form or pivot from long to wide format. With aggregations built-in, a pivot table is created with a single command.

Multiple tables can be concatenated both column wise and row wise as database-like join/merge operations are provided to combine multiple tables of data.

pandas has great support for time series and has an extensive set of tools for working with dates, times, and time-indexed data.
Datasets do not only contain numerical data. pandas provides a wide range of functions to clean textual data and extract useful information from it.

1.3 Coming from...

Are you familiar with other software for manipulating tabular data? Learn the pandas-equivalent operations compared to software you already know:

The R programming language provides the `data.frame` data structure and multiple packages, such as `tidyverse` use and extend `data.frame` for convenient data handling functionalities similar to pandas.

Already familiar to `SELECT`, `GROUP BY`, `JOIN`, etc.? Most of these SQL manipulations do have equivalents in pandas.

The data set included in the STATA statistical software suite corresponds to the pandas `DataFrame`. Many of the operations known from STATA have an equivalent in pandas.

Users of Excel or other spreadsheet programs will find that many of the concepts are transferrable to pandas.

The SAS statistical software suite also provides the data set corresponding to the pandas `DataFrame`. Also SAS vectorized operations, filtering, string processing operations, and more have similar functions in pandas.

1.4 Tutorials

For a quick overview of pandas functionality, see 10 Minutes to pandas.

You can also reference the pandas cheat sheet for a succinct guide for manipulating data with pandas.

The community produces a wide variety of tutorials available online. Some of the material is enlisted in the community contributed Community tutorials.
1.4.1 Installation

The easiest way to install pandas is to install it as part of the Anaconda distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, PyPI, ActivePython, various Linux distributions, or a development version are also provided.

Python version support

Officially Python 3.7.1 and above, 3.8, and 3.9.

Installing pandas

Installing with Anaconda

Installing pandas and the rest of the NumPy and SciPy stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the SciPy stack (IPython, NumPy, Matplotlib, ...) is with Anaconda, a cross-platform (Linux, macOS, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the SciPy stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for Anaconda can be found here.

A full list of the packages available as part of the Anaconda distribution can be found here.

Another advantage to installing Anaconda is that you don’t need admin rights to install it. Anaconda can install in the user’s home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

Installing with Miniconda

The previous section outlined how to get pandas installed as part of the Anaconda distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with Miniconda may be a better solution.

Conda is the package manager that the Anaconda distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

Miniconda allows you to create a minimal self contained Python installation, and then use the Conda command to install additional packages.

First you will need Conda to be installed and downloading and running the Miniconda will do this for you. The installer can be found here

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:
source activate name_of_my_env

On Windows the command is:

activate name_of_my_env

The final step required is to install pandas. This can be done with the following command:

conda install pandas

To install a specific pandas version:

conda install pandas=0.20.3

To install other packages, IPython for example:

conda install ipython

To install the full Anaconda distribution:

conda install anaconda

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

conda install pip
pip install django

**Installing from PyPI**

pandas can be installed via pip from PyPI.

pip install pandas

**Installing with ActivePython**

Installation instructions for ActivePython can be found here. Versions 2.7, 3.5 and 3.6 include pandas.

**Installing using your Linux distribution’s package manager.**

The commands in this table will install pandas for Python 3 from your distribution.
However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it's recommended to install using the pip or conda methods described above.

Handling ImportErrors

If you encounter an ImportError, it usually means that Python couldn't find pandas in the list of available libraries. Python internally has a list of directories it searches through, to find packages. You can obtain these directories with:

```python
import sys
sys.path
```

One way you could be encountering this error is if you have multiple Python installations on your system and you don’t have pandas installed in the Python installation you’re currently using. In Linux/Mac you can run `which python` on your terminal and it will tell you which Python installation you’re using. If it’s something like “/usr/bin/python”, you’re using the Python from the system, which is not recommended.

It is highly recommended to use conda, for quick installation and for package and dependency updates. You can find simple installation instructions for pandas in this document: installation instructions \( </getting_started.html \).

Installing from source

See the contributing guide for complete instructions on building from the git source tree. Further, see creating a development environment if you wish to create a pandas development environment.

Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have pytest >= 6.0 and Hypothesis >= 3.58, then run:

```bash
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-packages\pandas
```

(continues on next page)

</tr>
<tr>
<td>python-dateutil</td>
<td>2.7.3</td>
</tr>
<tr>
<td>pytz</td>
<td>2017.3</td>
</tr>
</tbody>
</table>

### Recommended dependencies

- **numexpr**: for accelerating certain numerical operations. `numexpr` uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.7.0 or higher.
- **bottleneck**: for accelerating certain types of `nan` evaluations. `bottleneck` uses specialized cython routines to achieve large speedups. If installed, must be Version 1.2.1 or higher.

**Note**: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

---

### Optional dependencies

Pandas has many optional dependencies that are only used for specific methods. For example, `pandas.read_hdf()` requires the `pytables` package, while `DataFrame.to_markdown()` requires the `tabulate` package. If the optional dependency is not installed, pandas will raise an `ImportError` when the method requiring that dependency is called.

1.4.2 Package overview

pandas is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, real-world data analysis in Python. Additionally, it has the broader goal of becoming the most powerful and flexible open source data analysis/manipulation tool available in any language. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, Series (1-dimensional) and DataFrame (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, DataFrame provides everything that R’s data.frame provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of missing data (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be inserted and deleted from DataFrame and higher dimensional objects
- Automatic and explicit data alignment: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let Series, DataFrame, etc. automatically align the data for you in computations
- Powerful, flexible group by functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it easy to convert ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based slicing, fancy indexing, and subsetting of large data sets
- Intuitive merging and joining data sets
- Flexible reshaping and pivoting of data sets
- Hierarchical labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from flat files (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast HDF5 format
- Time series-specific functionality: date range generation and frequency conversion, moving window statistics, date shifting, and lagging.
Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in Cython code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.

- pandas is a dependency of statsmodels, making it an important part of the statistical computing ecosystem in Python.

- pandas has been used extensively in production in financial applications.

### Data structures

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Series</td>
<td>1D labeled homogeneously-typed array</td>
</tr>
<tr>
<td>2</td>
<td>DataFrame</td>
<td>General 2D labeled, size-mutable tabular structure with potentially</td>
</tr>
<tr>
<td></td>
<td></td>
<td>heterogeneously-typed column</td>
</tr>
</tbody>
</table>

**Why more than one data structure?**

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using the N-dimensional array (ndarrays) to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguousness matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set, there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the index (the rows) and the columns rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```python
for col in df.columns:
    series = df[col]
    # do something with series
```
Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to favor immutability where sensible.

Getting support

The first stop for pandas issues and ideas is the Github Issue Tracker. If you have a general question, pandas community experts can answer through Stack Overflow.

Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to all of our contributors.

If you’re interested in contributing, please visit the contributing guide.

pandas is a NumFOCUS sponsored project. This will help ensure the success of the development of pandas as a world-class open-source project and makes it possible to donate to the project.

Project governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in Project Governance documents. The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

Development team

The list of the Core Team members and more detailed information can be found on the people’s page of the governance repo.

Institutional partners

The information about current institutional partners can be found on pandas website page.

### 1.4.3 Getting started tutorials

**What kind of data does pandas handle?**

I want to start using pandas

```python
In [1]: import pandas as pd
```

To load the pandas package and start working with it, import the package. The community agreed alias for pandas is pd, so loading pandas as pd is assumed standard practice for all of the pandas documentation.

**pandas data table representation**

I want to store passenger data of the Titanic. For a number of passengers, I know the name (characters), age (integers) and sex (male/female) data.

```python
In [2]: df = pd.DataFrame(
    ...:     {
    ...:       "Name": [
    ...:         "Braund, Mr. Owen Harris",
    ...:         "Allen, Mr. William Henry",
    ...:         "Bonnell, Miss. Elizabeth",
    ...:     ],
    ...:     }
```

(continues on next page)
To manually store data in a table, create a DataFrame. When using a Python dictionary of lists, the dictionary keys will be used as column headers and the values in each list as columns of the DataFrame.

A DataFrame is a 2-dimensional data structure that can store data of different types (including characters, integers, floating point values, categorical data and more) in columns. It is similar to a spreadsheet, a SQL table or the data.frame in R.

- The table has 3 columns, each of them with a column label. The column labels are respectively Name, Age and Sex.
- The column Name consists of textual data with each value a string, the column Age are numbers and the column Sex is textual data.

In spreadsheet software, the table representation of our data would look very similar:
Each column in a DataFrame is a Series

I’m just interested in working with the data in the column Age

In [4]: df["Age"]
Out[4]:
0   22
1   35
2   58
Name: Age, dtype: int64

When selecting a single column of a pandas DataFrame, the result is a pandas Series. To select the column, use the column label in between square brackets [].

Note: If you are familiar to Python dictionaries, the selection of a single column is very similar to selection of dictionary values based on the key.

You can create a Series from scratch as well:

In [5]: ages = pd.Series([22, 35, 58], name="Age")
In [6]: ages
Out[6]:
0   22
1   35
2   58
Name: Age, dtype: int64

A pandas Series has no column labels, as it is just a single column of a DataFrame. A Series does have row labels.

Do something with a DataFrame or Series

I want to know the maximum Age of the passengers

We can do this on the DataFrame by selecting the Age column and applying max():

In [7]: df["Age"].max()
Out[7]: 58

Or to the Series:

In [8]: ages.max()
Out[8]: 58

As illustrated by the max() method, you can do things with a DataFrame or Series. pandas provides a lot of functionalities, each of them a method you can apply to a DataFrame or Series. As methods are functions, do not forget to use parentheses ()

I’m interested in some basic statistics of the numerical data of my data table
In [9]: df.describe()

Out[9]:

    Age
count 3.000000
mean  38.333333
std   18.230012
min  22.000000
25%  28.500000
50%  35.000000
75%  46.500000
max  58.000000

The `describe()` method provides a quick overview of the numerical data in a DataFrame. As the Name and Sex columns are textual data, these are by default not taken into account by the `describe()` method.

Many pandas operations return a DataFrame or a Series. The `describe()` method is an example of a pandas operation returning a pandas Series or a pandas DataFrame.

Check more options on `describe` in the user guide section about `aggregations with describe`.

**Note:** This is just a starting point. Similar to spreadsheet software, pandas represents data as a table with columns and rows. Apart from the representation, also the data manipulations and calculations you would do in spreadsheet software are supported by pandas. Continue reading the next tutorials to get started!

- Import the package, aka `import pandas as pd`
- A table of data is stored as a pandas DataFrame
- Each column in a DataFrame is a Series
- You can do things by applying a method to a DataFrame or Series

A more extended explanation to DataFrame and Series is provided in the `introduction to data structures`.

In [1]: `import pandas as pd`

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.
How do I read and write tabular data?

I want to analyze the Titanic passenger data, available as a CSV file.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

pandas provides the `read_csv()` function to read data stored as a csv file into a pandas DataFrame. pandas supports many different file formats or data sources out of the box (csv, excel, sql, json, parquet, ...), each of them with the prefix `read_*`.

Make sure to always have a check on the data after reading in the data. When displaying a DataFrame, the first and last 5 rows will be shown by default:

```python
In [3]: titanic
Out[3]:
PassengerId  Survived  Pclass   Name                                      
0        1          0      3  Braund, Mr. Owen Harris       male  22.0  1  0 A/5 21171 7.2500  NaN  S
1        2          1      1  Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0  1  0 PC 17599 71.2833  C85  C
2        3          1      3  Heikkinen, Miss. Laina        female  26.0  0  0 STON/O2. 3101282 7.9250 NaN  S
3        4          1      3  Futrelle, Mrs. Jacques Heath (Lily May Peel) female  35.0  1  0  113803 53.1000  C123  S
4        5          1      3  Allen, Mr. William Henry       male  35.0  0  0  373450  8.0500 NaN  S
...     ...        ...    ...                                      ...
886    887          0      2 Montvila, Rev. Juozas          male  27.0  0  0  211536  13.0000 NaN  S
887    888          1      1 Graham, Miss. Margaret Edith     female  19.0  0  0  112053  30.0000  B42  S
888    889          0      3 Johnston, Miss. Catherine Helen "Carrie" female NaN  1  2 W./C. 6607 23.4500 NaN  S
889    890          1      1 Behr, Mr. Karl Howell          male  26.0  0  0  111369  30.0000  C148  C
890    891          0      3 Dooley, Mr. Patrick           male  32.0  0  0  370376  7.7500 NaN  Q
[891 rows x 12 columns]
```

I want to see the first 8 rows of a pandas DataFrame.

```python
In [4]: titanic.head(8)
Out[4]:
PassengerId  Survived  Pclass   Name                                      
0        1          0      3  Braund, Mr. Owen Harris       male  22.0  1  0 A/5 21171 7.2500  NaN  S
1        2          1      1  Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0  1  0 PC 17599 71.2833  C85  C
2        3          1      3  Heikkinen, Miss. Laina        female  26.0  0  0 STON/O2. 3101282 7.9250 NaN  S (continues on next page)
```

1.4. Tutorials 19
To see the first N rows of a DataFrame, use the `head()` method with the required number of rows (in this case 8) as argument.

**Note:** Interested in the last N rows instead? pandas also provides a `tail()` method. For example, `titanic.tail(10)` will return the last 10 rows of the DataFrame.

A check on how pandas interpreted each of the column data types can be done by requesting the pandas `dtypes` attribute:

```python
In [5]: titanic.dtypes
Out[5]:
PassengerId  int64
Survived     int64
Pclass       int64
Name         object
Sex          object
Age          float64
SibSp        int64
Parch        int64
Ticket       object
Fare         float64
Cabin        object
Embarked     object
dtype: object
```

For each of the columns, the used data type is enlisted. The data types in this DataFrame are integers (`int64`), floats (`float64`) and strings (`object`).

**Note:** When asking for the `dtypes`, no brackets are used! `dtypes` is an attribute of a DataFrame and Series. Attributes of DataFrame or Series do not need brackets. Attributes represent a characteristic of a DataFrame/Series, whereas a method (which requires brackets) *do something* with the DataFrame/Series as introduced in the *first tutorial*.

My colleague requested the Titanic data as a spreadsheet.

```python
In [6]: titanic.to_excel("titanic.xlsx", sheet_name="passengers", index=False)
```

Whereas `read_*` functions are used to read data to pandas, the `to_*` methods are used to store data. The `to_excel()` method stores the data as an excel file. In the example here, the `sheet_name` is named `passengers` instead of the default `Sheet1`. By setting `index=False` the row index labels are not saved in the spreadsheet.
The equivalent read function `read_excel()` will reload the data to a DataFrame:

```python
In [7]: titanic = pd.read_excel("titanic.xlsx", sheet_name="passengers")
```

```python
In [8]: titanic.head()
Out[8]:
         PassengerId  Survived  Pclass     Name                  Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
0          1          0      3  Braund, Mr. Owen Harris  male  22.0     1     0     A/5 21171  7.2500    NaN     S
1          2          1      1  Cumings, Mrs. John Bradley (Florence Briggs Th...  female  38.0     1     0       PC 17599 71.2833  C85     C
2          3          1      3  Heikkinen, Miss. Laina  female  26.0     0     0  STON/O2. 3101282  7.9250    NaN     S
3          4          1      1  Futrelle, Mrs. Jacques Heath (Lily May Peel)  female  35.0     1     0  113803 C123 53.1000     NaN     S
4          5          0      3  Allen, Mr. William Henry  male  35.0     0     0  373450  8.0500    NaN     S
```

I'm interested in a technical summary of a DataFrame

```python
In [9]: titanic.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 891 entries, 0 to 890
Data columns (total 12 columns):
 #    Column     Non-Null Count   Dtype
---  ------       --------------   -----
 0    PassengerId 891 non-null   int64
 1    Survived    891 non-null   int64
 2    Pclass      891 non-null   int64
 3    Name        891 non-null   object
 4    Sex         891 non-null   object
 5    Age         714 non-null   float64
 6    SibSp       891 non-null   int64
 7    Parch       891 non-null   int64
 8    Ticket      891 non-null   object
 9    Fare        891 non-null   float64
10   Cabin       204 non-null   object
11   Embarked    889 non-null   object
dtypes: float64(2), int64(5), object(5)
memory usage: 83.7+ KB
```

The method `info()` provides technical information about a DataFrame, so let's explain the output in more detail:

- It is indeed a DataFrame.
- There are 891 entries, i.e. 891 rows.
- Each row has a row label (aka the index) with values ranging from 0 to 890.
- The table has 12 columns. Most columns have a value for each of the rows (all 891 values are non-null). Some columns do have missing values and less than 891 non-null values.
- The columns Name, Sex, Cabin and Embarked consists of textual data (strings, aka object). The other columns are numerical data with some of them whole numbers (aka integer) and others are real numbers (aka float).
- The kind of data (characters, integers, ...) in the different columns are summarized by listing the dtypes.
The approximate amount of RAM used to hold the DataFrame is provided as well.

Getting data in to pandas from many different file formats or data sources is supported by read_ * functions.

Exporting data out of pandas is provided by different to_ * methods.

The head/tail/info methods and the dtypes attribute are convenient for a first check.

For a complete overview of the input and output possibilities from and to pandas, see the user guide section about reader and writer functions.

```python
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
- **Parch**: Whether a passenger is alone or have family.
- **Ticket**: Ticket number of passenger.
- **Fare**: Indicating the fare.
- **Cabin**: The cabin of passenger.
- **Embarked**: The embarked category.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
In [3]: titanic.head()
```

</table>
How do I select a subset of a DataFrame?

How do I select specific columns from a DataFrame?

I’m interested in the age of the Titanic passengers.

```python
In [4]: ages = titanic["Age"]
```

```python
In [5]: ages.head()
Out[5]:
0   22.0
1   38.0
2   26.0
3   35.0
4   35.0
Name: Age, dtype: float64
```

To select a single column, use square brackets `[]` with the column name of the column of interest.

Each column in a DataFrame is a Series. As a single column is selected, the returned object is a pandas Series. We can verify this by checking the type of the output:

```python
In [6]: type(titanic["Age"])
Out[6]: pandas.core.series.Series
```

And have a look at the shape of the output:

```python
In [7]: titanic["Age"].shape
Out[7]: (891,)
```

DataFrame.shape is an attribute (remember tutorial on reading and writing, do not use parentheses for attributes) of a pandas Series and DataFrame containing the number of rows and columns: (nrows, ncolumns). A pandas Series is 1-dimensional and only the number of rows is returned.

I’m interested in the age and sex of the Titanic passengers.

```python
In [8]: age_sex = titanic[["Age", "Sex"]]
```

```python
In [9]: age_sex.head()
Out[9]:
       Age  Sex
0   22.0  male
1   38.0 female
2   26.0 female
3   35.0 female
4   35.0  male
```

To select multiple columns, use a list of column names within the selection brackets `[]`.

**Note:** The inner square brackets define a Python list with column names, whereas the outer brackets are used to select the data from a pandas DataFrame as seen in the previous example.

The returned data type is a pandas DataFrame:
In [10]: type(titanic["Age", "Sex"])
Out[10]: pandas.core.frame.DataFrame

In [11]: titanic["Age", "Sex"].shape
Out[11]: (891, 2)

The selection returned a DataFrame with 891 rows and 2 columns. Remember, a DataFrame is 2-dimensional with both a row and column dimension.

For basic information on indexing, see the user guide section on indexing and selecting data.

How do I filter specific rows from a DataFrame?

I'm interested in the passengers older than 35 years.

In [12]: above_35 = titanic[titanic["Age"] > 35]

In [13]: above_35.head()

<table>
<thead>
<tr>
<th>PassengerId</th>

<td></td>
</tr>
</tbody>
</table>

To select rows based on a conditional expression, use a condition inside the selection brackets [].

The condition inside the selection brackets `titanic["Age"] > 35` checks for which rows the `Age` column has a value larger than 35:

In [14]: titanic["Age"] > 35
Out[14]:
0   False
1   True
2  False
3  False
4  False
   ...  
886  False
887  False
888  False
889  False
890  False
Name: Age, Length: 891, dtype: bool
The output of the conditional expression (>), but also ==, !=, <, <=,... would work) is actually a pandas Series of boolean values (either True or False) with the same number of rows as the original DataFrame. Such a Series of boolean values can be used to filter the DataFrame by putting it in between the selection brackets [ ]. Only rows for which the value is True will be selected.

We know from before that the original Titanic DataFrame consists of 891 rows. Let’s have a look at the number of rows which satisfy the condition by checking the shape attribute of the resulting DataFrame above_35:

```
In [15]: above_35.shape
Out[15]: (217, 12)
```

I’m interested in the Titanic passengers from cabin class 2 and 3.

```
In [16]: class_23 = titanic[titanic["Pclass"].isin([2, 3])]
In [17]: class_23.head()
Out[17]:
   PassengerId  Survived  Pclass       Name       Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
1 1       0   3     A/5 21171 22.00  1 0 0  NaN   NaN       NaN   S
2 2       0   3  STON/O2. 3101282 7.9250  3 1 0  NaN   NaN       NaN   S
3 3       1   3     373450 8.0500  3 0 0  NaN   NaN       NaN   S
4 4       0   3     330877 8.4583  3 0 0  NaN   NaN       NaN   Q
5 5       0   3  3349909 21.0750  3 0 0  NaN   NaN       NaN   S
6 6       0   3     Allen, Mr. William Henry male 35.0  0 0 0  NaN   NaN       NaN   S
```

Similar to the conditional expression, the isin() conditional function returns a True for each row the values are in the provided list. To filter the rows based on such a function, use the conditional function inside the selection brackets [ ]. In this case, the condition inside the selection brackets titanic["Pclass"].isin([2, 3]) checks for which rows the Pclass column is either 2 or 3.

The above is equivalent to filtering by rows for which the class is either 2 or 3 and combining the two statements with an | (or) operator:

```
In [18]: class_23 = titanic[(titanic["Pclass"] == 2) | (titanic["Pclass"] == 3)]
In [19]: class_23.head()
Out[19]:
   PassengerId  Survived  Pclass       Name       Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
1 1       0   3     A/5 21171 22.00  1 0 0  NaN   NaN       NaN   S
2 2       0   3  STON/O2. 3101282 7.9250  3 1 0  NaN   NaN       NaN   S
3 3       1   3     373450 8.0500  3 0 0  NaN   NaN       NaN   S
4 4       0   3     330877 8.4583  3 0 0  NaN   NaN       NaN   Q
5 5       0   3  3349909 21.0750  3 0 0  NaN   NaN       NaN   S
6 6       0   3     Moran, Mr. James male NaN  0 0 0  NaN   NaN       NaN   S
7 7       0   3     Palsson, Master. Gosta Leonard male 2.0  0 0 0  NaN   NaN       NaN   S
8 8       0   3     3349909 21.0750  3 0 0  NaN   NaN       NaN   S
```

1.4. Tutorials

25
When combining multiple conditional statements, each condition must be surrounded by parentheses (). Moreover, you cannot use or/and but need to use the or operator | and the and operator &.

See the dedicated section in the user guide about boolean indexing or about the isin function.

I want to work with passenger data for which the age is known.

```python
In [20]: age_no_na = titanic[titanic["Age"].notna()]

In [21]: age_no_na.head()
Out[21]:
   PassengerId  Survived  Pclass  Name         Sex    Age  SibSp  Parch  Ticket  Fare  Cabin    Embarked
0           0   0    3.0  Braund, Mr. Owen Harris  male  22.0      1      0    A/5 21171  7.2500    NaN      NaN
1           1   1    1.0  Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0      1      0    PC 17599  71.2833  C85      NaN
2           2   0    3.0  Heikkinen, Miss. Laina  female  26.0      1      0    STON/O2. 3101282  7.9250    NaN      NaN
3           3   0    1.0  Futrelle, Mrs. Jacques Heath (Lily May Peel)  female  35.0      1      0    113803  53.1000    C123      NaN
4           4   0    3.0  Allen, Mr. William Henry  male  35.0      0      0  373450  8.0500    NaN      NaN
```

The `notna()` conditional function returns a True for each row the values are not a Null value. As such, this can be combined with the selection brackets [] to filter the data table.

You might wonder what actually changed, as the first 5 lines are still the same values. One way to verify is to check if the shape has changed:

```python
In [22]: age_no_na.shape
Out[22]: (714, 12)
```

For more dedicated functions on missing values, see the user guide section about handling missing data.

How do I select specific rows and columns from a DataFrame?

I’m interested in the names of the passengers older than 35 years.

```python
In [23]: adult_names = titanic.loc[titanic["Age"] > 35, "Name"]

In [24]: adult_names.head()
Out[24]:
   Name
0  Cumings, Mrs. John Bradley (Florence Briggs Th...  
1  McCarthy, Mr. Timothy J
2  Bonnell, Miss. Elizabeth
3  Andersson, Mr. Anders Johan
4  Hewlett, Mrs. (Mary D Kingcome)
Name: Name, dtype: object
```
In this case, a subset of both rows and columns is made in one go and just using selection brackets [] is not sufficient anymore. The loc/iloc operators are required in front of the selection brackets[]. When using loc/iloc, the part before the comma is the rows you want, and the part after the comma is the columns you want to select.

When using the column names, row labels or a condition expression, use the loc operator in front of the selection brackets[]. For both the part before and after the comma, you can use a single label, a list of labels, a slice of labels, a conditional expression or a colon. Using a colon specifies you want to select all rows or columns.

I’m interested in rows 10 till 25 and columns 3 to 5.

```
in [25]: titanic.iloc[9:25, 2:5]
out[25]:
         Name     Sex
Pclass
9  2  Nasser, Mrs. Nicholas (Adele Achem)  female
10 3  Sandstrom, Miss. Marguerite Rut      female
11 1  Bonnell, Miss. Elizabeth            female
12 3  Saunderton, Mr. William Henry       male
13 3  Andersson, Mr. Anders Johan         male
.. ... ... ... ...
20 2  Fynney, Mr. Joseph J                male
21 2  Beesley, Mr. Lawrence               male
22 3  McGowan, Miss. Anna "Annie"         female
23 1  Sloper, Mr. William Thompson        male
24 3  Palsson, Miss. Torborg Danira       female

[16 rows x 3 columns]
```

Again, a subset of both rows and columns is made in one go and just using selection brackets [] is not sufficient anymore. When specifically interested in certain rows and/or columns based on their position in the table, use the iloc operator in front of the selection brackets[].

When selecting specific rows and/or columns with loc or iloc, new values can be assigned to the selected data. For example, to assign the name anonymous to the first 3 elements of the third column:

```
in [26]: titanic.iloc[0:3, 3] = "anonymous"
in [27]: titanic.head()
out[27]:
         Name     Sex
PassengerId Survived Pclass     Age SibSp Parch Ticket Fare Cabin Embarked
0  1 0 3  anonymous  male 22.0 1 0 A/5 21171 7.2500 NaN S
1  2 1 1  anonymous  female 38.0 1 0 PC 17599 71.2833 C85 C
2  3 1 3  anonymous  female 26.0 0 0 STON/O2. 3101282 7.9250 NaN S
3  4 1 1  Futrelle, Mrs. Jacques Heath (Lily May Peel) female 35.0 1 0 113803 53.1000 C123 S
4  5 0 3  Allen, Mr. William Henry  male 35.0 0 0 373450 8.0500 NaN S
```

See the user guide section on different choices for indexing to get more insight in the usage of loc and iloc.

- When selecting subsets of data, square brackets [] are used.
- Inside these brackets, you can use a single column/row label, a list of column/row labels, a slice of labels, a conditional expression or a colon.
pandas: powerful Python data analysis toolkit, Release 1.3.4

- Select specific rows and/or columns using `loc` when using the row and column names
- Select specific rows and/or columns using `iloc` when using the positions in the table
- You can assign new values to a selection based on `loc/iloc`.

A full overview of indexing is provided in the user guide pages on indexing and selecting data.

```python
In [1]: import pandas as pd
In [2]: import matplotlib.pyplot as plt
```

For this tutorial, air quality data about $NO_2$ is used, made available by openaq and using the py-openaq package. The `air_quality_no2.csv` data set provides $NO_2$ values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```python
In [3]: air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_dates=True)
In [4]: air_quality.head()
Out[4]:
   datetime  station_antwerp  station_paris  station_london
0  2019-05-07  02:00:00      NaN          NaN       23.0
1  2019-05-07  03:00:00     50.5         25.0       19.0
2  2019-05-07  04:00:00     45.0         27.7       19.0
3  2019-05-07  05:00:00      NaN         50.4       16.0
4  2019-05-07  06:00:00      NaN         61.9          NaN
```

**Note:** The usage of the `index_col` and `parse_dates` parameters of the `read_csv` function to define the first (0th) column as index of the resulting DataFrame and convert the dates in the column to `Timestamp` objects, respectively.

**How to create plots in pandas?**

I want a quick visual check of the data.

```python
In [5]: air_quality.plot()
Out[5]: <AxesSubplot:xlabel='datetime'>
```
With a DataFrame, pandas creates by default one line plot for each of the columns with numeric data.

I want to plot only the columns of the data table with the data from Paris.

In [6]: air_quality["station_paris"].plot()
Out[6]: <AxesSubplot:xlabel='datetime'>
To plot a specific column, use the selection method of the *subset data tutorial* in combination with the *plot()* method. Hence, the *plot()* method works on both *Series* and *DataFrame*.

I want to visually compare the $N_0_2$ values measured in London versus Paris.

```python
In [7]: air_quality.plot.scatter(x="station_london", y="station_paris", alpha=0.5)
Out[7]: <AxesSubplot:xlabel='station_london', ylabel='station_paris'>
```
Apart from the default line plot when using the `plot` function, a number of alternatives are available to plot data. Let’s use some standard Python to get an overview of the available plot methods:

```python
In [8]:
    ...:     method_name
    ...:     for method_name in dir(air_quality.plot)
    ...:     if not method_name.startswith('_')
    ...:     
    ...:
Out[8]:
['area',
 'bar',
 'barh',
 'box',
 'density',
 'hexbin',
 'hist',
 'kde',
 'line',
 'pie',
 'scatter']
```

Note: In many development environments as well as IPython and Jupyter Notebook, use the TAB button to get an
overview of the available methods, for example `air_quality.plot`.

One of the options is `DataFrame.plot.box()`, which refers to a boxplot. The box method is applicable on the air quality example data:

```python
In [9]: air_quality.plot.box()
Out[9]: <AxesSubplot:>
```

For an introduction to plots other than the default line plot, see the user guide section about `supported plot styles`. I want each of the columns in a separate subplot.

```python
In [10]: axs = air_quality.plot.area(figsize=(12, 4), subplots=True)
```
Separate subplots for each of the data columns are supported by the `subplots` argument of the `plot` functions. The builtin options available in each of the pandas plot functions are worth reviewing.

Some more formatting options are explained in the user guide section on *plot formatting*.

I want to further customize, extend or save the resulting plot.

```
In [11]: fig, axs = plt.subplots(figsize=(12, 4))
In [12]: air_quality.plot.area(ax=axs)
Out[12]: <AxesSubplot:xlabel='datetime'>
In [13]: axs.set.ylabel("NO$_2$ concentration")
Out[13]: Text(0, 0.5, 'NO$_2$ concentration')
In [14]: fig.savefig("no2_concentrations.png")
```

Each of the plot objects created by pandas is a `matplotlib` object. As Matplotlib provides plenty of options to customize plots, making the link between pandas and Matplotlib explicit enables all the power of matplotlib to the plot. This strategy is applied in the previous example:

```
fig, axs = plt.subplots(figsize=(12, 4))  # Create an empty matplotlib Figure and Axes
air_quality.plot.area(ax=axs)  # Use pandas to put the area plot on the prepared Figure/Axes
axs.set_ylabel("NO$_2$ concentration")  # Do any matplotlib customization you like
```

(continues on next page)
fig.savefig("no2_concentrations.png")  # Save the Figure/Axes using the existing matplotlib method.

- The .plot.* methods are applicable on both Series and DataFrames
- By default, each of the columns is plotted as a different element (line, boxplot,...)
- Any plot created by pandas is a Matplotlib object.

A full overview of plotting in pandas is provided in the visualization pages.

In [1]: import pandas as pd

For this tutorial, air quality data about NO₂ is used, made available by openaq and using the py-openaq package. The air_quality_no2.csv data set provides NO₂ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

In [2]: air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_dates=True)

In [3]: air_quality.head()
Out[3]:

<table>
<thead>
<tr>
<th>station_antwerp</th>
<th>station_paris</th>
<th>station_london</th>
<th>datetime</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>23.0</td>
<td>2019-05-07 02:00:00</td>
</tr>
<tr>
<td>50.5</td>
<td>25.0</td>
<td>19.0</td>
<td>2019-05-07 03:00:00</td>
</tr>
<tr>
<td>45.0</td>
<td>27.7</td>
<td>19.0</td>
<td>2019-05-07 04:00:00</td>
</tr>
<tr>
<td>NaN</td>
<td>50.4</td>
<td>16.0</td>
<td>2019-05-07 05:00:00</td>
</tr>
<tr>
<td>NaN</td>
<td>61.9</td>
<td>NaN</td>
<td>2019-05-07 06:00:00</td>
</tr>
</tbody>
</table>

How to create new columns derived from existing columns?

I want to express the NO₂ concentration of the station in London in mg/m³

*(If we assume temperature of 25 degrees Celsius and pressure of 1013 hPa, the conversion factor is 1.882)*

In [4]: air_quality["london_mg_per_cubic"] = air_quality["station_london"] * 1.882

In [5]: air_quality.head()
Out[5]:

<table>
<thead>
<tr>
<th>station_antwerp</th>
<th>station_paris</th>
<th>station_london</th>
<th>london_mg_per_cubic</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>23.0</td>
<td>43.286</td>
</tr>
<tr>
<td>50.5</td>
<td>25.0</td>
<td>19.0</td>
<td>35.758</td>
</tr>
<tr>
<td>45.0</td>
<td>27.7</td>
<td>19.0</td>
<td>35.758</td>
</tr>
<tr>
<td>NaN</td>
<td>50.4</td>
<td>16.0</td>
<td>30.112</td>
</tr>
<tr>
<td>NaN</td>
<td>61.9</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

To create a new column, use the [] brackets with the new column name at the left side of the assignment.

Note: The calculation of the values is done element_wise. This means all values in the given column are multiplied...
by the value 1.882 at once. You do not need to use a loop to iterate each of the rows!

I want to check the ratio of the values in Paris versus Antwerp and save the result in a new column

```
In [6]: air_quality["ratio_paris_antwerp"] = (  
    ...:     air_quality["station_paris"] / air_quality["station_antwerp"]  
    ...: )  
    ...

In [7]: air_quality.head()
Out[7]:
       station_antwerp  station_paris  station_london  london_mg_per_cubic  
   ratio_paris_antwerp  datetime
2019-05-07 02:00:00    NaN         NaN            23.0             43.286
2019-05-07 03:00:00  50.5          25.0            19.0             35.758
2019-05-07 04:00:00  45.0          27.7            19.0             35.758
2019-05-07 05:00:00    NaN         50.4            16.0             30.112
2019-05-07 06:00:00    NaN         61.9           NaN              NaN
```

The calculation is again element-wise, so the / is applied for the values in each row.

Also other mathematical operators (+, -, \*, /) or logical operators (<, >, =...) work element wise. The latter was already used in the subset data tutorial to filter rows of a table using a conditional expression.

If you need more advanced logic, you can use arbitrary Python code via apply().

I want to rename the data columns to the corresponding station identifiers used by openAQ

```
In [8]: air_quality_renamed = air_quality.rename(  
    ...:     columns={  
    ...:         "station_antwerp": "BETR801",  
    ...:         "station_paris": "FR04014",  
    ...:         "station_london": "London Westminster",  
    ...:     }  
    ...: )  
    ...

In [9]: air_quality_renamed.head()
Out[9]:
   BETR801  FR04014 London Westminster  london_mg_per_cubic  
paris_antwerp  datetime
2019-05-07 02:00:00    NaN         NaN            23.0             43.286
2019-05-07 03:00:00  50.5          25.0            19.0             35.758
2019-05-07 04:00:00  0.495050
```
The `rename()` function can be used for both row labels and column labels. Provide a dictionary with the keys the current names and the values the new names to update the corresponding names.

The mapping should not be restricted to fixed names only, but can be a mapping function as well. For example, converting the column names to lowercase letters can be done using a function as well:

```python
df_renamed = df_renamed.rename(columns=str.lower)
```

Details about column or row label renaming is provided in the user guide section on renames labels.

- Create a new column by assigning the output to the DataFrame with a new column name in between the `[]`.
- Operations are element-wise, no need to loop over rows.
- Use `rename` with a dictionary or function to rename row labels or column names.

The user guide contains a separate section on column addition and deletion.

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
• Parch: Whether a passenger is alone or have family.
• Ticket: Ticket number of passenger.
• Fare: Indicating the fare.
• Cabin: The cabin of passenger.
• Embarked: The embarked category.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()
Out[3]:
   PassengerId  Survived  Pclass  Name       Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
0             1        0       3  Braund, Mr. Owen Harris  male  22.0      1      0    A/5  21171  7.2500    NaN      S
1             2        1       1 Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0      1      0     PC 17599  71.2833   C85      C
2             3        0       3     Heikkinen, Miss. Laina  female  26.0      0      0  STON/O2. 3101282  7.9250    NaN      S
3             4        0       3 Futrelle, Mrs. Jacques Heath (Lily May Peel) female  35.0      1      0  113803     53.1000    C123      S
4             5        0       3            Allen, Mr. William Henry  male  35.0      0      0  373450  8.0500    NaN      S
```

How to calculate summary statistics?

Aggregating statistics

What is the average age of the Titanic passengers?

```
In [4]: titanic["Age"].mean()
Out[4]: 29.69911764705882
```

different statistics are available and can be applied to columns with numerical data. Operations in general exclude missing data and operate across rows by default.

What is the median age and ticket fare price of the Titanic passengers?

```
In [5]: titanic["Age", "Fare"].median()
Out[5]:
   Age   Fare
0  28.0000  14.4542
```

The statistic applied to multiple columns of a DataFrame (the selection of two columns return a DataFrame, see the subset data tutorial) is calculated for each numeric column.

The aggregating statistic can be calculated for multiple columns at the same time. Remember the describe function from first tutorial tutorial?
Instead of the predefined statistics, specific combinations of aggregating statistics for given columns can be defined using the `DataFrame.agg()` method:

```python
In [7]: titanic.agg({
    ...:     "Age": ["min", "max", "median", "skew"],
    ...:     "Fare": ["min", "max", "median", "mean"],
    ...: })
```

```python
Out[7]:
```

Instead of the predefined statistics, specific combinations of aggregating statistics for given columns can be defined using the `DataFrame.agg()` method:

Details about descriptive statistics are provided in the user guide section on descriptive statistics.

**Aggregating statistics grouped by category**

What is the average age for male versus female Titanic passengers?

```python
In [8]: titanic[["Sex", "Age"]].groupby("Sex").mean()
```

As our interest is the average age for each gender, a subselection on these two columns is made first: `titanic[["Sex", "Age"]].` Next, the `groupby()` method is applied on the Sex column to make a group per category. The average age for each gender is calculated and returned.

Calculating a given statistic (e.g. mean age) for each category in a column (e.g. male/female in the Sex column) is a common pattern. The `groupby` method is used to support this type of operations. More general, this fits in the more general split-apply-combine pattern:

- Split the data into groups
• **Apply** a function to each group independently
• **Combine** the results into a data structure

The apply and combine steps are typically done together in pandas.

In the previous example, we explicitly selected the 2 columns first. If not, the `mean` method is applied to each column containing numerical columns:

```python
In [9]: titanic.groupby("Sex").mean()
Out[9]:
         PassengerId  Survived   Pclass  Age   SibSp  Parch  Fare
Sex          
female  431.028662  0.742038  2.159236 27.915709  0.694268  0.649682 44.479818
male     454.147314  0.188908  2.389948 30.726645  0.429809  0.235702 25.523893
```

It does not make much sense to get the average value of the `Pclass` if we are only interested in the average age for each gender, the selection of columns (rectangular brackets `[]` as usual) is supported on the grouped data as well:

```python
In [10]: titanic.groupby("Sex")["Age"].mean()
Out[10]:
         Sex
female  27.915709
male     30.726645
Name: Age, dtype: float64
```

**Note:** The `Pclass` column contains numerical data but actually represents 3 categories (or factors) with respectively the labels ‘1’, ‘2’ and ‘3’. Calculating statistics on these does not make much sense. Therefore, pandas provides a *Categorical* data type to handle this type of data. More information is provided in the user guide *Categorical data* section.

What is the mean ticket fare price for each of the sex and cabin class combinations?

```python
In [11]: titanic.groupby(["Sex", "Pclass"])["Fare"].mean()
Out[11]:
         Sex   Pclass         
         
female  1   106.125798
        2    21.970121
        3    16.118810
male    1    67.226127
        2    19.741782
        3    12.661633
Name: Fare, dtype: float64
```

Grouping can be done by multiple columns at the same time. Provide the column names as a list to the `groupby()` method.

A full description on the split-apply-combine approach is provided in the user guide section on *groupby operations.*
**Count number of records by category**

What is the number of passengers in each of the cabin classes?

```
In [12]: titanic["Pclass"].value_counts()
Out[12]:
3    491
1    216
2    184
Name: Pclass, dtype: int64
```

The `value_counts()` method counts the number of records for each category in a column.

The function is a shortcut, as it is actually a groupby operation in combination with counting of the number of records within each group:

```
In [13]: titanic.groupby("Pclass")["Pclass"].count()
Out[13]:
Pclass
     1    216
     2    184
     3    491
Name: Pclass, dtype: int64
```

**Note:** Both `size` and `count` can be used in combination with `groupby`. Whereas `size` includes NaN values and just provides the number of rows (size of the table), `count` excludes the missing values. In the `value_counts` method, use the `dropna` argument to include or exclude the NaN values.

The user guide has a dedicated section on `value_counts`, see page on `discretization`.

- Aggregation statistics can be calculated on entire columns or rows
- `groupby` provides the power of the `split-apply-combine` pattern
- `value_counts` is a convenient shortcut to count the number of entries in each category of a variable

A full description on the split-apply-combine approach is provided in the user guide pages about `groupby operations`.

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
- **Parch**: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")
In [3]: titanic.head()
Out[3]:
    PassengerId  Survived  Pclass  Name       Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
0          1         0      3  Braund, Mr. Owen Harris     male  22.0     1     0    A/5 21171  7.2500    NaN     S
1          2         1      1   Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0     1     0      PC 17599  71.2833  C85     C
2          3         1      3   Heikkinen, Miss. Laina       female  26.0     0     0  STON/O2. 3101282  7.9250    NaN     S
3          4         0      0  Futrelle, Mrs. Jacques Heath (Lily May Peel) female  35.0     1     0     113803  53.1000  C123     S
4          5         0      0   Allen, Mr. William Henry     male  35.0     0     0     373450  8.0500    NaN     S
```

This tutorial uses air quality data about $NO_2$ and Particulate matter less than 2.5 micrometers, made available by openaq and using the py-openaq package. The `air_quality_long.csv` data set provides $NO_2$ and $PM_{2.5}$ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

The air-quality data set has the following columns:

- **city**: city where the sensor is used, either Paris, Antwerp or London
- **country**: country where the sensor is used, either FR, BE or GB
- **location**: the id of the sensor, either FR04014, BETR801 or London Westminster
- **parameter**: the parameter measured by the sensor, either $NO_2$ or Particulate matter
- **value**: the measured value
- **unit**: the unit of the measured parameter, in this case ‘µg/m$^3$’

and the index of the DataFrame is `datetime`, the datetime of the measurement.

**Note**: The air-quality data is provided in a so-called *long format* data representation with each observation on a separate row and each variable a separate column of the data table. The long/narrow format is also known as the tidy data format.

```
In [4]: air_quality = pd.read_csv(
    ...:     "data/air_quality_long.csv", index_col="date.utc", parse_dates=True
    ...: )

In [5]: air_quality.head()
Out[5]:
    city  country  location  parameter  value  unit
0     FR        FR04014  NO2          7.0  µg/m³
1     BE        BETR801  NO2          2.0  µg/m³
2     GB  London Westminster  NO2          3.0  µg/m³
3     FR        FR04014  PM2.5         5.0  µg/m³
4     BE        BETR801  PM2.5         6.0  µg/m³
```
How to reshape the layout of tables?

Sort table rows

I want to sort the Titanic data according to the age of the passengers.

\[
\text{In [6]: } \text{titanic.sort_values(by="Age").head()}
\]

<table>
<thead>
<tr>
<th>PassengerId</th>
<th>Survived</th>
<th>Pclass</th>
<th>Name</th>
<th>Sex</th>
<th>Age</th>
<th>SibSp</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>Thomas, Master. Assad Alexander</td>
<td>male</td>
<td>0.42</td>
<td>0</td>
</tr>
<tr>
<td>804</td>
<td>1</td>

<tr>
<td>2666</td>
<td>1</td>
<td>3</td>
<td>Baclini, Miss. Helene Barbara</td>
<td>female</td>
<td>0.75</td>
<td>2</td>
</tr>
<tr>
<td>248738</td>
<td>2</td>
<td>1</td>
<td>Caldwell, Master. Alden Gates</td>
<td>male</td>
<td>0.83</td>
<td>0</td>
</tr>
</tbody>
</table>

I want to sort the Titanic data according to the cabin class and age in descending order.

\[
\text{In [7]: } \text{titanic.sort_values(by=['Pclass', 'Age'], ascending=False).head()}
\]

<table>
<thead>
<tr>
<th>PassengerId</th>
<th>Survived</th>
<th>Pclass</th>
<th>Name</th>
<th>Sex</th>
<th>Age</th>
<th>SibSp</th>
</tr>
</thead>
<tbody>
<tr>
<td>852</td>
<td>0</td>
<td>3</td>
<td>Svensson, Mr. Johan</td>
<td>male</td>
<td>74.0</td>
<td>0</td>
</tr>
<tr>
<td>347060</td>
<td>0</td>
<td>3</td>
<td>Connors, Mr. Patrick</td>
<td>male</td>
<td>70.5</td>
<td>0</td>
</tr>
<tr>
<td>370369</td>
<td>0</td>
<td>3</td>
<td>Duane, Mr. Frank</td>
<td>male</td>
<td>65.0</td>
<td>0</td>
</tr>
<tr>
<td>4134</td>
<td>0</td>
<td>3</td>
<td>Nysveen, Mr. Johan Hansen</td>
<td>male</td>
<td>61.0</td>
<td>0</td>
</tr>
</tbody>
</table>

With `Series.sort_values()`, the rows in the table are sorted according to the defined column(s). The index will follow the row order.

More details about sorting of tables is provided in the using guide section on sorting data.
Let's use a small subset of the air quality data set. We focus on NO₂ data and only use the first two measurements of each location (i.e. the head of each group). The subset of data will be called no2_subset

```python
# filter for no2 data only
In [8]: no2 = air_quality[air_quality["parameter"] == "no2"]
```

```python
# use 2 measurements (head) for each location (groupby)
In [9]: no2_subset = no2.sort_index().groupby(["location"]).head(2)
```

```python
In [10]: no2_subset
```

<table>

<td>London</td>
<td>GB</td>
<td>London Westminster</td>
<td>no2</td>
<td>67.0</td>
<td>µg/m³</td>
</tr>
</tbody>
</table>

I want the values for the three stations as separate columns next to each other

```python
In [11]: no2_subset.pivot(columns="location", values="value")
```

```
<table>
<thead>
<tr>
<th>location</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td>date_utc</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2019-04-09 01:00:00+00:00</td>
<td>22.5</td>
<td>24.4</td>
<td>NaN</td>
</tr>
<tr>
<td>2019-04-09 02:00:00+00:00</td>
<td>53.5</td>
<td>27.4</td>
<td>67.0</td>
</tr>
<tr>
<td>2019-04-09 03:00:00+00:00</td>
<td>NaN</td>
<td>NaN</td>
<td>67.0</td>
</tr>
</tbody>
</table>
```

The `pivot()` function is purely reshaping of the data: a single value for each index/column combination is required.

As pandas support plotting of multiple columns (see plotting tutorial) out of the box, the conversion from long to wide table format enables the plotting of the different time series at the same time:

```python
In [12]: no2.head()
```

```
<table>
<thead>
<tr>
<th>city</th>
<th>country</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
<th>unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>20.0</td>
<td>µg/m³</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>21.8</td>
<td>µg/m³</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>26.5</td>
<td>µg/m³</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>24.9</td>
<td>µg/m³</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>21.4</td>
<td>µg/m³</td>
</tr>
</tbody>
</table>
```

```python
In [13]: no2.pivot(columns="location", values="value").plot()
```

```
In [13]: <AxesSubplot:xlabel='date.utc'>
```
Note: When the index parameter is not defined, the existing index (row labels) is used.

For more information about `pivot()`, see the user guide section on *pivoting DataFrame objects*.

**Pivot table**

I want the mean concentrations for \(NO_2\) and \(PM_{2.5}\) in each of the stations in table form

```
In [14]: air_quality.pivot_table(
   ....:     values="value", index="location", columns="parameter", aggfunc="mean"
   ....: )
```

```
Out[14]:

<table>
<thead>
<tr>
<th>location</th>
<th>parameter</th>
<th>no2</th>
<th>pm25</th>
</tr>
</thead>
<tbody>
<tr>
<td>BETR801</td>
<td>NO2</td>
<td>26.950920</td>
<td>23.169492</td>
</tr>
<tr>
<td>FR04014</td>
<td>PM2.5</td>
<td>29.374284</td>
<td>NaN</td>
</tr>
<tr>
<td>London Westminster</td>
<td>PM2.5</td>
<td>29.740050</td>
<td>13.443568</td>
</tr>
</tbody>
</table>
```

In the case of `pivot()`, the data is only rearranged. When multiple values need to be aggregated (in this specific case,
pivot_table() can be used, providing an aggregation function (e.g. mean) on how to combine these values.

Pivot table is a well known concept in spreadsheet software. When interested in summary columns for each variable separately as well, put the margin parameter to True:

```
In [15]: air_quality.pivot_table(
   ....:     values="value",
   ....:     index="location",
   ....:     columns="parameter",
   ....:     aggfunc="mean",
   ....:     margins=True,
   ....: )
```

```
Out[15]:

<table>
<thead>
<tr>
<th>parameter</th>
<th>no2</th>
<th>pm25</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>location</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BETR801</td>
<td>26.950920</td>
<td>23.169492</td>
<td>24.982353</td>
</tr>
<tr>
<td>FR04014</td>
<td>29.740050</td>
<td>13.443568</td>
<td>21.491708</td>
</tr>
<tr>
<td>All</td>
<td>29.430316</td>
<td>14.386849</td>
<td>24.222743</td>
</tr>
</tbody>
</table>
```

For more information about `pivot_table()`, see the user guide section on pivot tables.

Note: In case you are wondering, `pivot_table()` is indeed directly linked to `groupby()`. The same result can be derived by grouping on both parameter and location:

```
air_quality.groupby(["parameter", "location"]).mean()
```

Have a look at `groupby()` in combination with `unstack()` at the user guide section on combining stats and groupby.

### Wide to long format

Starting again from the wide format table created in the previous section:

```
In [16]: no2_pivoted = no2.pivot(columns="location", values="value").reset_index()
```

```
In [17]: no2_pivoted.head()
```

```
Out[17]:

<table>
<thead>
<tr>
<th>location</th>
<th>date.utc</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2019-04-09 01:00:00+00:00</td>
<td>22.5</td>
<td>24.4</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>2019-04-09 02:00:00+00:00</td>
<td>53.5</td>
<td>27.4</td>
<td>67.0</td>
</tr>
<tr>
<td>2</td>
<td>2019-04-09 03:00:00+00:00</td>
<td>54.5</td>
<td>34.2</td>
<td>67.0</td>
</tr>
<tr>
<td>3</td>
<td>2019-04-09 04:00:00+00:00</td>
<td>34.5</td>
<td>48.5</td>
<td>41.0</td>
</tr>
<tr>
<td>4</td>
<td>2019-04-09 05:00:00+00:00</td>
<td>46.5</td>
<td>59.5</td>
<td>41.0</td>
</tr>
</tbody>
</table>
```

I want to collect all air quality $NO_2$ measurements in a single column (long format)

```
In [18]: no_2 = no2_pivoted.melt(id_vars="date.utc")
```

(continues on next page)
The `pandas.melt()` method on a DataFrame converts the data table from wide format to long format. The column headers become the variable names in a newly created column.

The solution is the short version on how to apply `pandas.melt()`. The method will `melt` all columns NOT mentioned in `id_vars` together into two columns: A column with the column header names and a column with the values itself. The latter column gets by default the name `value`.

The `pandas.melt()` method can be defined in more detail:

```python
no_2 = no2_pivoted.melt(
    id_vars="date.utc",
    value_vars=["BETR801", "FR04014", "London Westminster"],
    value_name="NO_2",
    var_name="id_location",
    )
```

The result in the same, but in more detail defined:

- `value_vars` defines explicitly which columns to `melt` together
- `value_name` provides a custom column name for the values column instead of the default column name `value`
- `var_name` provides a custom column name for the column collecting the column header names. Otherwise it takes the index name or a default `variable`

Hence, the arguments `value_name` and `var_name` are just user-defined names for the two generated columns. The columns to melt are defined by `id_vars` and `value_vars`.

Conversion from wide to long format with `pandas.melt()` is explained in the user guide section on `reshaping by melt`.

- Sorting by one or more columns is supported by `sort_values`
- The `pivot` function is purely restructuring of the data, `pivot_table` supports aggregations
- The reverse of `pivot` (long to wide format) is `melt` (wide to long format)

A full overview is available in the user guide on the pages about `reshaping and pivoting`. 

---

46 Chapter 1. Getting started
For this tutorial, air quality data about $NO_2$ is used, made available by openaq and downloaded using the py-openaq package.

The `air_quality_no2_long.csv` data set provides $NO_2$ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

In [2]: air_quality_no2 = pd.read_csv("data/air_quality_no2_long.csv", 
...:     parse_dates=True)

In [3]: air_quality_no2 = air_quality_no2["date.utc", "location", 
...:     "parameter", "value"]

In [4]: air_quality_no2.head()

Out[4]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-06-21 00:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>20.0</td>
</tr>
<tr>
<td>2019-06-20 23:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>21.8</td>
</tr>
<tr>
<td>2019-06-20 22:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>26.5</td>
</tr>
<tr>
<td>2019-06-20 21:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>24.9</td>
</tr>
<tr>
<td>2019-06-20 20:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>21.4</td>
</tr>
</tbody>
</table>

For this tutorial, air quality data about Particulate matter less than 2.5 micrometers is used, made available by openaq and downloaded using the py-openaq package.

The `air_quality_pm25_long.csv` data set provides $PM_{2.5}$ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

In [5]: air_quality_pm25 = pd.read_csv("data/air_quality_pm25_long.csv", 
...:     parse_dates=True)

In [6]: air_quality_pm25 = air_quality_pm25["date.utc", "location", 
...:     "parameter", "value"]

In [7]: air_quality_pm25.head()

Out[7]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-06-18 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.0</td>
</tr>
<tr>
<td>2019-06-17 08:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>6.5</td>
</tr>
<tr>
<td>2019-06-17 07:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.5</td>
</tr>
<tr>
<td>2019-06-17 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>16.0</td>
</tr>
<tr>
<td>2019-06-17 05:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>7.5</td>
</tr>
</tbody>
</table>
How to combine data from multiple tables?

Concatenating objects

I want to combine the measurements of $NO_2$ and $PM_{25}$, two tables with a similar structure, in a single table.

```python
In [8]: air_quality = pd.concat([air_quality_pm25, air_quality_no2], axis=0)
In [9]: air_quality.head()
```

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-06-18 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.0</td>
</tr>
<tr>
<td>2019-06-17 08:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>6.5</td>
</tr>
<tr>
<td>2019-06-17 07:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.5</td>
</tr>
<tr>
<td>2019-06-17 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>16.0</td>
</tr>
<tr>
<td>2019-06-17 05:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>7.5</td>
</tr>
</tbody>
</table>

The `concat()` function performs concatenation operations of multiple tables along one of the axis (row-wise or column-wise).

By default concatenation is along axis 0, so the resulting table combines the rows of the input tables. Let’s check the shape of the original and the concatenated tables to verify the operation:

```python
In [10]: print('Shape of the `air_quality_pm25` table: ', air_quality_pm25.shape)
Shape of the `air_quality_pm25` table: (1110, 4)
In [11]: print('Shape of the `air_quality_no2` table: ', air_quality_no2.shape)
Shape of the `air_quality_no2` table: (2068, 4)
In [12]: print('Shape of the resulting `air_quality` table: ', air_quality.shape)
Shape of the resulting `air_quality` table: (3178, 4)
```

Hence, the resulting table has 3178 = 1110 + 2068 rows.

**Note:** The `axis` argument will return in a number of pandas methods that can be applied along an axis. A DataFrame has two corresponding axes: the first running vertically downwards across rows (axis 0), and the second running horizontally across columns (axis 1). Most operations like concatenation or summary statistics are by default across rows (axis 0), but can be applied across columns as well.

Sorting the table on the datetime information illustrates also the combination of both tables, with the parameter column defining the origin of the table (either `no2` from table `air_quality_no2` or `pm25` from table `air_quality_pm25`):

```python
In [13]: air_quality = air_quality.sort_values("date.utc")
In [14]: air_quality.head()
```

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-05-07 01:00:00+00:00</td>
<td>London</td>
<td>Westminster</td>
<td>no2</td>
</tr>
<tr>
<td>2019-05-07 01:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>25.0</td>
</tr>
<tr>
<td>2019-05-07 01:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>12.5</td>
</tr>
</tbody>
</table>
In this specific example, the parameter column provided by the data ensures that each of the original tables can be identified. This is not always the case. the concat function provides a convenient solution with the keys argument, adding an additional (hierarchical) row index. For example:

```
In [15]: air_quality_ = pd.concat([air_quality_pm25, air_quality_no2], keys=['PM25', 'NO2'])
```

```
In [16]: air_quality_.head()
Out[16]:
     date.utc location parameter value
PM25 0 2019-06-18 06:00:00+00:00 BETR801 pm25 18.0
   1 2019-06-17 08:00:00+00:00 BETR801 pm25 6.5
   2 2019-06-17 07:00:00+00:00 BETR801 pm25 18.5
   3 2019-06-17 06:00:00+00:00 BETR801 pm25 16.0
   4 2019-06-17 05:00:00+00:00 BETR801 pm25 7.5
```

**Note:** The existence of multiple row/column indices at the same time has not been mentioned within these tutorials. *Hierarchical indexing or MultiIndex* is an advanced and powerful pandas feature to analyze higher dimensional data.

Multi-indexing is out of scope for this pandas introduction. For the moment, remember that the function `reset_index` can be used to convert any level of an index to a column, e.g. `air_quality.reset_index(level=0)`

Feel free to dive into the world of multi-indexing at the user guide section on *advanced indexing*.

More options on table concatenation (row and column wise) and how `concat` can be used to define the logic (union or intersection) of the indexes on the other axes is provided at the section on *object concatenation*.

**Join tables using a common identifier**

Add the station coordinates, provided by the stations metadata table, to the corresponding rows in the measurements table.

**Warning:** The air quality measurement station coordinates are stored in a data file `air_quality_stations.csv`, downloaded using the `py-openaq` package.

```
In [17]: stations_coord = pd.read_csv("data/air_quality_stations.csv")
```

```
In [18]: stations_coord.head()
Out[18]:
       location coordinates.latitude coordinates.longitude
0     BELAL01          51.23619              4.38522
1    BELHB23          51.17030              4.34100
2    BELLD01          51.10998              5.00486
3    BELLD02          51.12038              5.02155
4    BELR833          51.32766              4.36226
```
Note: The stations used in this example (FR04014, BETR801 and London Westminster) are just three entries enlisted in the metadata table. We only want to add the coordinates of these three to the measurements table, each on the corresponding rows of the `air_quality` table.

```python
In [19]: air_quality.head()
Out[19]:
         date.utc location parameter value
0 2019-05-07 01:00:00+00:00  London Westminster  no2  23.0
1 2019-05-07 01:00:00+00:00    FR04014  no2  25.0
2 2019-05-07 01:00:00+00:00   BETR801   pm25  12.5
3 2019-05-07 01:00:00+00:00   BETR801    no2  50.5
4 2019-05-07 01:00:00+00:00  London Westminster   pm25   8.0
```

```python
In [20]: air_quality = pd.merge(air_quality, stations_coord, how="left", on="location")
```

```python
In [21]: air_quality.head()
Out[21]:
         date.utc location parameter value coordinates.latitude  coordinates.longitude
0 2019-05-07 01:00:00+00:00  London Westminster  no2  23.0                   51.49467
     -0.13193                    48.83724
1 2019-05-07 01:00:00+00:00    FR04014  no2  25.0                   48.83722
     2.39390
2 2019-05-07 01:00:00+00:00    FR04014   pm25  12.5                   51.20966
     4.43182
3 2019-05-07 01:00:00+00:00   BETR801    no2  50.5                   51.20966
     4.43182
```

Using the `merge()` function, for each of the rows in the `air_quality` table, the corresponding coordinates are added from the `air_quality_stations_coord` table. Both tables have the column `location` in common which is used as a key to combine the information. By choosing the `left` join, only the locations available in the `air_quality` (left) table, i.e. FR04014, BETR801 and London Westminster, end up in the resulting table. The `merge` function supports multiple join options similar to database-style operations.

Add the parameter full description and name, provided by the parameters metadata table, to the measurements table.

Warning: The air quality parameters metadata are stored in a data file `air_quality_parameters.csv`, downloaded using the `py-openaq` package.

```python
In [22]: air_quality_parameters = pd.read_csv("data/air_quality_parameters.csv")
```

```python
In [23]: air_quality_parameters.head()
Out[23]:
   id description  name
0  bc            Black Carbon  BC
1  co            Carbon Monoxide  CO
2  no2           Nitrogen Dioxide  NO2
3  o3            Ozone  O3
```
In [24]: air_quality = pd.merge(air_quality, air_quality_parameters,

....:

how='left', left_on='parameter', right_on='id')

....:

In [25]: air_quality.head()

Out[25]:

+---+-----+---+----------+-------+---+---+---+---+
|    | date: |  | location | parameter | value | ... | coordinates.       |
|----|------|  |          |           |       |     |                   |
| 0  | 2019 | 05-07| 01:00:00+00:00 | London Westminster | no2 23.0 | ... | -0.                             |
| 1  | 2019 | 05-07| 01:00:00+00:00 | FR04014 | no2 25.0 | ... | 2.                             |
| 2  | 2019 | 05-07| 01:00:00+00:00 | FR04014 | no2 25.0 | ... | 2.                             |
| 3  | 2019 | 05-07| 01:00:00+00:00 | BETR801 | pm25 12.5 | ... | 4.                             |
| 4  | 2019 | 05-07| 01:00:00+00:00 | BETR801 | no2 50.5 | ... | 4.                             |
| 5  | 2019 | 05-07| 01:00:00+00:00 | FR04014 | no2 25.0 | ... | 2.                             |
+---+-----+---+----------+-------+---+---+---+---+

[5 rows x 9 columns]

Compared to the previous example, there is no common column name. However, the parameter column in the air_quality table and the id column in the air_quality_parameters table both provide the measured variable in a common format. The left_on and right_on arguments are used here (instead of just on) to make the link between the two tables.

pandas supports also inner, outer, and right joins. More information on join/merge of tables is provided in the user guide section on database style merging of tables. Or have a look at the comparison with SQL page.

• Multiple tables can be concatenated both column-wise and row-wise using the concat function.

• For database-like merging/joining of tables, use the merge function.

See the user guide for a full description of the various facilities to combine data tables.

In [1]: import pandas as pd

In [2]: import matplotlib.pyplot as plt

For this tutorial, air quality data about $NO_2$ and Particulate matter less than 2.5 micrometers is used, made available by openaq and downloaded using the py-openaq package. The air_quality_no2_long.csv data set provides $NO_2$ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

In [3]: air_quality = pd.read_csv("data/air_quality_no2_long.csv")

In [4]: air_quality = air_quality.rename(columns={"date.utc": "datetime"})

In [5]: air_quality.head()

Out[5]:

+---+-----+---+---------+----------+-------+---+---+---+---+
<table>
<thead>
<tr>
<th></th>
<th>city</th>
<th>country</th>

(continues on next page)
How to handle time series data with ease?

Using pandas datetime properties

I want to work with the dates in the column `datetime` as datetime objects instead of plain text

```
In [7]: air_quality['datetime'] = pd.to_datetime(air_quality['datetime'])
```

```
In [8]: air_quality['datetime']
Out[8]:
0 2019-06-21 00:00:00+00:00
1 2019-06-20 23:00:00+00:00
2 2019-06-20 22:00:00+00:00
3 2019-06-20 21:00:00+00:00
4 2019-06-20 20:00:00+00:00
...
2063 2019-05-07 01:00:00+00:00
2064 2019-05-07 00:00:00+00:00
2065 2019-05-07 03:00:00+00:00
2066 2019-05-07 02:00:00+00:00
2067 2019-05-07 04:00:00+00:00
Name: datetime, Length: 2068, dtype: datetime64[ns, UTC]
```

Initially, the values in `datetime` are character strings and do not provide any datetime operations (e.g. extract the year, day of the week,...). By applying the `to_datetime` function, pandas interprets the strings and convert these to datetime (i.e. `datetime64[ns, UTC]`) objects. In pandas we call these datetime objects similar to `datetime.datetime` from the standard library as `pandas.Timestamp`.

Note: As many data sets do contain datetime information in one of the columns, pandas input function like `pandas.read_csv()` and `pandas.read_json()` can do the transformation to dates when reading the data using the `parse_dates` parameter with a list of the columns to read as Timestamp:

```
pd.read_csv("./data/air_quality_no2_long.csv", parse_dates=["datetime")
```

Why are these `pandas.Timestamp` objects useful? Let’s illustrate the added value with some example cases.

What is the start and end date of the time series data set we are working with?

```
In [9]: air_quality['datetime'].min(), air_quality['datetime'].max()
Out[9]:
(Timestamp('2019-05-07 01:00:00+0000', tz='UTC'),
 Timestamp('2019-06-21 00:00:00+0000', tz='UTC'))
```
Using `pandas.Timestamp` for datetimes enables us to calculate with date information and make them comparable. Hence, we can use this to get the length of our time series:

```python
In [10]: air_quality["datetime"].max() - air_quality["datetime"].min()
Out[10]: Timedelta('44 days 23:00:00')
```

The result is a `pandas.Timedelta` object, similar to `datetime.timedelta` from the standard Python library and defining a time duration.

The various time concepts supported by pandas are explained in the user guide section on time related concepts.

I want to add a new column to the DataFrame containing only the month of the measurement

```python
In [11]: air_quality["month"] = air_quality["datetime"].dt.month
In [12]: air_quality.head()
```

<table>
<thead>
<tr>
<th>city</th>
<th>country</th>
<th>datetime</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
<th>unit</th>
<th>month</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paris</td>
<td>FR</td>
<td>2019-06-21 00:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>20.0</td>
<td>µg/m³</td>
<td>6</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>2019-06-20 23:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>21.8</td>
<td>µg/m³</td>
<td>6</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>2019-06-20 22:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>26.5</td>
<td>µg/m³</td>
<td>6</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>2019-06-20 21:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>24.9</td>
<td>µg/m³</td>
<td>6</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>2019-06-20 20:00:00+00:00</td>
<td>FR04014</td>
<td>no2</td>
<td>21.4</td>
<td>µg/m³</td>
<td>6</td>
</tr>
</tbody>
</table>

By using `Timestamp` objects for dates, a lot of time-related properties are provided by pandas. For example the `month`, but also `year`, `weekofyear`, `quarter`,... All of these properties are accessible by the `dt` accessor.

An overview of the existing date properties is given in the time and date components overview table. More details about the `dt` accessor to return datetime like properties are explained in a dedicated section on the `dt accessor`.

What is the average $NO_2$ concentration for each day of the week for each of the measurement locations?

```python
In [13]: air_quality.groupby([air_quality["datetime"].dt.weekday, "location"])["value"].mean()
```

<table>
<thead>
<tr>
<th>datetime</th>
<th>location</th>
<th>value</th>
</tr>

<td>24.859155</td>
</tr>
</tbody>
</table>

Name: value, Length: 21, dtype: float64

Remember the split-apply-combine pattern provided by `groupby` from the tutorial on statistics calculation? Here, we want to calculate a given statistic (e.g. mean $NO_2$) for each weekday and for each measurement location. To group on weekdays, we use the datetime property `weekday` (with Monday=0 and Sunday=6) of pandas `Timestamp`, which is also accessible by the `dt accessor`. The grouping on both locations and weekdays can be done to split the calculation of the mean on each of these combinations.
**Danger:** As we are working with a very short time series in these examples, the analysis does not provide a long-term representative result!

Plot the typical $NO_2$ pattern during the day of our time series of all stations together. In other words, what is the average value for each hour of the day?

```python
In [14]: fig, axs = plt.subplots(figsize=(12, 4))

In [15]: air_quality.groupby(air_quality["datetime"].dt.hour)["value"].mean().plot(       kind='bar', rot=0, ax=axs
       ....:)
       ....:
Out[15]: <AxesSubplot:xlabel='datetime'>

In [16]: plt.xlabel("Hour of the day"); # custom x label using matplotlib

In [17]: plt.ylabel("$NO_2 (\mu g/m^3)$");
```

Similar to the previous case, we want to calculate a given statistic (e.g. mean $NO_2$) **for each hour of the day** and we can use the split-apply-combine approach again. For this case, we use the datetime property `hour` of pandas Timestamp, which is also accessible by the `dt` accessor.

**Datetime as index**

In the tutorial on reshaping, `pivot()` was introduced to reshape the data table with each of the measurements locations as a separate column:

```python
In [18]: no_2 = air_quality.pivot(index="datetime", columns="location", values="value")

In [19]: no_2.head()
Out[19]:
          location
         BETR801  FR04014   London Westminster
date\time        2019-05-07 01:00:00+00:00  50.5  25.0     23.0
date\time        2019-05-07 02:00:00+00:00  45.0  27.7     19.0
date\time        2019-05-07 03:00:00+00:00 NaN  58.4     19.0
date\time        2019-05-07 04:00:00+00:00 NaN  61.9     16.0
date\time        2019-05-07 05:00:00+00:00 NaN  72.4     NaN
```

54 Chapter 1. Getting started
**Note:** By pivoting the data, the datetime information became the index of the table. In general, setting a column as an index can be achieved by the `set_index` function.

Working with a datetime index (i.e. `DatetimeIndex`) provides powerful functionalities. For example, we do not need the `dt` accessor to get the time series properties, but have these properties available on the index directly:

```python
In [20]: no_2.index.year, no_2.index.weekday
Out[20]:
(Int64Index([2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019,
            ...,  
            dtype='int64', name='datetime', length=1033),
    Int64Index([1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
            ...,  
            3, 3, 3, 3, 3, 3, 3, 3, 3, 4],
            dtype='int64', name='datetime', length=1033))
```

Some other advantages are the convenient subsetting of time period or the adapted time scale on plots. Let’s apply this on our data.

Create a plot of the $NO_2$ values in the different stations from the 20th of May till the end of 21st of May

```python
In [21]: no_2["2019-05-20":"2019-05-21"].plot();
```
By providing a string that parses to a datetime, a specific subset of the data can be selected on a DatetimeIndex. More information on the DatetimeIndex and the slicing by using strings is provided in the section on time series indexing.

**Resample a time series to another frequency**

Aggregate the current hourly time series values to the monthly maximum value in each of the stations.

```python
In [22]: monthly_max = no_2.resample("M").max()

In [23]: monthly_max
Out[23]:
location         BETR801      FR04014   London Westminster
datetime                2019-05-31 00:00:00+00:00 74.5  97.0     97.0
                      2019-06-30 00:00:00+00:00 52.5  84.7     52.0
```

A very powerful method on time series data with a datetime index, is the ability to resample() time series to another frequency (e.g., converting secondly data into 5-minutely data).

The resample() method is similar to a groupby operation:

- it provides a time-based grouping, by using a string (e.g. M, 5H,...) that defines the target frequency
- it requires an aggregation function such as mean, max,...

An overview of the aliases used to define time series frequencies is given in the offset aliases overview table.

When defined, the frequency of the time series is provided by the freq attribute:

```python
In [24]: monthly_max.index.freq
Out[24]: <MonthEnd>
```

Make a plot of the daily mean $NO_2$ value in each of the stations.

```python
In [25]: no_2.resample("D").mean().plot(style="-o", figsize=(10, 5));
```
More details on the power of time series resampling is provided in the user guide section on resampling.

- Valid date strings can be converted to datetime objects using `to_datetime` function or as part of read functions.
- Datetime objects in pandas support calculations, logical operations and convenient date-related properties using the `dt` accessor.
- A `DateTimeIndex` contains these date-related properties and supports convenient slicing.
- `Resample` is a powerful method to change the frequency of a time series.

A full overview on time series is given on the pages on time series and date functionality.

In [1]: import pandas as pd

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.
```
In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()
Out[3]:
   PassengerId  Survived  Pclass  Name           Sex   Age  SibSp  Parch  Ticket  
0            1          0       3  Braund, Mr. Owen Harris  male  22.0     1     0    A/5 21171 
1            2          1       1  Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0     1     0       PC 17599 
2            3          1       3  Heikkinen, Miss. Laina  female  26.0     0     0      STON/O2.  
3            4          1       1  Futrelle, Mrs. Jacques Heath (Lily May Peel) female  35.0     1     0     113803  
4            5          0       3    Allen, Mr. William Henry  male  35.0     0     0      373450  
   Fare  Cabin   Embarked
0  7.2500    NaN      S
1  71.2833  C85       C
2  7.9250    NaN      S
3  53.1000   C       S
4  8.0500    NaN      S
```

**How to manipulate textual data?**

Make all name characters lowercase.

```
In [4]: titanic["Name"].str.lower()
Out[4]:
0  braund, mr. owen harris
1  cumings, mrs. john bradley (florence briggs th...
2  heikkinen, miss. laina
3  futrelle, mrs. jacques heath (lily may peel)
4  allen, mr. william henry
   ... 
886 montvila, rev. juozas
887 graham, miss. margaret edith
888 johnston, miss. catherine helen "carrie"
889 behr, mr. karl howell
890 dooley, mr. patrick
Name: Name, Length: 891, dtype: object
```

To make each of the strings in the Name column lowercase, select the Name column (see the tutorial on selection of data), add the str accessor and apply the lower method. As such, each of the strings is converted element-wise.

Similar to datetime objects in the time series tutorial having a dt accessor, a number of specialized string methods are available when using the str accessor. These methods have in general matching names with the equivalent built-in string methods for single elements, but are applied element-wise (remember element-wise calculations?) on each of the values of the columns.

Create a new column Surname that contains the surname of the passengers by extracting the part before the comma.

```
In [5]: titanic["Name"].str.split("", ")
Out[5]:
0       [Braund, Mr. Owen Harris]
1  [Cumings, Mrs. John Bradley (Florence Briggs th... 
2       [Heikkinen, Miss. Laina]
3  [Futrelle, Mrs. Jacques Heath (Lily May Peel)]
4       [Allen, Mr. William Henry]
   
(continues on next page)
```
Using the `Series.str.split()` method, each of the values is returned as a list of 2 elements. The first element is the part before the comma and the second element is the part after the comma.

```python
In [6]: titanic["Surname"] = titanic["Name"].str.split(",").str.get(0)
```

```python
In [7]: titanic["Surname"]
Out[7]:
0  Braund
1  Cumings
2  Heikkinen
3  Futrelle
4  Allen
...  
886  Montvila
887  Graham
888  Johnston
889  Behr
890  Dooley
Name: Surname, Length: 891, dtype: object
```

As we are only interested in the first part representing the surname (element 0), we can again use the `str` accessor and apply `Series.str.get()` to extract the relevant part. Indeed, these string functions can be concatenated to combine multiple functions at once!

More information on extracting parts of strings is available in the user guide section on *splitting and replacing strings*.

Extract the passenger data about the countesses on board of the Titanic.

```python
In [8]: titanic["Name"].str.contains("Countess")
Out[8]:
0   False
1   False
2   False
3   False
4   False
...   
886  False
887  False
888  False
889  False
890  False
Name: Name, Length: 891, dtype: bool
```

```python
In [9]: titanic[titanic["Name"].str.contains("Countess")]
Out[9]:
```
The string method `Series.str.contains()` checks for each of the values in the column `Name` if the string contains the word `Countess` and returns for each of the values `True` (`Countess` is part of the name) or `False` (`Countess` is not part of the name). This output can be used to subselect the data using conditional (boolean) indexing introduced in the subsetting of data tutorial. As there was only one countess on the Titanic, we get one row as a result.

Note: More powerful extractions on strings are supported, as the `Series.str.contains()` and `Series.str.extract()` methods accept regular expressions, but out of scope of this tutorial.

More information on extracting parts of strings is available in the user guide section on string matching and extracting.

Which passenger of the Titanic has the longest name?

```
In [10]: titanic["Name"].str.len()
```
```
Out[10]:
     0  23
     1  51
     2  22
     3  44
     4  24
     ..
    886 21
    887 28
    888 40
    889 21
    890 19
Name: Name, Length: 891, dtype: int64
```

To get the longest name we first have to get the lengths of each of the names in the `Name` column. By using pandas string methods, the `Series.str.len()` function is applied to each of the names individually (element-wise).

```
In [11]: titanic["Name"].str.len().idxmax()
```
```
Out[11]: 307
```

Next, we need to get the corresponding location, preferably the index label, in the table for which the name length is the largest. The `idxmax()` method does exactly that. It is not a string method and is applied to integers, so no `str` is used.

```
In [12]: titanic.loc[titanic["Name"].str.len().idxmax(), "Name"]
```
```
Out[12]: 'Penasco y Castellana, Mrs. Victor de Satode (Maria Josefa Perez de Soto y Vallejo)'
```

Based on the index name of the row (307) and the column (`Name`), we can do a selection using the `loc` operator, introduced in the tutorial on subsetting.

In the “Sex” column, replace values of “male” by “M” and values of “female” by “F”.
In [13]: titanic["Sex_short"] = titanic["Sex"].replace({"male": "M", "female": "F"})

In [14]: titanic["Sex_short"]

Out[14]:
0    M
1    F
2    F
3    F
4    M
   ... 
886  M
887  F
888  F
889  M
890  M
Name: Sex_short, Length: 891, dtype: object

Whereas \texttt{replace()} is not a string method, it provides a convenient way to use mappings or vocabularies to translate certain values. It requires a \texttt{dictionary} to define the mapping \{from : to\}.

\begin{Verbatim}
Warning: There is also a \texttt{replace()} method available to replace a specific set of characters. However, when having a mapping of multiple values, this would become:
\begin{verbatim}
titanic["Sex_short"] = titanic["Sex"].str.replace("female", "F")
titanic["Sex_short"] = titanic["Sex_short"].str.replace("male", "M")
\end{verbatim}
\end{Verbatim}

This would become cumbersome and easily lead to mistakes. Just think (or try out yourself) what would happen if those two statements are applied in the opposite order...

- String methods are available using the \texttt{str} accessor.
- String methods work element-wise and can be used for conditional indexing.
- The \texttt{replace} method is a convenient method to convert values according to a given dictionary.

A full overview is provided in the user guide pages on \textit{working with text data}.

\section*{1.4.4 Comparison with other tools}

\subsection*{Comparison with R / R libraries}

Since pandas aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the R language and its many third party libraries as they relate to pandas. In comparisons with R and CRAN libraries, we care about the following things:

- \textbf{Functionality / flexibility:} what can/cannot be done with each tool
- \textbf{Performance:} how fast are operations. Hard numbers/benchmarks are preferable
- \textbf{Ease-of-use:} Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.

For transfer of \texttt{DataFrame} objects from pandas to R, one option is to use HDF5 files, see \textit{External compatibility} for an example.
Quick reference

We’ll start off with a quick reference guide pairing some common R operations using `dplyr` with pandas equivalents.

### Querying, filtering, sampling

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dim(df)</code></td>
<td><code>df.shape</code></td>

<td><code>mutate(df, c=a-b)</code></td>
<td><code>df.assign(c=df['a']-df['b'])</code></td>
</tr>
</tbody>
</table>

### Grouping and summarizing

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>summary(df)</code></td>
<td><code>df.describe()</code></td>
</tr>
<tr>
<td><code>gdf &lt;- group_by(df, col1)</code></td>
<td><code>gdf = df.groupby('col1')</code></td>
</tr>
<tr>
<td><code>summarise(gdf, avg=mean(col1, na.rm=TRUE))</code></td>
<td><code>gdf.groupby('col1').agg({'col1': 'mean'})</code></td>
</tr>
<tr>
<td><code>summarise(gdf, total=sum(col1))</code></td>
<td><code>gdf.groupby('col1').sum()</code></td>
</tr>
</tbody>
</table>

¹ R’s shorthand for a subrange of columns (select(df, col1:col3)) can be approached cleanly in pandas, if you have the list of columns, for example `df[cols[1:3]]` or `df.drop(cols[1:3])`, but doing this by column name is a bit messy.
Base R

Slicing with R’s c

R makes it easy to access data.frame columns by name

```r
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```r
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list("abc"))

In [2]: df["a", "c"]
Out[2]:
           a       c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892

In [3]: df.loc[:, ["a", "c"]]
Out[3]:
           a       c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892
```

Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the iloc indexer attribute and numpy.r_.

```
In [4]: named = list("abcdefgh")

In [5]: n = 30
```

(continues on next page)
aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called df and splitting it into groups by1 and by2:

```r
df <- data.frame(
  v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),
  v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)
```

The `groupby()` method is similar to base R `aggregate` function.

```python
In [9]: df = pd.DataFrame(
    ...:
    ...:     
    ...:     "v1": [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
    ...:     "v2": [11, 33, 55, 77, 88, 33, 55, np.nan, 44, 55, 77, 99],
    (continues on next page)
```
...:
  "by1": ["red", "blue", 1, 2, np.nan, "big", 1, 2, "red", 1, np.nan, 12],
  "by2": [
    "wet",
    "dry",
    99,
    95,
    np.nan,
    "damp",
    95,
    99,
    "red",
    99,
    np.nan,
    np.nan,
  ],
  }
),

In [10]:
g = df.groupby(["by1", "by2"])

In [11]:
g[["v1", "v2"]].mean()

Out[11]:

   v1  v2
by1 by2
  1 95  5.0  55.0
  99  5.0  55.0
  2 95  7.0  77.0
  99 NaN NaN
big damp  3.0  33.0
blue dry  3.0  33.0
red red   4.0  44.0
wet  1.0  11.0

For more details and examples see the groupby documentation.

**match / %in%**

A common way to select data in R is using %in% which is defined using the function `match`. The operator %in% is used to return a logical vector indicating if there is a match or not:

s <- 0:4
s %in% c(2,4)

The `isin()` method is similar to R %in% operator:

In [12]:
s = pd.Series(np.arange(5), dtype=np.float32)

In [13]:
s.isin([2, 4])

Out[13]:
0   False

The `match` function returns a vector of the positions of matches of its first argument in its second:

```r
s <- 0:4
match(s, c(2,4))
```

For more details and examples see the reshaping documentation.

**tapply**

tapply is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a data.frame called `baseball`, and retrieving information based on the array `team`:

```r
baseball <-
data.frame(team = gl(5, 5,
  labels = paste("Team", LETTERS[1:5]),
  player = sample(letters, 25),
  batting.average = runif(25, .200, .400))
tapply(baseball$batting.average, baseball.example$team,
  max)
```

In pandas we may use `pivot_table()` method to handle this:

```python
In [14]: import random
In [15]: import string
In [16]: baseball = pd.DataFrame(
      {
        "team": ["team %d" % (x + 1) for x in range(5)] * 5,
        "player": random.sample(list(string.ascii_lowercase), 25),
        "batting avg": np.random.uniform(0.200, 0.400, 25),
      }
In [17]: baseball.pivot_table(values="batting avg", columns="team", aggfunc=np.max)
Out[17]:
team      team 1  team 2  team 3  team 4  team 5
batting avg 0.352134 0.295327 0.397191 0.394457 0.396194
```

For more details and examples see the reshaping documentation.
subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column’s values are less than another column’s values:

```r
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b,]  # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```python
In [18]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})
In [19]: df.query("a <= b")
Out[19]:
   a    b
1 0.174950 0.552887
2 -0.023167 0.148084
3 -0.495291 -0.300218
4 -0.860736 0.197378
5 -1.134146 1.720780
7 -0.290098 0.083515
8  0.238636 0.946550

In [20]: df[df["a"] <= df["b"]]
Out[20]:
   a    b
1 0.174950 0.552887
2 -0.023167 0.148084
3 -0.495291 -0.300218
4 -0.860736 0.197378
5 -1.134146 1.720780
7 -0.290098 0.083515
8  0.238636 0.946550

In [21]: df.loc[df["a"] <= df["b"]]
Out[21]:
   a    b
1 0.174950 0.552887
2 -0.023167 0.148084
3 -0.495291 -0.300218
4 -0.860736 0.197378
5 -1.134146 1.720780
7 -0.290098 0.083515
8  0.238636 0.946550
```

For more details and examples see the query documentation.
with

An expression using a data.frame called df in R with the columns a and b would be evaluated using with like so:

```r
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b  # same as the previous expression
```

In pandas the equivalent expression, using the `eval()` method, would be:

```python
In [22]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})
In [23]: df.eval("a + b")
Out[23]:
0  -0.091430  
1   -2.483890  
2   -0.252728  
3   -0.626444  
4   -0.261740  
5    2.149503  
6    0.799331  
7    2.377245  
8    0.799331  
9    2.104677  
dtype: float64

In [24]: df["a"] + df["b"]  # same as the previous expression
Out[24]:
0  -0.091430  
1   -2.483890  
2   -0.252728  
3   -0.626444  
4   -0.261740  
5    2.149503  
6    0.799331  
7    2.377245  
8    0.799331  
9    2.104677  
dtype: float64
```

In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see the `eval` documentation.

plyr

plyr is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, a for arrays, l for lists, and d for data.frame. The table below shows how these data structures could be mapped in Python.

<table>
<thead>
<tr>
<th>R</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>lists</td>
<td>dictionary or list of objects</td>
</tr>
<tr>
<td>data.frame</td>
<td>dataframe</td>
</tr>
</tbody>
</table>
ddply

An expression using a data.frame called `df` in R where you want to summarize `x` by month:

```r
require(plyr)
df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5,6,7,8),30),
  week = sample(1:4, 120, TRUE)
)
ddply(df, .(month, week), summarize,
  mean = round(mean(x), 2),
  sd = round(sd(x), 2))
```

In pandas the equivalent expression, using the `groupby()` method, would be:

```python
In [25]: df = pd.DataFrame(
      ....: { ....:
      ....:     "x": np.random.uniform(1.0, 168.0, 120),
      ....:     "y": np.random.uniform(7.0, 334.0, 120),
      ....:     "z": np.random.uniform(1.7, 20.7, 120),
      ....:     "month": [5, 6, 7, 8] * 30,
      ....:     "week": np.random.randint(1, 4, 120),
      ....:   }
      ....: )
      ....:

In [26]: grouped = df.groupby(["month", "week"])
In [27]: grouped["x"].agg([np.mean, np.std])
Out[27]:
          mean       std
    month week
      5   1  63.653367  40.601965
     2  78.126605  53.342400
     3  92.091886  57.630110
      6   1  81.747070  54.339218
     2  70.971205  54.687287
     3 100.968344  54.010081
      7   1  61.576332  38.844274
     2  61.733510  48.209013
     3  71.688795  37.595638
      8   1  62.741922  34.618153
     2  91.774627  49.790202
     3  73.936856  60.773900
```

For more details and examples see the groupby documentation.
reshape / reshape2

melt.array

An expression using a 3 dimensional array called a in R where you want to melt it into a data.frame:

```r
a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))
```

In Python, since a is a list, you can simply use list comprehension.

```python
In [28]: a = np.array(list(range(1, 24)) + [np.NAN]).reshape(2, 3, 4)

In [29]: pd.DataFrame([tuple(list(x) + [val]) for x, val in np.ndenumerate(a)])
Out[29]:
   0 1 2 3
0 0 0 0 1.0
1 0 0 1 2.0
2 0 0 2 3.0
3 0 0 3 4.0
4 0 1 0 5.0
... ... ... ... 
19 1 1 3 20.0
20 1 2 0 21.0
21 1 2 1 22.0
22 1 2 2 23.0
23 1 2 3 NaN
[24 rows x 4 columns]
```

melt.list

An expression using a list called a in R where you want to melt it into a data.frame:

```r
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```python
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NAN]))

In [31]: pd.DataFrame(a)
Out[31]:
   0 1
0 0 1.0
1 1 2.0
2 2 3.0
3 3 4.0
4 4 NaN

```

For more details and examples see the [Into to Data Structures documentation](#).
melt.data.frame

An expression using a data.frame called cheese in R where you want to reshape the data.frame:

```r
cheese <- data.frame(
  first = c('John', 'Mary'),
  last = c('Doe', 'Bo'),
  height = c(5.5, 6.0),
  weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```python
In [32]: cheese = pd.DataFrame(
    {....:
      "first": ["John", "Mary"],
      "last": ["Doe", "Bo"],
      "height": [5.5, 6.0],
      "weight": [130, 150],
    }
)

In [33]: pd.melt(cheese, id_vars=['first', 'last'])
Out[33]:
<table>
<thead>
<tr>
<th>first</th>
<th>last</th>
<th>variable</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>John</td>
<td>Doe</td>
<td>height</td>
<td>5.5</td>
</tr>
<tr>
<td>Mary</td>
<td>Bo</td>
<td>height</td>
<td>6.0</td>
</tr>
<tr>
<td>John</td>
<td>Doe</td>
<td>weight</td>
<td>130.0</td>
</tr>
<tr>
<td>Mary</td>
<td>Bo</td>
<td>weight</td>
<td>150.0</td>
</tr>
</tbody>
</table>

In [34]: cheese.set_index(['first', 'last']).stack() # alternative way
Out[34]:
first       last
John Doe    height 5.5
Mary Bo     height 6.0

For more details and examples see the reshaping documentation.

cast

In R acast is an expression using a data.frame called df in R to cast into a higher dimensional array:

```r
df <- data.frame(
  x = runif(12, 1, 168),
  y = runif(12, 7, 334),
  z = runif(12, 1.7, 20.7),
  month = rep(c(5,6,7),4),
)
```
In Python the best way is to make use of `pivot_table()`:

```python
In [35]: df = pd.DataFrame(
    ...:     {
    ...:         "x": np.random.uniform(1.0, 168.0, 12),
    ...:         "y": np.random.uniform(7.0, 334.0, 12),
    ...:         "z": np.random.uniform(1.7, 20.7, 12),
    ...:         "month": [5, 6, 7] * 4,
    ...:         "week": [1, 2] * 6,
    ...:     })
    ...:
In [36]: mdf = pd.melt(df, id_vars=['month', 'week'])
In [37]: pd.pivot_table(
    ...:     mdf,
    ...:     values='value',
    ...:     index=['variable', 'week'],
    ...:     columns=['month'],
    ...:     aggfunc=np.mean,
    ...: )
```

```
Out[37]:

<table>
<thead>
<tr>
<th>month</th>
<th>variable</th>
<th>week</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>x</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>y</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>z</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>
```

Similarly for `dcast` which uses a data.frame called `df` in R to aggregate information based on `Animal` and `FeedType`:

```r
df <- data.frame(
    Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
               'Animal2', 'Animal3'),
    FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
    Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
```

```
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```python
week = rep(c(1, 2), 6)
mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)
```
In [38]: df = pd.DataFrame(
    ...:     {
    ...:         "Animal": [
    ...:             "Animal1",
    ...:             "Animal2",
    ...:             "Animal3",
    ...:             "Animal2",
    ...:             "Animal1",
    ...:             "Animal2",
    ...:             "Animal3",
    ...:         ],
    ...:         "FeedType": ["A", "B", "A", "A", "B", "B", "A"],
    ...:         "Amount": [10, 7, 4, 2, 5, 6, 2],
    ...:     }
    ...: )

In [39]: df.pivot_table(values="Amount", index="Animal", columns="FeedType", aggfunc="sum")
Out[39]:
<table>
<thead>
<tr>
<th>FeedType</th>
<th>Animal</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Animal1</td>
</tr>
<tr>
<td>A</td>
<td>10.0</td>
</tr>
<tr>
<td>B</td>
<td>5.0</td>
</tr>
</tbody>
</table>

The second approach is to use the `groupby()` method:

```
In [40]: df.groupby(["Animal", "FeedType"])["Amount"].sum()
Out[40]:
<table>
<thead>
<tr>
<th>Animal</th>
<th>FeedType</th>
</tr>
</thead>
<tbody>
<tr>
<td>Animal1</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td>B</td>
</tr>
<tr>
<td>Animal2</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td>B</td>
</tr>
<tr>
<td>Animal3</td>
<td>A</td>
</tr>
<tr>
<td>Name: Amount, dtype: int64</td>
<td></td>
</tr>
</tbody>
</table>
```

For more details and examples see the reshaping documentation or the groupby documentation.

`factor`

pandas has a data type for categorical data.

```
cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))
```

In pandas this is accomplished with `pd.cut` and `astype("category")`:

```
In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
Out[41]:
0    (0.995, 2.667]
```

(continues on next page)
1 (0.995, 2.667]
2 (2.667, 4.333]
3 (2.667, 4.333]
4 (4.333, 6.0]
5 (4.333, 6.0]
dtype: category
Categories (3, interval[float64, right]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.0]]

In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
Out[42]:
0 1
1 2
2 3
3 2
4 2
5 3
dtype: category
Categories (3, int64): [1, 2, 3]

For more details and examples see categorical introduction and the API documentation. There is also a documentation regarding the differences to R’s factor.

Comparison with SQL

Since many potential pandas users have some familiarity with SQL, this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you’re new to pandas, you might want to first read through 10 Minutes to pandas to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

In [1]: import pandas as pd
In [2]: import numpy as np

Most of the examples will utilize the tips dataset found within pandas tests. We’ll read the data into a DataFrame called tips and assume we have a database table of the same name and structure.

In [3]: url = (...
   ...:    "https://raw.github.com/pandas-dev"
   ...:    "/pandas/master/pandas/tests/io/data/csv/tips.csv"
   ...: )
   ...
In [4]: tips = pd.read_csv(url)

In [5]: tips
Out[5]:
   total_bill  tip  sex  smoker  day  time  size
0  16.99  1.01  Female  No  Sun  Dinner   2
1  10.34  1.66  Male  No  Sun  Dinner   3
Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

**Note:** You will see an `inplace=True` keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```

Its use is discouraged. More information.

SELECT

In SQL, selection is done using a comma-separated list of columns you’d like to select (or a * to select all columns):

```
SELECT total_bill, tip, smoker, time
FROM tips;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```
in [6]: tips["total_bill", "tip", "smoker", "time"]
```

```
Out[6]:
total_bill  tip  smoker  time
0       16.99  1.01    No  Dinner
1       10.34  1.66    No  Dinner
2       21.01  3.50    No  Dinner
3       23.68  3.31    No  Dinner
4       24.59  3.61    No  Dinner
...     ...     ...    ...  ...
239     29.03  5.92    No  Dinner
```

(continues on next page)
Calling the DataFrame without the list of column names would display all columns (akin to SQL's `*`).

In SQL, you can add a calculated column:

```
SELECT *, tip/total_bill as tip_rate
FROM tips;
```

With pandas, you can use the `DataFrame.assign()` method of a DataFrame to append a new column:

```
In [7]: tips.assign(tip_rate=tips['tip'] / tips['total_bill'])
Out[7]:
   total_bill  tip  sex  smoker  day  time  size  tip_rate
0    16.99  1.01  Female     No    Sun  Dinner   2  0.059447
1    10.34  1.66    Male     No    Sun  Dinner   3  0.160542
2    21.01  3.50    Male     No    Sun  Dinner   3  0.166587
3    23.68  3.31    Male     No    Sun  Dinner   2  0.139780
4    24.59  3.61  Female     No    Sun  Dinner   4  0.146808
   ...     ...    ...    ...    ...    ...    ...     ...
239  29.03  5.92    Male     No    Sat  Dinner   3  0.203927
240  27.18  2.00  Female      Yes    Sat  Dinner   2  0.073584
241  22.67  2.00    Male      Yes    Sat  Dinner   2  0.088222
242  17.82  1.75    Male     No    Sat  Dinner   2  0.098204
243  18.78  3.00  Female     No    Thur  Dinner   2  0.159744
[244 rows x 8 columns]
```

WHERE

Filtering in SQL is done via a `WHERE` clause.

```
SELECT *
FROM tips
WHERE time = 'Dinner';
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```
In [8]: tips[tips['total_bill'] > 10]
Out[8]:
   total_bill  tip  sex  smoker  day  time  size
0    16.99  1.01  Female     No    Sun  Dinner   2
1    10.34  1.66    Male     No    Sun  Dinner   3
2    21.01  3.50    Male     No    Sun  Dinner   3
3    23.68  3.31    Male     No    Sun  Dinner   2
4    24.59  3.61  Female     No    Sun  Dinner   4
   ...     ...    ...    ...    ...    ...    ...
```

(continues on next page)
The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [9]: is_dinner = tips["time"] == "Dinner"
```

```
In [10]: is_dinner
Out[10]:
0   True
1   True
2   True
3   True
4   True
   ... 
239  True
240  True
241  True
242  True
243  True
Name: time, Length: 244, dtype: bool
```

```
In [11]: is_dinner.value_counts()
Out[11]:
True    176
False    68
Name: time, dtype: int64
```

```
In [12]: tips[is_dinner]
Out[12]:
     total_bill  tip  sex  smoker  day    time  size
0       16.99  1.01  Female    No   Sun  Dinner  2
1       10.34  1.66   Male    No   Sun  Dinner  3
2       21.01  3.50   Male    No   Sun  Dinner  3
3       23.68  3.31   Male    No   Sun  Dinner  2
4       24.59  3.61  Female    No   Sun  Dinner  4
   ...    ...    ...    ...    ...    ...    ...
239     29.03  5.92   Male    No   Sat  Dinner  3
240     27.18  2.00  Female    Yes   Sat  Dinner  2
241     22.67  2.00   Male    Yes   Sat  Dinner  2
242     17.82  1.75   Male    No   Sat  Dinner  2
243     18.78  3.00  Female    No  Thur  Dinner  2
```

Just like SQL’s OR and AND, multiple conditions can be passed to a DataFrame using | (OR) and & (AND).

1.4. Tutorials
Tips of more than $5 at Dinner meals:

```
SELECT *
FROM tips
WHERE time = 'Dinner' AND tip > 5.00;
```

```
In [13]: tips[(tips[“time”] == “Dinner”) & (tips[“tip”] > 5.00)]
Out[13]:
   total_bill  tip   sex  smoker  day    time  size
0       39.42  7.58  Male     No  Sat  Dinner   4
1       30.40  5.60  Male     No  Sun  Dinner   4
2       32.40  6.00  Male     No  Sun  Dinner   4
3       34.81  5.20  Female   No  Sun  Dinner   4
4       48.27  6.73  Male     No  Sat  Dinner   4
5       29.93  5.07  Male     No  Sun  Dinner   4
6       29.85  5.14  Female   No  Sun  Dinner   5
7       50.81 10.00  Male     Yes  Sat  Dinner   3
8       7.25   5.15  Male     Yes  Sun  Dinner   2
9       23.33  5.65  Male     Yes  Sun  Dinner   2
10      23.17  6.50  Male     Yes  Sun  Dinner   4
11      25.89  5.16  Male     Yes  Sat  Dinner   4
12      48.33  9.00  Male     No  Sat  Dinner   4
13      28.17  6.50  Female   Yes  Sun  Dinner   3
14      29.03  5.92  Male     No  Sat  Dinner   3
```

Tips by parties of at least 5 diners OR bill total was more than $45:

```
SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;
```

```
In [14]: tips[(tips[“size”] >= 5) | (tips[“total_bill”] > 45)]
Out[14]:
   total_bill  tip   sex  smoker  day    time  size
     59  48.27  6.73  Male     No  Sat  Dinner   4
  125  29.80  4.20 Female   No  Thur  Lunch   6
  141  34.30  6.70  Male     No  Thur  Lunch   6
  142  41.19  5.00  Male     No  Thur  Lunch   5
  143  27.05  5.00 Female   No  Thur  Lunch   6
  155  29.85  5.14 Female   No  Sun  Dinner   5
  156  48.17  5.00  Male     No  Sun  Dinner   6
  170  50.81 10.00  Male     Yes  Sat  Dinner   3
  182  45.35  3.50  Male     Yes  Sun  Dinner   3
  185  27.05  5.00  Male     Yes  Sun  Dinner   5
  187  30.46  2.00  Male     Yes  Sun  Dinner   5
  212  48.33  9.00  Male     No  Sat  Dinner   4
  216  28.15  3.00  Male     Yes  Sat  Dinner   5
```

NULL checking is done using the `notna()` and `isna()` methods.

```
In [15]: frame = pd.DataFrame(
       ....: )
```
In 

```
n= len(set(tips['sex']))
```  

(continues on next page)
The pandas equivalent would be:

```python
In [19]: tips.groupby("sex").size()
Out[19]:
sex
Female 87
Male 157
dtype: int64
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of NOT NULL records within each.

```python
In [20]: tips.groupby("sex").count()
Out[20]:
   total_bill  tip  smoker  day  time  size
sex
Female   87    87    87    87    87    87
Male    157   157   157   157   157   157
```

Alternatively, we could have applied the `count()` method to an individual column:

```python
In [21]: tips.groupby("sex")["total_bill"].count()
Out[21]:
sex
Female 87
Male 157
Name: total_bill, dtype: int64
```

Multiple functions can also be applied at once. For instance, say we'd like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```sql
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri 2.734737 19
Sat 2.993103 87
Sun 3.255132 76
Thu 2.771452 62
*/
```

```python
In [22]: tips.groupby("day").agg({"tip": np.mean, "day": np.size})
Out[22]:
   tip  day
day
Fri 2.734737 19
Sat 2.993103 87
Sun 3.255132 76
Thu 2.771452 62
```
Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```sql
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
```/*
smoker
day
No Fri 4 2.812500
Sat 45 3.102889
Sun 57 3.167895
Thu 45 2.673778
Yes Fri 15 2.714000
Sat 42 2.875476
Sun 19 3.516842
Thu 17 3.030000
*/

```python
In [23]: tips.groupby(["smoker", "day"]).agg({"tip": [np.size, np.mean]})
Out[23]:

<table>
<thead>
<tr>
<th>smoker</th>
<th>day</th>
<th>tip</th>
<th>size</th>
<th>mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>Fri</td>
<td>4</td>
<td>2.812500</td>
<td></td>
</tr>
<tr>
<td>Sat</td>
<td>45</td>
<td>3.102889</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sun</td>
<td>57</td>
<td>3.167895</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Thur</td>
<td>45</td>
<td>2.673778</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Yes</td>
<td>Fri</td>
<td>15</td>
<td>2.714000</td>
<td></td>
</tr>
<tr>
<td>Sat</td>
<td>42</td>
<td>2.875476</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sun</td>
<td>19</td>
<td>3.516842</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Thur</td>
<td>17</td>
<td>3.030000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**JOIN**

JOINs can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

```python
In [24]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})
In [25]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})
```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let’s go over the various types of JOINs.
INNER JOIN

```sql
SELECT *
FROM df1
INNER JOIN df2
  ON df1.key = df2.key;
```

# merge performs an INNER JOIN by default

```
In [26]: pd.merge(df1, df2, on="key")
Out[26]:
   key  value_x  value_y
0  A   0.469112   NaN
1  B  -0.282863  1.212112
2  C  -1.509059   NaN
3  D -1.135632  -0.173215
4  D -1.135632   0.119209
```

`merge()` also offers parameters for cases when you’d like to join one DataFrame’s column with another DataFrame’s index.

```
In [27]: indexed_df2 = df2.set_index("key")
In [28]: pd.merge(df1, indexed_df2, left_on="key", right_index=True)
Out[28]:
   key  value_x  value_y
1  B  -0.282863  1.212112
3  D -1.135632  -0.173215
3  D -1.135632   0.119209
```

LEFT OUTER JOIN

Show all records from df1.

```sql
SELECT *
FROM df1
LEFT OUTER JOIN df2
  ON df1.key = df2.key;
```

```
In [29]: pd.merge(df1, df2, on="key", how="left")
Out[29]:
   key  value_x  value_y
0  A   0.469112   NaN
1  B  -0.282863  1.212112
2  C  -1.509059   NaN
3  D -1.135632  -0.173215
4  D -1.135632   0.119209
```
RIGHT JOIN

Show all records from df2.

```
SELECT *
FROM df1
RIGHT OUTER JOIN df2
  ON df1.key = df2.key;
```

```
In [30]: pd.merge(df1, df2, on="key", how="right")
Out[30]:
   key  value_x  value_y
0   B  -0.282863  1.212112
1   D  -1.135632 -0.173215
2   D  -1.135632  0.119209
3   E  NaN      -1.044236
```

FULL JOIN

pandas also allows for FULL JOINs, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINs are not supported in all RDBMS (MySQL).

Show all records from both tables.

```
SELECT *
FROM df1
FULL OUTER JOIN df2
  ON df1.key = df2.key;
```

```
In [31]: pd.merge(df1, df2, on="key", how="outer")
Out[31]:
   key  value_x  value_y
0   A   0.469112  NaN
1   B  -0.282863  1.212112
2   C  -1.509059  NaN
3   D  -1.135632 -0.173215
4   D  -1.135632  0.119209
5   E   NaN      -1.044236
```

UNION

UNION ALL can be performed using `concat()`.

```
In [32]: df1 = pd.DataFrame(
          ....:     {"city": ["Chicago", "San Francisco", "New York City"], "rank": range(1, 4)}
          ....:     )
          ....:
```

```
In [33]: df2 = pd.DataFrame(
          ....:     {"city": ["Chicago", "Boston", "Los Angeles"], "rank": [1, 4, 5]}
(continues on next page)```
SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
city rank
Chicago 1
San Francisco 2
New York City 3
Chicago 1
Boston 4
Los Angeles 5
*/

In [34]: pd.concat([df1, df2])
Out[34]:
city rank
0 Chicago 1
1 San Francisco 2
2 New York City 3
0 Chicago 1
1 Boston 4
2 Los Angeles 5

SQL's UNION is similar to UNION ALL, however UNION will remove duplicate rows.

SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
city rank
Chicago 1
San Francisco 2
New York City 3
Boston 4
Los Angeles 5
*/

In pandas, you can use concat() in conjunction with drop_duplicates().

In [35]: pd.concat([df1, df2]).drop_duplicates()
Out[35]:
city rank
0 Chicago 1
1 San Francisco 2
LIMIT

```
SELECT * FROM tips
LIMIT 10;
```

In [36]: tips.head(10)
Out[36]:

-- Oracle's RANK() analytic function

```sql
SELECT * FROM (
    SELECT t.*,
        RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk
    FROM tips t
    WHERE tip < 2
) WHERE rnk < 3
ORDER BY sex, rnk;
```

Let's find tips with (rank < 3) per gender group for (tip < 2). Notice that when using rank(method='min') function rnk_min remains the same for the same tip (as Oracle's RANK() function)

```python
In [40]:
    tips[tips["tip"] < 2]
    ...: .assign(rnk_min=tips.groupby(["sex"])["tip"].rank(method="min"))
    ...: .query("rnk_min < 3")
    ...: .sort_values(["sex", "rnk_min"])
    ...:
```

```
Out[40]:

<table>
<thead>
<tr>
<th></th>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>

<td>2.0</td>
</tr>
</tbody>
</table>
```

**UPDATE**

```sql
UPDATE tips
SET tip = tip*2
WHERE tip < 2;
```

```
In [41]: tips.loc[tips["tip"] < 2, "tip"] *= 2
```
**DELETE**

```sql
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain instead of deleting them:

```python
In [42]: tips = tips.loc[tips["tip"] <= 9]
```

**Comparison with spreadsheets**

Since many potential pandas users have some familiarity with spreadsheet programs like Excel, this page is meant to provide some examples of how various spreadsheet operations would be performed using pandas. This page will use terminology and link to documentation for Excel, but much will be the same/similar in Google Sheets, LibreOffice Calc, Apple Numbers, and other Excel-compatible spreadsheet software.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```

**Data structures**

**General terminology translation**

<table>
<thead>
<tr>
<th>pandas</th>
<th>Excel</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame</td>
<td>worksheet</td>
</tr>
<tr>
<td>Series</td>
<td>column</td>
</tr>
<tr>
<td>Index</td>
<td>row headings</td>
</tr>
<tr>
<td>row</td>
<td>row</td>
</tr>
<tr>
<td>NaN</td>
<td>empty cell</td>
</tr>
</tbody>
</table>

**DataFrame**

A DataFrame in pandas is analogous to an Excel worksheet. While an Excel workbook can contain multiple worksheets, pandas DataFrames exist independently.
Series

A Series is the data structure that represents one column of a DataFrame. Working with a Series is analogous to referencing a column of a spreadsheet.

Index

Every DataFrame and Series has an Index, which are labels on the rows of the data. In pandas, if no index is specified, a RangeIndex is used by default (first row = 0, second row = 1, and so on), analogous to row headings/numbers in spreadsheets.

In pandas, indexes can be set to one (or multiple) unique values, which is like having a column that is used as the row identifier in a worksheet. Unlike most spreadsheets, these Index values can actually be used to reference the rows. (Note that this can be done in Excel with structured references.) For example, in spreadsheets, you would reference the first row as A1:Z1, while in pandas you could use populations.loc['Chicago'].

Index values are also persistent, so if you re-order the rows in a DataFrame, the label for a particular row don’t change. See the indexing documentation for much more on how to use an Index effectively.

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

Note: You will see an inplace=True keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```

Its use is discouraged. More information.

Data input / output

Constructing a DataFrame from values

In a spreadsheet, values can be typed directly into cells.

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```python
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
```

```python
In [4]: df
```

Out[4]:

```none
(continues on next page)
```
Reading external data

Both Excel and pandas can import data from various sources in various formats.

CSV

Let’s load and display the tips dataset from the pandas tests, which is a CSV file. In Excel, you would download and then open the CSV. In pandas, you pass the URL or local path of the CSV file to `read_csv()`:

```
In [5]: url = (
    ...:   "https://raw.github.com/pandas-dev"
    ...:   "/pandas/master/pandas/tests/io/data/csv/tips.csv"
    ...: )
    ...

In [6]: tips = pd.read_csv(url)

In [7]: tips
```

```
Out[7]:
          total_bill  tip  sex  smoker day     time  size
0       16.99  1.01  Female   No  Sun   Dinner   2
1       10.34  1.66     Male   No  Sun   Dinner   3
2       21.01  3.50     Male   No  Sun   Dinner   3
3       23.68  3.31     Male   No  Sun   Dinner   2
4       24.59  3.61  Female   No  Sun   Dinner   4
      ...   ...     ...     ...  ...     ...   ...
239   29.03  5.92     Male   No  Sat   Dinner   3
240   27.18  2.00  Female    Yes  Sat   Dinner   2
241   22.67  2.00     Male    Yes  Sat   Dinner   2
242   17.82  1.75     Male   No  Sat   Dinner   2
243   18.78  3.00  Female   No  Thur  Dinner   2
```

Like Excel’s Text Import Wizard, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv("tips.csv", sep="\t", header=None)
# alternatively, read_table is an alias to read_csv with tab delimiter
```
Excel files

Excel opens various Excel file formats by double-clicking them, or using the Open menu. In pandas, you use special methods for reading and writing from/to Excel files.

Let's first create a new Excel file based on the tips dataframe in the above example:

```python
tips.to_excel("./tips.xlsx")
```

Should you wish to subsequently access the data in the tips.xlsx file, you can read it into your module using

```python
tips_df = pd.read_excel("./tips.xlsx", index_col=0)
```

You have just read in an Excel file using pandas!

Limiting output

Spreadsheet programs will only show one screenful of data at a time and then allow you to scroll, so there isn't really a need to limit output. In pandas, you'll need to put a little more thought into controlling how your DataFrames are displayed.

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using DataFrame.head() or DataFrame.tail().

```python
In [8]: tips.head(5)
Out[8]:
   total_bill  tip  sex  smoker day  time  size
0     16.99  1.01  Female  No  Sun  Dinner    2
1     10.34  1.66   Male   No  Sun  Dinner    3
2     21.01  3.50   Male   No  Sun  Dinner    3
3     23.68  3.31   Male   No  Sun  Dinner    2
4     24.59  3.61  Female   No  Sun  Dinner    4
```

Exporting data

By default, desktop spreadsheet software will save to its respective file format (.xlsx, .ods, etc). You can, however, save to other file formats.

*pandas can create Excel files, CSV, or a number of other formats.*

Data operations

Operations on columns

In spreadsheets, formulas are often created in individual cells and then dragged into other cells to compute them for other columns. In pandas, you're able to do operations on whole columns directly.

pandas provides vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The DataFrame.drop() method drops a column from the DataFrame.
In [9]: tips["total_bill"] = tips["total_bill"] - 2

In [10]: tips["new_bill"] = tips["total_bill"] / 2

In [11]: tips

Out[11]:

<table>

<td>Thur</td>
<td>2</td>
<td>8.390</td>
</tr>
</tbody>
</table>

[244 rows x 8 columns]

In [12]: tips = tips.drop("new_bill", axis=1)

Note that we aren’t having to tell it to do that subtraction cell-by-cell — pandas handles that for us. See how to create new columns derived from existing columns.

Filtering

In Excel, filtering is done through a graphical menu.
DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```
In [13]: tips[tips["total_bill"] > 10]
```
```
Out[13]:
total_bill  tip  sex  smoker  day  time  size
0  14.99  1.01  Female  No  Sun  Dinner  2
2  19.01  3.50  Male  No  Sun  Dinner  3
3  21.68  3.31  Male  No  Sun  Dinner  2
4  22.59  3.61  Female  No  Sun  Dinner  4
(... continues on next page)
The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

In [14]: is_dinner = tips["time"] == "Dinner"

In [15]: is_dinner

Out[15]:
0    True
1    True
2    True
3    True
4    True
   ... 
239  True
240  True
241  True
242  True
243  True
Name: time, Length: 244, dtype: bool

In [16]: is_dinner.value_counts()

Out[16]:
True    176
False    68
Name: time, dtype: int64

In [17]: tips[is_dinner]

Out[17]:
   total_bill  tip  sex  smoker  day  time  size
0       14.99  1.01  Female   No  Sun  Dinner   2
1         8.34  1.66    Male    No  Sun  Dinner   3
2        19.01  3.50    Male    No  Sun  Dinner   3
3        21.68  3.31    Male    No  Sun  Dinner   2
4        22.59  3.61  Female   No  Sun  Dinner   4
   ...     ...     ...     ...    ...     ...     ...
239     27.03  5.92    Male    No  Sat  Dinner   3
240     25.18  2.00  Female   Yes  Sat  Dinner   2
241     20.67  2.00    Male   Yes  Sat  Dinner   2
242     15.82  1.75    Male    No  Sat  Dinner   2
243     16.78  3.00  Female   No  Thur  Dinner   2

[176 rows x 7 columns]
If/then logic

Let’s say we want to make a bucket column with values of low and high, based on whether the total_bill is less or more than $10.

In spreadsheets, logical comparison can be done with conditional formulas. We’d use a formula of =IF(A2 < 10, "low", "high"), dragged to all cells in a new bucket column.

The same operation in pandas can be accomplished using the where method from numpy.

```
In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```
In [19]: tips
Out[19]:
```

```
   total_bill  tip  sex  smoker  day  time  size  bucket
0    14.99  1.01  Female  No  Sun  Dinner   2    high
1    10.34  1.66    Male  No  Sun  Dinner   3    high
2    21.01  3.50    Male  No  Sun  Dinner   3    high
3    23.68  3.31    Male  No  Sun  Dinner   2    high
4    24.59  3.61  Female  No  Sun  Dinner   4    high
5    25.29  4.71    Male  No  Sun  Dinner   4    high
6    8.77   2.00    Male  No  Sun  Dinner   2    low
7   26.88  3.12    Male  No  Sun  Dinner   4    high
8   15.04  3.00  Female  No  Sun  Dinner   2    high
..  ...    ...    ...    ...    ...    ...    ...    ...
239 27.03  5.92    Male  No  Sat  Dinner   3    high
240 25.18  2.00  Female  Yes  Sat  Dinner   2    high
241 20.67  2.00    Male  Yes  Sat  Dinner   2    high
242 15.82  1.75    Male  No  Sat  Dinner   2    high
243 16.78  3.00  Female  No  Thur  Dinner   2    high
```

[244 rows x 8 columns]
Date functionality

This section will refer to “dates”, but timestamps are handled similarly.

We can think of date functionality in two parts: parsing, and output. In spreadsheets, date values are generally parsed automatically, though there is a DATEVALUE function if you need it. In pandas, you need to explicitly convert plain text to datetime objects, either while reading from a CSV or once in a DataFrame.

Once parsed, spreadsheets display the dates in a default format, though the format can be changed. In pandas, you’ll generally want to keep dates as datetime objects while you’re doing calculations with them. Outputting parts of dates (such as the year) is done through date functions in spreadsheets, and datetime properties in pandas.

Given date1 and date2 in columns A and B of a spreadsheet, you might have these formulas:

<table>
<thead>
<tr>
<th>column</th>
<th>formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>date1_year</td>
<td>YEAR(A2)</td>
</tr>
<tr>
<td>date2_month</td>
<td>MONTH(B2)</td>
</tr>
<tr>
<td>date1_next</td>
<td>DATE(YEAR(A2), MONTH(A2)+1, 1)</td>
</tr>
<tr>
<td>months_between</td>
<td>DATEDIF(A2, B2, &quot;M&quot;)</td>
</tr>
</tbody>
</table>

The equivalent pandas operations are shown below.

```python
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"].dt.to_period("M")

Out[26]:
          date1    date2 date1_year date2_month date1_next months_between
0  2013-01-15  2015-02-15      2013      2013-02-01       <25 * MonthEnds>
...        ...        ...       ...            ...             ...
```

(continues on next page)
Selection of columns

In spreadsheets, you can select columns you want by:

- Hiding columns
- Deleting columns
- Referencing a range from one worksheet into another

Since spreadsheet columns are typically named in a header row, renaming a column is simply a matter of changing the text in that first cell.

The same operations are expressed in pandas below.

Keep certain columns

```
In [27]: tips["sex", "total_bill", "tip"]
```

```
sex  total_bill  tip
0  Female  14.99  1.01
1  Male  8.34  1.66
2  Male  19.01  3.50
3  Male  21.68  3.31
4  Female  22.59  3.61
... ... ... ...
239  Male  27.03  5.92
240  Female  25.18  2.00
241  Male  20.67  2.00
242  Male  15.82  1.75
243  Female  16.78  3.00
```

Drop a column

```
In [28]: tips.drop("sex", axis=1)
```

```
total_bill  tip  smoker  day  time  size
0  14.99  1.01  No  Sun  Dinner  2
1  8.34  1.66  No  Sun  Dinner  3
2  19.01  3.50  No  Sun  Dinner  3
3  21.68  3.31  No  Sun  Dinner  2
4  22.59  3.61  No  Sun  Dinner  4
```
Rename a column

```python
In [29]: tips.rename(columns={"total_bill": "total_bill_2"})
```

```markdown

[244 rows x 7 columns]

Sorting by values

Sorting in spreadsheets is accomplished via the `sort` dialog.
pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```python
In [30]: tips = tips.sort_values(["sex", "total_bill"])

In [31]: tips
Out[31]:
   total_bill  tip  sex  smoker day  time  size
   67  1.07  1.00 Female   Yes  Sat  Dinner   1
   92  3.75  1.00 Female   Yes  Fri  Dinner   2
  111  5.25  1.00 Female   No    Sat  Dinner   1
  145  6.35  1.50 Female   No  Thur  Lunch    2
  135  6.51  1.25 Female   No  Thur  Lunch    2
      ... ... ... ... ... ... ...
  182 43.35  3.50    Male   Yes  Sun  Dinner   3
  156 46.17  5.00    Male    No  Sun  Dinner   6
  159 46.27  6.73    Male    No  Sat  Dinner   4
  212 46.33  9.00    Male    No  Sat  Dinner   4
  170 48.81 10.00    Male   Yes  Sat  Dinner   3

[244 rows x 7 columns]
```

**String processing**

**Finding length of string**

In spreadsheets, the number of characters in text can be found with the `LEN` function. This can be used with the `TRIM` function to remove extra whitespace.

```plaintext
=LEN(TRIM(A2))
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.
In [32]: tips["time"].str.len()
Out[32]:
   67   6
   92   6
  111   6
  145   5
  135   5
     ..
  182   6
  156   6
   59   6
  212   6
  170   6
Name: time, Length: 244, dtype: int64

In [33]: tips["time"].str.rstrip().str.len()
Out[33]:
   67   6
   92   6
  111   6
  145   5
  135   5
     ..
  182   6
  156   6
   59   6
  212   6
  170   6
Name: time, Length: 244, dtype: int64

Note this will still include multiple spaces within the string, so isn’t 100% equivalent.

Finding position of substring

The **FIND** spreadsheet function returns the position of a substring, with the first character being 1.
You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

In [34]: tips["sex"].str.find("ale")
Out[34]:
67   3
92   3
111  3
145  3
135  3
   ..
182  1
156  1
59   1
212  1
170  1
Name: sex, Length: 244, dtype: int64

### Extracting substring by position

Spreadsheets have a MID formula for extracting a substring from a given position. To get the first character:

=MID(A2,1,1)

With pandas you can use [ ] notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

In [35]: tips["sex"].str[0:1]
Out[35]:
67   F
92   F

(continues on next page)
Extracting nth word

In Excel, you might use the Text to Columns Wizard for splitting text and retrieving a specific column. (Note it’s possible to do so through a formula as well.)

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```
In [36]: firstlast = pd.DataFrame({'String': ["John Smith", "Jane Cook"]})
In [37]: firstlast["First_Name"] = firstlast["String"][str.split(" ", expand=True)[0]
In [38]: firstlast["Last_Name"] = firstlast["String"][str.rsplit(" ", expand=True)[0]
In [39]: firstlast
Out[39]:
       String  First_Name   Last_Name
 0  John Smith       John      John
 1   Jane Cook       Jane       Jane
```

Changing case

Spreadsheets provide UPPER, LOWER, and PROPER functions for converting text to upper, lower, and title case, respectively.

The equivalent pandas methods are Series.str.upper(), Series.str.lower(), and Series.str.title().

```
In [40]: firstlast = pd.DataFrame({'string': ["John Smith", "Jane Cook"]})
In [41]: firstlast["upper"] = firstlast["string"][str.upper()
In [42]: firstlast["lower"] = firstlast["string"][str.lower()]
In [43]: firstlast["title"] = firstlast["string"][str.title()]
In [44]: firstlast
Out[44]:
      string  upper   lower     title
 0   John Smith  JOHN SMITH  john smith     John Smith
 1    Jane Cook    JANE COOK  jane cook       Jane Cook
```
Merging

The following tables will be used in the merge examples:

```
In [45]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})

In [46]: df1
Out[46]:
   key  value
0   A   0.469112
1   B  -0.282863
2   C  -1.509059
3   D  -1.135632

In [47]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})

In [48]: df2
Out[48]:
   key  value
0   B   1.212112
1   D  -0.173215
2   D   0.119209
3   E  -1.044236
```

In Excel, there are merging of tables can be done through a VLOOKUP.

```
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [49]: inner_join = df1.merge(df2, on="key", how="inner")

In [50]: inner_join
Out[50]:
   key  value_x  value_y
0   B   -0.282863  1.212112
1   D  -1.135632 -0.173215
2   D  -1.135632  0.119209
```

(continues on next page)
In [51]: left_join = df1.merge(df2, on="key", how="left")

In [52]: left_join
Out[52]:
   key  value_x  value_y
0   A   0.469112      NaN
1   B  -0.282863  1.212112
2   C  -1.509059      NaN
3   D -1.135632  -0.173215
4   D -1.135632   0.119209

In [53]: right_join = df1.merge(df2, on="key", how="right")

In [54]: right_join
Out[54]:
   key  value_x  value_y
0   B  -0.282863  1.212112
1   D -1.135632  -0.173215
2   D -1.135632   0.119209
3   E      NaN  -1.044236

In [55]: outer_join = df1.merge(df2, on="key", how="outer")

In [56]: outer_join
Out[56]:
   key  value_x  value_y
0   A   0.469112      NaN
1   B  -0.282863  1.212112
2   C  -1.509059      NaN
3   D -1.135632  -0.173215
4   D -1.135632   0.119209
5   E      NaN  -1.044236

merge has a number of advantages over VLOOKUP:

- The lookup value doesn’t need to be the first column of the lookup table
- If multiple rows are matched, there will be one row for each match, instead of just the first
- It will include all columns from the lookup table, instead of just a single specified column
- It supports more complex join operations

Other considerations

Fill Handle

Create a series of numbers following a set pattern in a certain set of cells. In a spreadsheet, this would be done by shift+drag after entering the first number or by entering the first two or three values and then dragging.

This can be achieved by creating a series and assigning it to the desired cells.
In [57]: df = pd.DataFrame({'AAA': [1] * 8, 'BBB': list(range(0, 8)))

In [58]: df
Out[58]:
   AAA  BBB
0   1   0
1   1   1
2   1   2
3   1   3
4   1   4
5   1   5
6   1   6
7   1   7

In [59]: series = list(range(1, 5))

In [60]: series
Out[60]: [1, 2, 3, 4]

In [61]: df.loc[2:5, "AAA"] = series

In [62]: df
Out[62]:
   AAA  BBB
0   1   0
1   1   1
2   1   2
3   2   3
4   3   4
5   4   5
6   1   6
7   1   7

Drop Duplicates

Excel has built-in functionality for removing duplicate values. This is supported in pandas via `drop_duplicates()`.

In [63]: df = pd.DataFrame({
   .....:   "class": ["A", "A", "A", "B", "C", "D"],
   .....:   "student_count": [42, 35, 42, 50, 47, 45],
   .....:   "all_pass": ["Yes", "Yes", "Yes", "No", "No", "Yes"],
   .....: })
   .....:

In [64]: df.drop_duplicates()
Out[64]:
   class  student_count  all_pass
0   A       42          Yes
1   A       35          Yes

(continues on next page)
In [65]: df.drop_duplicates(["class", "student_count"])
Out[65]:

<table>
<thead>
<tr>
<th>class</th>
<th>student_count</th>
<th>all_pass</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>42</td>
<td>Yes</td>
</tr>
<tr>
<td>A</td>
<td>35</td>
<td>Yes</td>
</tr>
<tr>
<td>B</td>
<td>50</td>
<td>No</td>
</tr>
<tr>
<td>C</td>
<td>47</td>
<td>No</td>
</tr>
<tr>
<td>D</td>
<td>45</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Pivot Tables

PivotTables from spreadsheets can be replicated in pandas through Reshaping and pivot tables. Using the tips dataset again, let’s find the average gratuity by size of the party and sex of the server.

In Excel, we use the following configuration for the PivotTable:

The equivalent in pandas:

In [66]: pd.pivot_table(
    .....:     tips, values="tip", index=["size"], columns=["sex"], aggfunc=np.average
    .....: )

Out[66]:

<table>
<thead>
<tr>
<th>sex</th>
<th>Female</th>
<th>Male</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1.2766667</td>
<td>1.92</td>
</tr>
<tr>
<td>2</td>
<td>2.528448276</td>
<td>2.614183673</td>
</tr>
<tr>
<td>3</td>
<td>3.25</td>
<td>3.476666667</td>
</tr>

Adding a row
Assuming we are using a RangeIndex (numbered 0, 1, etc.), we can use DataFrame.append() to add a row to the
bottom of a DataFrame.
In [67]: df
Out[67]:
class student_count all_pass
0
A
42
Yes
1
A
35
Yes
2
A
42
Yes
3
B
50
No
4
C
47
No
5
D
45
Yes
In [68]: new_row = {"class": "E", "student_count": 51, "all_pass": True}
In [69]: df.append(new_row, ignore_index=True)
Out[69]:
class student_count all_pass
0
A
42
Yes
1
A
35
Yes
2
A
42
Yes
3
B
50
No
4
C
47
No
5
D
45
Yes
6
E
51
True

Find and Replace
Excel’s Find dialog takes you to cells that match, one by one. In pandas, this operation is generally done for an entire
column or DataFrame at once through conditional expressions.

pandas' `replace()` is comparable to Excel's Replace All.
Comparison with SAS

For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Data structures

**DataFrame**

A DataFrame in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS’s DATA step, can also be accomplished in pandas.

**Series**

A Series is the data structure that represents one column of a DataFrame. SAS doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column in the DATA step.
Index

Every DataFrame and Series has an Index - which are labels on the rows of the data. SAS does not have an exactly analogous concept. A data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed during the DATA step (_N_).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```
df = df.sort_values("col1")
```

Note: You will see an inplace=True keyword argument available for some methods:

```
df.sort_values("col1", inplace=True)
```

Its use is discouraged. More information.

Data input / output

Constructing a DataFrame from values

A SAS data set can be built from specified values by placing the data after a datalines statement and specifying the column names.

```
data df;
  input x y;
datalines;
  1 2
  3 4
  5 6
;
run;
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [1]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
```

```
In [2]: df
```
Reading external data

Like SAS, pandas provides utilities for reading in data from many formats. The tips dataset, found within the pandas tests (csv) will be used in many of the following examples.

SAS provides PROC IMPORT to read csv data into a data set.

```plaintext
proc import datafile='tips.csv' dbms=csv out=tips replace;
    getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```plaintext
In [3]: url = (  
            "https://raw.github.com/pandas-dev/
            "pandas/master/pandas/tests/io/data/csv/tips.csv"
            )  
            
In [4]: tips = pd.read_csv(url)

In [5]: tips
Out[5]:
   total_bill  tip  sex    smoker day time size
0    16.99  1.01 Female   No  Sun  Dinner  2
1    10.34  1.66     Male   No  Sun  Dinner  3
2    21.01  3.50     Male   No  Sun  Dinner  3
3    23.68  3.31     Male   No  Sun  Dinner  2
4    24.59  3.61 Female   No  Sun  Dinner  4
...   ...   ...     ...   ...     ...   ...   ...
239  29.03  5.92     Male   No  Sat  Dinner  3
240  27.18  2.00 Female   Yes  Sat  Dinner  2
241  22.67  2.00     Male   Yes  Sat  Dinner  2
242  17.82  1.75     Male   No  Sat  Dinner  2
243  18.78  3.00 Female   No  Thur  Dinner  2
[244 rows x 7 columns]
```

Like PROC IMPORT, read_csv can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```plaintext
tips = pd.read_csv("tips.csv", sep="\t", header=None)
```

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table("tips.csv", header=None)

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a `pd.read_*` function. See the IO documentation for more details.

### Limiting output

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using `DataFrame.head()` or `DataFrame.tail()`.

```python
In [1]: tips.head(5)
Out[1]:
   total_bill  tip     sex  smoker  day    time  size
0       16.99  1.01  Female    No  Sun    Dinner    2
1       10.34  1.66     Male    No  Sun    Dinner    3
2       21.01  3.50     Male    No  Sun    Dinner    3
3       23.68  3.31     Male    No  Sun    Dinner    2
4       24.59  3.61  Female    No  Sun    Dinner    4
```

The equivalent in SAS would be:

```sas
proc print data=df(obs=5); run;
```

### Exporting data

The inverse of `PROC IMPORT` in SAS is `PROC EXPORT`

```sas
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of `read_csv` is `to_csv()`, and other data formats follow a similar api.

```python
tips.to_csv("tips2.csv")
```

### Data operations

#### Operations on columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```sas
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.  

---

**Chapter 1. Getting started**
In [1]: tips["total_bill"] = tips["total_bill"] - 2

In [2]: tips["new_bill"] = tips["total_bill"] / 2

In [3]: tips

Out[3]:
    total_bill  tip   sex  smoker  day  time  size  new_bill
0      14.99  1.01  Female  No  Sun  Dinner  2  7.495
1       8.34  1.66    Male  No  Sun  Dinner  3  4.170
2      19.01  3.50    Male  No  Sun  Dinner  3  9.505
3      21.68  3.31    Male  No  Sun  Dinner  2 10.840
4      22.59  3.61  Female  No  Sun  Dinner  4 11.295
...     ...   ...     ...   ...    ...    ...     ...
239    27.03  5.92    Male  No  Sat  Dinner  3 13.515
240    25.18  2.00  Female   Yes  Sat  Dinner  2 12.590
241    20.67  2.00    Male   Yes  Sat  Dinner  2 10.335
242    15.82  1.75    Male  No  Sat  Dinner  2  7.910
243    16.78  3.00  Female  No  Thur  Dinner  2  8.390

[244 rows x 8 columns]

In [4]: tips = tips.drop("new_bill", axis=1)

Filtering

Filtering in SAS is done with an if or where statement, on one or more columns.

data tips;
    set tips;
    if total_bill > 10;
run;

data tips;
    set tips;
    where total_bill > 10;
    /* equivalent in this case - where happens before the
       DATA step begins and can also be used in PROC statements */
run;

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

In [1]: tips[tips["total_bill"] > 10]

Out[1]:
    total_bill  tip   sex  smoker  day  time  size
0      14.99  1.01  Female  No  Sun  Dinner  2
2      19.01  3.50    Male  No  Sun  Dinner  3
3      21.68  3.31    Male  No  Sun  Dinner  2
4      22.59  3.61  Female  No  Sun  Dinner  4
5      23.29  4.71    Male  No  Sun  Dinner  4
...     ...   ...     ...   ...    ...    ...
239    27.03  5.92    Male  No  Sat  Dinner  3
240    25.18  2.00  Female   Yes  Sat  Dinner  2
(continues on next page)
The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [1]: is_dinner = tips["time"] == "Dinner"
In [2]: is_dinner
Out[2]:
0    True
1    True
2    True
3    True
4    True
   ... 
239   True
240   True
241   True
242   True
243   True
Name: time, Length: 244, dtype: bool
In [3]: is_dinner.value_counts()
Out[3]:
   True     176
  False      68
Name: time, dtype: int64
In [4]: tips[is_dinner]
Out[4]:
     total_bill  tip  sex  smoker  day    time  size
0    14.99  1.01   Female  No  Sun  Dinner    2
1     8.34  1.66    Male  No  Sun  Dinner    3
2    19.01  3.50    Male  No  Sun  Dinner    3
3    21.68  3.31    Male  No  Sun  Dinner    2
4    22.59  3.61   Female  No  Sun  Dinner    4
   ...   ...   ...   ...   ...   ...   ...   ...
239  27.03  5.92    Male  No  Sat  Dinner    3
240  25.18  2.00  Female  Yes  Sat  Dinner    2
241  29.67  2.00    Male  Yes  Sat  Dinner    2
242  15.82  1.75    Male  No  Sat  Dinner    2
243  16.78  3.00  Female  No  Thur  Dinner    2
[176 rows x 7 columns]
```
If/then logic

In SAS, if/then logic can be used to create new columns.

```sas
data tips;
    set tips;
    format bucket $4.;
    if total_bill < 10 then bucket = 'low';
    else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```python
In [1]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```python
In [2]: tips
Out[2]:
   total_bill  tip  sex  smoker  day  time  size  bucket
0   14.99   1.01  Female   No  Sun  Dinner  2  high
1    8.34   1.66     Male   No  Sun  Dinner  3   low
2    9.01   3.50     Male   No  Sun  Dinner  3   high
3   21.68   3.31     Male   No  Sun  Dinner  2   high
4   22.59   3.61  Female   No  Sun  Dinner  4   high
...         ...     ...   ...   ...   ...    ...   ...
239  27.03   5.92     Male   No  Sat  Dinner  3  high
240  25.18   2.00  Female    Yes  Sat  Dinner  2  high
241  20.67   2.00     Male    Yes  Sat  Dinner  2  high
242  15.82   1.75     Male   No  Thur  Dinner  2  high
243  16.78   3.00  Female   No  Thur  Dinner  2  high
```

Date functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```sas
data tips;
    set tips;
    format date1 date2 date1_plusmonth mmddyy10.;
    date1 = mdy(1, 15, 2013);
    date2 = mdy(2, 15, 2015);
    date1_year = year(date1);
    date2_month = month(date2);
    * shift date to beginning of next interval;
    date1_next = intnx('MONTH', date1, 1);
    * count intervals between dates;
    months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the `timeseries documentation` for more details.
In [1]: tips["date1"] = pd.Timestamp("2013-01-15")

In [2]: tips["date2"] = pd.Timestamp("2015-02-15")

In [3]: tips["date1_year"] = tips["date1"].dt.year

In [4]: tips["date2_month"] = tips["date2"].dt.month

In [5]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()

In [6]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"].dt.to_period("M")

In [7]: tips["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]

Out[7]:

<table>
<thead>
<tr>
<th></th>
<th>date1</th>
<th>date2</th>
<th>date1_year</th>
<th>date2_month</th>
<th>date1_next</th>
<th>months_between</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2013-01-15</td>
<td>2015-02-15</td>
<td>2013</td>
<td>2</td>
<td>2013-02-01</td>
<td>&lt;25 * MonthEnds&gt;</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

[244 rows x 6 columns]

Selection of columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;
data tips;
(continues on next page)
The same operations are expressed in pandas below.

**Keep certain columns**

```python
In [1]: tips[["sex", "total_bill", "tip"]]
Out[1]:

<table>
<thead>
<tr>
<th>sex</th>
<th>total_bill</th>
<th>tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>14.99</td>
<td>1.01</td>
</tr>
<tr>
<td>Male</td>
<td>8.34</td>
<td>1.66</td>
</tr>
<tr>
<td>Male</td>
<td>19.01</td>
<td>3.50</td>
</tr>
<tr>
<td>Male</td>
<td>21.68</td>
<td>3.31</td>
</tr>
<tr>
<td>Female</td>
<td>22.59</td>
<td>3.61</td>
</tr>
</tbody>
</table>

.. ... ... ... ...

239 Male | 27.03 | 5.92 |
240 Female | 25.18 | 2.00 |
241 Male | 20.67 | 2.00 |
242 Male | 15.82 | 1.75 |
243 Female | 16.78 | 3.00 |
```

[244 rows x 3 columns]

**Drop a column**

```python
In [2]: tips.drop("sex", axis=1)
Out[2]:

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>14.99</td>
<td>1.01</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>8.34</td>
<td>1.66</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>19.01</td>
<td>3.50</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>21.68</td>
<td>3.31</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>22.59</td>
<td>3.61</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>4</td>
</tr>
</tbody>
</table>

.. ... ... ... ... ...

239 27.03 5.92 No Sat Dinner 3 |
240 25.18 2.00 Yes Sat Dinner 2 |
241 20.67 2.00 Yes Sat Dinner 2 |
242 15.82 1.75 No Sat Dinner 2 |
243 16.78 3.00 No Thur Dinner 2 |
```

[244 rows x 6 columns]
Rename a column

```python
In [1]: tips.rename(columns={"total_bill": "total_bill_2"})
```

```python
Out[1]:
   total_bill_2  tip  sex  smoker  day  time  size
0      14.99  1.01  Female    No  Sun  Dinner  2
1       8.34  1.66   Male    No  Sun  Dinner  3
2      19.01  3.50   Male    No  Sun  Dinner  3
3      21.68  3.31   Male    No  Sun  Dinner  2
4      22.59  3.61  Female    No  Sun  Dinner  4
..     ...    ...     ...    ...    ...    ...
239    27.03  5.92   Male    No  Sat  Dinner  3
240    25.18  2.00  Female    Yes  Sat  Dinner  2
241    20.67  2.00   Male    Yes  Sat  Dinner  2
242    15.82  1.75   Male    No  Sat  Dinner  2
243    16.78  3.00  Female    No  Thur  Dinner  2
```

[244 rows x 7 columns]

Sorting by values

Sorting in SAS is accomplished via PROC _SORT_

```bash
proc sort data=tips;
   by sex total_bill;
run;
```

pandas has a _DataFrame.sort_values_() method, which takes a list of columns to sort by.

```python
In [1]: tips = tips.sort_values(["sex", "total_bill"])
```

```python
In [2]: tips
```

```python
Out[2]:
   total_bill  tip  sex  smoker  day  time  size
67        1.07  1.00  Female    Yes  Sat  Dinner  1
92        3.75  1.00  Female    Yes  Fri  Dinner  2
111       5.25  1.00  Female    No  Sat  Dinner  1
145       6.35  1.50  Female    No  Thur  Lunch  2
135       6.51  1.25  Female    No  Thur  Lunch  2
..     ...    ...     ...    ...    ...    ...
182      43.35  3.50   Male    Yes  Sun  Dinner  3
156      46.17  5.00   Male    No  Sun  Dinner  6
59       46.27  6.73   Male    No  Sat  Dinner  4
212      46.33  9.00   Male    No  Sat  Dinner  4
170      48.81 10.00   Male    Yes  Sat  Dinner  3
```

[244 rows x 7 columns]
String processing

Finding length of string

SAS determines the length of a character string with the `LENGTHN` and `LENGTHC` functions. `LENGTHN` excludes trailing blanks and `LENGTHC` includes trailing blanks.

```sas
data _null_;
set tips;
put (LENGTHN(time));
put (LENGTHC(time));
run;
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [1]: tips["time"].str.len()
```
```
Out[1]:
   67    6
   92    6
  111    6
  145    5
  135    5
   ... 
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64
```

```
In [2]: tips["time"].str.rstrip().str.len()
```
```
Out[2]:
   67    6
   92    6
  111    6
  145    5
  135    5
   ... 
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64
```
Finding position of substring

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```plaintext
data _null_; set tips; put(FINDW(sex,'ale')); run;
```

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```plaintext
In [1]: tips['sex'].str.find('ale')
Out[1]:
   67   3
   92   3
  111   3
  145   3
  135   3
   ..
  182   1
  156   1
   59   1
  212   1
  170   1
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```plaintext
data _null_; set tips; put(substr(sex,1,1)); run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```plaintext
In [1]: tips['sex'][0:1]
Out[1]:
   67 F
   92 F
  111 F
  145 F
  135 F
   ..
  182 M
  156 M
   59 M
```

(continues on next page)
Extraction of nth word

The SAS `SCAN` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```sas
data firstlast;
input String $60.;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
John Smith;
Jane Cook;
;;
run;
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```python
In [1]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})
In [2]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]
In [3]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[0]
In [4]: firstlast
Out[4]:
   String  First_Name  Last_Name
0  John Smith  John    John
1    Jane Cook   Jane   Jane
```

Changing case

The SAS `UPCASE LOWCASE` and `PROPCASE` functions change the case of the argument.

```sas
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;
run;
```

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.
Merging

The following tables will be used in the merge examples:

```python
In [1]: df1 = pd.DataFrame(  
                {"key": ["A", "B", "C", "D"],   
                 "value": np.random.randn(4)})

In [2]: df1
Out[2]:
    key   value
0  A  0.469112
1  B -0.282863
2  C -1.509059
3  D -1.135632

In [3]: df2 = pd.DataFrame(  
                {"key": ["B", "D", "D", "E"],   
                 "value": np.random.randn(4)})

In [4]: df2
Out[4]:
    key   value
0  B  1.212112
1  D -0.173215
2  D  0.119209
3  E -1.044236
```

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```sas
proc sort data=df1;  
    by key;  
run;

proc sort data=df2;  
    by key;  
run;

data left_join inner_join right_join outer_join;  
    merge df1(in=a) df2(in=b);  
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
if a and b then output inner_join;
if a then output left_join;
if b then output right_join;
if a or b then output outer_join;
run;
```

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [1]: inner_join = df1.merge(df2, on=['key'], how='inner')

In [2]: inner_join
Out[2]:
   key  value_x  value_y
0    B  -0.282863  1.212112
1    D -1.135632 -0.173215
2    D -1.135632  0.119209

In [3]: left_join = df1.merge(df2, on=['key'], how='left')

In [4]: left_join
Out[4]:
   key  value_x  value_y
0    A   0.469112  NaN
1    B  -0.282863  1.212112
2    C  -1.509059  NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E   NaN        -1.044236

In [5]: right_join = df1.merge(df2, on=['key'], how='right')

In [6]: right_join
Out[6]:
   key  value_x  value_y
0    B  -0.282863  1.212112
1    D -1.135632 -0.173215
2    D -1.135632  0.119209
3    E   NaN        -1.044236

In [7]: outer_join = df1.merge(df2, on=['key'], how='outer')

In [8]: outer_join
Out[8]:
   key  value_x  value_y
0    A   0.469112  NaN
1    B  -0.282863  1.212112
2    C  -1.509059  NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E   NaN        -1.044236
```

1.4. Tutorials
Missing data

Both pandas and SAS have a representation for missing data.

pandas represents missing data with the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```python
In [1]: outer_join
Out[1]:
   key  value_x  value_y
0   A   0.469112      NaN
1   B -0.282863  1.212112
2   C -1.509059      NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
5   E      NaN -1.044236

In [2]: outer_join["value_x"] + outer_join["value_y"]
Out[2]:
   NaN
0   NaN
1   0.929249
2   NaN
3   NaN
4   -1.016424
5   NaN
dtype: float64

In [3]: outer_join["value_x"].sum()
Out[3]: -3.5940742896293765
```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```sas
data outer_join_nulls;
  set outer_join;
  if value_x = .;
run;

data outer_join_no_nulls;
  set outer_join;
  if value_x ^= .;
run;
```

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

```python
In [1]: outer_join[outer_join["value_x"].isna()]
Out[1]:
   key  value_x  value_y
5   E      NaN -1.044236

In [2]: outer_join[outer_join["value_x"].notna()]
Out[2]:
   key  value_x  value_y
0   A   0.469112      NaN
```
pandas provides *a variety of methods to work with missing data*. Here are some examples:

**Drop rows with missing values**

```python
In [3]: outer_join.dropna()
Out[3]:
   key  value_x  value_y
1    B   -0.282863   1.212112
3    D   -1.135632  -0.173215
4    D   -1.135632   0.119209
```

**Forward fill from previous rows**

```python
In [4]: outer_join.fillna(method="ffill")
Out[4]:
   key  value_x  value_y
 0    A    0.469112      NaN
 1    B   -0.282863  1.212112
 2    C   -1.500959  1.212112
 3    D   -1.135632  -0.173215
 4    D   -1.135632   0.119209
 5    E   -1.135632 -1.044236
```

**Replace missing values with a specified value**

Using the mean:

```python
In [1]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
Out[1]:
   0  0.469112
 1 -0.282863
 2 -1.500959
 3 -1.135632
 4 -1.135632
 5 -0.718815
Name: value_x, dtype: float64
```
GroupBy

Aggregation

SAS’s PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```bash
proc summary data=tips nway;
   class sex smoker;
   var total_bill tip;
   output out=tips_summed sum=;
run;
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the `groupby documentation` for more details and examples.

```
In [1]: tips_summed = tips.groupby(["sex", "smoker"])[["total_bill", "tip"]].sum()
```

```
<table>
<thead>
<tr>
<th></th>
<th>total_bill</th>
<th>tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female No</td>
<td>869.68</td>
<td>149.77</td>
</tr>
<tr>
<td>Yes</td>
<td>527.27</td>
<td>96.74</td>
</tr>
<tr>
<td>Male No</td>
<td>1725.75</td>
<td>302.00</td>
</tr>
<tr>
<td>Yes</td>
<td>1217.07</td>
<td>183.07</td>
</tr>
</tbody>
</table>
```

Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```bash
proc summary data=tips missing nway;
   class smoker;
   var total_bill;
   output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
   by smoker;
run;

data tips;
   merge tips(in=a) smoker_means(in=b);
   by smoker;
   adj_total_bill = total_bill - group_bill;
   if a and b;
run;
```

pandas provides a `Transformation` mechanism that allows these type of operations to be succinctly expressed in one operation.
In [1]: gb = tips.groupby("smoker")["total_bill"]

In [2]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")

In [3]: tips
Out[3]:
   total_bill  tip     sex  smoker  day   time  size  adj_total_bill
57  1.07  1.00  Female  Yes  Sat  Dinner  1  -17.686344
92  3.75  1.00  Female  Yes  Fri  Dinner  2  -15.006344
111 5.25  1.00  Female  No  Sat  Dinner  1  -11.938278
145 6.35  1.50  Female  No  Thur  Lunch  2  -10.838278
135 6.51  1.25  Female  No  Thur  Lunch  2  -10.678278
... ... ... ... ... ... ... ...
182 43.35  3.50  Male  Yes  Sun  Dinner  3  24.593656
156 46.17  5.00  Male  No  Sun  Dinner  6  28.981722
59  46.27  6.73  Male  No  Sat  Dinner  4  29.081722
212 46.33  9.00  Male  No  Sat  Dinner  4  29.141722
170 48.81 10.00  Male  Yes  Sat  Dinner  3  30.053656
[244 rows x 8 columns]

By group processing

In addition to aggregation, pandas groupby can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```
proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;
```

In pandas this would be written as:

```
In [4]: tips.groupby(["sex", "smoker"]).first()
Out[4]:
   total_bill  tip  day  time  size  adj_total_bill
sex  smoker
Female  No  5.25  1.00  Sat  Dinner  1  -11.938278
   Yes  1.07  1.00  Sat  Dinner  1  -17.686344
Male  No  5.51  2.00  Thur  Lunch  2  -11.678278
   Yes  5.25  5.15  Sun  Dinner  2  -13.506344
```
Other considerations

Disk vs memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to
be loaded in pandas is limited by your machine’s memory, but also that the operations on that data may be faster.
If out of core processing is needed, one possibility is the `dask.dataframe` library (currently in development) which
provides a subset of pandas functionality for an on-disk DataFrame

Data interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```python
libname xportout xport 'transport-file.xpt';
data xportout.tips;
  set tips(rename=(total_bill=tbill));
  * xport variable names limited to 6 characters;
run;
```

```python
df = pd.read_sas("transport-file.xpt")
df = pd.read_sas("binary-file.sas7bdat")
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```python
df = pd.read_sas("transport-file.xpt", format="xport")
df = pd.read_sas("binary-file.sas7bdat", format="sas7bdat")
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An
alternative way to interop data between SAS and pandas is to serialize to csv.

```
# version 0.17, 10M rows
In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s
In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

Comparison with Stata

For potential users coming from Stata this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you’re new to pandas, you might want to first read through 10 Minutes to pandas to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```
Data structures

General terminology translation

<table>

<tr>
<td>groupby</td>
<td>bysort</td>
</tr>
<tr>
<td>NaN</td>
<td>.</td>
</tr>
</tbody>
</table>

DataFrame

A DataFrame in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

Series

A Series is the data structure that represents one column of a DataFrame. Stata doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column of a data set in Stata.

Index

Every DataFrame and Series has an Index – labels on the rows of the data. Stata does not have an exactly analogous concept. In Stata, a data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed with _n.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

Note: You will see an inplace=True keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```
Data input / output

Constructing a DataFrame from values

A Stata data set can be built from specified values by placing the data after an `input` statement and specifying the column names.

```
input x y
  1 2
  3 4
  5 6
end
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
```

```
In [4]: df
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

Reading external data

Like Stata, pandas provides utilities for reading in data from many formats. The tips data set, found within the pandas tests (csv) will be used in many of the following examples.

Stata provides `import delimited` to read csv data into a data set in memory. If the `tips.csv` file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = (...
   ...: "https://raw.github.com/pandas-dev"...
   ...: "/pandas/master/pandas/tests/io/data/csv/tips.csv"
   ...: )
   ...

In [6]: tips = pd.read_csv(url)
```

```
In [7]: tips
Out[7]:
   total_bill  tip  sex  smoker  day  time  size
```
Like `import delimited, read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```python
import delimited, read_csv()
ap
tips = pd.read_csv("tips.csv", sep="	", header=None)
```

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table("tips.csv", header=None)

pandas can also read Stata data sets in .dta format with the `read_stata()` function.

```python
def = pd.read_stata("data.dta")
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the IO documentation for more details.

**Limiting output**

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using `DataFrame.head()` or `DataFrame.tail()`.

```python
In [8]: tips.head(5)
Out[8]:

<p>| | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16.99</td>
<td>1.01</td>
<td>Female</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
</tr>
<tr>
<td>1</td>
<td>10.34</td>
<td>1.66</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
</tr>
<tr>
<td>2</td>
<td>21.01</td>
<td>3.50</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
</tr>
<tr>
<td>3</td>
<td>23.68</td>
<td>3.31</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
</tr>
<tr>
<td>4</td>
<td>24.59</td>
<td>3.61</td>
<td>Female</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
</tr>
</tbody>
</table>
```

The equivalent in Stata would be:

```stata
list in 1/5
```
Exporting data

The inverse of import delimited in Stata is export delimited

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of read_csv is DataFrame.to_csv().

```
tips.to_csv("tips2.csv")
```

pandas can also export to Stata file format with the DataFrame.to_stata() method.

```
tips.to_stata("tips2.dta")
```

Data operations

Operations on columns

In Stata, arbitrary math expressions can be used with the generate and replace commands on new or existing columns. The drop command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

pandas provides vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The DataFrame.drop() method drops a column from the DataFrame.

```
In [9]: tips["total_bill"] = tips["total_bill"] - 2

In [10]: tips["new_bill"] = tips["total_bill"] / 2

In [11]: tips
```

```
Out[11]:
total_bill  tip  sex  smoker  day  time  size  new_bill
0  14.99  1.01  Female  No  Sun  Dinner  2   7.495
1   8.34  1.66   Male  No  Sun  Dinner  3   4.170
2  19.01  3.50  Male  No  Sun  Dinner  3   9.505
3  21.68  3.31  Male  No  Sun  Dinner  2  10.840
4  22.59  3.61  Female  No  Sun  Dinner  4  11.295
9  27.03  5.92  Male  No  Sat  Dinner  3  13.515
10  25.18  2.00  Female  Yes  Sat  Dinner  2  12.590
11  20.67  2.00  Male  Yes  Sat  Dinner  2  10.335
12  15.82  3.00  Male  No  Sat  Dinner  2   7.910
13  16.78  3.00  Female  No  Thur  Dinner  2   8.390
[244 rows x 8 columns]
```

```
In [12]: tips = tips.drop("new_bill", axis=1)
```

```
```
Filtering

Filtering in Stata is done with an if clause on one or more columns.

```plaintext
list if total_bill > 10
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```plaintext
In [13]: tips[tips["total_bill"] > 10]
Out[13]:
     total_bill  tip  sex  smoker day   time  size
0     14.99   1.01 Female    No  Sun  Dinner  2
1     19.01   3.50     Male    No  Sun  Dinner  3
2     21.68   3.31     Male    No  Sun  Dinner  2
3     22.59   3.61 Female    No  Sun  Dinner  4
4     23.29   4.71     Male    No  Sun  Dinner  4
... ... ... ... ... ... ...
239   27.03   5.92     Male    No  Sat  Dinner  3
240   25.18   2.00 Female     Yes  Sat  Dinner  2
241   20.67   2.00     Male     Yes  Sat  Dinner  2
242   15.82   1.75     Male    No  Sat  Dinner  2
243   16.78   3.00 Female    No  Thur  Dinner  2
[204 rows x 7 columns]
```

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```plaintext
In [14]: is_dinner = tips["time"] == "Dinner"
In [15]: is_dinner
Out[15]:
Name: time, Length: 244, dtype: bool
```

```plaintext
In [16]: is_dinner.value_counts()
Out[16]:
True   176
False  68
Name: time, dtype: int64
```

```plaintext
In [17]: tips[is_dinner]
Out[17]:
```

(continues on next page)
total_bill  tip  sex  smoker  day  time  size  bucket
0  14.99  1.01  Female  No  Sun  Dinner  2  high
1  8.34  1.66  Male  No  Sun  Dinner  3  low
2  19.01  3.50  Male  No  Sun  Dinner  3  high
3  21.68  3.31  Male  No  Sun  Dinner  2  high
4  22.59  3.61  Female  No  Sun  Dinner  4  high
..  ...  ...  ...  ...  ...  ...  ...  ...
239  27.03  5.92  Male  No  Sat  Dinner  3  high
240  25.18  2.00  Female  Yes  Sat  Dinner  2  high
241  20.67  2.00  Male  Yes  Sat  Dinner  2  high
242  15.82  1.75  Male  No  Sat  Dinner  2  high
243  16.78  3.00  Female  No  Thur  Dinner  2  high

[176 rows x 8 columns]

If/then logic

In Stata, an if clause can also be used to create new columns.

```stata
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the where method from numpy.

```python
In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```python
In [19]: tips
Out[19]:
           total_bill  tip  sex  smoker  day  time  size  bucket
0  14.990000  1.01  Female  No  Sun  Dinner  2  high
1   8.339999  1.66    Male  No  Sun  Dinner  3  low
2  19.010000  3.50    Male  No  Sun  Dinner  3  high
3  21.680000  3.31    Male  No  Sun  Dinner  2  high
4  22.590000  3.61  Female  No  Sun  Dinner  4  high

243  16.780000  3.00  Female  No  Thur  Dinner  2  high

[244 rows x 8 columns]
Date functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```stata
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")
generate date1_year = year(date1)
generate date2_month = month(date2)

* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)
list date1 date2 date1_year date2_month date1_next months_between
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the timeseries documentation for more details.

```python
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips[
   .....:   "date1"
   .....: ]
   .....:
In [26]: tips[
   .....:   ["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]
   .....: ]
   .....:
Out[26]:
```

<table>
<thead>
<tr>
<th></th>
<th>date1</th>
<th>date2</th>
<th>date1_year</th>
<th>date2_month</th>
<th>date1_next</th>
<th>months_between</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2013-01-15</td>
<td>2015-02-15</td>
<td>2013</td>
<td>2013-02-01</td>
<td>&lt;25 * MonthEnds&gt;</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```

(continues on next page)
Selection of columns

Stata provides keywords to select, drop, and rename columns.

```
keep sex total_bill tip

drop sex

rename total_bill total_bill_2
```

The same operations are expressed in pandas below.

**Keep certain columns**

```
In [27]: tips["sex", "total_bill", "tip"]
Out[27]:
   sex  total_bill  tip
0  Female     14.99  1.01
1     Male      8.34  1.66
2    Male     19.01  3.50
3     Male     21.68  3.31
4  Female     22.59  3.61
   ...       ... ... ...
239  Male     27.03  5.92
240 Female     25.18  2.00
241   Male     20.67  2.00
242   Male     15.82  1.75
243 Female     16.78  3.00
```

[244 rows x 3 columns]

**Drop a column**

```
In [28]: tips.drop("sex", axis=1)
Out[28]:
   total_bill  tip  smoker  day  time  size
0      14.99  1.01   No    Sun  Dinner  2
1       8.34  1.66   No    Sun  Dinner  3
2      19.01  3.50   No    Sun  Dinner  3
3      21.68  3.31   No    Sun  Dinner  2
4      22.59  3.61   No    Sun  Dinner  4
   ...    ... ...   ...   ...   ...
239    27.03  5.92   No     Sat  Dinner  3
240    25.18  2.00   Yes    Sat  Dinner  2
```

(continues on next page)
Rename a column

In [29]: tips.rename(columns={"total_bill": "total_bill_2"})
Out[29]:
   total_bill_2  tip  sex smoker  day   time  size
0     14.99  1.01  Female  No   Sun  Dinner  2
1      8.34  1.66   Male  No   Sun  Dinner  3
2     19.01  3.50   Male  No   Sun  Dinner  3
3     21.68  3.31   Male  No   Sun  Dinner  2
4     22.59  3.61  Female  No   Sun  Dinner  4
...     ...    ...      ...    ...    ...    ...
239   27.03  5.92   Male  No   Sat  Dinner  3
240   25.18  2.00  Female  Yes  Sat  Dinner  2
241   20.67  2.00   Male  Yes  Sat  Dinner  2
242   15.82  1.75   Male  No  Sat  Dinner  2
243   16.78  3.00  Female  No  Thur  Dinner  2

[244 rows x 7 columns]

Sorting by values

Sorting in Stata is accomplished via sort

```
sort sex total_bill
```

pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

In [30]: tips = tips.sort_values(['sex', 'total_bill'])

In [31]: tips
Out[31]:
   total_bill  tip  sex smoker  day   time  size
  67     1.07  1.00  Female  Yes   Sat  Dinner  1
  92     3.75  1.00  Female  Yes   Fri  Dinner  2
 111     5.25  1.00  Female  No   Sat  Dinner  1
 145     6.35  1.50  Female  No  Thur  Lunch  2
 135     6.51  1.25  Female  No  Thur  Lunch  2
...     ...    ...      ...    ...    ...    ...
182    43.35  3.50   Male  Yes   Sun  Dinner  3
156    46.17  5.00   Male  No   Sun  Dinner  6
 59    46.27  6.73   Male  No   Sat  Dinner  4
212    46.33  9.00   Male  No   Sat  Dinner  4
170    48.81 10.00  Female  Yes   Sat  Dinner  3

(continues on next page)
String processing

Finding length of string

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [32]: tips["time"].str.len()
Out[32]:
    67    6
   92    6
  111    6
  145    5
  135    5
    ..
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64

In [33]: tips["time"].str.rstrip().str.len()
Out[33]:
    67    6
   92    6
  111    6
  145    5
  135    5
    ..
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64
```
Finding position of substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```plaintext
generate str_position = strpos(sex, "ale")
```

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```plaintext
In [34]: tips["sex"].str.find("ale")
Out[34]:
   67  3
   92  3
  111  3
  145  3
  135  3
    ..
  182  1
  156  1
   59  1
  212  1
  170  1
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

Stata extracts a substring from a string based on its position with the `substr()` function.

```plaintext
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use [] notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```plaintext
In [35]: tips["sex"][0:1]
Out[35]:
   67  F
   92  F
  111  F
  145  F
  135  F
    ..
  182  M
  156  M
   59  M
  212  M
  170  M
Name: sex, Length: 244, dtype: object
```
Extracting nth word

The Stata `word()` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```plaintext
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```plaintext
In [36]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})
In [37]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]
In [38]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[0]
In [39]: firstlast
Out[39]:
      String     First_Name    Last_Name
   0  John Smith        John   John
   1  Jane Cook         Jane   Jane
```

Changing case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```plaintext
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list
```

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```plaintext
In [40]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})
In [41]: firstlast["upper"] = firstlast["string"].str.upper()
In [42]: firstlast["lower"] = firstlast["string"].str.lower()
```
In [43]: `firstlast["title"] = firstlast["string"]).str.title()

In [44]: firstlast

Out[44]:

<table>
<thead>
<tr>
<th>string</th>
<th>upper</th>
<th>lower</th>
<th>title</th>
</tr>
</thead>
<tbody>
<tr>
<td>John Smith</td>
<td>JOHN SMITH</td>
<td>john smith</td>
<td>John Smith</td>
</tr>
<tr>
<td>Jane Cook</td>
<td>JANE COOK</td>
<td>jane cook</td>
<td>Jane Cook</td>
</tr>
</tbody>
</table>

**Merging**

The following tables will be used in the merge examples:

In [45]: df1 = pd.DataFrame(
                   {
                     "key": ["A", "B", "C", "D"],
                     "value": np.random.randn(4)
                   })

In [46]: df1

Out[46]:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.469112</td>
</tr>
<tr>
<td>1</td>
<td>-0.282863</td>
</tr>
<tr>
<td>2</td>
<td>-1.509059</td>
</tr>
<tr>
<td>3</td>
<td>-1.135632</td>
</tr>
</tbody>
</table>

In [47]: df2 = pd.DataFrame(
                   {
                     "key": ["B", "D", "D", "E"],
                     "value": np.random.randn(4)
                   })

In [48]: df2

Out[48]:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.212112</td>
</tr>
<tr>
<td>1</td>
<td>-0.173215</td>
</tr>
<tr>
<td>2</td>
<td>0.119209</td>
</tr>
<tr>
<td>3</td>
<td>-1.044236</td>
</tr>
</tbody>
</table>

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both **DataFrames** already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the **_merge** variable.

* First create **df2** and save to disk

```stata
clear
input str1 key
B
D
D
E
end
generate value = rnormal() save df2.dta
```

(continues on next page)
Now create df1 in memory

```plaintext
clear
input str1 key  
A  
B  
C  
D
end
```

```plaintext
generate value = rnormal()

preserve

* **Left join**
merge 1:n key using df2.dta
keep if _merge == 1

* **Right join**
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* **Inner join**
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* **Outer join**
restore
merge 1:n key using df2.dta
```

Pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [49]: inner_join = df1.merge(df2, on=["key"], how="inner")
In [50]: inner_join
Out[50]:
   key  value_x  value_y
0   B  -0.282863  1.212112
1   D  -1.135632 -0.173215
2   D  -1.135632  0.119209
```

```
In [51]: left_join = df1.merge(df2, on=["key"], how="left")
In [52]: left_join
Out[52]:
   key  value_x  value_y
0   A   0.469112    NaN
1   B  -0.282863  1.212112
2   C  -1.509059    NaN
3   D  -1.135632 -0.173215
4   D  -1.135632  0.119209
```

(continues on next page)
In [53]: right_join = df1.merge(df2, on="key", how="right")

In [54]: right_join
Out[54]:
   key  value_x  value_y
0  B   -0.282863  1.212112
1  D   -1.135632 -0.173215
2  D   -1.135632  0.119209
3  E    NaN    -1.044236

In [55]: outer_join = df1.merge(df2, on="key", how="outer")

In [56]: outer_join
Out[56]:
   key  value_x  value_y
0  A    0.469112    NaN
1  B   -0.282863  1.212112
2  C   -1.509059    NaN
3  D   -1.135632 -0.173215
4  D   -1.135632  0.119209
5  E    NaN    -1.044236

**Missing data**

Both pandas and Stata have a representation for missing data.

pandas represents missing data with the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

In [57]: outer_join
Out[57]:
   key  value_x  value_y
0  A    0.469112    NaN
1  B   -0.282863  1.212112
2  C   -1.509059    NaN
3  D   -1.135632 -0.173215
4  D   -1.135632  0.119209
5  E    NaN    -1.044236

In [58]: outer_join["value_x"] + outer_join["value_y"]
Out[58]:
   0     NaN
   1  0.929249
   2     NaN
   3 -1.308847
   4 -1.016424
   5     NaN
dtype: float64

In [59]: outer_join["value_x"].sum()
One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```plaintext
* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .
```

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

```plaintext
In [60]: outer_join[outer_join["value_x"].isna()]
Out[60]:
   key  value_x  value_y
5   E       NaN  -1.044236

In [61]: outer_join[outer_join["value_x"].notna()]
Out[61]:
   key  value_x  value_y
0   A   0.469112   NaN
1   B  -0.282863  1.212112
2   C  -1.509059   NaN
3   D -1.135632  -0.173215
4   D -1.135632   0.119209
```

pandas provides *a variety of methods to work with missing data*. Here are some examples:

### Drop rows with missing values

```plaintext
In [62]: outer_join.dropna()
Out[62]:
   key  value_x  value_y
1   B  -0.282863  1.212112
3   D -1.135632  -0.173215
4   D -1.135632   0.119209
```

### Forward fill from previous rows

```plaintext
In [63]: outer_join.fillna(method="ffill")
Out[63]:
   key  value_x  value_y
0   A   0.469112   NaN
1   B  -0.282863  1.212112
2   C  -1.509059  1.212112
3   D -1.135632  -0.173215
4   D -1.135632   0.119209
5   E -1.135632 -1.044236
```
Replace missing values with a specified value

Using the mean:

```
In [64]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
Out[64]:
   0    0.469112
   1   -0.282863
   2  -1.509059
   3  -1.135632
   4  -1.135632
   5  -0.718815
Name: value_x, dtype: float64
```

GroupBy

Aggregation

Stata’s collapse can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the groupby documentation for more details and examples.

```
In [65]: tips_summed = tips.groupby(["sex", "smoker"]).[["total_bill", "tip"]].sum()
In [66]: tips_summed
Out[66]:
          total_bill   tip
    sex smoker         1         1
               Female No   869.68   149.77
                          Yes    527.27    96.74
               Male No  1725.75   302.00
                          Yes  1217.07   183.07
```

Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use bysort with egen(). For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas provides a Transformation mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [67]: gb = tips.groupby("smoker")[["total_bill"]]
In [68]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")
```
In [69]: tips
Out[69]:

</tbody>
</table>

[244 rows x 8 columns]

By group processing

In addition to aggregation, pandas `groupby` can be used to replicate most other `bysort` processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```plaintext
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [70]: tips.groupby(["sex", "smoker"]).first()
```

```
<table>
<thead>
<tr>
<th>sex</th>
<th>smoker</th>
<th>total_bill</th>
<th>tip</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>adj_total_bill</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>No</td>
<td>5.25</td>
<td>1.00</td>
<td>Sat</td>
<td>Dinner 1</td>
<td>1</td>
<td>-11.938278</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>1.07</td>
<td>1.00</td>
<td>Sat</td>
<td>Dinner 1</td>
<td>1</td>
<td>-17.686344</td>
</tr>
<tr>
<td>Male</td>
<td>No</td>
<td>5.51</td>
<td>2.00</td>
<td>Thur</td>
<td>Lunch 2</td>
<td>2</td>
<td>-11.678278</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>5.25</td>
<td>5.15</td>
<td>Sun</td>
<td>Dinner 2</td>
<td>2</td>
<td>-13.506344</td>
</tr>
</tbody>
</table>
```

Other considerations

Disk vs memory

pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine’s memory. If out of core processing is needed, one possibility is the `dask.dataframe` library, which provides a subset of pandas functionality for an on-disk DataFrame.
1.4.5 Community tutorials

This is a guide to many pandas tutorials by the community, geared mainly for new users.

**pandas cookbook by Julia Evans**

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the pandas-cookbook GitHub repository.

**Learn pandas by Hernan Rojas**

A set of lesson for new pandas users: https://bitbucket.org/hrojas/learn-pandas

**Practical data analysis with Python**

This guide is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as munging data, aggregating data, visualizing data and time series.

**Exercises for new users**

Practice your skills with real data sets and exercises. For more resources, please visit the main repository.

**Modern pandas**

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository TomAugspurger/effective-pandas.

- Modern Pandas
- Method Chaining
- Indexes
- Performance
- Tidy Data
- Visualization
- Timeseries

**Excel charts with pandas, vincent and xlsxwriter**

- Using Pandas and XlsxWriter to create Excel charts
Video tutorials

- Pandas: .head() to .tail() (2016) (1:26) GitHub repo
- Data analysis in Python with pandas (2016-2018) GitHub repo and Jupyter Notebook
- Best practices with pandas (2018) GitHub repo and Jupyter Notebook

Various tutorials

- Wes McKinney’s (pandas BDFL) blog
- Statistical analysis made easy in Python with SciPy and pandas DataFrames, by Randal Olson
- Statistical Data Analysis in Python, tutorial videos, by Christopher Fonnesbeck from SciPy 2013
- Financial analysis in Python, by Thomas Wiecki
- Intro to pandas data structures, by Greg Reda
- Pandas and Python: Top 10, by Manish Amde
- Pandas DataFrames Tutorial, by Karlijn Willems
- A concise tutorial with real life examples
CHAPTER TWO

USER GUIDE

The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10 minutes to pandas.

For a high level summary of the pandas fundamentals, see Intro to data structures and Essential basic functionality.

Further information on any specific method can be obtained in the API reference.

2.1 10 minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the Cookbook.

Customarily, we import as follows:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

2.1.1 Object creation

See the Data Structure Intro section.

Creating a Series by passing a list of values, letting pandas create a default integer index:

```
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])
In [4]: s
Out[4]:
0    1.0
1    3.0
2    5.0
3    NaN
4    6.0
5    8.0
dtype: float64
```

Creating a DataFrame by passing a NumPy array, with a datetime index and labeled columns:
In [5]: dates = pd.date_range("20130101", periods=6)

In [6]: dates
Out[6]:
dtype='datetime64[ns]', freq='D')

In [7]: df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list("ABCD"))

In [8]: df
Out[8]:
     A  B    C    D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-05 -0.424972  0.567020  0.276232 -1.087401
2013-01-06 -0.673690  0.113648 -1.478427  0.524988

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

In [9]: df2 = pd.DataFrame(  
...:     {  
...:         "A": 1.0,  
...:         "B": pd.Timestamp("20130102"),  
...:         "C": pd.Series(1, index=list(range(4)), dtype="float32"),  
...:         "D": np.array([3] * 4, dtype="int32"),  
...:         "E": pd.Categorical(["test", "train", "test", "train"]),  
...:         "F": "foo",  
...:     })

In [10]: df2
Out[10]:
     A  B      C  D  E       F
0  1.0 1.0 2013-01-02 3.0 test  foo
1  1.0 1.0 2013-01-02 3.0 train foo
2  1.0 1.0 2013-01-02 3.0 test  foo
3  1.0 1.0 2013-01-02 3.0 train foo

The columns of the resulting DataFrame have different dtypes.

In [11]: df2.dtypes
Out[11]:
A    float64
B  datetime64[ns]
C     float32
D      int32
E   category
F       object
dtype: object
If you’re using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here’s a subset of the attributes that will be completed:

```
In [12]: df2.<TAB>  # noqa: E225, E999
df2.A
df2.bool
df2.abs
df2.boxplot
df2.add
df2.C
df2.add_prefix
df2.clip
df2.add_suffix
df2.columns
df2.align
df2.copy
df2.all
df2.count
df2.any
df2.combine
df2.append
df2.D
df2.apply
df2.describe
df2.applymap
df2.diff
df2.B
df2.duplicated
```

As you can see, the columns A, B, C, and D are automatically tab completed. E and F are there as well; the rest of the attributes have been truncated for brevity.

### 2.1.2 Viewing data

See the Basics section.

Here is how to view the top and bottom rows of the frame:

```
In [13]: df.head()
Out[13]:
          A         B          C         D
2013-01-01  0.469112  -0.282863  -1.509059  -1.135632
2013-01-02  1.212112   0.173215   0.119209  -1.044236
2013-01-03  0.861849  -2.104569  -0.494929   1.071804
2013-01-04  0.721555  -0.706771  -1.039575   0.271860
2013-01-05  0.424972   0.567020   0.276232  -1.087401

In [14]: df.tail(3)
Out[14]:
          A         B          C         D
2013-01-04  0.721555  -0.706771  -1.039575   0.271860
2013-01-05  0.424972   0.567020   0.276232  -1.087401
2013-01-06  0.673690   0.113648  -1.478427   0.524988
```

Display the index, columns:

```
In [15]: df.index
Out[15]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')

In [16]: df.columns
Out[16]: Index(['A', 'B', 'C', 'D'], dtype='object')
```

`DataFrame.to_numpy()` gives a NumPy representation of the underlying data. Note that this can be an expensive
operation when your DataFrame has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column. When you call DataFrame.to_numpy(), pandas will find the NumPy dtype that can hold all of the dtypes in the DataFrame. This may end up being object, which requires casting every value to a Python object.

For df, our DataFrame of all floating-point values, DataFrame.to_numpy() is fast and doesn’t require copying data.

```
In [17]: df.to_numpy()
Out[17]:
array([[ 0.4691, -0.2829, -1.5091, -1.1356],
      [ 1.2121, -0.1732,  0.1192, -1.0442],
      [-0.8618, -2.1046, -0.4949,  1.0718],
      [ 0.7216, -0.7068, -1.0396,  0.2719],
      [-0.425 ,  0.567 ,  0.2762, -1.0874],
      [-0.6737,  0.1136, -1.4784,  0.525 ]])
```

For df2, the DataFrame with multiple dtypes, DataFrame.to_numpy() is relatively expensive.

```
In [18]: df2.to_numpy()
Out[18]:
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
      [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo'],
      [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
      [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']],
      dtype=object)
```

Note: DataFrame.to_numpy() does not include the index or column labels in the output.

```
In [19]: df.describe()
Out[19]:
    A       B       C       D
count 6.000000 6.000000 6.000000 6.000000
mean  0.073711 -0.431125 -0.687758 -0.233103
std   0.843157  0.922818  0.779887  0.973118
min  -0.861849 -2.104569 -1.509059 -1.135632
25%   -0.611510 -0.600794 -1.368714 -1.076610
50%   0.022070  0.228039  0.779887  0.973118
75%   0.658444  0.041933 -0.034326  0.461706
max   1.212112  0.567020  0.276232  1.071804
```

Transposing your data:

```
In [20]: df.T
Out[20]:
A     0.469112  1.212112  -0.861849  0.721555  -0.424972  -0.673690
B    -0.282863  -0.173215  -2.104569  -0.706771  0.567020  0.113648
C    -1.509059  0.119209  -2.104569  -0.494929  0.276232  1.071804
D    -1.135632  -0.424972  1.071804  0.271860  -1.087401  0.524988
```

Sorting by an axis:
In [21]: df.sort_index(axis=1, ascending=False)

Out[21]:

<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>C</th>
<th>B</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>-1.135632</td>
<td>-1.509059</td>
<td>-0.282863</td>
<td>0.469112</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>-1.044236</td>
<td>0.119209</td>
<td>-0.173215</td>
<td>1.212112</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>1.071804</td>
<td>-0.494929</td>
<td>-2.104569</td>
<td>-0.861849</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.271860</td>
<td>-1.039575</td>
<td>-0.706771</td>
<td>0.721555</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>-1.087401</td>
<td>0.276232</td>
<td>0.567020</td>
<td>-0.424972</td>
</tr>
<tr>
<td>2013-01-06</td>
<td>0.524988</td>
<td>-1.478427</td>
<td>0.113648</td>
<td>-0.673690</td>
</tr>
</tbody>
</table>

Sorting by values:

In [22]: df.sort_values(by="B")

Out[22]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>1.071804</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>0.271860</td>
</tr>
<tr>
<td>2013-01-01</td>
<td>0.469112</td>
<td>-0.282863</td>
<td>-1.509059</td>
<td>-1.135632</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>

</tr>
<tr>
<td>2013-01-06</td>
<td>-0.673690</td>
<td>0.113648</td>
<td>-1.478427</td>
<td>0.524988</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>-0.424972</td>
<td>0.567020</td>
<td>0.276232</td>
<td>-1.087401</td>
</tr>
</tbody>
</table>

2.1.3 Selection

Note: While standard Python / NumPy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, .at, .iat, .loc and .iloc.

See the indexing documentation Indexing and Selecting Data and MultiIndex / Advanced Indexing.

Getting

Selecting a single column, which yields a Series, equivalent to df.A:

In [23]: df["A"]

Out[23]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.469112</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.721555</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>-0.424972</td>
</tr>
<tr>
<td>2013-01-06</td>
<td>-0.673690</td>
</tr>
</tbody>
</table>

Freq: D, Name: A, dtype: float64

Selecting via [], which slices the rows.

In [24]: df[0:3]

Out[24]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.469112</td>
<td>-0.282863</td>
<td>-1.509059</td>
<td>-1.135632</td>
</tr>
</tbody>
</table>

(continues on next page)
In [25]: df["20130102":"20130104"]
Out[25]:
           A      B      C      D
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03  0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860

Selection by label

See more in Selection by Label.

For getting a cross section using a label:

In [26]: df.loc[dates[0]]
Out[26]:
   A   B   C   D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
Name: 2013-01-01 00:00:00, dtype: float64

Selecting on a multi-axis by label:

In [27]: df.loc[:, ["A", "B"]]
Out[27]:
          A     B
2013-01-01  0.469112 -0.282863
2013-01-02  1.212112 -0.173215
2013-01-03  0.861849 -2.104569
2013-01-04  0.721555 -0.706771
2013-01-05 -0.424972  0.567020
2013-01-06 -0.673690  0.113648

Showing label slicing, both endpoints are included:

In [28]: df.loc["20130102":"20130104", ["A", "B"]]
Out[28]:
          A     B
2013-01-02  1.212112 -0.173215
2013-01-03  0.861849 -2.104569
2013-01-04  0.721555 -0.706771

Reduction in the dimensions of the returned object:

In [29]: df.loc["20130102", ["A", "B"]]
Out[29]:
          A     B
2013-01-02  1.212112 -0.173215
Name: 2013-01-02 00:00:00, dtype: float64
For getting a scalar value:

```
In [30]: df.loc[dates[0], "A"]
Out[30]: 0.4691122999071863
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], "A"]
Out[31]: 0.4691122999071863
```

**Selection by position**

See more in *Selection by Position*.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
A   0.721555
B  -0.706771
C  -1.039575
D   0.271860
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to NumPy/Python:

```
In [33]: df.iloc[3:5, 0:2]
Out[33]:
   A   B
2013-01-04  0.721555 -0.706771
2013-01-05 -0.424972  0.567020
```

By lists of integer position locations, similar to the NumPy/Python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
   A   C
2013-01-02  1.212112  0.119209
2013-01-03 -0.861849 -0.494929
2013-01-05 -0.424972  0.276232
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out[35]:
   A   B   C   D
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out[36]:
   B   C
```

(continues on next page)
For getting a value explicitly:

```
In [37]: df.iloc[1, 1]
Out[37]: -0.17321464905330858
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [38]: df.iat[1, 1]
Out[38]: -0.17321464905330858
```

### Boolean indexing

Using a single column’s values to select data.

```
In [39]: df[df["A"] > 0]
Out[39]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.469112</td>
<td>-0.282863</td>
<td>-1.509059</td>
<td>-1.135632</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>-1.044236</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>0.271860</td>
</tr>
</tbody>
</table>
```

Selecting values from a DataFrame where a boolean condition is met.

```
In [40]: df[df > 0]
Out[40]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>NaN</td>
<td>0.119209</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>NaN</td>
<td>NaN</td>
<td>1.071804</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>NaN</td>
<td>0.271860</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>0.567020</td>
<td>0.276232</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-06</td>
<td>0.113648</td>
<td>0.524988</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```

Using the `isin()` method for filtering:

```
In [41]: df2 = df.copy()

In [42]: df2["E"] = ["one", "one", "two", "three", "four", "three"]

In [43]: df2
Out[43]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.469112</td>
<td>-0.282863</td>
<td>-1.509059</td>
<td>-1.135632</td>
<td>one</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>-1.044236</td>
<td>one</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>1.071804</td>
<td>two</td>
</tr>
</tbody>
</table>
```

(continues on next page)
Setting

Setting a new column automatically aligns the data by the indexes.

```python
In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range("20130102", periods=6))

In [46]: s1
Out[46]:
2013-01-02  1
2013-01-03  2
2013-01-04  3
2013-01-05  4
2013-01-06  5
2013-01-07  6
Freq: D, dtype: int64
```

```python
In [47]: df["F"] = s1
```

Setting values by label:

```python
In [48]: df.at[dates[0], "A"] = 0
```

Setting values by position:

```python
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```python
In [50]: df.loc[:, "D"] = np.array([5] * len(df))
```

The result of the prior setting operations.

```python
In [51]: df
Out[51]:
     A       B        C       D   F
2013-01-01  0.000000  0.000000 -1.509059  5  NaN
2013-01-02  1.212112 -0.173215  0.119209  5  1.0
2013-01-03 -0.861849 -2.104569 -0.494929  5  2.0
2013-01-04  0.721555 -0.706771 -1.039575  5  3.0
2013-01-05 -0.424972  0.567020  0.276232  5  4.0
2013-01-06 -0.673690  0.113648 -1.478427  5  5.0
```

A where operation with setting.

2.1. 10 minutes to pandas
In [52]: df2 = df.copy()

In [53]: df2[df2 > 0] = -df2

In [54]: df2

Out[54]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.000000</td>
<td>0.000000</td>
<td>-1.509059</td>
<td>5</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>-1.212112</td>
<td>-0.173215</td>
<td>-0.119209</td>
<td>5</td>

<td>-1.478427</td>
<td>5</td>
<td>-5.0</td>
</tr>
</tbody>
</table>

2.1.4 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the Missing Data section.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ["E"])

In [56]: df1.loc[dates[0] : dates[1], "E"] = 1

In [57]: df1

Out[57]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.000000</td>
<td>0.000000</td>
<td>-1.509059</td>
<td>5</td>
<td>NaN</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>5</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>5</td>
<td>2.0</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>5</td>
<td>3.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

To drop any rows that have missing data.

In [58]: df1.dropna(how="any")

Out[58]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>5</td>
<td>1.0</td>
<td>1.0</td>
</tr>
</tbody>
</table>

Filling missing data.

In [59]: df1.fillna(value=5)

Out[59]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.000000</td>
<td>0.000000</td>
<td>-1.509059</td>
<td>5</td>
<td>5.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>5</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>5</td>
<td>2.0</td>
<td>5.0</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>5</td>
<td>3.0</td>
<td>5.0</td>
</tr>
</tbody>
</table>

To get the boolean mask where values are nan.
2.1.5 Operations

See the Basic section on Binary Ops.

Stats

Operations in general exclude missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
A  -0.004474
B  -0.383981
C  -0.687758
D  5.000000
F  3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01  0.872735
2013-01-02  1.431621
2013-01-03  0.707731
2013-01-04  1.395042
2013-01-05  1.883656
2013-01-06  1.592306
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)
```
Apply

Applying functions to the data:

<table>
<thead>
<tr>
<th>In [66]:</th>
<th>df.apply(np.cumsum)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[66]:</td>
<td></td>
</tr>
<tr>
<td>2013-01-01</td>
<td>0.000000</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>0.350263</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>1.071818</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>0.646846</td>
</tr>
<tr>
<td>2013-01-06</td>
<td>-0.026844</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [67]:</th>
<th>df.apply(lambda x: x.max() - x.min())</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[67]:</td>
<td></td>
</tr>
<tr>
<td>A</td>
<td>2.073961</td>
</tr>
<tr>
<td>B</td>
<td>2.671590</td>
</tr>
<tr>
<td>C</td>
<td>1.785291</td>
</tr>
<tr>
<td>D</td>
<td>0.000000</td>
</tr>
<tr>
<td>F</td>
<td>4.000000</td>
</tr>
<tr>
<td>dtype:</td>
<td>float64</td>
</tr>
</tbody>
</table>

Histogramming

See more at *Histogramming and Discretization*.

<table>
<thead>
<tr>
<th>In [68]:</th>
<th>s = pd.Series(np.random.randint(0, 7, size=10))</th>
</tr>
</thead>
<tbody>
<tr>
<td>In [69]:</td>
<td>s</td>
</tr>
<tr>
<td>Out[69]:</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>4</td>
</tr>
</tbody>
</table>
7 6
data type: int64

In [70]: s.value_counts()
Out[70]:
4  5
2  2
6  2
1  1
data type: int64

String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at Vectorized String Methods.

In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])

In [72]: s.str.lower()
Out[72]:
0 a
1 b
2 c
3 aaba
4 baca
5 NaN
6 caba
7 dog
8 cat
data type: object

2.1.6 Merge

Concat

pandas provides various facilities for easily combining together Series and DataFrame objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the Merging section.

Concatenating pandas objects together with `concat()`:

In [73]: df = pd.DataFrame(np.random.randn(10, 4))

In [74]: df
Out[74]:
     0       1       2        3
0 -0.548702  1.467327 -1.015962 -0.483075
(continues on next page)
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3 -0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
7 -0.932132  1.956030  0.017587 -0.016692
8 -0.575247  0.254161 -1.143704  0.215897
9  1.193555 -0.077118 -0.408530 -0.862495

# break it into pieces
In [75]: pieces = [df[0:3], df[3:7], df[7:]]

In [76]: pd.concat(pieces)

Out[76]:
0 1 2 3
0 -0.548702  1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3 -0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
7 -0.932132  1.956030  0.017587 -0.016692
8 -0.575247  0.254161 -1.143704  0.215897
9  1.193555 -0.077118 -0.408530 -0.862495

Note: Adding a column to a DataFrame is relatively fast. However, adding a row requires a copy, and may be expensive. We recommend passing a pre-built list of records to the DataFrame constructor instead of building a DataFrame by iteratively appending records to it. See Appending to dataframe for more.

Join

SQL style merges. See the Database style joining section.

In [77]: left = pd.DataFrame({"key": ["foo", "foo"], "lval": [1, 2]})

In [78]: right = pd.DataFrame({"key": ["foo", "foo"], "rval": [4, 5]})

In [79]: left
Out[79]:
     key  lval
   0  foo   1
   1  foo   2

In [80]: right
Out[80]:
     key  rval
   0  foo    4
Another example that can be given is:

```
In [82]: left = pd.DataFrame({"key": ["foo", "bar"], "lval": [1, 2]})
In [83]: right = pd.DataFrame({"key": ["foo", "bar"], "rval": [4, 5]})
In [84]: left
Out[84]:
   key lval
0 foo  1
1 bar  2
In [85]: right
Out[85]:
   key rval
0 foo   4
1 bar   5
In [86]: pd.merge(left, right, on="key")
Out[86]:
   key lval rval
0 foo   1   4
1 bar   2   5
```

### 2.1.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the Grouping section.

```
In [87]: df = pd.DataFrame({
    ....: "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
    ....: "B": ["one", "one", "two", "three", "two", "two", "one", "three"],
    ....: "C": np.random.randn(8),
    ....: "D": np.random.randn(8),
    ....: })
```

(continues on next page)
In [88]: df
Out[88]:
```
   A  B  C   D
0  foo one 1.346061 -1.577585
1  bar one 1.511763  0.396823
2  foo two 1.627081 -0.105381
3  bar three -0.990582 -0.532532
4  foo two -0.441652  1.453749
5  bar two  1.211526  1.208843
6  foo one  0.268520 -0.080952
7  foo three 0.024580  0.264610
```

Grouping and then applying the `sum()` function to the resulting groups.

In [89]: df.groupby("A").sum()
Out[89]:
```
   C   D
A
bar  1.732707  1.073134
foo  2.824590 -0.574779
```

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum()` function.

In [90]: df.groupby(["A", "B"]).sum()
Out[90]:
```
     C   D
A B
bar one  1.511763  0.396823
      three -0.990582 -0.532532
two  1.211526  1.208843
foo one  1.614581 -1.658537
      three  0.024580 -0.264610
two  1.185429  1.348368
```

### 2.1.8 Reshaping

See the sections on `Hierarchical Indexing` and `Reshaping`.

**Stack**

In [91]: tuples = list(
   .....:     zip(
   .....:         *["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
   .....:         ["one", "two", "one", "two", "one", "two", "one", "two"],
   .....:     )
   .....: )
In [92]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [93]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [94]: df2 = df[:4]

In [95]: df2
Out[95]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>first second</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td>one</td>
<td>0.339355</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.884345</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>-0.339355</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.884345</td>
</tr>
</tbody>
</table>

The `stack()` method “compresses” a level in the DataFrame’s columns.

In [96]: stacked = df2.stack()

In [97]: stacked
Out[97]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>first second</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td>one</td>
<td>0.339355</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.884345</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>0.884345</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>1.591431</td>
</tr>
</tbody>
</table>

dtype: float64

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the last level:

In [98]: stacked.unstack()
Out[98]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>first second</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>

Pivot tables

See the section on Pivot Tables.

In [101]: df = pd.DataFrame(
......:     \{
......:         "A": ["one", "one", "two", "three"] * 3,
......:         "B": ["A", "B", "C"] * 4,
......:         "C": ["foo", "foo", "foo", "bar", "bar", "bar"] * 2,
......:         "D": np.random.randn(12),
......:         "E": np.random.randn(12),
......:     }
......: )

In [102]: df
Out[102]:
   A   B   C   D   E
0 one A  foo -1.202872 0.047609
1 one B  foo -1.814470 -0.136473
2 two C  foo  1.018601 -0.561757
3 three A  bar -0.595447 -1.623033
4 one B  bar  1.395433 -0.029399
5 one C  bar -0.392670 -0.542108
6 two A  foo  0.007207  0.282696
7 three B  foo  1.928123 -0.087302
8 one C  foo -0.055224 -1.575170
9 one A  bar  2.395985  1.771208
10 two B  bar  1.552825  0.816482
11 three C  bar  0.166599  1.100230

We can produce pivot tables from this data very easily:

In [103]: pd.pivot_table(df, values="D", index=["A", "B"], columns=["C"])
Out[103]:
   C  bar  foo
A  
one A  2.395985 -1.202872
2.1.9 Time series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the Time Series section.

In [104]:
rng = pd.date_range("1/1/2012", periods=100, freq="S")

In [105]:
ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)

In [106]:
ts.resample("5Min").sum()
Out[106]:
2012-01-01 24182
Freq: 5T, dtype: int64

Time zone representation:

In [107]:
rng = pd.date_range("3/6/2012 00:00", periods=5, freq="D")

In [108]:
ts = pd.Series(np.random.randn(len(rng)), rng)

In [109]:
ts
Out[109]:
2012-03-06  1.857704
2012-03-07  -1.193545
2012-03-08   0.677510
2012-03-09  -0.153931
2012-03-10   0.520091
Freq: D, dtype: float64

In [110]:
ts_utc = ts.tz_localize("UTC")

In [111]:
ts_utc
Out[111]:
2012-03-06 00:00:00+00:00  1.857704
2012-03-07 00:00:00+00:00  -1.193545
2012-03-08 00:00:00+00:00   0.677510
2012-03-09 00:00:00+00:00  -0.153931
2012-03-10 00:00:00+00:00   0.520091
Freq: D, dtype: float64

Converting to another time zone:
Converting between time span representations:

```python
In [113]: rng = pd.date_range("1/1/2012", periods=5, freq="M")
In [114]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [115]: ts
Out[115]:
2012-01-31 -1.475051
2012-02-29  0.722570
2012-03-31 -0.322646
2012-04-30 -1.601631
2012-05-31  0.778033
Freq: M, dtype: float64
In [116]: ps = ts.to_period()
In [117]: ps
Out[117]:
2012-01 -1.475051
2012-02  0.722570
2012-03 -0.322646
2012-04 -1.601631
2012-05  0.778033
Freq: M, dtype: float64
In [118]: ps.to_timestamp()
Out[118]:
2012-01-01 -1.475051
2012-02-01  0.722570
2012-03-01 -0.322646
2012-04-01 -1.601631
2012-05-01  0.778033
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```python
In [119]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")
In [120]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [121]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9
```

(continues on next page)
In [122]: ts.head()
Out[122]:
1990-03-01 09:00 -0.289342
1990-06-01 09:00 0.233141
1990-09-01 09:00 -0.223540
1990-12-01 09:00 0.542054
1991-03-01 09:00 -0.688585
Freq: H, dtype: float64

2.1.10 Categoricals

pandas can include categorical data in a DataFrame. For full docs, see the categorical introduction and the API documentation.

In [123]: df = pd.DataFrame(
.....:   {"id": [1, 2, 3, 4, 5, 6], "raw_grade": ["a", "b", "b", "a", "a", "e"]}
.....: )

Convert the raw grades to a categorical data type.

In [124]: df["grade"] = df["raw_grade"].astype("category")

In [125]: df["grade"]
Out[125]:
0 a
1 b
2 b
3 a
4 a
5 e
Name: grade, dtype: category
Categories (3, object): ['a', 'b', 'e']

Rename the categories to more meaningful names (assigning to Series.cat.categories() is in place!).

In [126]: df["grade"].cat.categories = ["very good", "good", "very bad"]

Reorder the categories and simultaneously add the missing categories (methods under Series.cat() return a new Series by default).

In [127]: df["grade"] = df["grade"].cat.set_categories(
.....:   ["very bad", "bad", "medium", "good", "very good"]
.....: )

In [128]: df["grade"]
Out[128]:
0 very good
1 good

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.4

2.11 Plotting

See the Plotting docs.

We use the standard convention for referencing the matplotlib API:

```python
In [131]: import matplotlib.pyplot as plt
In [132]: plt.close("all")
```

The close() method is used to close a figure window.

```python
In [133]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
In [134]: ts = ts.cumsum()
In [135]: ts.plot();
```
On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```python
In [136]: df = pd.DataFrame(
          ......:    np.random.randn(1000, 4), index=ts.index, columns=['A', 'B', 'C', 'D'])
          ......:

In [137]: df = df.cumsum()

In [138]: plt.figure();

In [139]: df.plot();

In [140]: plt.legend(loc='best');
```
2.1.12 Getting data in/out

CSV

Writing to a csv file.

```

2.1.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```python
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
... ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See Comparisons for an explanation and what to do.

See Gotchas as well.

2.2 Intro to data structures

We’ll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: data alignment is intrinsic. The link between labels and data will not be broken unless done so explicitly by you.

We’ll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

2.2.1 Series

Series is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the index. The basic method to create a Series is to call:

```python
>>> s = pd.Series(data, index=index)
```

Here, data can be many different things:

- a Python dict
- an ndarray
• a scalar value (like 5)

The passed index is a list of axis labels. Thus, this separates into a few cases depending on what data is:

**From ndarray**

If data is an ndarray, index must be the same length as data. If no index is passed, one will be created having values [0, ..., len(data) - 1].

```python
In [3]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
```

```python
In [4]: s
Out[4]:
   a    0.469112
   b   -0.282863
   c   -1.509059
   d   -1.135632
   e    1.212112
dtype: float64
```

```python
In [5]: s.index
Out[5]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
```

```python
In [6]: pd.Series(np.random.randn(5))
Out[6]:
   0   -0.173215
   1    0.119209
   2   -1.044236
   3   -0.861849
   4   -2.104569
dtype: float64
```

**Note:** pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

**From dict**

Series can be instantiated from dicts:

```python
In [7]: d = {"b": 1, "a": 0, "c": 2}
```

```python
In [8]: pd.Series(d)
Out[8]:
   b    1
   a    0
   c    2
dtype: int64
```

**Note:** When the data is a dict, and an index is not passed, the Series index will be ordered by the dict’s insertion order, if you’re using Python version >= 3.6 and pandas version >= 0.23.

If you’re using Python < 3.6 or pandas < 0.23, and an index is not passed, the Series index will be the lexically ordered
list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a pandas version lower than 0.23, the Series would be ordered by the lexical order of the dict keys (i.e. ['a', 'b', 'c'] rather than ['b', 'a', 'c']).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {"a": 0.0, "b": 1.0, "c": 2.0}
In [10]: pd.Series(d)
Out[10]:
    a   0.0
    b   1.0
    c   2.0
dtype: float64
In [11]: pd.Series(d, index=["b", "c", "d", "a"])
Out[11]:
    b   1.0
    c   2.0
d     NaN
    a   0.0
dtype: float64
```

**Note:** NaN (not a number) is the standard missing data marker used in pandas.

**From scalar value**

If `data` is a scalar value, an index must be provided. The value will be repeated to match the length of `index`.

```
In [12]: pd.Series(5.0, index=["a", "b", "c", "d", "e"])
Out[12]:
    a   5.0
    b   5.0
    c   5.0
d   5.0
e   5.0
dtype: float64
```

**Series is ndarray-like**

Series acts very similarly to a `ndarray`, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.4691122999071863
In [14]: s[:3]
Out[14]:
    a  0.469112
    b -0.282863
    c -1.509059
```

(continues on next page)
Like a NumPy array, a pandas Series has a `dtype`.

```
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy dtype. However, pandas and 3rd-party libraries extend NumPy’s type system in a few places, in which case the dtype would be an `ExtensionDtype`. Some examples within pandas are `Categorical data` and `Nullable integer data type`. See `dtypes` for more.

If you need the actual array backing a Series, use `Series.array`.

```
In [19]: s.array
Out[19]: <PandasArray>
[ 0.4691122999071863, -0.2828633443286633, -1.5090585031735124,
 -1.1356323710171934, 1.2121120250208506]
Length: 5, dtype: float64
```

Accessing the array can be useful when you need to do some operation without the index (to disable automatic alignment, for example).

`Series.array` will always be an `ExtensionArray`. Briefly, an ExtensionArray is a thin wrapper around one or more concrete arrays like a `numpy.ndarray`. pandas knows how to take an ExtensionArray and store it in a `Series` or a column of a `DataFrame`. See `dtypes` for more.

While Series is ndarray-like, if you need an actual ndarray, then use `Series.to_numpy()`.

---

2.2. Intro to data structures
In [20]: s.to_numpy()
Out[20]: array([ 0.4691, -0.2829, -1.5091, -1.1356, 1.2121])

Even if the Series is backed by a `ExtensionArray`, `Series.to_numpy()` will return a NumPy ndarray.

### Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

In [21]: s['a']
Out[21]: 0.4691122999071863

In [22]: s['e'] = 12.0

In [23]: s
Out[23]:
   a   0.469112
   b  -0.282863
   c  -1.509059
   d  -1.135632
   e   12.000000
   dtype: float64

In [24]: 'e' in s
Out[24]: True

In [25]: 'f' in s
Out[25]: False

If a label is not contained, an exception is raised:

```python
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return `None` or specified default:

In [26]: s.get("f")
In [27]: s.get("f", np.nan)
Out[27]: nan

See also the section on attribute access.

### Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

In [28]: s + s
Out[28]:
a   0.938225
b  -0.565727
(continues on next page)
A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

The result of an operation between unaligned Series will have the union of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

Note: In general, we chose to make the default result of operations between differently indexed objects yield the union of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the dropna function.
Name attribute

Series can also have a name attribute:

```python
In [32]: s = pd.Series(np.random.randn(5), name="something")

In [33]: s
Out[33]:
0  -0.494929
1   1.071804
2   0.721555
3  -0.706771
4  -1.039575
Name: something, dtype: float64

In [34]: s.name
Out[34]: 'something'
```

The Series name will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

You can rename a Series with the `pandas.Series.rename()` method.

```python
In [35]: s2 = s.rename("different")

In [36]: s2.name
Out[36]: 'different'
```

Note that s and s2 refer to different objects.

### 2.2.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass `index` (row labels) and `columns` (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

**Note:** When the data is a dict, and `columns` is not specified, the DataFrame columns will be ordered by the dict's insertion order, if you are using Python version >= 3.6 and pandas >= 0.23.

If you are using Python < 3.6 or pandas < 0.23, and `columns` is not specified, the DataFrame columns will be the lexically ordered list of dict keys.
From dict of Series or dicts

The resulting index will be the union of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [37]: d = {
    ....:     "one": pd.Series([1.0, 2.0, 3.0], index=["a", "b", "c"],
    ....:     "two": pd.Series([1.0, 2.0, 3.0, 4.0], index=["a", "b", "c", "d"],
    ....:     }
    ....:

In [38]: df = pd.DataFrame(d)
```

```
In [39]: df
Out[39]:
   one  two
  a   1.0   1.0
  b   2.0   2.0
  c   3.0   3.0
  d  NaN   4.0
```

```
In [40]: pd.DataFrame(d, index=["d", "b", "a"])
Out[40]:
   one  two
  d  NaN   4.0
  b   2.0   2.0
  a   1.0   1.0
```

```
In [41]: pd.DataFrame(d, index=["d", "b", "a"], columns=["two", "three"])
Out[41]:
   two  three
  d    4.0   NaN
  b    2.0   NaN
  a    1.0   NaN
```

The row and column labels can be accessed respectively by accessing the index and columns attributes:

```
Note: When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.
```

```
In [42]: df.index
Out[42]: Index(["a", "b", "c", "d"], dtype='object')
```

```
In [43]: df.columns
Out[43]: Index(["one", "two"], dtype='object')
```
From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be range(n), where n is the array length.

```python
In [44]: d = {"one": [1.0, 2.0, 3.0, 4.0], "two": [4.0, 3.0, 2.0, 1.0]}
In [45]: pd.DataFrame(d)
Out[45]:
    one  two
  0  1.0  4.0
  1  2.0  3.0
  2  3.0  2.0
  3  4.0  1.0
In [46]: pd.DataFrame(d, index=["a", "b", "c", "d")
Out[46]:
    one  two
     a  1.0  4.0
     b  2.0  3.0
     c  3.0  2.0
     d  4.0  1.0
```

From structured or record array

This case is handled identically to a dict of arrays.

```python
In [47]: data = np.zeros((2,), dtype=[("A", "i4"), ("B", "f4"), ("C", "a10")])
In [48]: data[:]= [(1, 2.0, "Hello"), (2, 3.0, "World")]
In [49]: pd.DataFrame(data)
Out[49]:
      A   B          C
     0  1.0  2.0      b'Hello'
     1  2.0  3.0      b'World'
In [50]: pd.DataFrame(data, index=["first", "second")
Out[50]:
     A   B          C
   first  1.0  2.0      b'Hello'
     second  2.0  3.0      b'World'
In [51]: pd.DataFrame(data, columns=["C", "A", "B")
Out[51]:
      C   A   B
     0  b'Hello'  1  2.0
     1  b'World'  2  3.0
```

Note: DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.
From a list of dicts

```
In [52]: data2 = [{"a": 1, "b": 2}, {"a": 5, "b": 10, "c": 20}]

In [53]: pd.DataFrame(data2)
Out[53]:
   a  b  c
0  1  2  NaN
1  5 10  20.0

In [54]: pd.DataFrame(data2, index=["first", "second"])
Out[54]:
   a  b  c
first 1  2  NaN
second 5 10  20.0

In [55]: pd.DataFrame(data2, columns=["a", "b"])
Out[55]:
   a  b
0  1  2
1  5 10
```

From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```
In [56]: pd.DataFrame(
    ....: {  
    ....:     ("a", "b"): {("A", "B"): 1, ("A", "C"): 2},  
    ....:     ("a", "a"): {("A", "C"): 3, ("A", "B"): 4},  
    ....:     ("a", "c"): {("A", "B"): 5, ("A", "C"): 6},  
    ....:     ("b", "a"): {("A", "C"): 7, ("A", "B"): 8},  
    ....:     ("b", "b"): {("A", "D"): 9, ("A", "B"): 10},  
    ....: }
    ....: )
    ....: )

Out[56]:
   a  b
  b a  c a  b
A B 1.0 4.0 5.0 8.0 10.0
C 2.0 3.0 6.0 7.0 NaN
D NaN NaN NaN NaN 9.0
```

2.2. Intro to data structures
From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

From a list of namedtuples

The field names of the first namedtuple in the list determine the columns of the DataFrame. The remaining namedtuples (or tuples) are simply unpacked and their values are fed into the rows of the DataFrame. If any of those tuples is shorter than the first namedtuple then the later columns in the corresponding row are marked as missing values. If any are longer than the first namedtuple, a ValueError is raised.

```
In [57]: from collections import namedtuple

In [58]: Point = namedtuple("Point", "x y")

In [59]: pd.DataFrame([[Point(0, 0), Point(0, 3), (2, 3)]])
Out[59]:
     x  y
0  0  0
1  0  3
2  2  3

In [60]: Point3D = namedtuple("Point3D", "x y z")

In [61]: pd.DataFrame([[Point3D(0, 0, 0), Point3D(0, 3, 5), Point(2, 3)]]
Out[61]:
     x  y  z
0  0  0  0.0
1  0  3  5.0
2  2  3  NaN
```

From a list of dataclasses

New in version 1.1.0.

Data Classes as introduced in PEP557, can be passed into the DataFrame constructor. Passing a list of dataclasses is equivalent to passing a list of dictionaries.

Please be aware, that all values in the list should be dataclasses, mixing types in the list would result in a TypeError.

```
In [62]: from dataclasses import make_dataclass

In [63]: Point = make_dataclass("Point", ["x", int], ["y", int])

In [64]: pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
Out[64]:
     x  y
0  0  0
1  0  3
2  2  3
```

Missing data
Much more will be said on this topic in the Missing data section. To construct a DataFrame with missing data, we use np.nan to represent missing values. Alternatively, you may pass a numpy.MaskedArray as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

**Alternate constructors**

**DataFrame.from_dict**

DataFrame.from_dict takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the orient parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```
In [65]: pd.DataFrame.from_dict(dict([("A", [1, 2, 3]), ("B", [4, 5, 6])]))
Out[65]:
   A  B
0  1  4
1  2  5
2  3  6
```

If you pass orient='index', the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [66]: pd.DataFrame.from_dict(dict((["A", [1, 2, 3]], ("B", [4, 5, 6]))),
                        orient="index",
                        columns=["one", "two", "three"],
                        )
```

**DataFrame.from_records**

DataFrame.from_records takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```
In [67]: data
Out[67]:
array([[1, 2., b'Hello'], [2, 3., b'World']],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])
```

```
In [68]: pd.DataFrame.from_records(data, index="C")
Out[68]:
   A  B
C b'Hello' 1  2.0
    b'World' 2  3.0
```
Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [69]: df["one"]
Out[69]:
     a   b   c   d
   NaN 1.0 3.0 NaN
Name: one, dtype: float64

In [70]: df["three"] = df["one"] * df["two"]
In [71]: df["flag"] = df["one"] > 2

In [72]: df
Out[72]:
     one two three  flag
   NaN 4.0  NaN  False
   a  1.0  1.0  1.0  False
   b  2.0  2.0  4.0  False
   c  3.0  3.0  9.0   True
   d NaN  4.0 NaN  False
```

Columns can be deleted or popped like with a dict:

```
In [73]: del df["two"]
In [74]: three = df.pop("three")

In [75]: df
Out[75]:
     one  flag
   NaN  False
   a  1.0  False
   b  2.0  False
   c  3.0   True
   d NaN False
```

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [76]: df["foo"] = "bar"

In [77]: df
Out[77]:
     one  flag  foo
   NaN  False  bar
   a  1.0  False  bar
   b  2.0  False  bar
   c  3.0   True  bar
   d NaN False  bar
```

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:
In [78]: df["one_trunc"] = df["one"][0:2]

In [79]: df
Out[79]:
  one  flag  foo  one_trunc
  a  1.0  False  bar  1.0
  b  2.0  False  bar  2.0
  c  3.0   True  bar  NaN
  d  NaN  False  bar  NaN

You can insert raw ndarrays but their length must match the length of the DataFrame’s index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

In [80]: df.insert(1, "bar", df["one"])

In [81]: df
Out[81]:
  one  bar  flag  foo  one_trunc
  a  1.0  1.0  False  bar  1.0
  b  2.0  2.0  False  bar  2.0
  c  3.0  3.0   True  bar  NaN
  d  NaN  NaN  False  bar  NaN

Assigning new columns in method chains

Inspired by dplyr’s `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

In [82]: iris = pd.read_csv("data/iris.data")

In [83]: iris.head()
Out[83]:
  SepalLength  SepalWidth  PetalLength  PetalWidth  Name
  0  5.1         3.5         1.4         0.2  Iris-setosa
  1  4.9         3.0         1.4         0.2  Iris-setosa
  2  4.7         3.2         1.3         0.2  Iris-setosa
  3  4.6         3.1         1.5         0.2  Iris-setosa
  4  5.0         3.6         1.4         0.2  Iris-setosa

In [84]: iris.assign(sepal_ratio=iris["SepalWidth"] / iris["SepalLength"]).head()
Out[84]:
  SepalLength  SepalWidth  PetalLength  PetalWidth  Name  sepal_ratio
  0  5.1         3.5         1.4         0.2  Iris-setosa  0.686275
  1  4.9         3.0         1.4         0.2  Iris-setosa  0.612245
  2  4.7         3.2         1.3         0.2  Iris-setosa  0.680851
  3  4.6         3.1         1.5         0.2  Iris-setosa  0.673913
  4  5.0         3.6         1.4         0.2  Iris-setosa  0.720000

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.
assign always returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don’t have a reference to the DataFrame at hand. This is common when using assign in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

```python
In [86]: (  
    ....:     iris.query("SepalLength > 5")  
    ....:     .assign(  
    ....:         SepalRatio=lambda x: x.SepalWidth / x.SepalLength,  
    ....:         PetalRatio=lambda x: x.PetalWidth / x.PetalLength,  
    ....:     )  
    ....:     .plot(kind="scatter", x="SepalRatio", y="PetalRatio")  
    ....: )
Out[86]: <AxesSubplot:xlabel='SepalRatio', ylabel='PetalRatio'>
```
Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that’s been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn’t have a reference to the filtered DataFrame available.

The function signature for `assign` is simply **kwargs. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a Series or NumPy array), or a function of one argument to be called on the DataFrame. A copy of the original DataFrame is returned, with the new values inserted.

Starting with Python 3.6 the order of **kwargs is preserved. This allows for dependent assignment, where an expression later in **kwargs can refer to a column created earlier in the same `assign()`.

```
In [87]: dfa = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})

In [88]: dfa.assign(C=lambda x: x['A'] + x['B'], D=lambda x: x['A'] + x['C'])
Out[88]:
    A  B  C  D
0  1  4  5  6
1  2  5  7  9
2  3  6  9 12
```

In the second expression, x['C'] will refer to the newly created column, that’s equal to `dfa['A'] + dfa['B']`. 

2.2. Intro to data structures 189
Indexing / selection

The basics of indexing are as follows:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select column</td>
<td>df[col]</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by label</td>
<td>df.loc[label]</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by integer location</td>
<td>df.iloc[loc]</td>
<td>Series</td>
</tr>
<tr>
<td>Slice rows</td>
<td>df[5:10]</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Select rows by boolean vector</td>
<td>df[bool_vec]</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```python
In [89]: df.loc["b"]
Out[89]:
one    2.0
bar    2.0
flag   False
foo    bar
one_trunc  2.0
Name: b, dtype: object
```

```python
In [90]: df.iloc[2]
Out[90]:
one    3.0
bar    3.0
flag   True
foo    bar
one_trunc  NaN
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the section on indexing. We will address the fundamentals of reindexing / conforming to new sets of labels in the section on reindexing.

Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on both the columns and the index (row labels). Again, the resulting object will have the union of the column and row labels.

```python
In [91]: df = pd.DataFrame(np.random.randn(10, 4), columns=["A", "B", "C", "D"])  
In [92]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=["A", "B", "C"])  
In [93]: df + df2
Out[93]:
   A      B      C      D
0  0.045691 -0.014138 1.380871 NaN
1 -0.955398 -1.501007 0.037181 NaN
2 -0.662690 1.534833 -0.859691 NaN
3 -2.452949 1.237274 -2.320422 NaN
4  1.414490 1.951676 -2.320422 NaN
5 -0.494922 -1.649727 -1.084601 NaN
```

(continues on next page)
When doing an operation between DataFrame and Series, the default behavior is to align the Series index on the DataFrame columns, thus broadcasting row-wise. For example:

```
In [94]: df - df.iloc[0]
Out[94]:
    A    B    C    D
0  0.0  0.0  0.0  0.0
1 -1.4  0.1  0.2 -1.9
2  0.2  0.5 -1.3 -0.8
3 -1.3  0.1 -1.2  0.6
4  0.5  1.0 -1.7 -0.8
5 -1.7  0.8 -1.2 -2.0
6 -1.2  0.1 -0.1  0.0
7 -0.7  0.4 -0.9 -0.3
8 -1.2  1.3 -1.1 -1.4
9  2.3  1.8  0.7 -1.4
```

For explicit control over the matching and broadcasting behavior, see the section on flexible binary operations.

Operations with scalars are just as you would expect:

```
In [95]: df * 5 + 2
Out[95]:
    A    B    C    D
0  3.3  4.8  1.8  3.6
1 -3.4  2.6 -6.6 -0.7
2  4.6  4.4  1.7  4.7
3 -3.2  0.1 -3.8 -0.7
4  6.2  7.3  0.5  6.6
5  5.3  3.8  0.5  5.5
6 -2.8  4.1  0.2  5.3
7  0.4  0.9 -0.8 -0.7
8  2.6  6.4  0.2 -0.5
9  1.3  0.7  0.7 -0.8
```

```
In [96]: 1 / df
Out[96]:
    A      B      C     D
0  3.7  -2.3  1.7  3.6
1 -0.9  -1.4  8.7  0.7
2  1.9  2.4  1.7  0.6
3  0.9  0.2  9.1 -0.5
4  2.0  2.8  3.0 -0.5
5 -0.3  2.1 -1.3 -5.8
6  2.4  4.7  6.0 -4.0
7  0.3  1.9  1.7 -3.8
8 -0.3  1.1  1.2 -0.8
9  0.4  0.7  0.7 -0.8
```

(continues on next page)
Boolean operators work as well:

```python
In [98]: df1 = pd.DataFrame({'a': [1, 0, 1], 'b': [0, 1, 1]}, dtype=bool)
In [99]: df2 = pd.DataFrame({'a': [0, 1, 1], 'b': [1, 1, 0]}, dtype=bool)

In [100]: df1 & df2
Out[100]:
     a  b
 0  False  False
 1   True   True
 2  False    True

In [101]: df1 | df2
Out[101]:
     a  b
 0   True   True
 1   True   True
 2   True   True

In [102]: df1 ^ df2
Out[102]:
     a  b
 0   True   True
 1   True    False
 2  False   True

In [103]: -df1
Out[103]:
     a  b
 0  False   True
 1   True    False
 2  False    False
```
Transposing

To transpose, access the T attribute (also the transpose function), similar to an ndarray:

```python
# only show the first 5 rows
In [104]: df[:5].T
Out[104]:
          0      1      2      3      4
A  0.271860 -1.087401  0.524988 -1.039268  0.844885
B -0.424972 -0.673690  0.404705 -0.370647  1.075770
C  0.567020  0.113648  0.577046 -1.157892 -0.109050

```

DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, …) and various other NumPy functions can be used with no issues on Series and DataFrame, assuming the data within are numeric:

```python
In [105]: np.exp(df)
Out[105]:
          A         B         C         D
0  1.312403  0.653788  1.763006  1.318154
1  0.337092  0.509824  1.120358  0.227996
2  1.690438  1.498861  1.780770  0.179963
3  0.353713  0.690288  0.314148  0.260719
4  2.327710  2.932249  0.896686  5.173571
5  0.230066  1.429065  0.509360  0.169161
6  0.379495  0.274028  1.512461  1.318720
7  0.623732  0.986137  0.695904  0.993865
8  0.397301  2.449092  2.237242  0.299269
9 13.009059  4.183951  3.820223  0.310274

In [106]: np.asarray(df)
Out[106]:
array([[ 0.2719, -0.425 ,  0.567 ,  0.2762],
       [-1.0874, -0.6737,  0.1136, -1.4784],
       [ 0.525 ,  0.4047,  0.577 , -1.715 ],
       [-1.0393, -0.3706, -1.1579, -1.3443],
       [ 0.8449,  1.0758, -0.109 ,  1.6436],
       [-1.4694,  0.357 , -0.6746, -1.7769],
       [-0.9689, -1.2945,  0.4137,  0.2767],
       [-0.472 , -0.014 , -0.3625, -0.0062],
       [-0.9231,  0.8957,  0.8052, -1.2064],
       [ 2.5656,  1.4313,  1.3403, -1.1703]])
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics and data model are quite different in places from an n-dimensional array.

*Series* implements `__array_ufunc__`, which allows it to work with NumPy’s universal functions.

The ufunc is applied to the underlying array in a Series.

```python
In [107]: ser = pd.Series([1, 2, 3, 4])
```
In [108]: np.exp(ser)
Out[108]:
    0   2.718282
    1   7.389056
    2  20.085537
    3  54.598150
   dtype: float64

Changed in version 0.25.0: When multiple Series are passed to a ufunc, they are aligned before performing the operation.

Like other parts of the library, pandas will automatically align labeled inputs as part of a ufunc with multiple inputs. For example, using numpy.remainder() on two Series with differently ordered labels will align before the operation.

In [109]: ser1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [110]: ser2 = pd.Series([1, 3, 5], index=['b', 'a', 'c'])
In [111]: ser1
Out[111]:
    a  1
    b  2
    c  3
   dtype: int64
In [112]: ser2
Out[112]:
    b  1
    a  3
    c  5
   dtype: int64
In [113]: np.remainder(ser1, ser2)
Out[113]:
    a  NaN
    b  0
    c  3
   dtype: int64

As usual, the union of the two indices is taken, and non-overlapping values are filled with missing values.

In [114]: ser3 = pd.Series([2, 4, 6], index=['b', 'c', 'd'])
In [115]: ser3
Out[115]:
    b  2
    c  4
    d  6
   dtype: int64
In [116]: np.remainder(ser1, ser3)
Out[116]:
    a  NaN
When a binary ufunc is applied to a `Series` and `Index`, the Series implementation takes precedence and a Series is returned.

```python
In [117]: ser = pd.Series([1, 2, 3])
In [118]: idx = pd.Index([4, 5, 6])
In [119]: np.maximum(ser, idx)
Out[119]:
      0 1 2
0    4 5 6
```

NumPy ufuncs are safe to apply to `Series` backed by non-ndarray arrays, for example `arrays.SparseArray` (see Sparse calculation). If possible, the ufunc is applied without converting the underlying data to an ndarray.

## Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the `baseball` dataset from the `plyr` R package):

```python
In [120]: baseball = pd.read_csv("data/baseball.csv")
In [121]: print(baseball)
   id   player    year stint   team   lg   g   ab   r   h   X2b   X3b   hr   rbi   sb cs          bb          hbp          sh          sf          gidp
 0   88641  womacto01 2006   2     CHN   NL  19  50   6  14   1  0   1   2.0  1.0   1.0
 1   88643  schilcu01 2006   1     BOS   AL  31  2   0   1   0   0   0   0.0  0.0  0.0
...               ...               ...               ...               ...               ...
98  89533   aloumo01 2007   1     NYN   NL  87 328  51 112 19  1  13  49.0  3.0  0.0
99  89534  alomasa02 2007   1     NYN   NL  8   22   1   3   1   0   0   0.0  0.0  0.0
[100 rows x 23 columns]
```

```
In [122]: baseball.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 100 entries, 0 to 99
Data columns (total 23 columns):
   #   Column    Non-Null Count  Dtype
   ---  --------  --------------  ----
   0    id       100 non-null   int64
```

(continues on next page)

## 2.2. Intro to data structures
However, using `to_string` will return a string representation of the DataFrame in tabular form, though it won’t always fit the console width:

```
In [123]: print(baseball.iloc[-20:, :12].to_string())

    id   player year  stint  team  lg  g  ab  r  h  X2b  X3b
80  89474  finlest01  2007   1  COL  NL   43  94   9  17   3  0
81  89480  embreal01  2007   1  OAK  AL   4  0  0  0  0  0
82  89481  edmonji01  2007   1  SLN  NL  117  365  39  92  15  2
83  89482  easleda01  2007   1  NYN  NL  76  193  24  54  12  0
84  89489  delgaca01  2007   1  NYN  NL  139  538  71  139  30  0
85  89493  cormirh01  2007   1  CIN  NL   6  0  0  0  0  0
86  89494  coninje01  2007   2  NYN  AL  21  41  2  8  2  0
87  89495  coninje01  2007   1  CIN  NL  80  215  23  57  11  1
88  89497  clemero02  2007   1  NYA  AL   2  2  0  1  0  0
89  89498  claytro01  2007   2  BOS  AL   8  6  1  0  0  0
90  89499  claytro01  2007   1  TOR  AL  69  189  23  48  14  0
91  89501  cirilje01  2007   2  ARI  NL  28  40  6  8  4  0
92  89502  cirilje01  2007   1  MIN  AL  50  153  18  40  9  2
93  89521  bondsba01  2007   1  SFN  NL  126  340  75  94  14  0
94  89523  biggicr01  2007   1  HOU  NL  141  517  68  130  31  3
95  89525  benitar01  2007   2  FLO  NL  34  0  0  0  0  0
96  89526  benitar01  2007   1  SFN  NL  19  0  0  0  0  0
97  89530  ausmubr01  2007   1  HOU  NL  117  349  38  82  16  3
98  89533  aloumo01  2007   1  NYN  NL  87  328  51  112  19  1
99  89534  alomasa02  2007   1  NYN  NL  8  22  1  3  1  0
```

Wide DataFrames will be printed across multiple rows by default:
You can change how much to print on a single row by setting the `display.width` option:

```python
In [125]: pd.set_option("display.width", 40)  # default is 80
```

```python
In [126]: pd.DataFrame(np.random.randn(3, 12))
```

You can adjust the max width of the individual columns by setting `display.max_colwidth`

```python
In [127]: datafile = {
   .....:     "filename": ["filename_01", "filename_02"],
   .....:     "path": [
   .....:         "media/user_name/storage/folder_01/filename_01",
   .....:         "media/user_name/storage/folder_02/filename_02",
   .....:     ],
   .....: }
```

```python
In [128]: pd.set_option("display.max_colwidth", 30)
```

```python
In [129]: pd.DataFrame(datafile)
```

```python
In [130]: pd.set_option("display.max_colwidth", 100)
```

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

---

2.2. Intro to data structures  197
DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```
In [132]: df = pd.DataFrame({'foo1': np.random.randn(5), 'foo2': np.random.randn(5)})

In [133]: df
Out[133]:
   foo1   foo2
0  1.1262  0.7818
1 -0.9773 -1.0714
2  1.4741  0.4411
3 -0.0640  2.3539
4 -1.2828  0.5838
```

The columns are also connected to the IPython completion mechanism so they can be tab-completed:

```
In [5]: df.foo<TAB>  # noqa: E225, E999
df.foo1  df.foo2
```

2.3 Essential basic functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. To begin, let’s create some example objects like we did in the 10 minutes to pandas section:

```
In [1]: index = pd.date_range("1/1/2000", periods=8)

In [2]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])

In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=["A", "B", "C"])
```

2.3.1 Head and tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [4]: long_series = pd.Series(np.random.randn(1000))

In [5]: long_series.head()
Out[5]:
0   -1.157892
   ...
492  1.473155
493 -0.585269
500  0.916200
```

(continues on next page)
2.3.2 Attributes and underlying data

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray

- **Axis labels**
  - **Series**: index (only axis)
  - **DataFrame**: index (rows) and columns

Note, these attributes can be safely assigned to!

```python
In [7]: df[:2]
Out[7]:
          A         B         C
2000-01-01 -0.173215  0.119209 -1.044236
2000-01-02 -0.861849 -2.104569 -0.494929
```

```python
In [8]: df.columns = [x.lower() for x in df.columns]
```

```python
In [9]: df
Out[9]:
          a         b         c
2000-01-01 -0.173215  0.119209 -1.044236
2000-01-02 -0.861849 -2.104569 -0.494929
2000-01-03  1.071804  0.721555 -0.706771
2000-01-04 -1.039575  0.271860 -0.424972
2000-01-05  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427
2000-01-07  0.524988  0.404705  0.577046
2000-01-08 -1.715002 -1.039268 -0.370647
```

pandas objects (**Index**, **Series**, **DataFrame**) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a **numpy.ndarray**. However, pandas and 3rd party libraries may extend NumPy’s type system to add support for custom arrays (see **dtypes**).

To get the actual data inside a **Index** or **Series**, use the **.array** property.
In [10]: s.array
Out[10]:
<PandasArray>
[ 0.4691122999071863, -0.2828633443286633, -1.5090585031735124,
 -1.135632710171934,  1.2121120250208506]
Length: 5, dtype: float64

In [11]: s.index.array
Out[11]:
<PandasArray>
['a', 'b', 'c', 'd', 'e']
Length: 5, dtype: object

array will always be an ExtensionArray. The exact details of what an ExtensionArray is and why pandas uses them are a bit beyond the scope of this introduction. See dtypes for more.

If you know you need a NumPy array, use to_numpy() or numpy.asarray().

In [12]: s.to_numpy()
Out[12]:
array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])

In [13]: np.asarray(s)
Out[13]:
array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])

When the Series or Index is backed by an ExtensionArray, to_numpy() may involve copying data and coercing values. See dtypes for more.

to_numpy() gives some control over the dtype of the resulting numpy.ndarray. For example, consider datetimes with timezones. NumPy doesn’t have a dtype to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-dtype numpy.ndarray with Timestamp objects, each with the correct tz
2. A datetime64[ns]-dtype numpy.ndarray, where the values have been converted to UTC and the timezone discarded

Timezones may be preserved with dtype=object

In [14]: ser = pd.Series(pd.date_range("2000", periods=2, tz="CET"))

In [15]: ser.to_numpy(dtype=object)
Out[15]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET')], dtype=object)

Or thrown away with dtype='datetime64[ns]'s

In [16]: ser.to_numpy(dtype="datetime64[ns]"")
Out[16]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')

Getting the “raw data” inside a DataFrame is possibly a bit more complex. When your DataFrame only has a single data type for all the columns, DataFrame.to_numpy() will return the underlying data:
In [17]: df.to_numpy()
Out[17]:
array([[-0.1732, 0.1192, -1.0442],
       [-0.8618, -2.1046, -0.4949],
       [ 1.0718, 0.7216, -0.7068],
       [-1.0396, 0.2719, -0.425],
       [ 0.567, 0.2762, -1.0874],
       [-0.6737, 0.1136, -1.4784],
       [ 0.525, 0.4047, 0.577],
       [-1.715, -1.0393, -0.3706]])

If a DataFrame contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame’s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

Note: When working with heterogeneous data, the dtype of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a Series or DataFrame. You’ll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your Series contains an extension type, it’s unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an ExtensionArray, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.

2. When your DataFrame contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the DataFrame.

### 2.3.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have nans.

Here is a sample (using 100 column x 100,000 row DataFrames):

<table>
<thead>
<tr>
<th>Operation</th>
<th>0.11.0 (ms)</th>
<th>Prior Version (ms)</th>
<th>Ratio to Prior</th>
</tr>
</thead>
<tbody>
<tr>
<td>df1 &gt; df2</td>
<td>13.32</td>
<td>125.35</td>
<td>0.1063</td>
</tr>
<tr>
<td>df1 &quot; df2</td>
<td>21.71</td>
<td>36.63</td>
<td>0.5928</td>
</tr>
<tr>
<td>df1 + df2</td>
<td>22.04</td>
<td>36.50</td>
<td>0.6039</td>
</tr>
</tbody>
</table>

You are highly encouraged to install both libraries. See the section `Recommended Dependencies` for more installation info.

These are both enabled to be used by default, you can control this by setting the options:
2.3.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

Matching / broadcasting behavior

DataFrame has the methods `add`, `sub`, `mul`, `div` and related functions `radd`, `rsub`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

```python
In [18]: df = pd.DataFrame(
   ...:     {'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
   ...:      'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
   ...:      'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd'])},
   ...:     dtype='float64')

In [19]: df
Out[19]:
   one   two   three
a  1.394981  1.772517  NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d  NaN      0.279344 -0.613172

In [20]: row = df.iloc[1]
In [21]: column = df['two']
In [22]: df.sub(row, axis='columns')
Out[22]:
   one   two   three
a  1.051928 -0.139606  NaN
b  0.000000  0.000000  0.000000
c  0.352192 -0.433754  1.277825
d  NaN    -1.632779 -0.562782

In [23]: df.sub(row, axis=1)
Out[23]:
   one   two   three
a  1.051928 -0.139606  NaN
```

(continues on next page)
Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

```python
In [26]: dfmi = df.copy()

In [27]: dfmi.index = pd.MultiIndex.from_tuples(
    ....:     [(1, "a"), (1, "b"), (1, "c"), (2, "a")], names=["first", "second"]
    ....: )

In [28]: dfmi.sub(column, axis=0, level="second")
```

```
Out[28]:
         one two  three
first second
    1 a  -0.377535 0.000000  NaN
    b     -1.569069 0.000000 -1.962513
    c    -0.783123 0.000000 -0.250933
    2 a    NaN  -1.493173 -2.385688
```

Series and Index also support the `divmod()` built-in. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```python
In [29]: s = pd.Series(np.arange(10))

In [30]: s
```

```
Out[30]:
0    0
1    1
2    2
3    3
4    4
5    5
6    6
```

(continues on next page)
In [31]: div, rem = divmod(s, 3)

In [32]: div
Out[32]:
0  0
1  0
2  0
3  1
4  1
5  1
6  2
7  2
8  2
9  3
dtype: int64

In [33]: rem
Out[33]:
0  0
1  1
2  2
3  0
4  1
5  2
6  0
7  1
8  2
9  0
dtype: int64

In [34]: idx = pd.Index(np.arange(10))

In [35]: idx
Out[35]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')

In [36]: div, rem = divmod(idx, 3)

In [37]: div
Out[37]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')

In [38]: rem
Out[38]: Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')

We can also do elementwise *divmod*:

In [39]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])

(continues on next page)
In [40]: div
Out[40]:
0  0
1  0
2  0
3  1
4  1
5  1
6  1
7  1
8  1
9  1
dtype: int64

In [41]: rem
Out[41]:
0  0
1  1
2  2
3  0
4  0
5  1
6  1
7  2
8  2
9  3
dtype: int64

**Missing data / operations with fill values**

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

In [42]: df
Out[42]:
   one  two  three
a  1.394981  1.772517   NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d   NaN    0.279344 -0.613172

In [43]: df2
Out[43]:
   one  two  three
a  1.394981  1.772517  1.000000
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d   NaN    0.279344 -0.613172
Flexible comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```python
In [46]: df.gt(df2)
Out[46]:
    one  two  three
a  False False False
b  False False False
c  False False False
d  False False False
```

```python
In [47]: df2.ne(df)
Out[47]:
    one  two  three
a  False False  True
b  False False False
c  False False False
d   True  False  False
```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on *Boolean indexing*.

Boolean reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```python
In [48]: (df > 0).all()
Out[48]:
one  False
two  True
three False
dtype: bool
```

(continues on next page)
In [49]: (df > 0).any()
Out[49]:
one    True
two    True
three   True
dtype: bool

You can reduce to a final boolean value.

In [50]: (df > 0).any().any()
Out[50]: True

You can test if a pandas object is empty, via the `empty` property.

In [51]: df.empty
Out[51]: False

In [52]: pd.DataFrame(columns=list("ABC")).empty
Out[52]: True

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

In [53]: pd.Series([True]).bool()
Out[53]: True

In [54]: pd.Series([False]).bool()
Out[54]: False

In [55]: pd.DataFrame([[True]]).bool()
Out[55]: True

In [56]: pd.DataFrame([[False]]).bool()
Out[56]: False

Warning: You might be tempted to do the following:

>>> if df:
...    pass

Or

>>> df and df2

These will both raise errors, as you are trying to compare multiple values.: ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().

See gotchas for a more detailed discussion.
Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider \( df + df \) and \( df * 2 \). To test that these two computations produce the same result, given the tools shown above, you might imagine using \((df + df == df * 2).all()\). But in fact, this expression is False:

```
In [57]: df + df == df * 2
Out[57]:
     one   two  three
a  True  True  False
b  True  True   True
c  True  True   True
d False  True   True

In [58]: (df + df == df * 2).all()
Out[58]:
   one  False
two   True
three False
dtype: bool
```

Notice that the boolean DataFrame \( df + df == df * 2 \) contains some False values! This is because NaNs do not compare as equals:

```
In [59]: np.nan == np.nan
Out[59]: False
```

So, NDFrames (such as Series and DataFrames) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [60]: (df + df).equals(df * 2)
Out[60]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [61]: df1 = pd.DataFrame({"col": ["foo", 0, np.nan]})

In [62]: df2 = pd.DataFrame({"col": [np.nan, 0, "foo"], index=[2, 1, 0]})

In [63]: df1.equals(df2)
Out[63]: False

In [64]: df1.equals(df2.sort_index())
Out[64]: True
```
Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

In [65]: pd.Series(["foo", "bar", "baz"]) == "foo"
Out[65]:
0   True
1   False
2   False
dtype: bool

In [66]: pd.Index(["foo", "bar", "baz"]) == "foo"
Out[66]: array([ True, False, False])

pandas also handles element-wise comparisons between different array-like objects of the same length:

In [67]: pd.Series(["foo", "bar", "baz"]) == pd.Index(["foo", "bar", "qux"])
Out[67]:
0   True
1   True
2   False
dtype: bool

In [68]: pd.Series(["foo", "bar", "baz"]) == np.array(["foo", "bar", "qux"])
Out[68]:
0   True
1   True
2   False
dtype: bool

Trying to compare Index or Series objects of different lengths will raise a ValueError:

In [55]: pd.Series(["foo", "bar", "baz"]) == pd.Series(["foo", "bar"])
ValueError: Series lengths must match to compare

In [56]: pd.Series(["foo", "bar", "baz"]) == pd.Series(["foo"])
ValueError: Series lengths must match to compare

Note that this is different from the NumPy behavior where a comparison can be broadcast:

In [69]: np.array([1, 2, 3]) == np.array([2])
Out[69]: array([False, True, False])

or it can return False if broadcasting can not be done:

In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

```python
In [71]: df1 = pd.DataFrame(
       ....:     {"A": [1.0, np.nan, 3.0, 5.0, np.nan], "B": [np.nan, 2.0, 3.0, np.nan, 6.0]}
       ....: )
       ....:

In [72]: df2 = pd.DataFrame(
       ....:     {
       ....:         "A": [5.0, 2.0, 4.0, np.nan, 3.0, 7.0],
       ....:         "B": [np.nan, np.nan, 3.0, 4.0, 6.0, 8.0],
       ....:     }
       ....: )
       ....:

In [73]: df1
Out[73]:
   A  B
0  1.0 NaN
1 NaN  2.0
2  3.0  3.0
3  5.0 NaN
4 NaN  6.0

In [74]: df2
Out[74]:
   A  B
0  5.0 NaN
1  2.0 NaN
2  4.0  3.0
3 NaN  4.0
4  3.0  6.0
5  7.0  8.0

In [75]: df1.combine_first(df2)
Out[75]:
   A  B
0  1.0 NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0
```
General DataFrame combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```python
In [76]: def combiner(x, y):
    ....:     return np.where(pd.isna(x), y, x)
    ....:

In [77]: df1.combine(df2, combiner)
Out[77]:
   A  B
0  1.0 NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0
```

### 2.3.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on `Series`, `DataFrame`. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an `axis` argument, just like `ndarray.(sum, std, ...)`, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)

For example:

```python
In [78]: df
Out[78]:
   one  two  three
a 1.394981 1.772517 NaN
b 0.343054 1.912123 -0.050390
c 0.695246 1.478369 1.227435
d  NaN 0.279344 -0.613172

In [79]: df.mean(0)
Out[79]:
   one  0.811094
two  1.360588
three 0.187958
dtype: float64

In [80]: df.mean(1)
Out[80]:
   a  1.583749
   b  1.032601
   c  1.060464
   d  0.279344
```

(continues on next page)
All such methods have a `skipna` option signaling whether to exclude missing data (True by default):

```python
In [81]: df.sum(0, skipna=False)
Out[81]:
one   NaN
two  5.442353
three  NaN
dtype: float64
```

```python
In [82]: df.sum(axis=1, skipna=True)
Out[82]:
a  3.167498
b  2.204786
c  3.401050
d -0.333828
dtype: float64
```

Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation of 1), very concisely:

```python
In [83]: ts_stand = (df - df.mean()) / df.std()
In [84]: ts_stand.std()
Out[84]:
one   1.0
two   1.0
three  1.0
dtype: float64
```

```python
In [85]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)
In [86]: xs_stand.std(1)
Out[86]:
a  1.0
b  1.0
c  1.0
d  1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()` since NaN behavior is furthermore dictated by a `min_periods` parameter.

```python
In [87]: df.cumsum()
Out[87]:
              one   two   three
a  1.394981  1.772517   NaN
b  1.738035  3.684640 -0.050390
```

(continues on next page)
Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a hierarchical index.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>Number of non-NA observations</td>
</tr>
<tr>
<td>sum</td>
<td>Sum of values</td>
</tr>
<tr>
<td>mean</td>
<td>Mean of values</td>
</tr>
<tr>
<td>mad</td>
<td>Mean absolute deviation</td>
</tr>
<tr>
<td>median</td>
<td>Arithmetic median of values</td>
</tr>
<tr>
<td>min</td>
<td>Minimum</td>
</tr>
<tr>
<td>max</td>
<td>Maximum</td>
</tr>
<tr>
<td>mode</td>
<td>Mode</td>
</tr>
<tr>
<td>abs</td>
<td>Absolute Value</td>
</tr>
<tr>
<td>prod</td>
<td>Product of values</td>
</tr>
<tr>
<td>std</td>
<td>Bessel-corrected sample standard deviation</td>
</tr>
<tr>
<td>var</td>
<td>Unbiased variance</td>
</tr>
<tr>
<td>sem</td>
<td>Standard error of the mean</td>
</tr>
<tr>
<td>skew</td>
<td>Sample skewness (3rd moment)</td>
</tr>
<tr>
<td>kurt</td>
<td>Sample kurtosis (4th moment)</td>
</tr>
<tr>
<td>quantile</td>
<td>Sample quantile (value at %)</td>
</tr>
<tr>
<td>cumsum</td>
<td>Cumulative sum</td>
</tr>
<tr>
<td>cumprod</td>
<td>Cumulative product</td>
</tr>
<tr>
<td>cummax</td>
<td>Cumulative maximum</td>
</tr>
<tr>
<td>cummin</td>
<td>Cumulative minimum</td>
</tr>
</tbody>
</table>

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [88]: np.mean(df["one"])
Out[88]: 0.8110935116651192

In [89]: np.mean(df["one"].to_numpy())
Out[89]: nan
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```
In [90]: series = pd.Series(np.random.randn(500))
In [91]: series[20:500] = np.nan
In [92]: series[10:20] = 5
In [93]: series.nunique()
Out[93]: 11
```
### Summarizing data: `describe`

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [94]: series = pd.Series(np.random.randn(1000))
In [95]: series[::2] = np.nan
In [96]: series.describe()
Out[96]:
    count      500.000000
    mean    -0.021292
    std      1.015906
    min     -2.683763
    25%   -0.699070
    50%   -0.069718
    75%    0.714483
    max     3.160915
    dtype: float64
```

```
In [97]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e'])
In [98]: frame.iloc[::2] = np.nan
In [99]: frame.describe()
Out[99]:
      a          b          c          d          e
      count  500.000000  500.000000  500.000000  500.000000  500.000000
      mean   0.033387   0.030045   -0.043719  -0.051686   0.005979
      std    1.017152   0.978743   1.025270   1.015988   1.006695
      25%  -0.647623  -0.576449  -0.712369  -0.691338  -0.691115
      50%   0.047578  -0.021499  -0.023888  -0.032652  -0.025363
      75%   0.729907   0.775880   0.618896   0.670047   0.649748
      max   2.740139   2.752332   3.004229   2.728702   3.240991
```

You can select specific percentiles to include in the output:

```
In [100]: series.describe(percentiles=[0.05, 0.25, 0.75, 0.95])
Out[100]:
    count      500.000000
    mean    -0.021292
    std      1.015906
    min     -2.683763
    5%     -1.645423
    25%    -0.699070
    50%   -0.069718
    75%    0.714483
    95%    1.711409
    max     3.160915
    dtype: float64
```
By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```python
In [101]: s = pd.Series(["a", "a", "b", "b", "a", "a", np.nan, "c", "d", "a"])

In [102]: s.describe()
Out[102]:
         count    9
     unique    4
          top    a
          freq    5
dtype: object
```

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```python
In [103]: frame = pd.DataFrame({"a": ["Yes", "Yes", "No", "No"], "b": range(4)})

In [104]: frame.describe()
Out[104]:
       b
count 4.000000
mean  1.500000
std   1.290994
min   0.000000
25%   0.750000
50%   1.500000
75%   2.250000
max   3.000000
```

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```python
In [105]: frame.describe(include=["object"])
Out[105]:
        a
    count   4
    unique   2
        top   Yes
        freq   2

In [106]: frame.describe(include=["number"])
Out[106]:
         b
    count 4.000000
    mean  1.500000
     std  1.290994
    min   0.000000
   25%   0.750000
   50%   1.500000
   75%   2.250000
    max  3.000000
```

(continues on next page)
That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

**Index of min/max values**

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:
When there are multiple rows (or columns) matching the minimum or maximum value, \texttt{idxmin()} and \texttt{idxmax()} return the first matching index:

```python
In [115]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=["A"], index=list("edcba"))
In [116]: df3
Out[116]:
    A
  e  2.0
  d  1.0
  c  1.0
  b  3.0
  a  NaN
In [117]: df3["A"].idxmin()
Out[117]: 'd'
```

Note: \texttt{idxmin} and \texttt{idxmax} are called \texttt{argmin} and \texttt{argmax} in NumPy.

### Value counts (histogramming) / mode

The \texttt{value_counts()} Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```python
In [118]: data = np.random.randint(0, 7, size=50)
In [119]: data
Out[119]: array([6, 6, 2, 3, 5, 3, 2, 5, 4, 5, 4, 3, 4, 5, 0, 2, 0, 4, 2, 0, 3, 2,
           2, 5, 6, 5, 3, 4, 6, 4, 3, 5, 6, 4, 3, 6, 2, 6, 6, 2, 3, 4, 2, 1,
           6, 2, 6, 1, 5, 4])
In [120]: s = pd.Series(data)
In [121]: s.value_counts()
Out[121]:
6    10
```

(continues on next page)
New in version 1.1.0.

The `value_counts()` method can be used to count combinations across multiple columns. By default all columns are used but a subset can be selected using the `subset` argument.

```python
In [123]: data = {"a": [1, 2, 3, 4], "b": ["x", "x", "y", "y"]}

In [124]: frame = pd.DataFrame(data)

In [125]: frame.value_counts()
Out[125]:
a  b
1  x  1
2  x  1
3  y  1
4  y  1
dtype: int64
```

Similarly, you can get the most frequently occurring value(s), i.e. the mode, of the values in a Series or DataFrame:

```python
In [126]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])

In [127]: s5.mode()
Out[127]:
0  3
1  7
dtype: int64

In [128]: df5 = pd.DataFrame(
   ......:   { .....:       "A": np.random.randint(0, 7, size=50), .....:       "B": np.random.randint(-10, 15, size=50), .....:   ......:     })
......:
```
In [129]: df5.mode()
Out[129]:
   A  B
0  1.0 -9
1  NaN 10
2  NaN 13

Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

In [130]: arr = np.random.randn(20)
In [131]: factor = pd.cut(arr, 4)
In [132]: factor
Out[132]:
[(-0.251, 0.464], (-0.968, -0.251], (0.464, 1.179], (-0.251, 0.464], (-0.968, -0.251], ...
˓→]
Length: 20
Categories (4, interval[float64, right]): 

In [133]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])
In [134]: factor
Out[134]:
[(0, 1], (-1, 0], (0, 1], (0, 1], (-1, 0], ..., (-1, 0], (-1, 0], (-1, 0], (-1, 0], (-1, 0]
˓→]
Length: 20
Categories (4, interval[int64, right]): 

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

In [135]: arr = np.random.randn(30)
In [136]: factor = pd.qcut(arr, [0, 0.25, 0.5, 0.75, 1])
In [137]: factor
Out[137]:
[(0.569, 1.184], (-2.278, -0.301], (-2.278, -0.301], (0.569, 1.184], (0.569, 1.184], ...
˓→]
Length: 30
Categories (4, interval[float64, right]): ...

(continues on next page)
We can also pass infinite values to define the bins:

```python
In [139]: arr = np.random.randn(20)
In [140]: factor = pd.cut(arr, [-np.inf, 0, np.inf])
In [141]: factor
```

```
[(-inf, 0.0], (0.0, inf], (0.0, inf], (-inf, 0.0], (-inf, 0.0], ..., (-inf, 0.0], (-inf, ...
...0.0], (-inf, 0.0], (0.0, inf], (0.0, inf]
Length: 20
Categories (2, interval[float64, right]): [(-inf, 0.0] < (0.0, inf]]
```

### 2.3.6 Function application

To apply your own or another library’s functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. **Tablewise Function Application**: `pipe()`
2. **Row or Column-wise Function Application**: `apply()`
3. **Aggregation API**: `agg()` and `transform()`
4. **Applying Elementwise Functions**: `applymap()`

#### Tablewise function application

DataFrames and Series can be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method.

First some setup:

```python
In [142]: def extract_city_name(df):
   ....:     """
   ....:     Chicago, IL -> Chicago for city_name column
   ....:     """
   ....:     df["city_name"] = df["city_and_code"].str.split(",").str.get(0)
   ....:     return df
   ....:
In [143]: def add_country_name(df, country_name=None):
```

(continues on next page)
extract_city_name and add_country_name are functions taking and returning DataFrames.

Now compare the following:

```python
In [144]: df_p = pd.DataFrame({"city_and_code": ["Chicago, IL"]})
```

```python
In [145]: add_country_name(extract_city_name(df_p), country_name="US")
Out[145]:
   city_and_code   city_name city_and_country
0       Chicago, IL     Chicago      ChicagoUS
```

Is equivalent to:

```python
In [146]: df_p.pipe(extract_city_name).pipe(add_country_name, country_name="US")
Out[146]:
   city_and_code   city_name city_and_country
0       Chicago, IL     Chicago      ChicagoUS
```

pandas encourages the second style, which is known as method chaining. pipe makes it easy to use your own or another library’s functions in method chains, alongside pandas’ methods.

In the example above, the functions extract_city_name and add_country_name each expected a DataFrame as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide pipe with a tuple of (callable, data_keyword) .pipe will route the DataFrame to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a DataFrame as the second argument, data. We pass in the function, keyword pair (sm.ols, 'data') to pipe:

```python
In [147]: import statsmodels.formula.api as sm

In [148]: bb = pd.read_csv("data/baseball.csv", index_col="id")

In [149]: (bb.query("h > 0")
    ...:   .assign(ln_h=lambda df: np.log(df.h))
    ...:   .pipe((sm.ols, "data"), "hr ~ ln_h + year + g + C(lg)")
    ...:   .fit()
    ...:   .summary()
    ...: )
```

```python
Out[149]:
<class 'statsmodels.iolib.summary.Summary'>

   OLS Regression Results
   =======================
```

(continues on next page)
The pipe method is inspired by unix pipes and more recently dplyr and magrittr, which have introduced the popular (%>%) (read pipe) operator for R. The implementation of pipe here is quite clean and feels right at home in Python. We encourage you to view the source code of pipe().

Row or column-wise function application

Arbitrary functions can be applied along the axes of a DataFrame using the apply() method, which, like the descriptive statistics methods, takes an optional axis argument:

In [150]: df.apply(np.mean)
Out[150]:
one 0.811094
two 1.360588
three 0.187958
dtype: float64

In [151]: df.apply(np.mean, axis=1)
Out[151]:
a 1.583749
b 0.734929
c  1.133683
d  -0.166914
dtype: float64

In [152]: df.apply(lambda x: x.max() - x.min())
Out[152]:
one    1.051928
two    1.632779
three  1.840607
dtype: float64

In [153]: df.apply(np.cumsum)
Out[153]:
          one    two    three
  a     1.394981  1.772517    NaN
  b     1.738035  3.684640 -0.050390
  c     2.433281  5.163008  1.177045
  d    NaN      5.442353  0.563873

In [154]: df.apply(np.exp)
Out[154]:
          one    two    three
  a     4.034899  5.885648    NaN
  b     1.409244  6.767440  0.950858
  c     2.004201  4.385785  3.412466
  d    NaN      1.322262  0.541630

The `apply()` method will also dispatch on a string method name.

In [155]: df.apply("mean")
Out[155]:
          one    two    three
  a    0.811094  0.577098    NaN
  b    1.360588  1.540847 -0.050390
  c    0.187958  1.133683  0.306742
  d    NaN      0.541630  0.166914
dtype: float64

In [156]: df.apply("mean", axis=1)
Out[156]:
          a    b    c    d
  a    1.583749  0.734929  1.133683 -0.166914
dtype: float64

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-likes return values expand (or not) to a `DataFrame`.  

2.3. Essential basic functionality
apply() combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```python
In [157]: tsdf = pd.DataFrame(
    .....: np.random.randn(1000, 3),
    .....: columns=['A', 'B', 'C'],
    .....: index=pd.date_range('1/1/2000', periods=1000),
    .....: )

In [158]: tsdf.apply(lambda x: x.idxmax())
```

```python
Out[158]:
     A     B     C
2000-08-06  NaN  NaN  NaN
2001-01-18  NaN  NaN  NaN
2001-07-18  NaN  NaN  NaN
```

You may also pass additional arguments and keyword arguments to the apply() method. For instance, consider the following function you would like to apply:

```python
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```python
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

```python
In [159]: tsdf
Out[159]:
     A     B     C
2000-01-01 -0.158131 -0.232466 0.321604
2000-01-02 -1.810340 -3.105758 0.433834
2000-01-03 -1.209847 -1.156793 -0.136794
2000-01-04 NaN   NaN   NaN
2000-01-05 NaN   NaN   NaN
2000-01-06 NaN   NaN   NaN
2000-01-07 NaN   NaN   NaN
2000-01-08 -0.653602 0.178875 1.008298
2000-01-09 1.007996 0.462824 0.254472
2000-01-10 0.307473 0.600337 1.643950

In [160]: tsdf.apply(pd.Series.interpolate)
Out[160]:
     A     B     C
2000-01-01 -0.158131 -0.232466 0.321604
2000-01-02 -1.810340 -3.105758 0.433834
2000-01-03 -1.209847 -1.156793 -0.136794
2000-01-04 -1.098598 -0.889659 0.092225
2000-01-05 -0.987349 -0.622526 0.321243
2000-01-06 -0.876100 -0.355392 0.550262
2000-01-07 -0.764851 -0.088259 0.779280
2000-01-08 -0.653602 0.178875 1.008298
```

(continues on next page)
Finally, `apply()` takes an argument `raw` which is False by default, which converts each row or column into a Series before applying the function. When set to True, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

### Aggregation API

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see `groupby API`, the `window API`, and the `resample API`. The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [161]: tsdf = pd.DataFrame(
        ....:     np.random.randn(10, 3),
        ....:     columns=['A', 'B', 'C'],
        ....:     index=pd.date_range("1/1/2000", periods=10),
        ....:     )

In [162]: tsdf.iloc[3:7] = np.nan

In [163]: tsdf
```

```
Out[163]:
          A      B      C
2000-01-01  1.257606  1.004194  0.167574
2000-01-02  0.363709 -0.632537 -0.721178
2000-01-03  0.629427  0.194220 -0.351242
2000-01-04  NaN     NaN     NaN
2000-01-05  NaN     NaN     NaN
2000-01-06  NaN     NaN     NaN
2000-01-07  NaN     NaN     NaN
2000-01-08  0.814347  0.257623  0.869226
2000-01-09  -0.250663 -1.206601  0.896839
2000-01-10  2.169758 -1.333363  0.283157
```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```
In [164]: tsdf.agg(np.sum)
Out[164]:
A   3.033606
B  -1.803879
C   1.575510
dtype: float64

In [165]: tsdf.agg("sum")
Out[165]:
A   3.033606
B  -1.803879
```
C 1.575510
dtype: float64

# these are equivalent to a `.sum()` because we are aggregating
# on a single function
In [166]: tsdf.sum()
Out[166]:
A  3.033606
B -1.803879
C  1.575510
dtype: float64

Single aggregations on a Series this will return a scalar value:

In [167]: tsdf["A"].agg("sum")
Out[167]: 3.033606102414146

Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

In [168]: tsdf.agg(["sum"])  
Out[168]:
   A  B  C
sum 3.033606 -1.803879  1.575510

Multiple functions yield multiple rows:

In [169]: tsdf.agg(["sum", "mean"])
Out[169]:
   A  B     C
sum 3.033606 -1.803879  1.575510
mean 0.505601  0.300647  0.262585

On a Series, multiple functions return a Series, indexed by the function names:

In [170]: tsdf["A"].agg(["sum", "mean"])
Out[170]:
sum 3.033606
mean 0.505601
Name: A, dtype: float64

Passing a lambda function will yield a <lambda> named row:

In [171]: tsdf["A"].agg(["sum", lambda x: x.mean()])
Out[171]:
sum 3.033606
<lambda> 0.505601
Name: A, dtype: float64

Passing a named function will yield that name for the row:
```python
In [172]: def mymean(x):
.....:     return x.mean()
.....:

In [173]: tsdf["A"].agg(\"sum\", mymean)
Out[173]:
    sum  3.033606
    mymean  0.505601
Name: A, dtype: float64
```

## Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

```python
In [174]: tsdf.agg({"A": "mean", "B": "sum"})
Out[174]:
   A   B
0  0.505601 -1.803879
```

Passing a list-like will generate a `DataFrame` output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be `NaN`:

```python
In [175]: tsdf.agg({"A": ["mean", "min"], "B": "sum"})
Out[175]:
      A   B
   mean  0.505601   NaN
   min -0.749892   NaN
   sum   NaN -1.803879
```

## Mixed dtypes

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `.groupby.agg` works.

```python
In [176]: mdf = pd.DataFrame(
      .....:     {  
      .....:         "A": [1, 2, 3],
      .....:         "B": [1.0, 2.0, 3.0],
      .....:         "C": ["foo", "bar", "baz"],
      .....:         "D": pd.date_range("20130101", periods=3),
      .....:     })
      .....:

In [177]: mdf.dtypes
Out[177]:
   A  int64
```
Custom describe

With `.agg()` it is possible to easily create a custom describe function, similar to the built in `describe function`.

```
In [179]: from functools import partial

In [180]: q_25 = partial(pd.Series.quantile, q=0.25)

In [181]: q_25.__name__ = "25%"

In [182]: q_75 = partial(pd.Series.quantile, q=0.75)

In [183]: q_75.__name__ = "75%"

In [184]: tsdf.agg(["count", "mean", "std", "min", q_25, "median", q_75, "max"])
```

```
Out[184]:
             A         B         C
count 6.000000 6.000000 6.000000
mean  0.505601 -0.300647 0.262585
std   1.103362 0.887508 0.606860
min  -0.749892 -1.333363 -0.757304
25%   -0.239885 -0.979600 0.128907
median 0.303398 -0.278111 0.225365
75%   1.146791  0.151678 0.722709
max   2.169758  1.004194 0.896839
```

Transform API

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide multiple operations at the same time rather than one-by-one. Its API is quite similar to the `.agg API.

We create a frame similar to the one used in the above sections.

```
In [185]: tsdf = pd.DataFrame(
                  np.random.randn(10, 3),
                  columns=["A", "B", "C"],
                  index=pd.date_range("1/1/2000", periods=10),
                  )
```

In [186]: tsdf.iloc[3:7] = np.nan

In [187]: tsdf
Out[187]:
   A      B      C
0  2000-01-01 -0.428759 -0.864890 -0.675341
1  2000-01-02 -0.168731  1.338144 -1.279321
2  2000-01-03  1.621034  0.438107  0.903794
3  2000-01-04   NaN   NaN   NaN
4  2000-01-05   NaN   NaN   NaN
5  2000-01-06   NaN   NaN   NaN
6  2000-01-07   NaN   NaN   NaN
7  2000-01-08  0.254374 -1.240447 -0.201052
8  2000-01-09 -0.157795  0.791197 -1.144209
9  2000-01-10 -0.030876  0.371900  0.061932

Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

In [188]: tsdf.transform(np.abs)
Out[188]:
   A      B      C
0  2000-01-01  0.428759  0.864890  0.675341
1  2000-01-02  0.168731  1.338144  1.279321
2  2000-01-03  1.621034  0.438107  0.903794
3  2000-01-04   NaN   NaN   NaN
4  2000-01-05   NaN   NaN   NaN
5  2000-01-06   NaN   NaN   NaN
6  2000-01-07   NaN   NaN   NaN
7  2000-01-08  0.254374  1.240447  0.201052
8  2000-01-09  0.157795  0.791197  1.144209
9  2000-01-10  0.030876  0.371900  0.061932

In [189]: tsdf.transform("abs")
Out[189]:
   A      B      C
0  2000-01-01  0.428759  0.864890  0.675341
1  2000-01-02  0.168731  1.338144  1.279321
2  2000-01-03  1.621034  0.438107  0.903794

6  2000-01-07   NaN   NaN   NaN
7  2000-01-08  0.254374  1.240447  0.201052
8  2000-01-09  0.157795  0.791197  1.144209
9  2000-01-10  0.030876  0.371900  0.061932

In [190]: tsdf.transform(lambda x: x.abs())
Out[190]:
   A      B      C
0  2000-01-01  0.428759  0.864890  0.675341

(continues on next page)
Here `transform()` received a single function; this is equivalent to a `ufunc` application.

```python
In [191]: np.abs(tsdf)
Out[191]:
          A       B       C
2000-01-01 0.428759 0.864890 0.675341
2000-01-02 0.168731 1.338144 1.279321
2000-01-03 1.621034 0.438107 0.903794
2000-01-04   NaN      NaN      NaN
2000-01-05   NaN      NaN      NaN
2000-01-06   NaN      NaN      NaN
2000-01-07   NaN      NaN      NaN
2000-01-08 0.254374 1.240447 0.201052
2000-01-09 0.157795 0.791197 1.144209
2000-01-10 0.030876 0.371900 0.061932
```

Passing a single function to `.transform()` with a Series will yield a single Series in return.

```python
In [192]: tsdf['A'].transform(np.abs)
Out[192]:
          A
2000-01-01 0.428759
2000-01-02 0.168731
2000-01-03 1.621034
2000-01-04   NaN
2000-01-05   NaN
2000-01-06   NaN
2000-01-07   NaN
2000-01-08 0.254374
2000-01-09 0.157795
2000-01-10 0.030876
Freq: D, Name: A, dtype: float64
```

### Transform with multiple functions

Passing multiple functions will yield a column MultiIndexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```python
In [193]: tsdf.transform([np.abs, lambda x: x + 1])
Out[193]:
          A       B       C
           absolute <lambda> absolute <lambda> absolute <lambda>
2000-01-01 0.428759 0.428759 0.428759 0.428759 0.428759
2000-01-02 0.168731 0.215802 0.168731 0.215802 0.168731
2000-01-03 1.621034 2.621034 1.621034 2.621034 1.621034
2000-01-04   NaN      NaN      NaN      NaN      NaN
2000-01-05   NaN      NaN      NaN      NaN      NaN
2000-01-06   NaN      NaN      NaN      NaN      NaN
2000-01-07   NaN      NaN      NaN      NaN      NaN
2000-01-08 0.254374 0.304847 0.254374 0.304847 0.254374
2000-01-09 0.157795 0.205590 0.157795 0.205590 0.157795
2000-01-10 0.030876 0.061752 0.030876 0.061752 0.030876
```

(continues on next page)
Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```python
In [194]: tsdf["A"].transform([np.abs, lambda x: x + 1])
Out[194]:
   absolute <lambda>
2000-01-01  0.428759  0.571241
2000-01-02  0.168731  0.831269
2000-01-03  1.621034  1.240447
2000-01-04  NaN     NaN
2000-01-05  NaN     NaN
2000-01-06  NaN     NaN
2000-01-07  NaN     NaN
2000-01-08  0.254374  1.254374
2000-01-09  0.157795  0.842205
2000-01-10  0.030876  0.969124
```

Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```python
In [195]: tsdf.transform({"A": np.abs, "B": lambda x: x + 1})
Out[195]:
   A     B
2000-01-01  0.428759  0.135110
2000-01-02  0.168731  2.338144
2000-01-03  1.621034  1.438107
2000-01-04  NaN      NaN
2000-01-05  NaN      NaN
2000-01-06  NaN      NaN
2000-01-07  NaN      NaN
2000-01-08  0.254374  1.254374
2000-01-09  0.157795  1.791197
2000-01-10  0.030876  1.371900
```

Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```python
In [196]: tsdf.transform({"A": np.abs, "B": [lambda x: x + 1, "sqrt"]})
Out[196]:
   A     B
2000-01-01  0.428759  0.324659
2000-01-02  0.168731  2.338144
2000-01-03  1.621034  1.438107
2000-01-04  NaN      NaN
2000-01-05  NaN      NaN
2000-01-06  NaN      NaN
2000-01-07  NaN      NaN
2000-01-08  0.254374  1.903794
2000-01-09  0.157795  1.279321
2000-01-10  0.030876  0.675341
```
Applying elementwise functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```
In [197]: df4
Out[197]:
one  two  three
a  1.394981  1.772517  NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d  NaN     0.279344 -0.613172
```

```
In [198]: def f(x):
.....:     return len(str(x))
.....: 
In [199]: df4["one"].map(f)
Out[199]:
a  18
b  19
c  18
d  3
Name: one, dtype: int64
```

```
In [200]: df4.applymap(f)
Out[200]:
one  two  three
  a  18   17  15
  b  19   18  23
  c  18   18  16
  d  3    19  19
```

`Series.map()` has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to merging/joining functionality:

```
In [201]: s = pd.Series(
.....:     ["six", "seven", "six", "seven", "six"], index=["a", "b", "c", "d", "e"])
```

(continues on next page)
In [202]: t = pd.Series({"six": 6.0, "seven": 7.0})

In [203]: s
Out[203]:
   a    six
   b    seven
   c    six
   d    seven
   e    six
   dtype: object

In [204]: s.map(t)
Out[204]:
   a   6.0
   b   7.0
   c   6.0
   d   7.0
   e   6.0
   dtype: float64

### 2.3.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To *reindex* means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, fill data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

In [205]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])

In [206]: s
Out[206]:
   a    1.695148
   b    1.328614
   c    1.234686
   d   -0.385845
   e   -1.326508
   dtype: float64

In [207]: s.reindex(["e", "b", "f", "d"])
Out[207]:
   e   -1.326508
   b    1.328614
   f     NaN

(continues on next page)
Here, the $f$ label was not contained in the Series and hence appears as $\text{NaN}$ in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

```
In [208]: df
Out[208]:
   one   two   three
a  1.394981  1.772517    NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d    NaN     0.279344 -0.613172
```

```
In [209]: df.reindex(index=["c", "f", "b"], columns=["three", "two", "one"])
Out[209]:
   three   two   one
  c  1.227435  1.478369  0.695246
  f    NaN    NaN    NaN
  b -0.050390  1.912123  0.343054
```

You may also use `reindex` with an `axis` keyword:

```
In [210]: df.reindex(["c", "f", "b"], axis="index")
Out[210]:
   one   two   three
  c  0.695246  1.478369  1.227435
  f    NaN    NaN    NaN
  b  0.343054  1.912123 -0.050390
```

Note that the `Index` objects containing the actual axis labels can be **shared** between objects. So if we have a Series and a DataFrame, the following can be done:

```
In [211]: rs = s.reindex(df.index)

In [212]: rs
Out[212]:
   a  1.695148
   b  1.328614
   c  0.695246
   d -0.385845

In [213]: rs.index is df.index
Out[213]: True
```

This means that the reindexed Series’s index is the same Python object as the DataFrame’s index.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single `labels` argument and the axis it applies to.

```
In [214]: df.reindex(["c", "f", "b"], axis="index")
Out[214]:
```

(continues on next page)
See also:

_MultiIndex / Advanced Indexing_ is an even more concise way of doing reindexing.

**Note:** When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: _many operations are faster on pre-aligned data_. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because _reindex_ has been heavily optimized), but when CPU cycles matter sprinkling a few explicit _reindex_ calls here and there can have an impact.

### Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the _reindex_like()_ method is available to make this simpler:

```
In [216]: df2
Out[216]:
   one     two
a  1.394981  1.772517
b  0.343054  1.912123
c  0.695246  1.478369

In [217]: df3
Out[217]:
   one     two
a  0.583888  0.051514
b -0.468040  0.191120
c -0.115848 -0.242634

In [218]: df.reindex_like(df2)
Out[218]:
   one     two
a  1.394981  1.772517
b  0.343054  1.912123
c  0.695246  1.478369
```
Aligning objects with each other with `align`

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```python
In [219]: s = pd.Series(np.random.randn(5), index=
   ...:                     ['a', 'b', 'c', 'd', 'e'])
In [220]: s1 = s[:4]
In [221]: s2 = s[1:]
In [222]: s1.align(s2)
Out[222]:
(a -0.186646  
b -1.692424  
c -0.303893  
d -1.425662  
e NaN
   dtype: float64,
   a NaN
   b -1.692424
   c -0.303893
   d -1.425662
e 1.114285
dtype: float64)
```

```python
In [223]: s1.align(s2, join="inner")
Out[223]:
(b -1.692424  
c -0.303893  
d -1.425662  
   dtype: float64,
   b -1.692424
   c -0.303893
   d -1.425662
   dtype: float64)
```

```python
In [224]: s1.align(s2, join="left")
Out[224]:
(a -0.186646  
b -1.692424  
c -0.303893  
d -1.425662  
e NaN
   dtype: float64,
   a NaN
   b -1.692424
```

(continues on next page)
c  -0.303893
d  -1.425662
dtype: float64)

For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [225]: df.align(df2, join="inner")
Out[225]:
(  one  two
  a  1.394981  1.772517
  b  0.343054  1.912123
  c  0.695246  1.478369,
    one  two
    a  1.394981  1.772517
    b  0.343054  1.912123
    c  0.695246  1.478369)
```

You can also pass an axis option to only align on the specified axis:

```
In [226]: df.align(df2, join="inner", axis=0)
Out[226]:
(  one  two  three
  a  1.394981  1.772517  NaN
  b  0.343054  1.912123 -0.050390
  c  0.695246  1.478369  1.227435,
    one  two
    a  1.394981  1.772517
    b  0.343054  1.912123
    c  0.695246  1.478369
```

If you pass a Series to :meth:`DataFrame.align()`, you can choose to align both objects either on the DataFrame’s index or columns using the axis argument:

```
In [227]: df.align(df2.iloc[0], axis=1)
Out[227]:
(  one  three  two
  a  1.394981  NaN  1.772517
  b  0.343054 -0.050390  1.912123
  c  0.695246  1.227435  1.478369
    d  NaN -0.613172  0.279344,
    one
    a  1.394981
    three  NaN
two  1.772517
Name: a, dtype: float64)
```
Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
<tr>
<td>nearest</td>
<td>Fill from the nearest index value</td>
</tr>
</tbody>
</table>

We illustrate these fill methods on a simple Series:

```
In [228]: rng = pd.date_range("1/3/2000", periods=8)
In [229]: ts = pd.Series(np.random.randn(8), index=rng)
In [230]: ts2 = ts[[0, 3, 6]]
```

```
In [231]: ts
Out[231]:
2000-01-03  0.183051
2000-01-04  0.400528
2000-01-05  -0.015083

2000-01-10  NaN
Freq: D, dtype: float64
```

```
In [234]: ts2.reindex(ts.index, method="ffill")
Out[234]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  0.183051
```

(continues on next page)
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  2.395489
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64

In [235]: ts2.reindex(ts.index, method="bfill")
Out[235]:
2000-01-03  0.183051
2000-01-04  2.395489
2000-01-05  2.395489
2000-01-06  2.395489
2000-01-07  0.733639
2000-01-08  0.733639
2000-01-09  0.733639
2000-01-10  NaN
Freq: D, dtype: float64

In [236]: ts2.reindex(ts.index, method="nearest")
Out[236]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  2.395489
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  0.733639
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64

These methods require that the indexes are ordered increasing or decreasing.

Note that the same result could have been achieved using fillna (except for method='nearest') or interpolate:

In [237]: ts2.reindex(ts.index).fillna(method="ffill")
Out[237]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  0.183051
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  2.395489
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64

reindex() will raise a ValueError if the index is not monotonically increasing or decreasing. fillna() and interpolate() will not perform any checks on the order of the index.
### Limits on filling while reindexing

The limit and tolerance arguments provide additional control over filling while reindexing. Limit specifies the maximum count of consecutive matches:

```
In [238]: ts2.reindex(ts.index, method="ffill", limit=1)
Out[238]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

In contrast, tolerance specifies the maximum distance between the index and indexer values:

```
In [239]: ts2.reindex(ts.index, method="ffill", tolerance="1 day")
Out[239]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

Notice that when used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, tolerance will coerced into a `Timedelta` if possible. This allows you to specify tolerance with appropriate strings.

### Dropping labels from an axis

A method closely related to `reindex` is the `drop()` function. It removes a set of labels from an axis:

```
In [240]: df
Out[240]:
one  two  three
a  1.394981  1.772517 NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d  NaN  0.279344 -0.613172

In [241]: df.drop(["a", "d"], axis=0)
Out[241]:
one  two  three
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435

In [242]: df.drop(["one"], axis=1)
```

(continues on next page)
Note that the following also works, but is a bit less obvious / clean:

```python
In [243]: df.reindex(df.index.difference(['a', 'd']))
Out[243]:
     one  two  three
b  0.343054 1.912123 -0.050390
c  0.695246 1.478369 1.227435
```

### Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```python
In [244]: s
Out[244]:
da    0.186646
b    -1.692424
c    -0.303893
d    -1.425662
e     1.114285
dtype: float64
```

```python
In [245]: s.rename(str.upper)
Out[245]:
     A  B  C  D  E
a -0.186646
b -1.692424
c -0.303893
d -1.425662
e  1.114285
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```python
In [246]: df.rename(  
      ...:     columns={"one": "foo", "two": "bar"},  
      ...:     index={"a": "apple", "b": "banana", "d": "durian"},  
      ...:     )
```

```python
Out[246]:
     foo  bar  three
apple 1.394981 1.772517 NaN
banana 0.343054 1.912123 -0.050390
c  0.695246 1.478369 1.227435
durian NaN 0.279344 -0.613172
```

2.3. Essential basic functionality
If the mapping doesn’t include a column/index label, it isn’t renamed. Note that extra labels in the mapping don’t throw an error.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.

```python
In [247]: df.rename({"one": "foo", "two": "bar"}, axis="columns")
Out[247]:
   foo   bar   three
  a  1.394981  1.772517    NaN
  b   0.343054  1.912123 -0.050390
  c   0.695246  1.478369  1.227435
  d    NaN    0.279344 -0.613172

In [248]: df.rename({"a": "apple", "b": "banana", "d": "durian"}, axis="index")
Out[248]:
   one   two   three
apple  1.394981  1.772517    NaN
banana  0.343054  1.912123 -0.050390
      c  0.695246  1.478369  1.227435
durian    NaN    0.279344 -0.613172
```

The `rename()` method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

Finally, `rename()` also accepts a scalar or list-like for altering the Series.name attribute.

```python
In [249]: s.rename("scalar-name")
Out[249]:
a -0.186646
b -1.692424
c -0.303893
d -1.425662
e  1.114285
Name: scalar-name, dtype: float64
```

The methods `DataFrame.rename_axis()` and `Series.rename_axis()` allow specific names of a MultiIndex to be changed (as opposed to the labels).

```python
In [250]: df = pd.DataFrame(
    ......:     .....:      "{"x": [1, 2, 3, 4, 5, 6], "y": [10, 20, 30, 40, 50, 60]},
    ......:      index=pd.MultiIndex.from_product(
    ......:          [["a", "b", "c"], [1, 2]], names=["let", "num"]
    ......:     ),
    ......:    )

In [251]: df
Out[251]:
    x    y
let num
a 1   10
   2   20
b 1   30
   2   40
```

(continues on next page)
2.3.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. DataFrames follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (for i in object) produces:

• Series: values
• DataFrame: column labels

Thus, for example, iterating over a DataFrame gives you the column names:

```python
In [254]: df = pd.DataFrame(
    ..........:     {"col1": np.random.randn(3), "col2": np.random.randn(3)}, index=\["a", "b", 
----------:     "c"]
    ..........:     )
    ..........: 

In [255]: for col in df:
    ..........:     print(col)
    ..........:     
    ..........:     col1
    ..........:     col2
```

pandas objects also have the dict-like `items()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:
• **iterrows():** Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.

• **itertuples():** Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning:** Iterating through pandas objects is generally slow. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a vectorized solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, …

- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on function application.

- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the enhancing performance section for some examples of this approach.

**Warning:** You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```python
In [256]: df = pd.DataFrame({"a": [1, 2, 3], "b": ["a", "b", "c"]})

In [257]: for index, row in df.iterrows():
    ......:    row["a"] = 10
    ......:
In [258]: df
Out[258]:
   a  b
0  1  a
1  2  b
2  3  c
```

**items**

Consistent with the dict-like interface, `items()` iterates through key-value pairs:

- **Series:** (index, scalar value) pairs
- **DataFrame:** (column, Series) pairs

For example:

```python
In [259]: for label, ser in df.items():
    ......:    print(label)
    ......:    print(ser)
    ......:
a
0   1
1   2
```

(continues on next page)
2 3
Name: a, dtype: int64
b
0 a
1 b
2 c
Name: b, dtype: object

iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```python
In [260]: for row_index, row in df.iterrows():
      ....:     print(row_index, row, sep="\n")
      ....:
0
a 1
b a
Name: 0, dtype: object
1
a 2
b b
Name: 1, dtype: object
2
a 3
b c
Name: 2, dtype: object
```

**Note:** Because `iterrows()` returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
In [261]: df_orig = pd.DataFrame([[1, 1.5]], columns=["int", "float"])

In [262]: df_orig.dtypes
Out[262]:
int    int64
float  float64
dtype: object

In [263]: row = next(df_orig.iterrows())[1]

In [264]: row
Out[264]:
int  1.0
float  1.5
Name: 0, dtype: float64
```

All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column x:

2.3. Essential basic functionality
To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```python
In [267]: df2 = pd.DataFrame({"x": [1, 2, 3], "y": [4, 5, 6]})

In [268]: print(df2)
   x  y
0 1 4
1 2 5
2 3 6

In [269]: print(df2.T)
   0 1 2
   x 1 2 3
   y 4 5 6

In [270]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})

In [271]: print(df2_t)
   0 1 2
   x 1 2 3
   y 4 5 6
```

**itertuples**

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row’s corresponding index value, while the remaining values are the row values.

For instance:

```python
In [272]: for row in df.itertuples():
   ....:   print(row)
   ....:
   Pandas(Index=0, a=1, b='a')
   Pandas(Index=1, a=2, b='b')
   Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

**Note:** The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.
2.3.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the values of the Series, if it is a datetime/period like Series. This will return a Series, indexed like the existing Series.

```python
In [273]: s = pd.Series(pd.date_range("20130101 09:10:12", periods=4))

In [274]: s
Out[274]:
0  2013-01-01 09:10:12
1  2013-01-02 09:10:12
2  2013-01-03 09:10:12
3  2013-01-04 09:10:12
dtype: datetime64[ns]

In [275]: s.dt.hour
Out[275]:
0   9
1   9
2   9
3   9
dtype: int64

In [276]: s.dt.second
Out[276]:
0   12
1   12
2   12
3   12
dtype: int64

In [277]: s.dt.day
Out[277]:
0   1
1   2
2   3
3   4
dtype: int64
```

This enables nice expressions like this:

```python
In [278]: s[s.dt.day == 2]
Out[278]:
1  2013-01-02 09:10:12
dtype: datetime64[ns]
```

You can easily produces tz aware transformations:

```python
In [279]: stz = s.dt.tz_localize("US/Eastern")

In [280]: stz
Out[280]:
0  2013-01-01 09:10:12-05:00
(continues on next page)
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

(continued from previous page)

<table>
<thead>
<tr>
<th></th>
<th>2013-01-02 09:10:12-05:00</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2013-01-03 09:10:12-05:00</td>
</tr>
<tr>
<td>3</td>
<td>2013-01-04 09:10:12-05:00</td>
</tr>
</tbody>
</table>

dtype: datetime64[ns, US/Eastern]

```
In [281]: stz.dt.tz
Out[281]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>
```

You can also chain these types of operations:

```
In [282]: s.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")
Out[282]:
0  2013-01-01 04:10:12-05:00
1  2013-01-02 04:10:12-05:00
2  2013-01-03 04:10:12-05:00
3  2013-01-04 04:10:12-05:00

dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

# DatetimeIndex

```
In [283]: s = pd.Series(pd.date_range("20130101", periods=4))

In [284]: s
Out[284]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04

dtype: datetime64[ns]

In [285]: s.dt.strftime("%Y/%m/%d")
Out[285]:
0  2013/01/01
1  2013/01/02
2  2013/01/03
3  2013/01/04

dtype: object
```

# PeriodIndex

```
In [286]: s = pd.Series(pd.period_range("20130101", periods=4))

In [287]: s
Out[287]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04

dtype: period[D]

In [288]: s.dt.strftime("%Y/%m/%d")
```

(continues on next page)
The `.dt` accessor works for period and timedelta dtypes.

```python
# period
In [289]: s = pd.Series(pd.period_range("20130101", periods=4, freq="D"))

In [290]: s
Out[290]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04
dtype: period[D]

In [291]: s.dt.year
Out[291]:
0  2013
1  2013
2  2013
3  2013
dtype: int64

In [292]: s.dt.day
Out[292]:
0  1
1  2
2  3
3  4
dtype: int64

# timedelta
In [293]: s = pd.Series(pd.timedelta_range("1 day 00:00:05", periods=4, freq="s"))

In [294]: s
Out[294]:
0  1 days 00:00:05
1  1 days 00:00:06
2  1 days 00:00:07
3  1 days 00:00:08
dtype: timedelta64[ns]

In [295]: s.dt.days
Out[295]:
0  1
1  1
2  1

(continues on next page)
In [296]: s.dt.seconds
Out[296]:
0    5
1    6
2    7
3    8
dtype: int64

In [297]: s.dt.components
Out[297]:
     days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     1     0       0       5           0            0            0
1     1     0       0       6           0            0            0
2     1     0       0       7           0            0            0
3     1     0       0       8           0            0            0

debug: Series.dt will raise a TypeError if you access with a non-datetime-like values.

2.3.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series's str attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

In [298]: s = pd.Series(.....:
                    ['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
                    dtype='string'
.....:

In [299]: s.str.lower()
Out[299]:
0    a
1    b
2    c
3   aaba
4   baca
5  <NA>
6    caba
7    dog
8    cat
dtype: string

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

Note: Prior to pandas 1.0, string methods were only available on object-dtype Series. pandas 1.0 added the
StringDtype which is dedicated to strings. See Text data types for more.

Please see Vectorized String Methods for a complete description.

2.3.11 Sorting

pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

By index

The Series.sort_index() and DataFrame.sort_index() methods are used to sort a pandas object by its index levels.

```
In [300]: df = pd.DataFrame(
    .....:
    .....:    "one": pd.Series(np.random.randn(3), index=["a", "b", "c"],
    .....:
    .....:    "two": pd.Series(np.random.randn(4), index=["a", "b", "c", "d"],
    .....:
    .....:    "three": pd.Series(np.random.randn(3), index=["b", "c", "d"],
    .....:
    .....: )
    .....:
    .....:
In [301]: unsorted_df = df.reindex(
    .....:
    .....:    index=["a", "d", "c", "b"], columns=["three", "two", "one"]
    .....:
    .....: )
    .....:
    .....:
In [302]: unsorted_df
Out[302]:
         three  two  one
       a   NaN  -1.152244  0.562973
       d  -0.252916  -0.109597    NaN
       c   1.273388  -0.167123  0.640382
       b  -0.098217   0.009797 -1.299504

# DataFrame
In [303]: unsorted_df.sort_index()
Out[303]:
         three  two  one
       a   NaN  -1.152244  0.562973
       b  -0.098217   0.009797 -1.299504
       c   1.273388  -0.167123  0.640382
       d  -0.252916  -0.109597    NaN

In [304]: unsorted_df.sort_index(ascending=False)
Out[304]:
         three  two  one
       d  -0.252916  -0.109597    NaN
       c   1.273388  -0.167123  0.640382
       b  -0.098217   0.009797 -1.299504
```

Name: three, dtype: float64

New in version 1.1.0.

Sorting by index also supports a key parameter that takes a callable function to apply to the index being sorted. For `MultiIndex` objects, the key is applied per-level to the levels specified by level.

In [307]: s1 = pd.DataFrame({"a": ["B", "a", "C"], "b": [1, 2, 3], "c": [2, 3, 4]}).set_index(

   |   |
   |   |
   | "ab" |
   | ) |

In [308]: s1

Out[308]:

</tbody>
</table>
For information on key sorting by value, see *value sorting*.

**By values**

The `Series.sort_values()` method is used to sort a `Series` by its values. The `DataFrame.sort_values()` method is used to sort a DataFrame by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may be used to specify one or more columns to use to determine the sorted order.

```python
In [311]: df1 = pd.DataFrame(
    ...:     {"one": [2, 1, 1, 1], "two": [1, 3, 2, 4], "three": [5, 4, 3, 2]}
    ...: )
    ...

In [312]: df1.sort_values(by="two")
Out[312]:
    one two three
   0  2  1  5
   2  1  2  3
   1  1  3  4
   3  1  4  2
```

The `by` parameter can take a list of column names, e.g.:

```python
In [313]: df1["one", "two", "three"].sort_values(by=["one", "two"])
Out[313]:
    one two three
   2  1  2  3
   1  1  3  4
   3  1  4  2
   0  2  1  5
```

These methods have special treatment of NA values via the `na_position` argument:

```python
In [314]: s[2] = np.nan

In [315]: s.sort_values()
Out[315]:
    0  A
    3  Aaba
    1  B
    4  Baca
    6  CABA
    8  cat
    7  dog
    2  <NA>
    5  <NA>
    dtype: string

In [316]: s.sort_values(na_position="first")
Out[316]:
    2  <NA>
    5  <NA>
    0  A
```

(continues on next page)
New in version 1.1.0.

Sorting also supports a key parameter that takes a callable function to apply to the values being sorted.

```python
In [317]: s1 = pd.Series(["B", "a", "C"])

In [318]: s1.sort_values()
Out[318]:
0  B
2  C
1  a
dtype: object

In [319]: s1.sort_values(key=lambda x: x.str.lower())
Out[319]:
1  a
0  B
2  C
dtype: object
```

The name or type of each column can be used to apply different functions to different columns.
By indexes and values

Strings passed as the by parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```python
# Build MultiIndex
In [323]: idx = pd.MultiIndex.from_tuples(
        .....: [("a", 1), ("a", 2), ("a", 2), ("b", 2), ("b", 1), ("b", 1)]
        .....: )
        .....:
In [324]: idx.names = ["first", "second"]

# Build DataFrame
In [325]: df_multi = pd.DataFrame({"A": np.arange(6, 0, -1)}, index=idx)

In [326]: df_multi
Out[326]:
   A
first second
a  1   6
   2   5
   2   4
b  2   3
   1   2
   1   1

Sort by ‘second’ (index) and ‘A’ (column)

In [327]: df_multi.sort_values(by=["second", "A"])
Out[327]:
   A
first second
b  1   1
   1   2
a  1   6
1  2   3
a  2   4
b  2   5

Note: If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.
**searchsorted**

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [328]: ser = pd.Series([1, 2, 3])
In [329]: ser.searchsorted([0, 3])
Out[329]: array([0, 2])
In [330]: ser.searchsorted([0, 4])
Out[330]: array([0, 3])
In [331]: ser.searchsorted([1, 3], side="right")
Out[331]: array([1, 3])
In [332]: ser.searchsorted([1, 3], side="left")
Out[332]: array([0, 2])
In [333]: ser = pd.Series([3, 1, 2])
In [334]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[334]: array([0, 2])
```

**smallest / largest values**

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest \( n \) values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```
In [335]: s = pd.Series(np.random.permutation(10))
In [336]: s
Out[336]:
0   2
1   0
2   3
3   7
4   1
5   5
6   9
7   6
8   8
9   4
dtype: int64
In [337]: s.sort_values()
Out[337]:
1   0
4   1
0   2
2   3
9   4
5   5
```
DataFrame also has the `nlargest` and `nsmallest` methods.

```python
In [340]: df = pd.DataFrame(
    ...:     {
    ...:         "a": [-2, -1, 1, 10, 8, 11, -1],
    ...:         "b": list("abdceff"),
    ...:         "c": [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0],
    ...:     }
    ...: )

In [341]: df.nlargest(3, "a")
Out[341]:
   a  b  c
0 5  f  3.0
1 3  c  3.2
2 4  e  NaN

In [342]: df.nlargest(5, ["a", "c"])
Out[342]:
   a  b  c
0 5  f  3.0
1 3  c  3.2
2 4  e  NaN
3 2  d  4.0
4 6 -1 f  4.0

In [343]: df.nsmallest(3, "a")
Out[343]:
   a  b  c
0 -2 a  1.0
1 -1 b  2.0
```
Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to by.

```python
In [345]: df1.columns = pd.MultiIndex.from_tuples(
       ....:     [('a', 'one'), ('a', 'two'), ('b', 'three')]
       ....:     )

In [346]: df1.sort_values(by=('a', 'two'))
Out[346]:
         a    b
one two three
0   2   1   5
2   1   2   3
1   1   3   4
3   1   4   2
```

2.3.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that it is seldom necessary to copy objects. For example, there are only a handful of ways to alter a DataFrame in-place:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.
2.3.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for float, int, bool, timedelta64[ns] and datetime64[ns] (note that NumPy does not support timezone-aware datetimes).

pandas and third-party libraries extend NumPy’s type system in a few places. This section describes the extensions pandas has made internally. See Extension types for how to write your own extension that works with pandas. See ecosystem.extensions for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. For methods requiring dtype arguments, strings can be specified as indicated. See the respective documentation sections for more on each type.

<table>
<thead>
<tr>
<th>Kind of Data</th>
<th>Data Type</th>
<th>Scalar</th>
<th>Array</th>
<th>String Aliases</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>tz-aware date-time</td>
<td>DatetimeTZDtype</td>
<td>Timestamp</td>
<td>DatetimeArray</td>
<td>'datetime64[ns, &lt;tz&gt;]’</td>
<td>Time zone handling</td>
</tr>
<tr>
<td>Categorical</td>
<td>CategoricalDtype</td>
<td>(none)</td>
<td>CategoricalArray</td>
<td>'category'</td>
<td>Categorical data</td>
</tr>
<tr>
<td>period (time spans)</td>
<td>PeriodDtype</td>
<td>Period</td>
<td>PeriodArray</td>
<td>'period[&lt;freq&gt;]', 'Period[&lt;freq&gt;]’</td>
<td>Time span representation</td>
</tr>
<tr>
<td>sparse</td>
<td>SparseDtype</td>
<td>(none)</td>
<td>SparseArray</td>
<td>'Sparse', 'Sparse[int]', 'Sparse[float]'</td>
<td>Sparse data structures</td>
</tr>
<tr>
<td>intervals</td>
<td>IntervalDtype</td>
<td>Interval</td>
<td>IntervalArray</td>
<td>'interval', 'Interval', 'Interval[&lt;numpy_dtype&gt;]', 'Interval[datetime64[ns, &lt;tz&gt;]]', 'Interval[timedelta64[&lt;freq&gt;]]’</td>
<td>IntervalIndex</td>
</tr>
<tr>
<td>nullable integer</td>
<td>Int64Dtype</td>
<td>(none)</td>
<td>IntegerArray</td>
<td>'Int8', 'Int16', 'Int32', 'Int64', 'UInt8', 'UInt16', 'UInt32', 'UInt64'</td>
<td>Nullable integer data type</td>
</tr>
<tr>
<td>Strings</td>
<td>StringDtype</td>
<td>(none)</td>
<td>StringArray</td>
<td>'string'</td>
<td>Working with text data</td>
</tr>
<tr>
<td>Boolean (with NA)</td>
<td>BooleanDtype</td>
<td>(none)</td>
<td>BooleanArray</td>
<td>'boolean'</td>
<td>Boolean data with missing values</td>
</tr>
</tbody>
</table>

pandas has two ways to store strings.

1. **object dtype**, which can hold any Python object, including strings.
2. **StringDtype**, which is dedicated to strings.

Generally, we recommend using **StringDtype**. See Text data types for more.

Finally, arbitrary objects may be stored using the **object dtype**, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See object conversion).

A convenient **dtypes** attribute for DataFrame returns a Series with the data type of each column.

2.3. Essential basic functionality
In [347]: dft = pd.DataFrame(
    ...:     {
    ...:         "A": np.random.rand(3),
    ...:         "B": 1,
    ...:         "C": "foo",
    ...:         "D": pd.Timestamp("20010102"),
    ...:         "E": pd.Series([1.0] * 3).astype("float32"),
    ...:         "F": False,
    ...:         "G": pd.Series([1] * 3, dtype="int8"),
    ...:     }
    ...
)

In [348]: dft
Out[348]:
   A    B    C         D       E      F     G
0  0.035962  1.0 foo 2001-01-02 1.0  False  1
1  0.701379  1.0 foo 2001-01-02 1.0  False  1
2  0.281885  1.0 foo 2001-01-02 1.0  False  1

In [349]: dft.dtypes
Out[349]:
A     float64
B       int64
C          object
D  datetime64[ns]
E      float32
F       bool
G        int8
dtype: object

On a Series object, use the `dtype` attribute.

In [350]: dft["A"].dtype
Out[350]: dtype('float64')

If a pandas object contains data with multiple dtypes in a single column, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

# these ints are coerced to floats
In [351]: pd.Series([1, 2, 3, 4, 5, 6.0])
Out[351]:
0    1.0
1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64

# string data forces an 'object' dtype
In [352]: pd.Series([1, 2, 3.0, "foo"])
Out[352]:
The number of columns of each type in a DataFrame can be found by calling `DataFrame.dtypes.value_counts()`.

```
In [353]: dft.dtypes.value_counts()
Out[353]:
float64    1
int64      1
object     1
datetime64[ns] 1
float32    1
bool       1
int8       1
dtype: int64
```

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`), then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [354]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=["A"], dtype="float32")
In [355]: df1
Out[355]:
     A
0  0.224364
1  1.890546
2  0.182879
3  0.787847
4 -0.188449
5  0.667715
6 -0.011736
7 -0.399073
In [356]: df1.dtypes
Out[356]:
A      float32
dtype: object
```

```
In [357]: df2 = pd.DataFrame(
    ....:     {  
    ....:         "A": pd.Series(np.random.randn(8), dtype="float16"),  
    ....:         "B": pd.Series(np.random.randn(8)),  
    ....:         "C": pd.Series(np.array(np.random.randn(8), dtype="uint8")),  
    ....:     }  
    ....: )
    ....:
```

2.3. Essential basic functionality
pandas: powerful Python data analysis toolkit, Release 1.3.4

(continued from previous page)

In [359]: df2.dtypes
Out[359]:
A
float16
B
float64
C
uint8
dtype: object

defaults
By default integer types are int64 and float types are float64, regardless of platform (32-bit or 64-bit). The following
will all result in int64 dtypes.
In [360]: pd.DataFrame([1, 2], columns=["a"]).dtypes
Out[360]:
a
int64
dtype: object
In [361]: pd.DataFrame({"a": [1, 2]}).dtypes
Out[361]:
a
int64
dtype: object
In [362]: pd.DataFrame({"a": 1}, index=list(range(2))).dtypes
Out[362]:
a
int64
dtype: object
Note that Numpy will choose platform-dependent types when creating arrays. The following WILL result in int32
on 32-bit platform.
In [363]: frame = pd.DataFrame(np.array([1, 2]))

262

Chapter 2. User Guide


upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. int to float).

```
In [364]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [365]: df3
Out[365]:
   A    B   C
0  1.047606  0.256090  0.0
1  3.497968  1.426469  0.0
2 -0.150862 -0.416203  255.0
3  0.724370  1.139976  0.0
4  1.203098 -1.193477  0.0
5  1.346426  0.096706  0.0
6 -0.052599 -1.956850  1.0
7 -0.756495 -0.714337  0.0
```

```
In [366]: df3.dtypes
Out[366]:
A    float32
B    float64
C    float64
dtype: object
```

`DataFrame.to_numpy()` will return the *lower-common-denominator* of the dtypes, meaning the dtype that can accommodate ALL of the types in the resulting homogeneous dtyped NumPy array. This can force some *upcasting*.

```
In [367]: df3.to_numpy().dtype
Out[367]:
dtype('float64')
```

**astype**

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the NumPy rules. If two different dtypes are involved in an operation, then the more *general* one will be used as the result of the operation.

```
In [368]: df3
Out[368]:
   A    B   C
0  1.047606  0.256090  0.0
1  3.497968  1.426469  0.0
2 -0.150862 -0.416203  255.0
3  0.724370  1.139976  0.0
4  1.203098 -1.193477  0.0
5  1.346426  0.096706  0.0
6 -0.052599 -1.956850  1.0
7 -0.756495 -0.714337  0.0
```
In [369]: df3.dtypes
Out[369]:
A float32
B float64
C float64
dtype: object

# conversion of dtypes
In [370]: df3.astype("float32").dtypes
Out[370]:
A float32
B float32
C float32
dtype: object

Convert a subset of columns to a specified type using `astype()`.

In [371]: dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})
In [372]: dft[["a", "b"]].astype(np.uint8)
Out[372]:
   a  b
0  1  4
1  2  5
2  3  6

In [373]: dft.dtypes
Out[373]:
a uint8
b uint8
c int64
dtype: object

Convert certain columns to a specific dtype by passing a dict to `astype()`.

In [375]: df1 = pd.DataFrame({"a": [1, 0, 1], "b": [4, 5, 6], "c": [7, 8, 9]})
In [376]: df1 = df1.astype({"a": np.bool_, "c": np.float64})
In [377]: df1
Out[377]:
   a   b   c
0  True  4  7.0
1 False  5  8.0
2  True  6  9.0

In [378]: df1.dtypes
Out[378]:
a    bool
b    int64
Note: When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. `loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```python
In [379]: dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})

In [380]: dft.loc[:, ["a", "b"]].astype(np.uint8).dtypes
Out[380]:
   a   b
0 uint8  uint8

dtype: object

In [381]: dft.loc[:, ["a", "b"]].astype(np.uint8) = dft.loc[:, ["a", "b"]].astype(np.uint8)

In [382]: dft.dtypes
Out[382]:
   a   b   c
0 int64  int64  int64

dtype: object
```

**Object conversion**

Pandas offers various functions to try to force conversion of types from the `object` dtype to other types. In cases where the data is already of the correct type, but stored in an `object` array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

```python
In [383]: import datetime

In [384]: df = pd.DataFrame(
      ....:     [1, 2],
      ....:     ["a", "b"],
      ....:     [datetime.datetime(2016, 3, 2), datetime.datetime(2016, 3, 2)],
      ....: )

In [385]: df = df.T

In [386]: df
Out[386]:
   0 1 2
0 a 1 2016-03-02
1 b 2 2016-03-02
```

(continues on next page)
Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

```python
In [388]: df.infer_objects().dtypes
Out[388]:
0    int64
1   object
2  datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

  ```python
  In [389]: m = ["1.1", 2, 3]
  In [390]: pd.to_numeric(m)
  Out[390]: array([1.1, 2., 3.])
  ```

- `to_datetime()` (conversion to datetime objects)

  ```python
  In [391]: import datetime
  In [392]: m = ["2016-07-09", datetime.datetime(2016, 3, 2)]
  In [393]: pd.to_datetime(m)
  Out[393]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]', freq=None)
  ```

- `to_timedelta()` (conversion to timedelta objects)

  ```python
  In [394]: m = ["5s", pd.Timedelta("1day")]
  In [395]: pd.to_timedelta(m)
  Out[395]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)
  ```

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```python
In [396]: import datetime
```
In [397]: m = ["apple", datetime.datetime(2016, 3, 2)]

In [398]: pd.to_datetime(m, errors="coerce")
Out[398]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [399]: m = ["apple", 2, 3]

In [400]: pd.to_numeric(m, errors="coerce")
Out[400]: array([nan, 2., 3.])

In [402]: pd.to_timedelta(m, errors="coerce")
Out[402]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)

The errors parameter has a third option of errors='ignore', which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

In [403]: import datetime

In [404]: m = ["apple", datetime.datetime(2016, 3, 2)]

In [405]: pd.to_datetime(m, errors="ignore")
Out[405]: Index(['apple', 2016-03-02 00:00:00], dtype='object')

In [406]: m = ["apple", 2, 3]

In [407]: pd.to_numeric(m, errors="ignore")
Out[407]: array(['apple', 2, 3], dtype=object)

In [408]: m = ["apple", pd.Timedelta("1day")]

In [409]: pd.to_timedelta(m, errors="ignore")
Out[409]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)

In addition to object conversion, to_numeric() provides another argument downcast, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

In [410]: m = ["1", 2, 3]

In [411]: pd.to_numeric(m, downcast="integer") # smallest signed int dtype
Out[411]: array([1, 2, 3], dtype=int8)

In [412]: pd.to_numeric(m, downcast="signed") # same as 'integer'
Out[412]: array([1, 2, 3], dtype=int8)

In [413]: pd.to_numeric(m, downcast="unsigned") # smallest unsigned int dtype
Out[413]: array([1, 2, 3], dtype=uint8)

In [414]: pd.to_numeric(m, downcast="float") # smallest float dtype
Out[414]: array([1., 2., 3.], dtype=float32)

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-
dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```python
In [415]: import datetime

In [416]: df = pd.DataFrame([["2016-07-09", datetime.datetime(2016, 3, 2)] * 2, dtype="O"
˓→]

In [417]: df
Out[417]:
     0   1
0 2016-07-09 2016-03-02 00:00:00
1 2016-07-09 2016-03-02 00:00:00

In [418]: df.apply(pd.to_datetime)
Out[418]:
     0   1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02

In [419]: df = pd.DataFrame([["1.1", 2, 3]] * 2, dtype="O")

In [420]: df
Out[420]:
      0  1  2
0  1.1  2  3
1  1.1  2  3

In [421]: df.apply(pd.to_numeric)
Out[421]:
      0  1  2
0  1.1  2  3
1  1.1  2  3

In [422]: df = pd.DataFrame([["5us", pd.Timedelta("1day")]] * 2, dtype="O")

In [423]: df
Out[423]:
       0  1
0  5us 1 days 00:00:00
1  5us 1 days 00:00:00

In [424]: df.apply(pd.to_timedelta)
Out[424]:
       0  1
0  0 days 00:00:00.000005 1 days
1  0 days 00:00:00.000005 1 days
```
gotchas

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also Support for integer NA.

```
In [425]: dfi = df3.astype("int32")

In [426]: dfi["E"] = 1

In [427]: dfi
Out[427]:
   A  B  C  E
0  1  0  0  1
1  3  1  0  1
2  0  0  255 1
3  0  1  0  1
4  0  -1  0  1
5  1  0  0  1
6  0  -1  1  1
7  0  0  0  1

In [428]: dfi.dtypes
Out[428]:
A    int32
B    int32
C    int32
E    int64
dtype: object

In [429]: casted = dfi[dfi > 0]

In [430]: casted
Out[430]:
   A  B  C  E
0  1.0 NaN NaN  1
1  3.0  1.0 NaN  1
2  NaN  NaN  255.0  1
3  NaN  1.0 NaN  1
4  NaN  NaN  NaN  1
5  1.0  NaN  NaN  1
6  NaN  NaN  1.0  1
7  NaN  NaN  NaN  1

In [431]: casted.dtypes
Out[431]:
A   float64
B   float64
C   float64
E    int64
dtype: object
```

While float dtypes are unchanged.

2.3. Essential basic functionality
In [432]: dfa = df3.copy()

In [433]: dfa["A"] = dfa["A"].astype("float32")

In [434]: dfa.dtypes
Out[434]:
A float32
B float64
C float64
dtype: object

In [435]: casted = dfa[df2 > 0]

In [436]: casted
Out[436]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.047606</td>
<td>0.256090</td>

<tr>
<td>7</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

In [437]: casted.dtypes
Out[437]:
A float32
B float64
C float64
dtype: object

2.3.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their `dtype`.

First, let's create a DataFrame with a slew of different dtypes:

In [438]: df = pd.DataFrame(
    .....:     
    .....:     
    | "string": list("abc"),
    | "int64": list(range(1, 4)),
    | "uint8": np.arange(3, 6).astype("u1"),
    | "float64": np.arange(4.0, 7.0),
    | "bool1": [True, False, True],
    | "bool2": [False, True, False],
    | "dates": pd.date_range("now", periods=3),
    | "category": pd.Series(list("ABC")).astype("category"),
    .....:     
    .....:     
)[continues on next page]
In [439]: df["tdeltas"] = df.dates.diff()

In [440]: df["uint64"] = np.arange(3, 6).astype("u8")

In [441]: df["other_dates"] = pd.date_range("20130101", periods=3)

In [442]: df["tz_aware_dates"] = pd.date_range("20130101", periods=3, tz="US/Eastern")

In [443]: df

Out [443]:

<table>
<thead>
<tr>
<th></th>
<th>string</th>
<th>int64</th>
<th>uint8</th>
<th>float64</th>
<th>bool1</th>
<th>bool2</th>
<th>dates category</th>
<th>tdeltas int64</th>
<th>other_dates</th>
<th>tz_aware_dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>1</td>
<td>3</td>
<td>4.0</td>
<td>True</td>
<td>False</td>
<td>2021-10-17 14:57:33.076171</td>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>NaT</td>
<td>3</td>
<td>2013-01-01 2013-01-01 00:00:00-05:00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>2</td>
<td>4</td>
<td>5.0</td>
<td>False</td>
<td>True</td>
<td>2021-10-18 14:57:33.076171</td>
<td>B</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>days</td>
<td>4</td>
<td>2013-01-02 2013-01-02 00:00:00-05:00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>c</td>
<td>3</td>
<td>5</td>
<td>6.0</td>
<td>True</td>
<td>False</td>
<td>2021-10-19 14:57:33.076171</td>
<td>C</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>days</td>
<td>5</td>
<td>2013-01-03 2013-01-03 00:00:00-05:00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

And the dtypes:

In [444]: df.dtypes

Out [444]:

<p>| | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>int64</td>
<td>uint8</td>
<td>float64</td>
<td>bool1</td>
<td>bool2</td>
<td>dates category</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>tdeltas int64</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>other_dates</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>tz_aware_dates</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>dtype: object</td>
</tr>
</tbody>
</table>

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns with these dtypes” (include) and/or “give the columns without these dtypes” (exclude).

For example, to select bool columns:

In [445]: df.select_dtypes(include=[bool])

Out [445]:

<table>
<thead>
<tr>
<th></th>
<th>bool1</th>
<th>bool2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>1</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>2</td>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>

You can also pass the name of a dtype in the NumPy dtype hierarchy:

In [446]: df.select_dtypes(include=["bool"])

Out [446]:

(continues on next page)
bool1  bool2
0    True  False
1    False  True
2    True  False

(select_dtypes()) also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```
In [447]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[447]:
int64  float64  bool1  bool2  tdeltas
0     1       4.0     True    False    NaT
1     2       5.0    False    True   1 days
2     3       6.0     True    False   1 days
```

To select string columns you must use the object dtype:

```
In [448]: df.select_dtypes(include=['object'])
Out[448]:
string
0  a
1  b
2  c
```

To see all the child dtypes of a generic dtype like numpy.number you can define a function that returns a tree of child dtypes:

```
In [449]: def subdtypes(dtype):
    ....:     subs = dtype.__subclasses__()
    ....:     if not subs:
    ....:         return dtype
    ....:     return [dtype, [subdtypes(dt) for dt in subs]]
```

All NumPy dtypes are subclasses of numpy.generic:

```
In [450]: subdtypes(np.generic)
Out[450]:
[numpy.generic,
 [numpy.number,
  [[numpy.integer,
    [[numpy.signedinteger,
      [numpy.int8,
       numpy.int16,
       numpy.int32,
       numpy.int64,
       numpy.longlong,
       numpy.timedelta64]],
    [numpy.unsignedinteger,
      [numpy.uint8,
       numpy.uint16,
       numpy.uint32,
       numpy.uint64]],
    [numpy.floating,
      [numpy.float64,
       numpy.float128]],
    [numpy.complex,
      [numpy.complex64,
       numpy.complex128]],
    [numpy.datetime,
      [numpy.datetime64]],
    [numpy.timedelta]],
  [numpy.object]],
 [numpy.bool]]]
```

(continues on next page)
Note: pandas also defines the types category, and datetime64[ns, tz], which are not integrated into the normal NumPy hierarchy and won’t show up with the above function.

2.4 IO tools (text, CSV, HDF5, …)

The pandas I/O API is a set of top level reader functions accessed like pandas.read_csv() that generally return a pandas object. The corresponding writer functions are object methods that are accessed like DataFrame.to_csv(). Below is a table containing available readers and writers.

<table>
<thead>
<tr>
<th>Format Type</th>
<th>Data Description</th>
<th>Reader</th>
<th>Writer</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>CSV</td>
<td>read_csv</td>
<td>to_csv</td>
</tr>
<tr>
<td>text</td>

<td>read_sql</td>
<td>to_sql</td>
</tr>
<tr>
<td>SQL</td>
<td>Google BigQuery</td>
<td>read_gbq</td>
<td>to_gbq</td>
</tr>
</tbody>
</table>

Here is an informal performance comparison for some of these IO methods.

Note: For examples that use the StringIO class, make sure you import it with from io import StringIO for
Python 3.

2.4.1 CSV & text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the cookbook for some advanced strategies.

Parsing options

`read_csv()` accepts the following common arguments:

Basic

`filepath_or_buffer` [various] Either a path to a file (a `str`, `pathlib.Path`, or `py._path.local.LocalPath`), URL (including http, ftp, and S3 locations), or any object with a `read()` method (such as an open file or `StringIO`).

`sep` [str, defaults to ' , ' for `read_csv()`, \t for `read_table()`] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `\s+` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\r\t'`.

`delimiter` [str, default `None`] Alternative argument name for `sep`.

`delim_whitespace` [boolean, default `False`] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the delimiter. Equivalent to setting `sep='\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

Column and index locations and names

`header` [int or list of ints, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names.

The header can be a list of ints that specify row locations for a MultiIndex on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

`names` [array-like, default `None`] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list are not allowed.

`index_col` [int, str, sequence of int / str, or `False`, default `None`] Column(s) to use as the row labels of the `DataFrame`, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used. Note: `index_col=False` can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

The default value of `None` instructs pandas to guess. If the number of fields in the column header row is equal to the number of fields in the body of the data file, then a default index is used. If it is larger, then the first columns are used as index so that the remaining number of fields in the body are equal to the number of fields in the header.
usecols [list-like or callable, default None] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz'].

Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:

```python
In [1]: import pandas as pd
In [2]: from io import StringIO
In [3]: data = "col1,col2,col3
   \n   a,b,1
   a,b,2
   c,d,3"
In [4]: pd.read_csv(StringIO(data))
Out[4]:
   col1  col2  col3
0    a    b    1
1    a    b    2
2    c    d    3
In [5]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COl1', 'COl3'])
Out[5]:
   col1  col3
0    a    1
1    a    2
2    c    3
```

Using this parameter results in much faster parsing time and lower memory usage.

squeeze [boolean, default False] If the parsed data only contains one column then return a Series.

prefix [str, default None] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

mangle_dupe_cols [boolean, default True] Duplicate columns will be specified as ‘X’, ‘X.1’...’X.N’, rather than ‘X’...’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**General parsing configuration**

dtype [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use str or object together with suitable na_values settings to preserve and not interpret dtype.

engine [['c', 'python']] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, default None] Values to consider as True.

false_values [list, default None] Values to consider as False.
skipinitialspace [boolean, default False] Skip spaces after delimiter.

skiprows [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:

```
In [6]: data = "col1,col2,col3\na,b,1\na,b,2\nc,d,3"
In [7]: pd.read_csv(StringIO(data))
Out[7]:
col1  col2  col3
 0      a      b      1
 1      a      b      2
 2      c      d      3
```

```
In [8]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out[8]:
col1  col2  col3
 0      a      b      2
```

skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').

nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

low_memory [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)

memory_map [boolean, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

### NA and missing data handling

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See na values const below for a list of the values interpreted as NaN by default.

keep_default_na [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

- If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.
- If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.
- If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.
- If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter [boolean, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.
verbose [boolean, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [boolean, default True] If True, skip over blank lines rather than interpreting as NaN values.

**Datetime handling**

parse_dates [boolean or list of ints or names or list of lists or dict, default False]
- If True -> try parsing the index.
- If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- If {'foo': [1, 3]} -> parse columns 1, 3 as date and call result 'foo'. A fast-path exists for iso8601-formatted dates.

infer_datetime_format [boolean, default False] If True and parse_dates is enabled for a column, attempt to infer the datetime format to speed up the processing.

keep_date_col [boolean, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.

date_parser [function, default None] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses dateutil.parser.parser to do the conversion. pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

dayfirst [boolean, default False] DD/MM format dates, international and European format.

cache_dates [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

**Iteration**

iterator [boolean, default False] Return TextFileReader object for iteration or getting chunks with get_chunk().

chunksize [int, default None] Return TextFileReader object for iteration. See iterating and chunking below.

**Quoting, compression, and file format**

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None, dict}, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip, or xz if filepath_or_buffer is path-like ending in '.gz', '.bz2', '.zip', or '.xz', respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, or bz2.BZ2File. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={"method": 'gzip', 'compresslevel': 1, 'mtime': 1}.

Changed in version 1.1.0: dict option extended to support gzip and bz2.

thousands [str, default None]Thousands separator.
**pandas: powerful Python data analysis toolkit, Release 1.3.4**

**decimal** [str, default ' . '] Character to recognize as decimal point. E.g. use ',' for European data.

**float_precision** [str, default None] Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.

**lineterminator** [str (length 1), default None] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

**doublequote** [boolean, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements inside a field as a single quotechar element.

**escapechar** [str (length 1), default None] One-character string used to escape delimiter when quoting is QUOTE_NONE.

**comment** [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment=' # ', parsing '# empty/a,b,c/1,2,3' with header=0 will result in 'a,b,c' being treated as the header.

**encoding** [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). List of Python standard encodings.

**dialect** [str or csv.Dialect instance, default None] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

**Error handling**

**error_bad_lines** [boolean, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned. See bad lines below.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

**warn_bad_lines** [boolean, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

**on_bad_lines** [({'error', 'warn', 'skip'}, default 'error')] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are:

- 'error', raise an ParserError when a bad line is encountered.
- 'warn', print a warning when a bad line is encountered and skip that line.
- 'skip', skip bad lines without raising or warning when they are encountered.

New in version 1.3.0.
Specifying column data types

You can indicate the data type for the whole DataFrame or individual columns:

```
In [9]: import numpy as np

In [10]: data = "a,b,c,d\n1,2,3,4\n5,6,7,8\n9,10,11"

In [11]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11

In [12]: df = pd.read_csv(StringIO(data), dtype=object)

In [13]: df
Out[13]:
   a  b  c  d
0  1  2  3  4
1  5  6  7  8
2  9 10 11  NaN

In [14]: df["a"][0]
Out[14]: '1'

In [15]: df = pd.read_csv(StringIO(data), dtype={"b": object, "c": np.float64, "d": "Int64"})

In [16]: df.dtypes
Out[16]:
   a    int64
  b    object
  c   float64
  d    Int64
dtype: object
```

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you’re unfamiliar with these concepts, you can see here to learn more about dtypes, and here to learn more about object conversion in pandas.

For instance, you can use the converters argument of `read_csv()`:

```
In [17]: data = "col_1\n1\n2\'A'\n4.22"

In [18]: df = pd.read_csv(StringIO(data), converters="col_1": str)

In [19]: df
Out[19]:
   col_1
0    1
1    2
2   'A'
3  4.22

(continues on next page)
```
In [20]: df["col_1"].apply(type).value_counts()
Out[20]:
<class 'str'>  4
Name: col_1, dtype: int64

Or you can use the `to_numeric()` function to coerce the dtypes after reading in the data,

In [21]: df2 = pd.read_csv(StringIO(data))
In [22]: df2["col_1"] = pd.to_numeric(df2["col_1"], errors="coerce")
In [23]: df2
Out[23]:
col_1
0  1.00
1  2.00
2  NaN
3  4.22

In [24]: df2["col_1"].apply(type).value_counts()
Out[24]:
<class 'float'>  4
Name: col_1, dtype: int64

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the `converters` argument of `read_csv()` would certainly be worth trying.

Note: In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

In [25]: col_1 = list(range(500000)) + ["a", "b"] + list(range(500000))
In [26]: df = pd.DataFrame({"col_1": col_1})
In [27]: df.to_csv("foo.csv")
In [28]: mixed_df = pd.read_csv("foo.csv")
In [29]: mixed_df["col_1"].apply(type).value_counts()
Out[29]:
<class 'int'>  737858
<class 'str'>  262144
Name: col_1, dtype: int64

In [30]: mixed_df["col_1"].dtype
Out[30]: dtype('O')
will result with `mixed_df` containing an `int` dtype for certain chunks of the column, and `str` for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of `object`, which is used for columns with mixed dtypes.

### Specifying categorical dtype

Categorical columns can be parsed directly by specifying `dtype='category'` or `dtype=CategoricalDtype(categories, ordered).`

```python
In [31]: data = "col1,col2,col3\na,b,1\nb,a,2\nc,d,3"

In [32]: pd.read_csv(StringIO(data))
Out[32]:
col1  col2  col3
0    a   b    1
1    b   a    2
2    c   d    3

In [33]: pd.read_csv(StringIO(data)).dtypes
Out[33]:
col1  object
col2  object
col3  int64
dtype: object

In [34]: pd.read_csv(StringIO(data), dtype="category").dtypes
Out[34]:
col1  category
col2  category
col3  category
dtype: object
```

Individual columns can be parsed as a `Categorical` using a dict specification:

```python
In [35]: pd.read_csv(StringIO(data), dtype={"col1": "category").dtypes
Out[35]:
col1  category
col2  object
col3  int64
dtype: object
```

Specifying `dtype='category'` will result in an unordered `Categorical` whose categories are the unique values observed in the data. For more control on the categories and order, create a `CategoricalDtype` ahead of time, and pass that for that column's `dtype`.

```python
In [36]: from pandas.api.types import CategoricalDtype

In [37]: dtype = CategoricalDtype(["d", "c", "b", "a"], ordered=True)

In [38]: pd.read_csv(StringIO(data), dtype={"col1": dtype}).dtypes
Out[38]:
col1  category
```

(continues on next page)
When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.

```
In [39]: dtype = CategoricalDtype(['a', 'b', 'd'])  # No 'c'
In [40]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
Out[40]:
0   a
1   a
2  NaN
Name: col1, dtype: category
Categories (3, object): ['a', 'b', 'd']
```

This matches the behavior of `CategoricalDtype.set_categories()`.

**Note:** With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

```
In [41]: df = pd.read_csv(StringIO(data), dtype='category')
In [42]: df.dtypes
Out[42]:
    col1    col2    col3
dtype: category  category  category
In [43]: df['col3']
Out[43]:
0   1
1   2
2   3
Name: col3, dtype: category
Categories (3, object): ['1', '2', '3']
In [44]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)
In [45]: df['col3']
Out[45]:
0   1
1   2
2   3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]
```
Naming and using columns

Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```
In [46]: data = "a,b,c\n1,2,3\n4,5,6\n7,8,9"

In [47]: print(data)
a, b, c
1, 2, 3
4, 5, 6
7, 8, 9

In [48]: pd.read_csv(StringIO(data))
Out[48]:
     a  b  c
0   1  2  3
1   4  5  6
2   7  8  9
```

By specifying the names argument in conjunction with header you can indicate other names to use and whether or not to throw away the header row (if any):

```
In [49]: print(data)
a, b, c
1, 2, 3
4, 5, 6
7, 8, 9

In [50]: pd.read_csv(StringIO(data), names=["foo", "bar", "baz"], header=0)
Out[50]:
      foo  bar  baz
0  1  2  3
1  4  5  6
2  7  8  9

In [51]: pd.read_csv(StringIO(data), names=["foo", "bar", "baz"], header=None)
Out[51]:
      foo  bar  baz
0   a   b   c
1   1   2   3
2   4   5   6
3   7   8   9
```

If the header is in a row other than the first, pass the row number to header. This will skip the preceding rows:

```
In [52]: data = "skip this skip it\na,b,c\n1,2,3\n4,5,6\n7,8,9"

In [53]: pd.read_csv(StringIO(data), header=1)
Out[53]:
     a  b  c
0   1  2  3
```

(continues on next page)
Note: Default behavior is to infer the column names: if no names are passed the behavior is identical to \texttt{header=0} and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to \texttt{header=None}.

**Duplicate names parsing**

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```python
In [54]: data = "a,b,a\n0,1,2\n3,4,5"
In [55]: pd.read_csv(StringIO(data))
Out[55]:
   a  b  a.1
0  0  1  2
1  3  4  5
```

There is no more duplicate data because \texttt{mangle_dupe_cols=True} by default, which modifies a series of duplicate columns ‘X’, ‘X1’, ‘X2’ to become ‘X’, ‘X1’, ‘X2’. If \texttt{mangle_dupe_cols=False}, duplicate data can arise:

```python
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a  b  a
0  2  1  2
1  5  4  5
```

To prevent users from encountering this problem with duplicate data, a \texttt{ValueError} exception is raised if \texttt{mangle_dupe_cols != True}:

```python
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
...  
ValueError: Setting mangle_dupe_cols=False is not supported yet
```

**Filtering columns (usecols)**

The \texttt{usecols} argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

```python
In [56]: data = "a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz"
In [57]: pd.read_csv(StringIO(data))
Out[57]:
   a  b  c  d
0  1  2  3  foo
```

(continues on next page)
In [58]: `pd.read_csv(StringIO(data), usecols=['b', 'd'])`

Out[58]:
```
   b   d
0  2  foo
1  5  bar
2  8  baz
```

In [59]: `pd.read_csv(StringIO(data), usecols=[0, 2, 3])`

Out[59]:
```
   a   c   d
0  1  3   foo
1  4  6   bar
2  7  9   baz
```

In [60]: `pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])`

Out[60]:
```
   a   c
0  1  3
1  4  6
2  7  9
```

The `usecols` argument can also be used to specify which columns not to use in the final result:

In [61]: `pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])`

Out[61]:
```
   b   d
0  2  foo
1  5  bar
2  8  baz
```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

**Comments and empty lines**

**Ignoring line comments and empty lines**

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

In [62]: `data = "\na,b,c
\n# commented line\n1,2,3\n4,5,6"

In [63]: `print(data)`

```
a,b,c

# commented line
1,2,3
```

(continues on next page)
If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:

```python
In [65]: data = "a,b,c
1,2,3
4,5,6"

In [66]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[66]:
   a  b  c
0  NaN NaN NaN
1  1.0 2.0 3.0
2  NaN NaN NaN
3  NaN NaN NaN
4  4.0 5.0 6.0
```

**Warning:** The presence of ignored lines might create ambiguities involving line numbers; the parameter `header` uses row numbers (ignoring commented/empty lines), while `skiprows` uses line numbers (including commented/empty lines):

```python
In [67]: data = "#comment
a,b,c
X,Y,Z
1,2,3"

In [68]: pd.read_csv(StringIO(data), comment="#", header=1)
Out[68]:
   A  B  C
0  1  2  3

In [69]: data = "A,B,C
#comment
a,b,c
1,2,3"

In [70]: pd.read_csv(StringIO(data), comment="#", skiprows=2)
Out[70]:
   a  b  c
0  1  2  3
```

If both `header` and `skiprows` are specified, `header` will be relative to the end of `skiprows`. For example:

```python
In [71]: data = (  ....:  "# empty\n"
....:  "# second empty line\n"
....:  "# third empty line\n"
....:  "X,Y,Z\n"
....:  "1,2,3\n"
....:  "A,B,C\n"
....:  "1,2,4.\n"
....:  "5.,NaN,10.0\n"
....:  )
```
In [72]: print(data)
# empty
# second empty line
# third empty line
X,Y,Z
1,2,3
A,B,C

In [73]: pd.read_csv(StringIO(data), comment="#", skiprows=4, header=1)
Out[73]:
    A   B   C
0  1.0  2.0  4.0
1  5.0  NaN 10.0

Comments

Sometimes comments or meta data may be included in a file:

In [74]: print(open("tmp.csv").read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome

By default, the parser includes the comments in the output:

In [75]: df = pd.read_csv("tmp.csv")

In [76]: df
Out[76]:
   ID   level  category
0  Patient1  123000          x
1  Patient2  23000          y
2  Patient3  1234018         z

We can suppress the comments using the comment keyword:

In [77]: df = pd.read_csv("tmp.csv", comment="#")

In [78]: df
Out[78]:
   ID   level  category
0  Patient1  123000          x
1  Patient2  23000          y
2  Patient3  1234018         z

2.4. IO tools (text, CSV, HDF5, …)
Dealing with Unicode data

The encoding argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```python
In [79]: from io import BytesIO
In [80]: data = b"word,length\nTräumen,7\nGrüße,5"
In [81]: data = data.decode("utf8").encode("latin-1")
In [82]: df = pd.read_csv(BytesIO(data), encoding="latin-1")
In [83]: df
Out[83]:
<table>
<thead>
<tr>
<th>word</th>
<th>length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Träumen</td>
<td>7</td>
</tr>
<tr>
<td>Grüße</td>
<td>5</td>
</tr>
</tbody>
</table>
```

Some formats which encode all characters as multiple bytes, like UTF-16, won’t parse correctly at all without specifying the encoding. Full list of Python standard encodings.

Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame’s row names:

```python
In [85]: data = "a,b,c\n4,apple,bat,5.7\n8,orange,cow,10"
In [86]: pd.read_csv(StringIO(data))
Out[86]:
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>apple</td>
<td>bat</td>
</tr>
<tr>
<td>8</td>
<td>orange</td>
<td>cow</td>
</tr>
</tbody>
</table>
```

```python
In [87]: data = "index,a,b,c\n4,apple,bat,5.7\n8,orange,cow,10"
In [88]: pd.read_csv(StringIO(data), index_col=0)
Out[88]:
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
</table>
| index
| 4   | apple | bat | 5.7 |
| 8   | orange | cow | 10.0 |
```

Ordinarily, you can achieve this behavior using the index_col option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass `index_col=False`:
In [89]: data = "a,b,c\n4,apple,bat,\n8,orange,cow,"

In [90]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [91]: pd.read_csv(StringIO(data))
Out[91]:
a  b  c
4  apple bat NaN
8  orange cow NaN

In [92]: pd.read_csv(StringIO(data), index_col=False)
Out[92]:
a  b  c
0 4  apple  bat
1 8  orange  cow

If a subset of data is being parsed using the usecols option, the index_col specification is based on that subset, not the original data.

In [93]: data = "a,b,c\n4,apple,bat,\n8,orange,cow,"

In [94]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [95]: pd.read_csv(StringIO(data), usecols=["b", "c"])
Out[95]:
b  c
4  bat NaN
8  cow NaN

In [96]: pd.read_csv(StringIO(data), usecols=["b", "c"], index_col=0)
Out[96]:
b  c
0 4  bat NaN
1 8  cow NaN

Date Handling

Specifying date columns

To better facilitate working with datetime data, read_csv() uses the keyword arguments parse_dates and date_parser to allow users to specify a variety of columns and date/time formats to turn the input text data into datetime objects.

The simplest case is to just pass in parse_dates=True:
# Use a column as an index, and parse it as dates.
```
In [97]: df = pd.read_csv("foo.csv", index_col=0, parse_dates=True)
```
```
In [98]: df
Out[98]:
   A   B   C
date
2009-01-01 a  1  2
2009-01-02 b  3  4
2009-01-03 c  4  5
```

# These are Python datetime objects
```
In [99]: df.index
Out[99]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns] →', name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```
In [100]: print(open("tmp.csv").read())
KORD,19990127,19:00:00,19:56:00,0.8100
KORD,19990127,20:00:00,19:56:00,0.0100
KORD,19990127,21:00:00,20:56:00,-0.5900
KORD,19990127,21:00:00,21:18:00,-0.9900
KORD,19990127,22:00:00,21:56:00,-0.5900
KORD,19990127,23:00:00,22:56:00,-0.5900
```
```
In [101]: df = pd.read_csv("tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]])
```
```
In [102]: df
Out[102]:
   1_2   1_3   0   4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```
In [103]: df = pd.read_csv("tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]], keep_date_col=True)
```
```
In [104]: df
Out[104]:
   1_2   1_3   0   1   2   3   4
(continues on next page)
Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[[1, 2]]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

In [105]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}

In [106]: df = pd.read_csv("tmp.csv", header=None, parse_dates=date_spec)

In [107]: df
Out[107]:
          nominal   actual  0   4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

In [108]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}

In [109]: df = pd.read_csv("tmp.csv", header=None, parse_dates=date_spec, index_col=0)

# index is the nominal column

In [110]: df
Out[110]:
          actual  0   4
nominal
1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

Note: If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

2.4. IO tools (text, CSV, HDF5, …)
Note: read_csv has a fast_path for parsing datetime strings in iso8601 format, e.g. “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

Date parsing functions

Finally, the parser allows you to specify a custom date_parser function to take full advantage of the flexibility of the date parsing API:

```
In [111]: df = pd.read_csv(
    .....:       "tmp.csv", header=None, parse_dates=date_spec, date_parser=pd.to_datetime
    .....:       )
```

```
In [112]: df
Out[112]:
   nominal       actual          0       4
0 1999-01-27 19:00:00 1999-01-27 18:56:00   KORD   0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00   KORD   0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00   KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00   KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00   KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00   KORD -0.59
```

Pandas will try to call the date_parser function in three different ways. If an exception is raised, the next one is tried:

1. date_parser is first called with one or more arrays as arguments, as defined using parse_dates (e.g., date_parser(['2013', '2013'], ['1', '2'])).
2. If #1 fails, date_parser is called with all the columns concatenated row-wise into a single array (e.g., date_parser(['2013 1', '2013 2'])).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using infer_datetime_format=True (see section below).
2. If you know the format, use pd.to_datetime(): date_parser=lambda x: pd.to_datetime(x, format=...).
3. If you have a really non-standard format, use a custom date_parser function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

Parsing a CSV with mixed timezones

Pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with parse_dates.

```
In [113]: content = """
   .....:       a
   .....:       2000-01-01T00:00:00+05:00
   .....:       2000-01-01T00:00:00+06:00"""
```

(continues on next page)
To parse the mixed-timezone values as a datetime column, pass a partially-applied `to_datetime()` with `utc=True` as the `date_parser`.

```
In [116]: df = pd.read_csv(StringIO(content),
                 parse_dates=['a'],
                 date_parser=lambda col: pd.to_datetime(col, utc=True),
                )
```

```
In [117]: df['a']
Out[117]:
0  1999-12-31 19:00:00+00:00
1  1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```

### Inferring datetime format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```
# Try to infer the format for the index column
In [118]: df = pd.read_csv('foo.csv',
                  index_col=0,
                  parse_dates=True,
                 )
```

(continues on previous page)
.. code-block:: python

    .....:
    infer_datetime_format=True,
    .....:
    .....:

In [119]: df
Out[119]:
A   B   C
date
2009-01-01 a 1 2
2009-01-02 b 3 4
2009-01-03 c 4 5

**International date formats**

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

In [120]: print(open("tmp.csv").read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

In [121]: pd.read_csv("tmp.csv", parse_dates=[0])
Out[121]:
   date  value  cat
0 2000-01-06   5   a
1 2000-02-06  10   b
2 2000-03-06  15   c

In [122]: pd.read_csv("tmp.csv", dayfirst=True, parse_dates=[0])
Out[122]:
   date  value  cat
0 2000-06-01   5   a
1 2000-06-02  10   b
2 2000-06-03  15   c

**Writing CSVs to binary file objects**

New in version 1.2.0.

`df.to_csv(..., mode="wb")` allows writing a CSV to a file object opened binary mode. In most cases, it is not necessary to specify `mode` as Pandas will auto-detect whether the file object is opened in text or binary mode.

In [123]: import io
In [124]: data = pd.DataFrame([[0, 1, 2]])
In [125]: buffer = io.BytesIO()
In [126]: data.to_csv(buffer, encoding="utf-8", compression="gzip")

Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

In [127]: val = "0.3066101993807095471566981359501369297504425048828125"

In [128]: data = "a,b,c\n1,2,{}").format(val)

In [129]: abs(pd.read_csv(StringIO(data), engine="c", float_precision=None)["c"] - float(val))

Out[129]: 5.551115123125783e-17

In [130]: abs(pd.read_csv(StringIO(data), engine="c", float_precision="high")['c'] - float(val))

Out[130]: 5.551115123125783e-17

In [131]: abs(pd.read_csv(StringIO(data), engine="c", float_precision="round_trip")['c'] - float(val))

Out[131]: 0.0
Thousand separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```
In [132]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z
```

```
In [133]: df = pd.read_csv("tmp.csv", sep="|
```

```
In [134]: df
Out[134]:
      ID    level     category
0  Patient1  123,000        x
1  Patient2   23,000        y
2  Patient3 1,234,018       z
```

```
In [135]: df.level.dtype
Out[135]: dtype('O')
```

The `thousands` keyword allows integers to be parsed correctly:

```
In [136]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z
```

```
In [137]: df = pd.read_csv("tmp.csv", sep="|", thousands="",)
```

```
In [138]: df
Out[138]:
     ID    level     category
0 Patient1  123000        x
1  Patient2   23000        y
2  Patient3  1234018       z
```

```
In [139]: df.level.dtype
Out[139]: dtype('int64')
```
**NA values**

To control which values are parsed as missing values (which are signified by NaN), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are ['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A N/A', 'N/A', 'n/a', 'NA', '<NA>', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', ''].

Let us consider some examples:

```
pd.read_csv("path_to_file.csv", na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```
pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=[''])
```

Above, only an empty field will be recognized as NaN.

```
pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=['"NA", "0"'])
```

Above, both NA and 0 as strings are NaN.

```
pd.read_csv("path_to_file.csv", na_values=['"Nope"'])
```

The default values, in addition to the string "Nope" are recognized as NaN.

**Infinity**

`inf` like values will be parsed as `np.inf` (positive infinity), and `-inf` as `-np.inf` (negative infinity). These will ignore the case of the value, meaning Inf, will also be parsed as np.inf.

**Returning Series**

Using the `squeeze` keyword, the parser will return output with a single column as a Series:

```
In [140]: print(open("tmp.csv").read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [141]: output = pd.read_csv("tmp.csv", squeeze=True)

In [142]: output
```

```
Out[142]:
Patient1   123000
Patient2   23000
Patient3  1234018
```

(continues on next page)
Boolean values

The common values True, False, TRUE, and FALSE are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the true_values and false_values options as follows:

```python
In [144]: data = "a,b,c\n1,Yes,2\n3,No,4"

In [145]: print(data)
a,b,c
1,Yes,2
3,No,4

In [146]: pd.read_csv(StringIO(data))
Out[146]:
a b c
0 1 Yes 2
1 3 No 4

In [147]: pd.read_csv(StringIO(data), true_values=["Yes"], false_values=["No"],)
Out[147]:
a b c
0 1 True 2
1 3 False 4
```

Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```python
In [148]: data = "a,b,c\n1,2,3\n4,5,6,7\n8,9,10"

In [149]: pd.read_csv(StringIO(data))
---------------------------------------------------------------------------

```

(continued from previous page)
kwds.update(kwds_defaults)

return _read(filepath_or_buffer, kwds)

kwds.update(kwds_defaults)

return _read(filepath_or_buffer, kwds)

with parser:
    return parser.read(nrows)

def read(self, nrows=None):
    nrows = validate_integer("nrows", nrows)
    index, columns, col_dict = self._engine.read(nrows)
    if index is None:
        chunks = self._reader.read_low_memory(nrows)
        # destructive to chunks
        data = _concatenate_chunks(chunks)

try:
    if self.low_memory:
        chunks = self._reader.read_low_memory(nrows)
        # destructive to chunks
        data = _concatenate_chunks(chunks)

ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4

You can elect to skip bad lines:

```
In [29]: pd.read_csv(StringIO(data), on_bad_lines="warn")
Skipping line 3: expected 3 fields, saw 4
```

```
Out[29]:
   a  b  c
0  1  2  3
1  8  9 10
```

You can also use the usecols parameter to eliminate extraneous column data that appear in some lines but not others:

```
In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])
```

```
Out[30]:
   0  1  2
0  1  2  3
1  8  9 10
```
Dialect

The dialect keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```python
In [150]: print(data)
label1, label2, label3
index1,"a,c,e
index2, b, d, f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```python
In [151]: import csv
In [152]: dia = csv.excel()
In [153]: dia.quoting = csv.QUOTE_NONE
In [154]: pd.read_csv(StringIO(data), dialect=dia)
Out[154]:
           label1  label2  label3
index1     a   c     e
index2     b   d     f
```

All of the dialect options can be specified separately by keyword arguments:

```python
In [155]: data = "a, b, c~1, 2, 3~4, 5, 6"
In [156]: pd.read_csv(StringIO(data), lineterminator="~")
Out[156]:
     a   b   c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:

```python
In [157]: data = "a, b, c\n1, 2, 3\n4, 5, 6"
In [158]: print(data)
a, b, c
1, 2, 3
4, 5, 6
```

(continues on next page)
The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

**Quoting and Escape Characters**

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```
In [160]: data = 'a,b
"hello, "Bob\", nice to see you",5'
In [161]: print(data)
a,b
"hello, "Bob\", nice to see you",5
In [162]: pd.read_csv(StringIO(data), escapechar='\\')
Out[162]:
     a  b
0 hello, "Bob", nice to see you 5
```

**Files with fixed width columns**

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- `colspecs`: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., `[from, to)`). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.
- `widths`: A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.
- `delimiter`: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

```
In [163]: print(open("bar.csv").read())
id8141  360.242940  149.910199  11950.7
id1594  444.953632  166.985655  11788.4
id1849  364.136849  183.628767  11806.2
id1230  413.836124  184.375703  11916.8
id1948  502.953953  173.237159  12468.3
```

In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf` function along with the file name:
# Column specifications are a list of half-intervals

```python
In [164]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [165]: df = pd.read_fwf("bar.csv", colspecs=colspecs, header=None, index_col=0)

In [166]: df
```

```
Out[166]:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>id8141</td>
<td>360.24</td>
<td>149.91</td>
</tr>
<tr>
<td>1</td>
<td>id1594</td>
<td>444.95</td>
<td>166.98</td>
</tr>
<tr>
<td>2</td>
<td>id1849</td>
<td>364.14</td>
<td>183.63</td>
</tr>
<tr>
<td>3</td>
<td>id1230</td>
<td>413.84</td>
<td>184.38</td>
</tr>
<tr>
<td>4</td>
<td>id1948</td>
<td>502.95</td>
<td>173.24</td>
</tr>
</tbody>
</table>
```

Note how the parser automatically picks column names `X.<column number>` when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```python
# Widths are a list of integers

In [167]: widths = [6, 14, 13, 10]

In [168]: df = pd.read_fwf("bar.csv", widths=widths, header=None)

In [169]: df
```

```
Out[169]:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>id8141</td>
<td>360.24</td>
<td>149.91</td>
</tr>
<tr>
<td>1</td>
<td>id1594</td>
<td>444.95</td>
<td>166.98</td>
</tr>
<tr>
<td>2</td>
<td>id1849</td>
<td>364.14</td>
<td>183.63</td>
</tr>
<tr>
<td>3</td>
<td>id1230</td>
<td>413.84</td>
<td>184.38</td>
</tr>
<tr>
<td>4</td>
<td>id1948</td>
<td>502.95</td>
<td>173.24</td>
</tr>
</tbody>
</table>
```

The parser will take care of extra white spaces around the columns so it’s ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file’s `colspecs` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided delimiter (default delimiter is whitespace).

```python
In [170]: df = pd.read_fwf("bar.csv", header=None, index_col=0)

In [171]: df
```

```
Out[171]:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>id8141</td>
<td>360.24</td>
<td>149.91</td>
</tr>
<tr>
<td>1</td>
<td>id1594</td>
<td>444.95</td>
<td>166.98</td>
</tr>
<tr>
<td>2</td>
<td>id1849</td>
<td>364.14</td>
<td>183.63</td>
</tr>
<tr>
<td>3</td>
<td>id1230</td>
<td>413.84</td>
<td>184.38</td>
</tr>
<tr>
<td>4</td>
<td>id1948</td>
<td>502.95</td>
<td>173.24</td>
</tr>
</tbody>
</table>
```

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.
In [172]: pd.read_fwf("bar.csv", header=None, index_col=0).dtypes
Out[172]:
1    float64
2    float64
3    float64
dtype: object

In [173]: pd.read_fwf("bar.csv", header=None, dtype={2: "object"}).dtypes
Out[173]:
0    object
1    float64
2    object
3    float64
dtype: object

Indexes

Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

In [174]: print(open("foo.csv").read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5

In this special case, read_csv assumes that the first column is to be used as the index of the DataFrame:

In [175]: pd.read_csv("foo.csv")
Out[175]:
     A  B  C
20090101 a  1  2
20090102 b  3  4
20090103 c  4  5

Note that the dates weren’t automatically parsed. In that case you would need to do as before:

In [176]: df = pd.read_csv("foo.csv", parse_dates=True)

In [177]: df.index
Out[177]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns] ...
    freq=None)
Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```python
In [178]: print(open("data/mindex_ex.csv").read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",1.4,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a `MultiIndex` for the index of the returned object:

```python
In [179]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0, 1])
In [180]: df
Out[180]:
    zit  xit
year indiv
1977 A  1.20  0.60
      B  1.50  0.50
      C  1.70  0.80
1978 A  0.20  0.06
      B  0.70  0.20
      C  0.80  0.30
      D  0.90  0.50
      E  1.40  0.90
1979 C  0.20  0.15
      D  0.14  0.05
      E  0.50  0.15
      F  1.20  0.50
      G  3.40  1.90
      H  5.40  2.70
      I  6.40  1.20
```

```python
In [181]: df.loc[1978]
Out[181]:
    zit  xit
indiv
A  0.2  0.06
B  0.7  0.20
```
Reading columns with a MultiIndex

By specifying list of row locations for the `header` argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

```python
In [182]: from pandas._testing import makeCustomDataframe as mkdf

In [183]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [184]: df.to_csv("mi.csv")

In [185]: pd.read_csv("mi.csv", header=[0, 1, 2, 3], index_col=[0, 1])
```

`read_csv` is also able to interpret a more common format of multi-columns indices.

```python
In [187]: print(open("mi2.csv").read())
```

2.4. IO tools (text, CSV, HDF5, ...) 305
Note: If an `index_col` is not specified (e.g. you don’t have an index, or wrote it with `df.to_csv(..., index=False)`, then any names on the columns index will be *lost*.

Automatically “sniffing” the delimiter

read_csv is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the `csv.Sniffer` class of the csv module. For this, you have to specify `sep=None`.

```
In [189]: print(open("tmp2.sv").read())
```

```

```

Reading multiple files to create a single DataFrame

It’s best to use `concat()` to combine multiple files. See the cookbook for an example.
Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```
In [191]: print(open("tmp.sv").read())
|0|1|2|3
0|0.4691122999071863|-0.282863443286633|-1.5090585031735124|-1.135632731071934
1|1.2121120250208506|-0.17321464905330858|0.11920871129693428|-0.1442359662799567
2|--0.8618489633477999|2.104569218948986|-0.4949292740687813|0.1071803807037338
3|0.721551622443669|-0.706771336300845|-1.0395749851146963|0.27185988554282986
4|--0.4249723298883753|0.567020349793672|0.27623201927771873|-0.1084006912859915
5|--0.6736897080883706|0.1136484096888855|1.4784265524372235|0.52498766771147047
6|0.40470521868202365|0.577045895204836|-1.71500020161146375|-0.1039268435147725

</table>
```

By specifying a chunksize to `read_csv`, the return value will be an iterable object of type `TextFileReader`:

```
In [194]: with pd.read_csv("tmp.sv", sep="|", chunksize=4) as reader:
    ...:     for chunk in reader:
    ...:         print(chunk)
```

(continues on next page)
Changed in version 1.2: `read_csv/json/sas` return a context-manager when iterating through a file. Specifying `iterator=True` will also return the `TextFileReader` object:

```python
In [195]: with pd.read_csv("tmp.csv", sep="|", iterator=True) as reader:
.....:          reader.get_chunk(5)
.....:
```

**Specifying the parser engine**

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

**Reading/writing remote files**

You can pass in a URL to read or write remote files to many of pandas' IO functions - the following example shows reading a CSV file:

```python
df = pd.read_csv("https://download.bls.gov/pub/time.series/cu/cu.item", sep="\t")
```

New in version 1.3.0.

A custom header can be sent alongside HTTP(s) requests by passing a dictionary of header key value mappings to the `storage_options` keyword argument as shown below:

```python
headers = {"User-Agent": "pandas"}
df = pd.read_csv(
    "https://download.bls.gov/pub/time.series/cu/cu.item",
    sep="\t",
    storage_options=headers
)
```

All URLs which are not local files or HTTP(s) are handled by `fsspec`, if installed, and its various filesystem implementations (including Amazon S3, Google Cloud, SSH, FTP, webHDFS...). Some of these implementations will require additional packages to be installed, for example S3 URLs require the `s3fs` library:

```python
df = pd.read_json("s3://pandas-test/adatafile.json")
```

When dealing with remote storage systems, you might need extra configuration with environment variables or config files in special locations. For example, to access data in your S3 bucket, you will need to define credentials in one of the several ways listed in the `S3Fs documentation`. The same is true for several of the storage backends, and you should follow the links at `fsspec1` for implementations built into `fsspec` and `fsspec2` for those not included in the main `fsspec` distribution.
You can also pass parameters directly to the backend driver. For example, if you do not have S3 credentials, you can still access public data by specifying an anonymous connection, such as

```
pd.read_csv(
    "s3://ncei-wcsd-archive/data/processed/SH1305/18kHz/SaKe2013"
    "-D20130523-T080854_to_SaKe2013-D20130523-T085643.csv",
    storage_options={"anon": True},
)
```

`fsspec` also allows complex URLs, for accessing data in compressed archives, local caching of files, and more. To locally cache the above example, you would modify the call to

```
pd.read_csv(
    "simplecache::s3://ncei-wcsd-archive/data/processed/SH1305/18kHz/
    "SaKe2013-D20130523-T080854_to_SaKe2013-D20130523-T085643.csv",
    storage_options={"s3": {"anon": True}},
)
```

where we specify that the “anon” parameter is meant for the “s3” part of the implementation, not to the caching implementation. Note that this caches to a temporary directory for the duration of the session only, but you can also specify a permanent store.

### Writing out data

#### Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- **path_or_buf**: A string path to the file to write or a file object. If a file object it must be opened with `newline=''`
- **sep**: Field delimiter for the output file (default ",")
- **na_rep**: A string representation of a missing value (default ")")
- **float_format**: Format string for floating point numbers
- **columns**: Columns to write (default None)
- **header**: Whether to write out the column names (default True)
- **index**: whether to write row (index) names (default True)
- **index_label**: Column label(s) for index column(s) if desired. If None (default), and header and index are True, then the index names are used. (A sequence should be given if the DataFrame uses MultiIndex).
- **mode**: Python write mode, default 'w'
- **encoding**: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- **line_terminator**: Character sequence denoting line end (default `os.linesep`)
- **quoting**: Set quoting rules as in csv module (default `csv.QUOTE_MINIMAL`). Note that if you have set a `float_format` then floats are converted to strings and `csv.QUOTE_NONNUMERIC` will treat them as non-numeric
- **quotechar**: Character used to quote fields (default "));")

2.4. IO tools (text, CSV, HDF5, ...) 309
• doublequote: Control quoting of quotechar in fields (default True)
• escapechar: Character used to escape sep and quotechar when appropriate (default None)
• chunksize: Number of rows to write at a time
• date_format: Format string for datetime objects

Writing a formatted string

The DataFrame object has an instance method to_string which allows control over the string representation of the object. All arguments are optional:
• buf default None, for example a StringIO object
• columns default None, which columns to write
• col_size default None, minimum width of each column.
• na_rep default NaN, representation of NA value
• formatters default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
• float_format default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the DataFrame.
• sparsify default True, set to False for a DataFrame with a hierarchical index to print every MultiIndex key at each row.
• index_names default True, will print the names of the indices
• index default True, will print the index (ie, row labels)
• header default True, will print the column labels
• justify default left, will print column headers left- or right-justified

The Series object also has a to_string method, but with only the buf, na_rep, float_format arguments. There is also a length argument which, if set to True, will additionally output the length of the Series.

2.4.2 JSON

Read and write JSON format files and strings.

Writing JSON

A Series or DataFrame can be converted to a valid JSON string. Use to_json with optional parameters:
• path_or_buf : the pathname or buffer to write the output This can be None in which case a JSON string is returned
• orient:
  Series:
    – default is index
    – allowed values are {split, records, index}
  DataFrame:
- default is columns
- allowed values are \{split, records, index, columns, values, table\}

The format of the JSON string

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>split</td>
<td>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</td>
</tr>
<tr>
<td>records</td>
<td>list like [[column -&gt; value], ..., [column -&gt; value]]</td>
</tr>
<tr>
<td>index</td>
<td>dict like {index -&gt; [column -&gt; value]}</td>
</tr>
<tr>
<td>columns</td>
<td>dict like {column -&gt; [index -&gt; value]}</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
</tbody>
</table>

- `date_format`: string, type of date conversion, ‘epoch’ for timestamp, ‘iso’ for ISO8601.
- `double_precision`: The number of decimal places to use when encoding floating point values, default 10.
- `force_ascii`: force encoded string to be ASCII, default True.
- `date_unit`: The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’ or ‘ns’ for seconds, milliseconds, microseconds and nanoseconds respectively. Default ‘ms’.
- `default_handler`: The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- `lines`: If records orient, then will write each record per line as json.

Note NaN’s, NaT’s and None will be converted to null and datetime objects will be converted based on the `date_format` and `date_unit` parameters.

```python
In [196]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))
In [197]: json = dfj.to_json()
In [198]: json
Out[198]: '{"A":{"0":-1.2945235903,"1":0.2766617129,"2":-0.0139597524,"3":-0.0061536999,"4":0.8957173022},"B":{"0":0.4137381054,"1":-0.472034511,"2":-0.3625429925,"3":-0.923060654,"4":0.8052440254}}'
```

### Orient options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```python
In [199]: dfjo = pd.DataFrame(
    ...:     dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
    ...:     columns=list("ABC"),
    ...:     index=list("xyz"),
    ...: )
    ...: 
In [200]: dfjo
Out[200]:
   A  B  C
  x 1  4  7
  y 2  5  8
```

(continues on next page)
In [201]: sjo = pd.Series(dict(x=15, y=16, z=17), name="D")

In [202]: sjo
Out[202]:
x 15
y 16
z 17
Name: D, dtype: int64

Column oriented (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

In [203]: dfjo.to_json(orient="columns")
Out[203]: '{"A":{"x":1,"y":2,"z":3},"B":{"x":4,"y":5,"z":6},"C":{"x":7,"y":8,"z":9}}'

Index oriented (the default for Series) similar to column oriented but the index labels are now primary:

In [204]: dfjo.to_json(orient="index")
Out[204]: '{"x":{"A":1,"B":4,"C":7},"y":{"A":2,"B":5,"C":8},"z":{"A":3,"B":6,"C":9}}'

In [205]: sjo.to_json(orient="index")
Out[205]: '{"x":15,"y":16,"z":17}''

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

In [206]: dfjo.to_json(orient="records")
Out[206]: '[["A"],["B"],["C"]]
In [207]: sjo.to_json(orient="records")
Out[207]: '[[15,16,17]]'

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

In [208]: dfjo.to_json(orient="values")
Out[208]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series

Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

In [209]: dfjo.to_json(orient="split")
Out[209]: '{"columns":["A","B","C"],"index":null,"data":[1,4,7],[2,5,8],[3,6,9]}'

In [210]: sjo.to_json(orient="split")
Out[210]: '{"name":"D","index":null,"data":[15,16,17]}'
Table oriented serializes to the JSON Table Schema, allowing for the preservation of metadata including but not limited to dtypes and index names.

Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the split option as it uses ordered containers.

Date handling

Writing in ISO date format:

In [211]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))

In [212]: dfd["date"] = pd.Timestamp("20130101")

In [213]: dfd = dfd.sort_index(axis=1, ascending=False)

In [214]: json = dfd.to_json(date_format="iso")

In [215]: json

Out[215]: '{"date":{"0":"2013-01-01T00:00:00.000Z","1":"2013-01-01T00:00:00.000Z","2": "2013-01-01T00:00:00.000Z","3": "2013-01-01T00:00:00.000Z","4": "2013-01-01T00:00:00.000Z"}, "B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4":0.

... 8273169356}, "A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112,"4":0.1320031703}}'

Writing in ISO date format, with microseconds:

In [216]: json = dfd.to_json(date_format="iso", date_unit="us")

In [217]: json

Out[217]: '{"date":{"0":"2013-01-01T00:00:00.000000Z","1":"2013-01-01T00:00:00.000000Z","2": "2013-01-01T00:00:00.000000Z","3": "2013-01-01T00:00:00.000000Z","4": "2013-01-01T00:00:00.000000Z"}, "B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4":-0.

... 8138502857,"4":-0.8273169356}, "A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112,"4":0.1320031703}}'

Epoch timestamps, in seconds:

In [218]: json = dfd.to_json(date_format="epoch", date_unit="s")

In [219]: json

Out[219]: '{"date":{"0":1356998400,"1":1356998400,"2":1356998400,"3":1356998400,"4":1356998400}, "B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4":-0.8273169356}, "A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112,"4":0.1320031703}}'

Writing to a file, with a date index and a date column:

In [220]: dfj2 = dfj.copy()

In [221]: dfj2["date"] = pd.Timestamp("20130101")

(continues on next page)
In [222]: dfj2["ints"] = list(range(5))
In [223]: dfj2["bools"] = True
In [224]: dfj2.index = pd.date_range("20130101", periods=5)
In [225]: dfj2.to_json("test.json")
In [226]: with open("test.json") as fh:
......: print(fh.read())
......:
{"A":{"1356998400000":-1.2945235903,"1357084800000":0.2766617129,"1357171200000":0.
0061535699,"1357344000000":0.8957173022},"B":{"1356998400000":0.4137381054,"1357084800000":-0.472034511,"1357171200000":-0.

Fallback behavior

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. np.complex_) then the default_handler, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
  - check if the object has defined a toDict method and call it. A toDict method should return a dict which will then be JSON serialized.
  - invoke the default_handler if one was provided.
  - convert the object to a dict by traversing its contents. However this will often fail with an OverflowError or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a default_handler. For example:

```python
>>> DataFrame([[1.0, 2.0, complex(1.0, 2.0)]].to_json()  # raises RuntimeWarning: Unhandled numpy dtype 15
```

can be dealt with by specifying a simple default_handler:

```python
In [227]: pd.DataFrame([[1.0, 2.0, complex(1.0, 2.0)]].to_json(default_handler=str)
Out[227]: '{"0":{(1+0j),"1":(2+0j),"2":(1+2j)}}'
```
Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a DataFrame if typ is not supplied or is None. To explicitly force Series parsing, pass typ=series

- filepath_or_buffer: a VALID JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file://localhost/path/to/table.json
- typ : type of object to recover (series or frame), default ‘frame’
- orient :
  - Series :
    - default is index
    - allowed values are {split, records, index}
  - DataFrame
    - default is columns
    - allowed values are {split, records, index, columns, values, table}

The format of the JSON string

<table>
<thead>
<tr>
<th>split</th>
<th>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td>list like [[column -&gt; value], ..., [column -&gt; value]]</td>
</tr>
<tr>
<td>index</td>
<td>dict like {index -&gt; [column -&gt; value]}</td>
</tr>
<tr>
<td>columns</td>
<td>dict like {column -&gt; {index -&gt; value}}</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
<tr>
<td>table</td>
<td>adhering to the JSON Table Schema</td>
</tr>
</tbody>
</table>

- dtype : if True, infer dtypes, if a dict of column to dtype, then use those, if False, then don’t infer dtypes at all, default is True, apply only to the data.
- convert_axes : boolean, try to convert the axes to the proper dtypes, default is True
- convert_dates : a list of columns to parse for dates; If True, then try to parse date-like columns, default is True.
- keep_default_dates : boolean, default True. If parsing dates, then parse the default date-like columns.
- numpy : direct decoding to NumPy arrays. default is False. Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering MUST be the same for each term if numpy=True.
- precise_float : boolean, default False. Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality.
- date_unit : string, the timestamp unit to detect if converting dates. Default None. By default the timestamp precision will be detected, if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- lines : reads file as one json object per line.
- encoding : The encoding to use to decode py3 bytes.
- chunksize : when used in combination with lines=True, return a JsonReader which reads in chunksize lines per iteration.
The parser will raise one of `ValueError/TypeError/AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see Orient Options for an overview.

### Data conversion

The default of `convert_axes=True, dtype=True, and convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to `False` if you need to preserve string-like numbers (e.g. ‘1’, ‘2’) in an axes.

**Note:** Large integer values may be converted to dates if `convert_dates=True` and the data and / or column labels appear ‘date-like’. The exact threshold depends on the `date_unit` specified. ‘date-like’ means that the column label meets one of the following criteria:

- it ends with '_at'
- it ends with '_time'
- it begins with 'timestamp'
- it is 'modified'
- it is 'date'

**Warning:** When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was float data will be converted to integer if it can be done safely, e.g. a column of 1.
- bool columns will be converted to integer on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```
In [228]: pd.read_json(json)
Out[228]:
          date    B    A
0 2013-01-01  2.565646 -1.206412
1 2013-01-01  1.340309  1.431256
2 2013-01-01 -0.226169 -1.170299
3 2013-01-01  0.813850  0.410835
4 2013-01-01 -0.827317  0.132003
```

Reading from a file:

```
In [229]: pd.read_json("test.json")
Out[229]:
          A    B     date     ints  bools
2013-01-01 -1.294524  0.413738 2013-01-01  0  True
2013-01-02  0.276662 -0.472035 2013-01-01  1  True
2013-01-03 -0.013960 -0.362543 2013-01-01  2  True
```

(continues on next page)
Don’t convert any data (but still convert axes and dates):

```python
In [230]: pd.read_json("test.json", dtype=object).dtypes
Out[230]:
A  object
B  object
date  object
ints  object
bools  object
dtype: object
```

Specify dtypes for conversion:

```python
In [231]: pd.read_json("test.json", dtype={"A": "float32", "bools": "int8"}).dtypes
Out[231]:
A  float32
B  float64
date  datetime64[ns]
ints  int64
bools  int8
dtype: object
```

Preserve string indices:

```python
In [232]: si = pd.DataFrame(
       ....:     np.zeros((4, 4)), columns=list(range(4)), index=[str(i) for i in range(4)]
       ....: )
       ....:
In [233]: si
Out[233]:
   0  1  2  3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0
In [234]: si.index
Out[234]: Index(['0', '1', '2', '3'], dtype='object')
In [235]: si.columns
Out[235]: Int64Index([0, 1, 2, 3], dtype='int64')
In [236]: json = si.to_json()
In [237]: sij = pd.read_json(json, convert_axes=False)
In [238]: sij
Out[238]:
   0  1  2  3
0  0  1  2  3
```

(continues on next page)
Dates written in nanoseconds need to be read back in nanoseconds:

```python
In [241]: json = dfj2.to_json(date_unit="ns")

# Try to parse timestamps as milliseconds -> Won't Work
In [242]: dfju = pd.read_json(json, date_unit="ms")

In [243]: dfju
Out[243]:
   A         B     date  ints  bools
0 1356998400000000000 -1.294524  0.413738  1356998400000000000  0  True
1 1357084800000000000  0.276662 -0.472035  1356998400000000000  1  True
2 1357171200000000000 -0.013960 -0.362543  1356998400000000000  2  True
3 1357257600000000000 -0.006154 -0.923061  1356998400000000000  3  True
4 1357344000000000000  0.895717  0.805244  1356998400000000000  4  True

# Let pandas detect the correct precision
In [244]: dfju = pd.read_json(json)

In [245]: dfju
Out[245]:
   A         B     date  ints  bools
0 2013-01-01 -1.294524  0.413738  2013-01-01  0  True
1 2013-01-02  0.276662 -0.472035  2013-01-01  1  True
2 2013-01-03 -0.013960 -0.362543  2013-01-01  2  True
3 2013-01-04 -0.006154 -0.923061  2013-01-01  3  True
4 2013-01-05  0.895717  0.805244  2013-01-01  4  True

# Or specify that all timestamps are in nanoseconds
In [246]: dfju = pd.read_json(json, date_unit="ns")

In [247]: dfju
Out[247]:
   A         B     date  ints  bools
0 2013-01-01 -1.294524  0.413738  2013-01-01  0  True
1 2013-01-02  0.276662 -0.472035  2013-01-01  1  True
2 2013-01-03 -0.013960 -0.362543  2013-01-01  2  True
3 2013-01-04 -0.006154 -0.923061  2013-01-01  3  True
4 2013-01-05  0.895717  0.805244  2013-01-01  4  True
```
The Numpy parameter

Note: This param has been deprecated as of version 1.0.0 and will raise a FutureWarning.
This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If numpy=True is passed to read_json an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.
This can provide speedups if you are deserialising a large amount of numeric data:

```python
In [248]: randfloats = np.random.uniform(-100, 1000, 10000)
In [249]: randfloats.shape = (1000, 10)
In [250]: dffloats = pd.DataFrame(randfloats, columns=list("ABCDEFGHIJ"))
In [251]: jsonfloats = dffloats.to_json()

In [252]: %timeit pd.read_json(jsonfloats)
    7.53 ms +- 568 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [253]: %timeit pd.read_json(jsonfloats, numpy=True)
    5.17 ms +- 40.6 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```python
In [254]: jsonfloats = dffloats.head(100).to_json()

In [255]: %timeit pd.read_json(jsonfloats)
    4.67 ms +- 252 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [256]: %timeit pd.read_json(jsonfloats, numpy=True)
    3.82 ms +- 48.9 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**Warning:** Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A ValueError may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using to_json but may not be the case if the JSON is from another source.
Normalization

pandas provides a utility function to take a dict or list of dicts and normalize this semi-structured data into a flat table.

In [257]: data = [
    ....:     {"id": 1, "name": {"first": "Coleen", "last": "Volk"}},
    ....:     {"name": {"given": "Mark", "family": "Regner"}},
    ....:     {"id": 2, "name": "Faye Raker"},
    ....:     ]

In [258]: pd.json_normalize(data)
Out[258]:
   id    name.first    name.last    name.given    name.family

    ....:        {"name": "Cuyahoga", "population": 1337},
    ....:      ],
    ....:     },
    ....:     ]

In [260]: pd.json_normalize(data, "county", ["state", "shortname", ["info", "governor"]])
Out[260]:
   name population  state  shortname  info.governor
0  Dade         12345  Florida     FL          Rick Scott
1  Broward     40000  Florida     FL          Rick Scott
2  Palm Beach  60000  Florida     FL          Rick Scott
3  Summit       1234  Ohio         OH        John Kasich
4  Cuyahoga     1337  Ohio         OH        John Kasich

The max_level parameter provides more control over which level to end normalization. With max_level=1 the following snippet normalizes until 1st nesting level of the provided dict.
In [261]: data = [
   ....:     {
   ....:         "CreatedBy": {"Name": "User001"},
   ....:         "Lookup": {
   ....:             "TextField": "Some text",
   ....:             "UserField": {"Id": "ID001", "Name": "Name001"},
   ....:         },
   ....:         "Image": {"a": "b"},
   ....:     }
   ....: ]
   ....:
In [262]: pd.json_normalize(data, max_level=1)
Out[262]:
CreatedBy.Name Lookup.TextField Lookup.UserField Image.a
0  User001 Some text {Id': 'ID001', 'Name': 'Name001'} b

Line delimited json

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

For line-delimited json files, pandas can also return an iterator which reads in chunksize lines at a time. This can be useful for large files or to read from a stream.

In [263]: jsonl = ""
   ....:     {"a": 1, "b": 2}
   ....:     {"a": 3, "b": 4}
   ....:     ""
   ....:
In [264]: df = pd.read_json(jsonl, lines=True)
In [265]: df
Out[265]:
a  b
0 1 2
1 3 4

In [266]: df.to_json(orient="records", lines=True)
Out[266]: '{"a":1,"b":2}\n{"a":3,"b":4}\n'

# reader is an iterator that returns `chunksize` lines each iteration
In [267]: with pd.read_json(StringIO(jsonl), lines=True, chunksize=1) as reader:
   ....:     reader
   ....:     for chunk in reader:
   ....:         print(chunk)
Empty DataFrame
Columns: []
Index: []
a  b
(continues on next page)
Table schema

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the orient `table` to build a JSON string with two fields, schema and data.

```
In [268]: df = pd.DataFrame(
      ....:     {
      ....:         "A": [1, 2, 3],
      ....:         "B": ["a", "b", "c"],
      ....:         "C": pd.date_range("2016-01-01", freq="d", periods=3),
      ....:     },
      ....:     index=pd.Index(range(3), name="idx"),
      ....: )
```

```
In [269]: df
Out[269]:
   idx    A    B          C
0    0  1  a  2016-01-01
1    1  2  b  2016-01-02
2    2  3  c  2016-01-03
```

```
In [270]: df.to_json(orient="table", date_format="iso")
Out[270]:
'{"schema":{"fields":["idx","A","B","C"],"schema":
  "integer",["name":"idx","type":"integer"],"name":"A","type":
  "integer"},"name":"B","type":"string"},"name":"C","type":"datetime"},"primaryKey":
  "idx"},"pandas_version":"0.20.0"},"data":
  ["idx":0,"A":1,"B":"a","C":"2016-01-01T00:00:00.000Z"],"idx":1,"A":2,"B":"b","C":"2016-01-02T00:00:00.000Z"],
  ["idx":2,"A":3,"B":"c","C":"2016-01-03T00:00:00.000Z"]}'
```

The `schema` field contains the `fields` key, which itself contains a list of column name to type pairs, including the `Index` or `MultiIndex` (see below for a list of types). The `schema` field also contains a `primaryKey` field if the (Multi)index is unique.

The second field, `data`, contains the serialized data with the `records` orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:
## Table Schema type

<table>
<thead>
<tr>
<th>pandas type</th>
<th>Table Schema type</th>
</tr>
</thead>
<tbody>
<tr>
<td>int64</td>
<td>integer</td>
</tr>
<tr>
<td>float64</td>
<td>number</td>
</tr>
<tr>
<td>bool</td>
<td>boolean</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime</td>
</tr>
<tr>
<td>timedelta64[ns]</td>
<td>duration</td>
</tr>
<tr>
<td>categorical</td>
<td>any</td>
</tr>
<tr>
<td>object</td>
<td>str</td>
</tr>
</tbody>
</table>

A few notes on the generated table schema:

- The schema object contains a pandas_version field. This contains the version of pandas' dialect of the schema, and will be incremented with each revision.

- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

```python
In [271]: from pandas.io.json import build_table_schema
In [272]: s = pd.Series(pd.date_range("2016", periods=4))
In [273]: build_table_schema(s)
Out[273]:

```{|'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime'}],
'primaryKey': ['index'],
'pandas_version': "0.20.0"}
```  

- Datetimes with a timezone (before serializing), include an additional field tz with the time zone name (e.g. 'US/Central').

```python
In [274]: s_tz = pd.Series(pd.date_range("2016", periods=12, tz="US/Central"))
In [275]: build_table_schema(s_tz)
Out[275]:

```{|'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'},
             {'primaryKey': ['index'],
             'pandas_version': "0.20.0"}
```  

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain an additional field freq with the period's frequency, e.g. 'A-DEC'.

```python
In [276]: s_per = pd.Series(1, index=pd.period_range("2016", freq="A-DEC", periods=4))
In [277]: build_table_schema(s_per)
Out[277]:

```{|'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
             {'name': 'values', 'type': 'integer'}],
'primaryKey': ['index'],
'pandas_version': "0.20.0"}
```  

- Categoricals use the any type and an enum constraint listing the set of possible values. Additionally, an ordered field is included:

```python
2.4. IO tools (text, CSV, HDF5, ...) 323
```
In [278]: s_cat = pd.Series(pd.Categorical(["a", "b", "a"]))

In [279]: build_table_schema(s_cat)
Out[279]:
{
    'fields': [{
        'name': 'index', 'type': 'integer',
        'name': 'values',
        'type': 'any',
        'constraints': {'enum': ['a', 'b'],
                        'ordered': False},
        'primaryKey': ['index'],
        'pandas_version': '0.20.0'}
}

• A primary_key field, containing an array of labels, is included if the index is unique:

In [280]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [281]: build_table_schema(s_dupe)
Out[281]:
{
    'fields': [{
        'name': 'index', 'type': 'integer',
        'name': 'values', 'type': 'integer'}],
    'primaryKey': 'index',
    'pandas_version': '0.20.0'}

• The primary_key behavior is the same with MultiIndexes, but in this case the primary_key is an array:

In [282]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product(["a", "b"], [0, 1]))

In [283]: build_table_schema(s_multi)
Out[283]:
{
    'fields': [{
        'name': 'level_0', 'type': 'string',
        'name': 'level_1', 'type': 'integer',
        'name': 'values', 'type': 'integer'}],
    'primaryKey': FrozenList(['level_0', 'level_1']),
    'pandas_version': '0.20.0'}

• The default naming roughly follows these rules:
  – For series, the object.name is used. If that’s none, then the name is values
  – For DataFrames, the stringified version of the column name is used
  – For Index (not MultiIndex), index.name is used, with a fallback to index if that is None.
  – For MultiIndex, mi.names is used. If any level has no name, then level_<i> is used.

read_json also accepts orient='table' as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner:

In [284]: df = pd.DataFrame(
    .....:     { .....:         "foo": [1, 2, 3, 4],
         .....:         "bar": ["a", "b", "c", "d"],
         .....:         "baz": pd.date_range("2018-01-01", freq="d", periods=4),
         .....:         "qux": pd.Categorical(["a", "b", "c", "c"]),
         .....:     }, .....:     index=pd.Index(range(4), name="idx"),
)
In [285]: df
Out[285]:
    foo  bar  baz  qux
idx
0  1  a  '2018-01-01'  a
1  2  b  '2018-01-02'  b
2  3  c  '2018-01-03'  c
3  4  d  '2018-01-04'  c

In [286]: df.dtypes
Out[286]:
foo    int64
bar    object
baz  datetime64[ns]
qux    category
dtype: object

In [287]: df.to_json("test.json", orient="table")

In [288]: new_df = pd.read_json("test.json", orient="table")

In [289]: new_df
Out[289]:
    foo  bar  baz  qux
idx
0  1  a  '2018-01-01'  a
1  2  b  '2018-01-02'  b
2  3  c  '2018-01-03'  c
3  4  d  '2018-01-04'  c

In [290]: new_df.dtypes
Out[290]:
foo    int64
bar    object
baz  datetime64[ns]
qux    category
dtype: object

Please note that the literal string ‘index’ as the name of an Index is not round-trippable, nor are any names beginning with 'level_' within a MultiIndex. These are used by default in DataFrame.to_json() to indicate missing values and the subsequent read cannot distinguish the intent.

In [291]: df.index.name = "index"

In [292]: df.to_json("test.json", orient="table")

In [293]: new_df = pd.read_json("test.json", orient="table")

In [294]: print(new_df.index.name)
## 2.4.3 HTML

### Reading HTML content

**Warning:** We highly encourage you to read the *HTML Table Parsing gotchas* below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas `DataFrame` objects. Let’s look at a few examples.

**Note:** `read_html` returns a list of `DataFrame` objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```python
In [295]: url = (  
       .....: "https://raw.githubusercontent.com/pandas-dev/pandas/master/"  
       .....: "pandas/tests/io/data/html/spam.html"  
       .....: )  
       .....:

In [296]: dfs = pd.read_html(url)

In [297]: dfs
Out[297]:
```

```
[       Nutrient     Unit Value per 100.0g oz 1 NLEA serving

   (continues on next page)
```

(continues on next page)
Read in the content of the “banklist.html” file and pass it to `read_html` as a string:

```python
In [298]: with open(file_path, "r") as f:
    .....:
   dfs = pd.read_html(f.read())
    .....:
In [299]: dfs
Out[299]:
```

<table>

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn’t run, please do not hesitate to report it over on pandas GitHub issues page.

Read a URL and match a table that contains specific text:

```python
match = "Metcalf Bank"
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default <th> or <td> elements located within a <thead> are used to form the column index, if multiple rows are contained within <thead> then a MultiIndex is created); if specified, the header row is taken from the data minus the parsed header elements (<th> elements).

```python
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```python
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:

```python
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (range works as well):

```python
dfs = pd.read_html(url, skiprows=range(2))
```
Specify an HTML attribute:

```python
dfs1 = pd.read_html(url, attrs="id": "table")
dfs2 = pd.read_html(url, attrs="class": "sortable")
print(np.array_equal(dfs1[0], dfs2[0]))  # Should be True
```

Specify values that should be converted to NaN:

```python
dfs = pd.read_html(url, na_values=["No Acquirer"])
```

Specify whether to keep the default set of NaN values:

```python
dfs = pd.read_html(url, keep_default_na=False)
```

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```python
url_mcc = "https://en.wikipedia.org/wiki/Mobile_country_code"
dfs = pd.read_html(
    url_mcc,
    match="Telekom Albania",
    header=0,
    converters={"MNC": str},
)
```

Use some combination of the above:

```python
dfs = pd.read_html(url, match="Metcalf Bank", index_col=0)
```

Read in pandas to_html output (with some loss of floating point precision):

```python
df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format="{0:.40g}".format)
dfin = pd.read_html(s, index_col=0)
```

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor=["lxml"])
```

Or you could pass flavor='lxml' without a list:

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor="lxml")
```

However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that as soon as a parse succeeds, the function will return.

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor=["lxml", "bs4"])
```
Writing to HTML files

DataFrames objects have an instance method `to_html` which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method `to_string` described above.

**Note:** Not all of the possible options for `DataFrame.to_html` are shown here for brevity’s sake. See `to_html()` for the full set of options.

```
In [303]: df = pd.DataFrame(np.random.randn(2, 2))
In [304]: df
Out[304]:
   0    1
0 -0.184744  0.496971
1 -0.856240  1.857977
```

```
In [305]: print(df.to_html())  # raw html
<table border="1" class="dataframe">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>0</th>
            <th>1</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <th>0</th>
            <td>-0.184744</td>
            <td>0.496971</td>
        </tr>
        <tr>
            <th>1</th>
            <td>-0.856240</td>
            <td>1.857977</td>
        </tr>
    </tbody>
</table>
```

**HTML:**

The `columns` argument will limit the columns shown:

```
In [306]: print(df.to_html(columns=[0]))
<table border="1" class="dataframe">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>0</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <th>0</th>
            <td>-0.184744</td>
            <td>0.496971</td>
        </tr>
        <tr>
            <th>1</th>
            <td>-0.856240</td>
            <td>1.857977</td>
        </tr>
    </tbody>
</table>
```
HTML:

float_format takes a Python callable to control the precision of floating point values:

```python
In [307]: print(df.to_html(float_format="{0:.10f}".format))
```

```
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>0</th>  
<th>1</th>  
</tr>
</thead>
<tbody>
<tr>  
<td>0</td>  
<td>-0.1847438576</td>  
<td>0.4969711327</td>  
</tr>
<tr>  
<td>1</td>  
<td>-0.8562396763</td>  
<td>1.8579766508</td>  
</tr>
</tbody>
</table>
```

HTML:

bold_rows will make the row labels bold by default, but you can turn that off:

```python
In [308]: print(df.to_html(bold_rows=False))
```

```
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>0</th>  
<th>1</th>  
</tr>
</thead>
<tbody>
<tr>  
<td>0</td>  
<td>-0.1847438576</td>  
<td>0.4969711327</td>  
</tr>
<tr>  
<td>1</td>  
<td>-0.8562396763</td>  
<td>1.8579766508</td>  
</tr>
</tbody>
</table>
```
The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are appended to the existing 'dataframe' class.

```
In [309]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class']))
```

```
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
<thead>
<tr style="text-align: right;"> 
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.184744</td>
<td>0.496971</td>
</tr>
<tr>
<th>1</th>
<td>-0.856240</td>
<td>1.857977</td>
</tr>
</tbody>
</table>
```

The `render_links` argument provides the ability to add hyperlinks to cells that contain URLs.

```
In [310]: url_df = pd.DataFrame(
       ....:     { 
       ....:         "name": ["Python", "pandas"],
       ....:         "url": ["https://www.python.org/", "https://pandas.pydata.org"],
       ....:     } 
       ....: )
```

```
In [311]: print(url_df.to_html(render_links=True))
```

```
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;"> 
<th></th>
</tr>
</thead>
</table>
```
Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is True). So to get the HTML without escaped characters pass `escape=False`.

```python
In [312]: df = pd.DataFrame({"a": list("&<>"), "b": np.random.randn(3)})
```

Escaped:

```python
In [313]: print(df.to_html())
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>a</th>  
<th>b</th>  
</tr>
</thead>
<tbody>
<tr>
<th>0</th>  
<td>&amp;</td>  
<td>-0.474063</td>  
</tr>
<tr>
<th>1</th>  
<td>&lt;</td>  
<td>-0.230305</td>  
</tr>
<tr>
<th>2</th>  
<td>&gt;</td>  
<td>-0.400654</td>  
</tr>
</tbody>
</table>
```
Not escaped:

```python
In [314]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
   <thead>
      <tr style="text-align: right;">
         <th></th>
         <th>a</th>
         <th>b</th>
      </tr>
   </thead>
   <tbody>
      <tr>
         <th>0</th>
         <td>&</td>
         <td>-0.474063</td>
      </tr>
      <tr>
         <th>1</th>
         <td><</td>
         <td>-0.230305</td>
      </tr>
      <tr>
         <th>2</th>
         <td>></td>
         <td>-0.400654</td>
      </tr>
   </tbody>
</table>
```

Note: Some browsers may not show a difference in the rendering of the previous two HTML tables.

**HTML Table Parsing Gotchas**

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas io function `read_html`.

**Issues with lxml**

- **Benefits**
  - lxml is very fast.
  - lxml requires Cython to install correctly.
- **Drawbacks**
  - lxml does *not* make any guarantees about the results of its parse *unless* it is given strictly valid markup.
– In light of the above, we have chosen to allow you, the user, to use the lxml backend, but this backend will use html5lib if lxml fails to parse
– It is therefore highly recommended that you install both BeautifulSoup4 and html5lib, so that you will still get a valid result (provided everything else is valid) even if lxml fails.

**Issues with BeautifulSoup4 using lxml as a backend**

- The above issues hold here as well since BeautifulSoup4 is essentially just a wrapper around a parser backend.

**Issues with BeautifulSoup4 using html5lib as a backend**

- **Benefits**
  - html5lib is far more lenient than lxml and consequently deals with real-life markup in a much saner way rather than just, e.g., dropping an element without notifying you.
  - html5lib generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  - html5lib is pure Python and requires no additional build steps beyond its own installation.

- **Drawbacks**
  - The biggest drawback to using html5lib is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

### 2.4.4 LaTeX

New in version 1.3.0.

Currently there are no methods to read from LaTeX, only output methods.

**Writing to LaTeX files**

**Note:** DataFrame and Styler objects currently have a to_latex method. We recommend using the Styler.to_latex() method over DataFrame.to_latex() due to the former’s greater flexibility with conditional styling, and the latter’s possible future deprecation.

Review the documentation for Styler.to_latex, which gives examples of conditional styling and explains the operation of its keyword arguments.

For simple application the following pattern is sufficient.

```python
In [315]: df = pd.DataFrame([[1, 2], [3, 4]], index=['a', 'b'], columns=['c', 'd'])

In [316]: print(df.style.to_latex())
\begin{tabular}{lrr}
{} & {c} & {d} \\
{a} & 1 & 2 \\
{b} & 3 & 4 \\
\end{tabular}
```

To format values before output, chain the Styler.format method.

### 2.4. IO tools (text, CSV, HDF5, …)
2.4.5 XML

Reading XML

New in version 1.3.0.

The top-level `read_xml()` function can accept an XML string/file/URL and will parse nodes and attributes into a `pandas DataFrame`.

**Note:** Since there is no standard XML structure where design types can vary in many ways, `read_xml` works best with flatter, shallow versions. If an XML document is deeply nested, use the `stylesheet` feature to transform XML into a flatter version.

Let's look at a few examples.

Read an XML string:

```python
In [318]: xml = """"<?xml version="1.0" encoding="UTF-8"?>
......: <bookstore>
......:   <book category="cooking">
......:     <title lang="en">Everyday Italian</title>
......:     <author>Giada De Laurentiis</author>
......:     <year>2005</year>
......:     <price>30.00</price>
......:   </book>
......: <book category="children">
......:   <title lang="en">Harry Potter</title>
......:   <author>J K. Rowling</author>
......:   <year>2005</year>
......:   <price>29.99</price>
......: </book>
......: <book category="web">
......:   <title lang="en">Learning XML</title>
......:   <author>Erik T. Ray</author>
......:   <year>2003</year>
......:   <price>39.95</price>
......: </book>
......: </bookstore>"
```

```python
In [319]: df = pd.read_xml(xml)
```

```python
In [320]: df
Out[320]:
```

(continues on next page)
category           title             author         year    price
0  cooking   Everyday Italian   Giada De Laurentiis 2005    30.00
2   web      Learning XML       Erik T. Ray    2003   39.95

Read a URL with no options:

```
In [321]: df = pd.read_xml("https://www.w3schools.com/xml/books.xml")
```

```
In [322]: df
Out[322]:
          category    title             author         year    price
0     cooking   Everyday Italian   Giada De Laurentiis 2005    30.00
2      web      Learning XML       Erik T. Ray    2003   39.95

Read in the content of the “books.xml” file and pass it to `read_xml` as a string:

```
In [323]: with open(file_path, "r") as f:
   ....:     df = pd.read_xml(f.read())
   ....:

In [324]: df
Out[324]:
          category    title             author         year    price
0     cooking   Everyday Italian   Giada De Laurentiis 2005    30.00
2      web      Learning XML       Erik T. Ray    2003   39.95

Read in the content of the “books.xml” as instance of `StringIO` or `BytesIO` and pass it to `read_xml`:

```
In [325]: with open(file_path, "r") as f:
   ....:     sio = StringIO(f.read())
   ....:

In [326]: df = pd.read_xml(sio)

In [327]: df
Out[327]:
          category    title             author         year    price
0     cooking   Everyday Italian   Giada De Laurentiis 2005    30.00
2      web      Learning XML       Erik T. Ray    2003   39.95
```

2.4. IO tools (text, CSV, HDF5, …)
```python
In [331]: df = pd.read_xml(
        .....:  "s3://irs-form-990/201923199349319487_public.xml",
        .....:  xpath="//irs:Form990PartVIISectionAGrp",
        .....:  namespaces={"irs": "http://www.irs.gov/efile"}
        .....:  )
```

```python
In [332]: df
Out[332]:
```

<table>
<thead>
<tr>
<th>PersonNm</th>
<th>TitleTxt</th>
</tr>
</thead>
<tbody>
<tr>
<td>Naomi Ceder</td>
<td>Chair</td>
</tr>
<tr>
<td>Van Lindberg</td>
<td>Vice Chair, General Counsel</td>
</tr>
<tr>
<td>Kurt Kaiser</td>
<td>Treasurer</td>
</tr>
<tr>
<td>Ewa Jodlowska</td>
<td>Secretary, Director of Operations</td>
</tr>
<tr>
<td>Thomas Wouters</td>
<td>Director, Vice Chair</td>
</tr>
<tr>
<td>Kenneth Reitz</td>
<td>Director</td>
</tr>
<tr>
<td>Jeffrey Triplett</td>
<td>Director</td>
</tr>
<tr>
<td>Betsy Waliszewski</td>
<td>Assistant Secretary, Event Coordinator</td>
</tr>
<tr>
<td>Guido van Rossum</td>
<td>President</td>
</tr>
<tr>
<td>Ernest W Durbin III</td>
<td>Director of Infrastructure, PyCon Chair</td>
</tr>
</tbody>
</table>

[21 rows x 10 columns]
```

With `lxml` as default parser, you access the full-featured XML library that extends Python’s ElementTree API. One powerful tool is ability to query nodes selectively or conditionally with more expressive XPath:
Specify only elements or only attributes to parse:

In [335]: df = pd.read_xml(file_path, elems_only=True)

In [336]: df
Out[336]:

<table>
<thead>
<tr>
<th>title</th>
<th>author</th>
<th>year</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Everyday Italian</td>
<td>Giada De Laurentiis</td>
<td>2005</td>
<td>30.00</td>
</tr>
<tr>
<td>Harry Potter</td>
<td>J K. Rowling</td>
<td>2005</td>
<td>29.99</td>
</tr>
<tr>
<td>Learning XML</td>
<td>Erik T. Ray</td>
<td>2003</td>
<td>39.95</td>
</tr>
</tbody>
</table>

In [337]: df = pd.read_xml(file_path, attrs_only=True)

In [338]: df
Out[338]:

<table>
<thead>
<tr>
<th>category</th>
</tr>
</thead>
<tbody>
<tr>
<td>cooking</td>
</tr>
<tr>
<td>children</td>
</tr>
<tr>
<td>web</td>
</tr>
</tbody>
</table>

XML documents can have namespaces with prefixes and default namespaces without prefixes both of which are denoted with a special attribute `xmlns`. In order to parse by node under a namespace context, `xpath` must reference a prefix.

For example, below XML contains a namespace with prefix, `doc`, and URI at `https://example.com`. In order to parse `doc:row` nodes, namespaces must be used.

In [339]: xml = """<?xml version='1.0' encoding='utf-8'?>
   ....: <doc:data xmlns:doc="https://example.com">
   ....:   <doc:row>
   ....:     <doc:shape>square</doc:shape>
   ....:     <doc:degrees>360</doc:degrees>
   ....:     <doc:sides>4.0</doc:sides>
   ....:   </doc:row>
   ....:   <doc:row>
   ....:     <doc:shape>circle</doc:shape>
   ....:     <doc:degrees>360</doc:degrees>
   ....:     <doc:sides/>
   ....:   </doc:row>
   ....:   <doc:row>
   ....:     <doc:shape>triangle</doc:shape>
   ....:     <doc:degrees>180</doc:degrees>
   ....:     <doc:sides>3.0</doc:sides>
   ....:   </doc:row>
   ....: </doc:data>"

In [340]: df = pd.read_xml(xml, 
          ....: xpath="//doc:row",
          ....: namespaces={"doc": "https://example.com"})
Similarly, an XML document can have a default namespace without prefix. Failing to assign a temporary prefix will return no nodes and raise a `ValueError`. But assigning *any* temporary name to correct URI allows parsing by nodes.

```python
In [342]: xml = """"<?xml version='1.0' encoding='utf-8'?>
......:   <data xmlns="https://example.com">
......:     <row>
......:       <shape>square</shape>
......:       <degrees>360</degrees>
......:       <sides>4.0</sides>
......:     </row>
......:     <row>
......:       <shape>circle</shape>
......:       <degrees>360</degrees>
......:       <sides/>
......:     </row>
......:     <row>
......:       <shape>triangle</shape>
......:       <degrees>180</degrees>
......:       <sides>3.0</sides>
......:     </row>
......: </data>"
```

```python
In [343]: df = pd.read_xml(xml, 
......:                 xpath="/pandas:row",
......:                 namespaces={"pandas": "https://example.com"})
```

```python
In [344]: df
Out[344]:
    shape    degrees  sides
 0  square    360    4.0
 1  circle    360   NaN
 2 triangle   180    3.0
```

However, if XPath does not reference node names such as default, `/*`, then `namespaces` is not required.

With `lxml` as parser, you can flatten nested XML documents with an XSLT script which also can be string/file/URL types. As background, XSLT is a special-purpose language written in a special XML file that can transform original XML documents into other XML, HTML, even text (CSV, JSON, etc.) using an XSLT processor.

For example, consider this somewhat nested structure of Chicago “L” Rides where station and rides elements encapsulate data in their own sections. With below XSLT, `lxml` can transform original nested document into a flatter output (as shown below for demonstration) for easier parse into `DataFrame`:

```xml
<?xml version='1.0' encoding='utf-8'?>
<data xmlns="https://example.com">
  <row>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
  </row>
  <row>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
  </row>
</data>
```
In [345]: xml = """<?xml version='1.0' encoding='utf-8'?> 
......: <response> 
......: <row> 
......:   <station id="40850" name="Library"/> 
......:   <month>2020-09-01T00:00:00</month> 
......:   <rides> 
......:     <avg_weekday_rides>864.2</avg_weekday_rides> 
......:     <avg_saturday_rides>534</avg_saturday_rides> 
......:     <avg_sunday_holiday_rides>417.2</avg_sunday_holiday_rides> 
......:   </rides> 
......: </row> 
......: <row> 
......:   <station id="41700" name="Washington/Wabash"/> 
......:   <month>2020-09-01T00:00:00</month> 
......:   <rides> 
......:     <avg_weekday_rides>2707.4</avg_weekday_rides> 
......:     <avg_saturday_rides>1909.8</avg_saturday_rides> 
......:     <avg_sunday_holiday_rides>1438.6</avg_sunday_holiday_rides> 
......:   </rides> 
......: </row> 
......: <row> 
......:   <station id="40380" name="Clark/Lake"/> 
......:   <month>2020-09-01T00:00:00</month> 
......:   <rides> 
......:     <avg_weekday_rides>2949.6</avg_weekday_rides> 
......:     <avg_saturday_rides>1657</avg_saturday_rides> 
......:     <avg_sunday_holiday_rides>1453.8</avg_sunday_holiday_rides> 
......:   </rides> 
......: </row> 
......: </response>
"""

In [346]: xsl = """"<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"> 
......:   <xsl:output method="xml" omit-xml-declaration="no" indent="yes"/> 
......:   <xsl:strip-space elements="*"/> 
......:   <xsl:template match="/response">

Writing XML

New in version 1.3.0.

DataFrame objects have an instance method to_xml which renders the contents of the DataFrame as an XML document.

**Note:** This method does not support special properties of XML including DTD, CData, XSD schemas, processing instructions, comments, and others. Only namespaces at the root level is supported. However, stylesheet allows design changes after initial output.
Let's look at a few examples.

Write an XML without options:

```python
In [350]: geom_df = pd.DataFrame(
    ....:     {
    ....:         "shape": ["square", "circle", "triangle"],
    ....:         "degrees": [360, 360, 180],
    ....:         "sides": [4, np.nan, 3],
    ....:     }
    ....: )
```

```xml
<?xml version='1.0' encoding='utf-8'>
<data>
<row>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
</row>
<row>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
</row>
<row>
    <index>2</index>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
</row>
</data>
```

Write an XML with new root and row name:

```python
In [351]: print(geom_df.to_xml(root_name="geometry", row_name="objects"))
```

```xml
<?xml version='1.0' encoding='utf-8'>
<geometry>
<objects>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
</objects>
<objects>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
</objects>
<objects>
    <index>2</index>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
</objects>
</geometry>
```
Write an attribute-centric XML:

```python
In [353]: print(geom_df.to_xml(attr_cols=geom_df.columns.tolist()))
<?xml version='1.0' encoding='utf-8'>
<data>
    <row index="0" shape="square" degrees="360" sides="4.0"/>
    <row index="1" shape="circle" degrees="360"/>
    <row index="2" shape="triangle" degrees="180" sides="3.0"/>
</data>
```

Write a mix of elements and attributes:

```python
In [354]: print(
    ....:   geom_df.to_xml(
    ....:       index=False,
    ....:       attr_cols=['shape'],
    ....:       elem_cols=['degrees', 'sides'])
    ....:)
<?xml version='1.0' encoding='utf-8'>
<data>
    <row shape="square">
        <degrees>360</degrees>
        <sides>4.0</sides>
    </row>
    <row shape="circle">
        <degrees>360</degrees>
        <sides/>
    </row>
    <row shape="triangle">
        <degrees>180</degrees>
        <sides>3.0</sides>
    </row>
</data>
```

Any DataFrames with hierarchical columns will be flattened for XML element names with levels delimited by underscores:

```python
In [355]: ext_geom_df = pd.DataFrame(  
    ....:   {
    ....:       "type": ["polygon", "other", "polygon"],
    ....:       "shape": ["square", "circle", "triangle"],
    ....:       "degrees": [360, 360, 180],
    ....:       "sides": [4, np.nan, 3],
    ....:   })
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

(continued from previous page)

.....:
In [356]: pvt_df = ext_geom_df.pivot_table(index='shape',
.....:
columns='type',
.....:
values=['degrees', 'sides'],
.....:
aggfunc='sum')
.....:
In [357]: pvt_df

2.4. IO tools (text, CSV, HDF5, . . . )

345


Write an XML with namespace prefix:

```python
In [360]: print(
    ....:     geom_df.to_xml(namespaces={'doc': 'https://example.com'},
    ....:                     prefix='doc')
    ....: )
```

```xml
<?xml version='1.0' encoding='utf-8'>
<doc:data xmlns:doc="https://example.com">
<doc:row>
    <doc:index>0</doc:index>
    <doc:shape>square</doc:shape>
    <doc:degrees>360</doc:degrees>
    <doc:sides>4.0</doc:sides>
</doc:row>
<doc:row>
    <doc:index>1</doc:index>
    <doc:shape>circle</doc:shape>
    <doc:degrees>360</doc:degrees>
    <doc:sides/>
</doc:row>
<doc:row>
    <doc:index>2</doc:index>
    <doc:shape>triangle</doc:shape>
    <doc:degrees>180</doc:degrees>
    <doc:sides>3.0</doc:sides>
</doc:row>
</doc:data>
```

Write an XML without declaration or pretty print:

```python
In [361]: print(
    ....:     geom_df.to_xml(xml_declaration=False,
    ....:                           pretty_print=False)
    ....: )
```

(continues on next page)
Write an XML and transform with stylesheet:

```python
In [362]: xsl = """
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
  <xsl:output method="xml" omit-xml-declaration="no" indent="yes"/>
  <xsl:strip-space elements="*"/>
  <xsl:template match="/data">
    <geometry>
      <xsl:apply-templates select="row"/>
    </geometry>
  </xsl:template>
  <xsl:template match="row">
    <object index="{index}" type="polygon">
      <xsl:if test="shape!='circle'">
        <xsl:attribute name="type">polygon</xsl:attribute>
      </xsl:if>
      <shape>{shape}</shape>
      <property>
        <degrees>{degrees}</degrees>
        <sides>{sides}</sides>
      </property>
    </object>
  </xsl:template>
</xsl:stylesheet>"
```

In [363]: print(geom_df.to_xml(stylesheet=xsl))

```xml
<?xml version="1.0"?>
<geometry>
  <object index="0" type="polygon">
    <shape>square</shape>
    <property>
      <degrees>360</degrees>
      <sides>4.0</sides>
    </property>
  </object>
  <object index="1">
    <shape>circle</shape>
    <property>
      <degrees>360</degrees>
      <sides/>
    </property>
  </object>
  <object index="2" type="polygon">
    <shape>triangle</shape>
    <property>
      <degrees>180</degrees>
      <sides>3.0</sides>
    </property>
  </object>
</geometry>
```

(continues on next page)
XML Final Notes

- All XML documents adhere to W3C specifications. Both etree and lxml parsers will fail to parse any markup document that is not well-formed or follows XML syntax rules. Do be aware HTML is not an XML document unless it follows XHTML specs. However, other popular markup types including KML, XAML, RSS, MusicML, MathML are compliant XML schemas.

- For above reason, if your application builds XML prior to pandas operations, use appropriate DOM libraries like etree and lxml to build the necessary document and not by string concatenation or regex adjustments. Always remember XML is a special text file with markup rules.

- With very large XML files (several hundred MBs to GBs), XPath and XSLT can become memory-intensive operations. Be sure to have enough available RAM for reading and writing to large XML files (roughly about 5 times the size of text).

- Because XSLT is a programming language, use it with caution since such scripts can pose a security risk in your environment and can run large or infinite recursive operations. Always test scripts on small fragments before full run.

- The etree parser supports all functionality of both read_xml and to_xml except for complex XPath and any XSLT. Though limited in features, etree is still a reliable and capable parser and tree builder. Its performance may trail lxml to a certain degree for larger files but relatively unnoticeable on small to medium size files.

2.4.6 Excel files

The read_excel() method can read Excel 2007+ (.xlsx) files using the openpyxl Python module. Excel 2003 (.xls) files can be read using xlrd. Binary Excel (.xlsb) files can be read using pyxlsb. The to_excel() instance method is used for saving a DataFrame to Excel. Generally the semantics are similar to working with csv data. See the cookbook for some advanced strategies.

**Warning:** The xlwt package for writing old-style .xls excel files is no longer maintained. The xlrd package is now only for reading old-style .xls files.

Before pandas 1.3.0, the default argument engine=None to read_excel() would result in using the xlrd engine in many cases, including new Excel 2007+ (.xlsx) files. pandas will now default to using the openpyxl engine.

It is strongly encouraged to install openpyxl to read Excel 2007+ (.xlsx) files. Please do not report issues when using "xlrd" to read "xlsx" files. This is no longer supported, switch to using openpyxl instead.

Attempting to use the the xlwt engine will raise a FutureWarning unless the option io.excel.xls.writer is set to "xlwt". While this option is now deprecated and will also raise a FutureWarning, it can be globally set and the warning suppressed. Users are recommended to write .xlsx files using the openpyxl engine instead.
Reading Excel files

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xls", sheet_name=",Sheet1")
```

ExcelFile class

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel`. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```python
xlsx = pd.ExcelFile("path_to_file.xls")
df = pd.read_excel(xlsx, "Sheet1")
```

The `ExcelFile` class can also be used as a context manager.

```python
with pd.ExcelFile("path_to_file.xls") as xls:
    df1 = pd.read_excel(xls, "Sheet1")
    df2 = pd.read_excel(xls, "Sheet2")
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```python
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values=[]"
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```python
# using the ExcelFile class
data = {}
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values=\"NA\")
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=1)
```

```python
# equivalent using the read_excel function
data = pd.read_excel(
    "path_to_file.xls", ["Sheet1", "Sheet2"], index_col=None, na_values=\"NA\"
)
```

ExcelFile can also be called with a `xlrd.book.Book` object as a parameter. This allows the user to control how the excel file is read. For example, sheets can be loaded on demand by calling `xlrd.open_workbook()` with `on_demand=True`.

```python
import xlrd
```

(continues on next page)
Specifying sheets

Note: The second argument is sheet_name, not to be confused with ExcelFile.sheet_names.

Note: An ExcelFile’s attribute sheet_names provides access to a list of sheets.

• The arguments sheet_name allows specifying the sheet or sheets to read.
• The default value for sheet_name is 0, indicating to read the first sheet.
• Pass a string to refer to the name of a particular sheet in the workbook.
• Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
• Pass a list of either strings or integers, to return a dictionary of specified sheets.
• Pass a None to return a dictionary of all available sheets.

# Returns a DataFrame
pd.read_excel("path_to_file.xls", "Sheet1", index_col=None, na_values=\["NA"])

Using the sheet index:

# Returns a DataFrame
pd.read_excel("path_to_file.xls", 0, index_col=None, na_values=\["NA"])

Using all default values:

# Returns a DataFrame
pd.read_excel("path_to_file.xls")

Using None to get all sheets:

# Returns a dictionary of DataFrames
pd.read_excel("path_to_file.xls", sheet_name=None)

Using a list to get multiple sheets:

# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel("path_to_file.xls", sheet_name=["Sheet1", 3])

read_excel can read more than one sheet, by setting sheet_name to either a list of sheet names, a list of sheet positions, or None to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.
Reading a MultiIndex

`read_excel` can read a `MultiIndex` index, by passing a list of columns to `index_col` and a `MultiIndex` column by passing a list of rows to `header`. If either the `index` or `columns` have serialized level names, those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a `MultiIndex` index without names:

```python
In [364]: df = pd.DataFrame({
    .....:     "a": [1, 2, 3, 4], "b": [5, 6, 7, 8],
    .....:     index=pd.MultiIndex.from_product(["a", "b"], ["c", "d"]),
    .....:     )
    .....:
In [365]: df.to_excel("path_to_file.xlsx")
In [366]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])
```

```python
In [367]: df
Out[367]:
   a b
a c 1 5
d 2 6
b c 3 7
d 4 8
```

If the index has level names, they will parsed as well, using the same parameters.

```python
In [368]: df.index = df.index.set_names(["lvl1", "lvl2"])
In [369]: df.to_excel("path_to_file.xlsx")
In [370]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])
```

```python
In [371]: df
Out[371]:
   lvl1 lvl2
a c 1 5
d 2 6
b c 3 7
d 4 8
```

If the source file has both `MultiIndex` index and columns, lists specifying each should be passed to `index_col` and `header`:

```python
In [372]: df.columns = pd.MultiIndex.from_product(["a", ["b", "d"], names=["c1", "c2"]])
In [373]: df.to_excel("path_to_file.xlsx")
In [374]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1], header=[0, 1])
In [375]: df
```

(continues on next page)
Parsing specific columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Changed in version 1.0.0.

Passing in an integer for `usecols` will no longer work. Please pass in a list of ints from 0 to `usecols` inclusive instead.

You can specify a comma-delimited set of Excel columns and ranges as a string:

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols="A,C:E")
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in `names` or inferred from the document header row(s). Those strings define which columns will be parsed:

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols=["foo", "bar"])
```

Element order is ignored, so `usecols=["baz", "joe"]` is the same as `['joe', 'baz']`.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`.

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols=lambda x: x.isalpha())
```

Parsing dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that `look` like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```
pd.read_excel("path_to_file.xls", "Sheet1", parse_dates=["date_strings")
```
Cell converters

It is possible to transform the contents of Excel cells via the converters option. For instance, to convert a column to boolean:

```python
pd.read_excel("path_to_file.xls", "Sheet1", converters={"MyBools": bool})
```

This option handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```python
def cfun(x):
    return int(x) if x else -1

pd.read_excel("path_to_file.xls", "Sheet1", converters={"MyInts": cfun})
```

Dtype specifications

As an alternative to converters, the type for an entire column can be specified using the dtype keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type str or object.

```python
pd.read_excel("path_to_file.xls", dtype={"MyInts": "int64", "MyText": str})
```

Writing Excel files

Writing Excel files to disk

To write a DataFrame object to a sheet of an Excel file, you can use the to_excel instance method. The arguments are largely the same as to_csv described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the DataFrame should be written. For example:

```python
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")
```

Files with a .xls extension will be written using xlwt and those with a .xlsx extension will be written using xlsxwriter (if available) or openpyxl.

The DataFrame will be written in a way that tries to mimic the REPL output. The index_label will be placed in the second row instead of the first. You can place it in the first row by setting the merge_cells option in to_excel() to False:

```python
df.to_excel("path_to_file.xlsx", index_label="label", merge_cells=False)
```

In order to write separate DataFrames to separate sheets in a single Excel file, one can pass an ExcelWriter.

```python
with pd.ExcelWriter("path_to_file.xlsx") as writer:
    df1.to_excel(writer, sheet_name="Sheet1")
    df2.to_excel(writer, sheet_name="Sheet2")
```
Writing Excel files to memory

pandas supports writing Excel files to buffer-like objects such as StringIO or BytesIO using ExcelWriter.

```python
from io import BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine="xlsxwriter")
df.to_excel(writer, sheet_name="Sheet1")

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

Note: engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

Excel writer engines

Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed from a future version of pandas. This is the only engine in pandas that supports writing to .xls files.

pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the XlsxWriter for .xlsx, openpyxl for .xlsm, and xlwt for .xls files. If you have multiple engines installed, you can set the default engine through setting the config options io.excel.xlsx.writer and io.excel.xls.writer. pandas will fall back on openpyxl for .xlsx files if Xlsxwriter is not available.

To specify which writer you want to use, you can pass an engine keyword argument to to_excel and to ExcelWriter. The built-in engines are:

- openpyxl: version 2.4 or higher is required
- xlsxwriter
- xlwt

```python
# By setting the 'engine' in the DataFrame 'to_excel()' methods.
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1", engine="xlsxwriter")

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter("path_to_file.xlsx", engine="xlsxwriter")

# Or via pandas configuration.
```

(continues on next page)
from pandas import options  # noqa: E402

options.io.excel.xlsx.writer = "xlsxwriter"

df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")

### Style and formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame's to_excel method.

- **float_format**: Format string for floating point numbers (default None).
- **freeze_panes**: A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so (1, 1) will freeze the first row and first column (default None).

Using the Xlsxwriter engine provides many options for controlling the format of an Excel worksheet created with the to_excel method. Excellent examples can be found in the Xlsxwriter documentation here: https://xlsxwriter.readthedocs.io/working_with_pandas.html

### 2.4.7 OpenDocument Spreadsheets

New in version 0.25.

The read_excel() method can also read OpenDocument spreadsheets using the odfpy module. The semantics and features for reading OpenDocument spreadsheets match what can be done for Excel files using engine='odf'.

```python
# Returns a DataFrame
pd.read_excel("path_to_file.ods", engine="odf")
```

**Note:** Currently pandas only supports reading OpenDocument spreadsheets. Writing is not implemented.

### 2.4.8 Binary Excel (.xlsb) files

New in version 1.0.0.

The read_excel() method can also read binary Excel files using the pyxlsb module. The semantics and features for reading binary Excel files mostly match what can be done for Excel files using engine='pyxlsb'. pyxlsb does not recognize datetime types in files and will return floats instead.

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xlsb", engine="pyxlsb")
```

**Note:** Currently pandas only supports reading binary Excel files. Writing is not implemented.
2.4.9 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A  B  C
x  1  4  p
y  2  5  q
z  3  6  r
```

And then import the data directly to a DataFrame by calling:

```
>>> clipdf = pd.read_clipboard()
>>> clipdf
   A  B  C
  x  1  4  p
  y  2  5  q
  z  3  6  r
```

The `to_clipboard` method can be used to write the contents of a DataFrame to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a DataFrame into clipboard and reading it back.

```
>>> df = pd.DataFrame(
...     {"A": [1, 2, 3], "B": [4, 5, 6], "C": ["p", "q", "r"], index=["x", "y", "z"]
... )

>>> df
   A  B  C
  x  1  4  p
  y  2  5  q
  z  3  6  r

>>> df.to_clipboard()
>>> pd.read_clipboard()
   A  B  C
  x  1  4  p
  y  2  5  q
  z  3  6  r
```

We can see that we got the same content back, which we had earlier written to the clipboard.

**Note:** You may need to install xclip or xsel (with PyQt5, PyQt4 or qtpy) on Linux to use these methods.
2.4.10 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's `cPickle` module to save data structures to disk using the pickle format.

```python
In [376]: df
Out[376]:
   c1    c2
a   a   b
lvl1  lvl2
   a   c   1   5
   d   2   6
b   c   3   7
   d   4   8

In [377]: df.to_pickle("foo.pkl")
```

The `read_pickle` function in the `pandas` namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```python
In [378]: pd.read_pickle("foo.pkl")
Out[378]:
   c1    c2
a   a   b
lvl1  lvl2

```

**Warning:** Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html

**Warning:** `read_pickle()` is only guaranteed backwards compatible back to pandas version 0.20.3

### Compressed pickle files

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of `gzip`, `bz2`, `xz` are supported for reading and writing. The `zip` file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If 'infer', then use `gzip`, `bz2`, `zip`, or `xz` if filename ends in '.gz', '.bz2', '.zip', or '.xz', respectively.

The compression parameter can also be a `dict` in order to pass options to the compression protocol. It must have a 'method' key set to the name of the compression protocol, which must be one of {'zip', 'gzip', 'bz2'}. All other key-value pairs are passed to the underlying compression library.

```python
In [379]: df = pd.DataFrame(
            .....:
```
Using an explicit compression type:

```
In [381]: df.to_pickle("data.pkl.compress", compression="gzip")
```

```
In [382]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
```

```
In [383]: rt
```

```
A  B         C
0 -0.288267 foo 2013-01-01 00:00:00
1 -0.084905 foo 2013-01-01 00:00:01
2  0.004772 foo 2013-01-01 00:00:02
3  1.382989 foo 2013-01-01 00:00:03

</tbody>
</table>
Passing options to the compression protocol in order to speed up compression:

```
In [393]: df.to_pickle("data.pkl.gz", compression={"method": "gzip", "compresslevel": 1})
```

## 2.4.11 msgpack

Pandas support for `msgpack` has been removed in version 1.0.0. It is recommended to use `pickle` instead.

Alternatively, you can also use the Arrow IPC serialization format for on-the-wire transmission of pandas objects. For documentation on pyarrow, see here.

## 2.4.12 HDF5 (PyTables)

`HDFStore` is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent PyTables library. See the cookbook for some advanced strategies.

**Warning:** pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle. Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html for more.

```
In [394]: store = pd.HDFStore("store.h5")

In [395]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Objects can be written to the file just like adding key-value pairs to a dict:

```
In [396]: index = pd.date_range("1/1/2000", periods=8)

In [397]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])  

In [398]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=["A", "B", "C"])

# store.put('s', s) is an equivalent method
In [399]: store['s'] = s

In [400]: store['df'] = df

In [401]: store
```
In a current or later Python session, you can retrieve stored objects:

```python
# store.get('df') is an equivalent method
In [402]: store['df']
Out[402]:
   A      B      C
0 2000-01-01  1.334065  0.521036  0.930384
1 2000-01-02 -1.613932  1.088104 -0.632963
2 2000-01-03 -0.585314 -0.275038 -0.937512
3 2000-01-04  0.632369 -1.249657  0.975593
4 2000-01-05  1.060617 -0.143682  0.218423
5 2000-01-06  3.050329  1.317933 -0.963725
6 2000-01-07 -0.539452 -0.771133  0.023751
7 2000-01-08  0.649464 -1.736427  0.197288
```

# dotted (attribute) access provides get as well
```python
In [403]: store.df
Out[403]:
   A      B      C
0 2000-01-01  1.334065  0.521036  0.930384
1 2000-01-02 -1.613932  1.088104 -0.632963
2 2000-01-03 -0.585314 -0.275038 -0.937512
3 2000-01-04  0.632369 -1.249657  0.975593
4 2000-01-05  1.060617 -0.143682  0.218423
5 2000-01-06  3.050329  1.317933 -0.963725
6 2000-01-07 -0.539452 -0.771133  0.023751
7 2000-01-08  0.649464 -1.736427  0.197288
```

Deletion of the object specified by the key:

```python
# store.remove('df') is an equivalent method
In [404]: del store['df']
```

```python
In [405]: store
Out[405]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Closing a Store and using a context manager:

```python
In [406]: store.close()
```

```python
In [407]: store
Out[407]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

```python
In [408]: store.is_open
Out[408]: False
```

(continues on next page)
# Working with, and automatically closing the store using a context manager

```
In [409]: with pd.HDFStore("store.h5") as store:
    .....:
    store.keys()
    .....:
```

Read/write API

HDFStore supports a top-level API using `read_hdf` for reading and `to_hdf` for writing, similar to how `read_csv` and `to_csv` work.

```
In [410]: df_tl = pd.DataFrame({"A": list(range(5)), "B": list(range(5))})

In [411]: df_tl.to_hdf("store_tl.h5", "table", append=True)

In [412]: pd.read_hdf("store_tl.h5", "table", where=["index>2"])
Out[412]:
A  B
3  3  3
4  4  4
```

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting `dropna=True`.

```
In [413]: df_with_missing = pd.DataFrame({
    .....:
    "col1": [0, np.nan, 2],
    .....:
    "col2": [1, np.nan, np.nan],
    .....:
    .....:
}

In [414]: df_with_missing
Out[414]:
col1  col2
0  0.0  1.0
1 NaN  NaN
2  2.0  NaN

In [415]: df_with_missing.to_hdf("file.h5", "df_with_missing", format="table", mode="w")

In [416]: pd.read_hdf("file.h5", "df_with_missing")
Out[416]:
col1  col2
0  0.0  1.0
1 NaN  NaN
2  2.0  NaN

In [417]: df_with_missing.to_hdf("file.h5", "df_with_missing", format="table", mode="w", dropna=True)
```

(continues on next page)
Fixed format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the fixed format. These types of stores are not appendable once written (though you can simply remove them and rewrite). Nor are they queryable; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The fixed format stores offer very fast writing and slightly faster reading than table stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='t'`.

**Warning:** A fixed format will raise a `TypeError` if you try to retrieve using a `where`:

```python
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf("test_fixed.h5", "df")
>>> pd.read_hdf("test_fixed.h5", "df", where="index>5")
TypeError: cannot pass a where specification when reading a fixed format.
this store must be selected in its entirety
```

Table format

HDFStore supports another PyTables format on disk, the table format. Conceptually a table is shaped very much like a DataFrame, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by `format='table'` or `format='t'` to append or `put` or `to_hdf`.

This format can be set as an option as well `pd.set_option('io.hdf.default_format','table')` to enable `put/append/to_hdf` to by default store in the table format.

```python
In [419]: store = pd.HDFStore("store.h5")
In [420]: df1 = df[0:4]
In [421]: df2 = df[4:]

# append data (creates a table automatically)
In [422]: store.append("df", df1)
In [423]: store.append("df", df2)

In [424]: store
Out[424]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
```
In [425]: store.select("df")

Out[425]:

<p>| | | |</p>

<td>-1.736427</td>
</tr>
</tbody>
</table>

# the type of stored data
In [426]: store.root.df._v_attrs.pandas_type

Out[426]: 'frame_table'

Note: You can also create a table by passing format='table' or format='t' to a put operation.

Hierarchical keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. foo/bar/bah), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading '/' and are always absolute (e.g. ‘foo’ refers to ‘/foo’). Removal operations can remove everything in the sub-store and below, so be careful.

In [427]: store.put("foo/bar/bah", df)

In [428]: store.append("food/orange", df)

In [429]: store.append("food/apple", df)

In [430]: store

Out[430]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# a list of keys are returned
In [431]: store.keys()

Out[431]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']

# remove all nodes under this level
In [432]: store.remove("food")

In [433]: store

Out[433]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

You can walk through the group hierarchy using the walk method which will yield a tuple for each group key along with the relative keys of its contents.
```python
In [434]: for path, subgroups, subkeys in store.walk():
    ....:     for subgroup in subgroups:
    ....:         print("GROUP: {}".format(path, subgroup))
    ....:     for subkey in subkeys:
    ....:         key = "/".join([path, subkey])
    ....:         print("KEY: {}".format(key))
    ....:         print(store.get(key))

GROUP: /foo

2000-01-08   0.649464  -1.736427   0.197288
```
Storing types

Storing mixed types in a table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize=` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
In [436]: df_mixed = pd.DataFrame(
    ...:     {'A': np.random.randn(8),
    ...:      'B': np.random.randn(8),
    ...:      'C': np.array(np.random.randn(8), dtype='float32'),
    ...:      'string': 'string',
    ...:      'int': 1,
    ...:      'bool': True,
    ...:      'datetime64': pd.Timestamp('20010102'),
    ...:      },
    ...:     index=list(range(8)),
    ...:    )

In [437]: df_mixed.loc[df_mixed.index[3:5], ['A', 'B', 'string', 'datetime64']] = np.nan

In [438]: store.append("df_mixed", df_mixed, min_itemsize={'values': 50})

In [439]: df_mixed1 = store.select("df_mixed")

In [440]: df_mixed1
Out[440]:
   A       B       C       string       int    bool      datetime64
0 -0.116008  0.743946 -0.398501   string  1       True  2001-01-02
1  0.592375 -0.533097 -0.677311   string  1       True  2001-01-02
2  0.476481 -0.140850 -0.874991   string  1       True  2001-01-02
3    NaN      NaN -1.167564   string  1       True      NaT
4    NaN      NaN  -0.593353   string  1       True      NaT
5  0.852727  0.463819  0.146262   string  1       True  2001-01-02

Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

In [443]: index = pd.MultiIndex(....: levels=["foo", "bar", "baz", "qux"], ["one", "two", "three"],....: codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2],....: names=["foo", "bar"],.....: )

In [444]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B", "C"])

In [445]: df_mi
Out[445]:

<table>
<thead>
<tr>
<th>foo</th>
<th>bar</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo one</td>
<td>0.667450</td>
<td>0.169405</td>
<td>-1.358046</td>
<td></td>
</tr>
<tr>
<td>two</td>
<td>-0.105563</td>
<td>0.492195</td>
<td>0.076693</td>
<td></td>
</tr>
<tr>
<td>three</td>
<td>0.213685</td>
<td>-0.285283</td>
<td>-1.210529</td>
<td></td>
</tr>
<tr>
<td>bar one</td>
<td>-1.408386</td>
<td>0.941577</td>
<td>-0.342447</td>
<td></td>
</tr>
<tr>
<td>two</td>
<td>0.222031</td>
<td>0.052607</td>
<td>2.093214</td>
<td></td>
</tr>
<tr>
<td>baz two</td>
<td>1.064908</td>
<td>1.778161</td>
<td>-0.913867</td>
<td></td>
</tr>
<tr>
<td>qux one</td>
<td>-0.030004</td>
<td>-0.399846</td>
<td>-1.234765</td>
<td></td>
</tr>
<tr>
<td>two</td>
<td>-0.898283</td>
<td>-0.218499</td>
<td>1.408028</td>
<td></td>
</tr>
<tr>
<td>three</td>
<td>-1.267828</td>
<td>-0.689263</td>
<td>0.520995</td>
<td></td>
</tr>
</tbody>
</table>
**Querying**

**Querying a table**

`select` and `delete` operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the `Term` class under the hood, as a boolean expression.

- `index` and `columns` are supported indexers of DataFrames.
- If `data_columns` are specified, these can be used as additional indexers.
- Level name in a MultiIndex, with default name `level_0, level_1,...` if not provided.

Valid comparison operators are:

- `=`, `==`, `!=`, `>`, `>=`, `<`, `<=`

Valid boolean expressions are combined with:

- `|`: or
- `&`: and
- `(` and `)`: for grouping

---

**Note:** The `index` keyword is reserved and cannot be used as a level name.
These rules are similar to how boolean expressions are used in pandas for indexing.

Note:
- = will be automatically expanded to the comparison operator ==
- ~ is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via &

The following are valid expressions:
- 'index >= date'
- "columns = ['A', 'D']"
- "columns in ['A', 'D']"
- 'columns = A'
- 'columns == A'
- "~(columns = ['A', 'B'])"
- 'index > df.index[3] & string = "bar"'
- '(index > df.index[3] & index <= df.index[6]) | string = "bar"'
- "ts >= Timestamp('2012-02-01')"
- "major_axis>=20130101"

The indexers are on the left-hand side of the sub-expression:
columns, major_axis, ts

The right-hand side of the sub-expression (after a comparison operator) can be:
- functions that will be evaluated, e.g. Timestamp('2012-02-01')
- strings, e.g. "bar"
- date-like, e.g. 20130101, or "20130101"
- lists, e.g. "['A', 'B']"
- variables that are defined in the local names space, e.g. date

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```python
string = "HolyMoly"
store.select("df", "index == string")
```

instead of this

```python
string = "HolyMoly"
store.select('df', f'index == {string}')
```

The latter will not work and will raise a SyntaxError. Note that there's a single quote followed by a double quote in the string variable.

If you must interpolate, use the '%r' format specifier.
store.select("df", "index == \%r\% string")

which will quote string.

Here are some examples:

```python
In [449]: dfq = pd.DataFrame(
    ....:     np.random.randn(10, 4),
    ....:     columns=list("ABCD"),
    ....:     index=pd.date_range("20130101", periods=10),
    ....: )
```

```python
In [450]: store.append("dfq", dfq, format="table", data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```python
In [451]: store.select("dfq", "index>pd.Timestamp('20130104') & columns=['A', 'B']")
```

```python
Out[451]:
```

Use inline column reference.

```python
In [452]: store.select("dfq", where="A>0 or C>0")
```

```python
Out[452]:
```

The `columns` keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a 'columns=list_of_columns_to_filter':

```python
In [453]: store.select("df", "columns=['A', 'B']")
```

```python
Out[453]:
```

(continues on next page)
start and stop parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

**Note:** select will raise a **ValueError** if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is not a data_column.

select will raise a **SyntaxError** if the query expression is not valid.

### Query timedelta64[ns]

You can store and query using the timedelta64[ns] type. Terms can be specified in the format: `<float>(<unit>)`, where float may be signed (and fractional), and unit can be D,s,ms,us,ns for the timedelta. Here’s an example:

```python
In [454]: from datetime import timedelta

In [455]: dftd = pd.DataFrame(
    ...:     {
    ...:         "A": pd.Timestamp("20130101"),
    ...:         "B": [pd.Timestamp("20130101") + timedelta(days=i, seconds=10) for i in range(10)]
    ...:     }
    ...: )

In [456]: dftd["C"] = dftd["A"] - dftd["B"]

In [457]: dftd
Out[457]:
   A        B        C
0 2013-01-01  2013-01-01  00:00:10  -1 days 23:59:50
1 2013-01-01  2013-01-02  00:00:10  -2 days 23:59:50
2 2013-01-01  2013-01-03  00:00:10  -3 days 23:59:50
3 2013-01-01  2013-01-04  00:00:10  -4 days 23:59:50
4 2013-01-01  2013-01-05  00:00:10  -5 days 23:59:50
5 2013-01-01  2013-01-06  00:00:10  -6 days 23:59:50
6 2013-01-01  2013-01-07  00:00:10  -7 days 23:59:50
7 2013-01-01  2013-01-08  00:00:10  -8 days 23:59:50
8 2013-01-01  2013-01-09  00:00:10  -9 days 23:59:50
9 2013-01-01  2013-01-10  00:00:10  -10 days 23:59:50

In [458]: store.append("dftd", dftd, data_columns=True)

In [459]: store.select("dftd", "C<'-3.5D'")
Out[459]:
   A        B        C
0 2013-01-01  2013-01-01  00:00:10  -1 days 23:59:50
1 2013-01-01  2013-01-02  00:00:10  -2 days 23:59:50
2 2013-01-01  2013-01-03  00:00:10  -3 days 23:59:50
3 2013-01-01  2013-01-04  00:00:10  -4 days 23:59:50
4 2013-01-01  2013-01-05  00:00:10  -5 days 23:59:50
5 2013-01-01  2013-01-06  00:00:10  -6 days 23:59:50
6 2013-01-01  2013-01-07  00:00:10  -7 days 23:59:50
7 2013-01-01  2013-01-08  00:00:10  -8 days 23:59:50
8 2013-01-01  2013-01-09  00:00:10  -9 days 23:59:50
9 2013-01-01  2013-01-10  00:00:10  -10 days 23:59:50
```
Query MultiIndex

Selecting from a MultiIndex can be achieved by using the name of the level.

```python
In [460]: df_mi.index.names
Out[460]: ['foo', 'bar']

In [461]: store.select("df_mi", "foo=baz and bar=two")
Out[461]:
   A    B    C
foo baz 1.064908 1.778161 -0.913867
bar two 0.337920 -0.634027 0.421107

In [462]:
   : index = pd.MultiIndex(
   :     .....:     levels=["foo", "bar", "baz", "qux"], ["one", "two", "three"],
   :     .....:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
   :     .....: )
   :
   :

In [463]: df_mi_2 = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B", "C"])

In [464]: df_mi_2
Out[464]:
   A    B    C
foo one 0.856838 1.491776 0.001283
two 0.701816 -1.097917 0.102588
three 0.661740 0.443531 0.559313
bar one -0.459055 -1.222598 -0.455304
two -0.781163 0.826204 -0.530057
baz two 0.296135 1.366810 1.073372
three -0.994957 0.755314 2.119746
qux one -2.628174 -0.089460 -0.133636
two 0.337920 -0.634027 0.421107
three 0.604303 1.053434 1.109090

In [465]: store.append("df_mi_2", df_mi_2)

# the levels are automatically included as data columns with keyword level_n

In [466]: store.select("df_mi_2", "level_0=foo and level_1=two")
```

(continues on next page)
Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and append/put operation). Creating a table index is highly encouraged. This will speed your queries a great deal when you use a `select` with the indexed dimension as the `where`.

**Note:** Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.

```python
# we have automagically already created an index (in the first section)
In [467]: i = store.root.df.table.cols.index.index

In [468]: i.optlevel, i.kind
Out[468]: (6, 'medium')

# change an index by passing new parameters
In [469]: store.create_table_index("df", optlevel=9, kind="full")

In [470]: i = store.root.df.table.cols.index.index

In [471]: i.optlevel, i.kind
Out[471]: (9, 'full')
```

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

```python
In [472]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [473]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [474]: st = pd.HDFStore("appends.h5", mode="w")

In [475]: st.append("df", df_1, data_columns=['B'], index=False)

In [476]: st.append("df", df_2, data_columns=['B'], index=False)

In [477]: st.get_storer("df").table
Out[477]: /df/table (Table(20,)) ''
   description := {
     "index": Int64Col(shape=(), dflt=0, pos=0),
     "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
     "B": Float64Col(shape=(), dflt=0.0, pos=2)}
   byteorder := 'little'
   chunkshape := (2730,)
```

Then create the index when finished appending.
In [478]: st.create_table_index("df", columns=["B"], optlevel=9, kind="full")

In [479]: st.get_storer("df").table
Out[479]:
/df/table (Table(20,)) ''
   description := {
   "index": Int64Col(shape=(), dflt=0, pos=0),
   "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
   "B": Float64Col(shape=(), dflt=0.0, pos=2)}

byteorder := 'little'
chunkshape := (2730,)
autoindex := True
colindexes := {
   "B": Index(9, full, shuffle, zlib(1)).is_csi=True}

In [480]: st.close()

See here for how to create a completely-sorted-index (CSI) on an existing store.

**Query via data columns**

You can designate (and index) certain columns that you want to be able to perform queries (other than the indexable columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify data_columns = True to force all columns to be data_columns.

In [481]: df_dc = df.copy()

In [482]: df_dc["string"] = "foo"

In [483]: df_dc.loc[df_dc.index[4:6], "string"] = np.nan

In [484]: df_dc.loc[df_dc.index[7:9], "string"] = "bar"

In [485]: df_dc["string2"] = "cool"

In [486]: df_dc.loc[df_dc.index[1:3], ["B", "C"]]
    = 1.0

In [487]: df_dc
Out[487]:
   A   B      C   string   string2
 0 2000-01-01  1.334065  0.521036 foo    cool
 1 2000-01-02 -1.613932  1.000000 foo    cool
 2 2000-01-03  -0.585314  1.000000 foo    cool
 3 2000-01-04   0.632369 -1.249657 foo    cool
 4 2000-01-05   3.050329 -0.963725  NaN    cool
 5 2000-01-06   3.050329  1.317933 -0.963725  NaN    cool
 6 2000-01-07  -0.539452  0.023751  NaN    cool
 7 2000-01-08   0.649464 -1.736427  NaN    cool

# on-disk operations
In [488]: store.append("df_dc", df_dc, data_columns=["B", "C", "string", "string2"])
(continues on next page)
In [489]: store.select("df_dc", where="B > 0")
Out[489]:
   A          B           C     string   string2
0  2000-01-01 1.334065 0.521036 0.930384   foo    cool
1  2000-01-02 -1.613932 1.000000 1.000000   foo    cool
2  2000-01-03 -0.585314 1.000000 1.000000   foo    cool
3  2000-01-06  3.050329 1.317933 -0.963725  NaN     cool

# getting creative
In [490]: store.select("df_dc", "B > 0 & C > 0 & string == foo")
Out[490]:
   A          B           C     string   string2
0  2000-01-01 1.334065 0.521036 0.930384   foo    cool
1  2000-01-02 -1.613932 1.000000 1.000000   foo    cool
2  2000-01-03 -0.585314 1.000000 1.000000   foo    cool

# this is in-memory version of this type of selection
In [491]: df_dc[(df_dc.B > 0) & (df_dc.C > 0) & (df_dc.string == "foo")]
Out[491]:
   A          B           C     string   string2
0  2000-01-01 1.334065 0.521036 0.930384   foo    cool
1  2000-01-02 -1.613932 1.000000 1.000000   foo    cool
2  2000-01-03 -0.585314 1.000000 1.000000   foo    cool

# we have automagically created this index and the B/C/string/string2
# columns are stored separately as PyTables columns
In [492]: store.root.df_dc.table
Out[492]:
'/df_dc/table (Table(8,))'
   description := {
   "index": Int64Col(shape=(), dflt=0, pos=0),
   "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
   "B": Float64Col(shape=(), dflt=0.0, pos=2),
   "C": Float64Col(shape=(), dflt=0.0, pos=3),
   "string": StringCol(itemsize=3, shape=(), dflt=b'', pos=4),
   "string2": StringCol(itemsize=4, shape=(), dflt=b'', pos=5)}
   byteorder := 'little'
   chunkshape := (1680,)
   autoindex := True
   colindexes := {
   "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "B": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "C": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "string": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "string2": Index(6, medium, shuffle, zlib(1)).is_csi=False}

There is some performance degradation by making lots of columns into data columns, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

2.4. IO tools (text, CSV, HDF5, ...)
Iterator

You can pass `iterator=True` or `chunksize=number_in_a_chunk` to `select` and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```python
In [493]: for df in store.select("df", chunksize=3):
    .....:     print(df)
    .....:
       A  B  C
2000-01-01  1.334065 0.521036 0.930384
2000-01-02  -1.613932 1.088104 0.632963
2000-01-03  -0.585314 -0.275038 -0.937512
       A  B  C
2000-01-04  0.632369 -1.249657 0.975593
2000-01-05  1.060617 -0.143682 0.218423
2000-01-06  3.050329 1.317933 -0.963725
       A  B  C
2000-01-07  -0.539452 -0.771133 0.023751
2000-01-08  0.649464 -1.736427 0.197288
```

**Note:** You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```python
for df in pd.read_hdf("store.h5", "df", chunksize=3):
    print(df)
```

Note, that the chunksize keyword applies to the source rows. So if you are doing a query, then the chunksize will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```python
In [494]: dfeq = pd.DataFrame({"number": np.arange(1, 11)})

In [495]: dfeq
Out[495]:
number
0   1
1   2
2   3
3   4
4   5
5   6
6   7
7   8
8   9
9  10

In [496]: store.append("dfeq", dfeq, data_columns=["number"])

In [497]: def chunks(l, n):
    .....:     return [l[i: i + n] for i in range(0, len(l), n)]
    .....:
```
Advanced queries

Select a single column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a Series of the result, indexed by the row number. These do not currently accept the `where` selector.

```python
In [501]: store.select_column("df_dc", "index")
Out[501]:
0   2000-01-01
1   2000-01-02
2   2000-01-03
3   2000-01-04
4   2000-01-05
5   2000-01-06
6   2000-01-07
7   2000-01-08
Name: index, dtype: datetime64[ns]
```

```python
In [502]: store.select_column("df_dc", "string")
Out[502]:
0  foo
1  foo
2  foo
3  foo
4   NaN
5   NaN
6  foo
7  bar
Name: string, dtype: object
```
Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an Int64Index of the resulting locations. These coordinates can also be passed to subsequent where operations.

```python
In [503]: df_coord = pd.DataFrame(
       ...:     np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)
       ...: )
       ...

In [504]: store.append("df_coord", df_coord)

In [505]: c = store.select_as_coordinates("df_coord", "index > 20020101")

In [506]: c
Out[506]:
Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,
            ... 990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
            dtype='int64', length=268)

In [507]: store.select("df_coord", where=c)
Out[507]:
     0         1
2002-01-02 -0.165548  0.646989
2002-01-03  0.782753 -0.123409
2002-01-04 -0.391932 -0.740915
2002-01-05  1.211070 -0.668715
2002-01-06  0.341987 -0.685867
...         ...
2002-09-22  1.788110 -0.405908
2002-09-23 -0.801912  0.768460
2002-09-24  0.466284 -0.457411
2002-09-25 -0.364060  0.785367
2002-09-26 -1.463093  1.187315
[268 rows x 2 columns]
```

Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting index from an indexing operation. This example selects the months of a datetimeindex which are 5.

```python
In [508]: df_mask = pd.DataFrame(
       ...:     np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)
       ...: )
       ...

In [509]: store.append("df_mask", df_mask)

In [510]: c = store.select_column("df_mask", "index")

(continues on next page)
```
In [511]: where = c[pd.DatetimeIndex(c).month == 5].index

In [512]: store.select("df_mask", where=where)
Out[512]:
0   1
2000-05-01  1.735883 -2.615261
2000-05-02  0.422173  2.425154
2000-05-03  0.632453 -0.165640
2000-05-04 -1.017207  0.005696
2000-05-05  0.299606  0.070606
... ... ...
2002-05-27  0.234503  1.199126
2002-05-28 -3.021833 -1.016828
2002-05-29  0.522794  0.063465
2002-05-30 -1.653736  0.031709
2002-05-31 -0.968402 -0.393583
[93 rows x 2 columns]

Storer object

If you want to inspect the stored object, retrieve via get_storer. You could use this programmatically to say get the number of rows in an object.

In [513]: store.get_storer("df_dc").nrows
Out[513]: 8

Multiple table queries

The methods append_to_multiple and select_as_multiple can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table’s index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The append_to_multiple method splits a given single DataFrame into multiple tables according to d, a dictionary that maps the table names to a list of ‘columns’ you want in that table. If None is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument selector defines which table is the selector table (which you can make queries from). The argument dropna will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely np.Nan, that row will be dropped from all tables.

If dropna is False, THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES. Remember that entirely np.Nan rows are not written to the HDFStore, so if you choose to call dropna=False, some tables may have more rows than others, and therefore select_as_multiple may not work or it may return unexpected results.

In [514]: df_mt = pd.DataFrame(
    ....:     np.random.randn(8, 6),
    ....:     index=pd.date_range("1/1/2000", periods=8),
    ....:     columns=["A", "B", "C", "D", "E", "F"],
   (continues on next page)
In [515]: df_mt["foo"] = "bar"

In [516]: dfMt.loc[dfMt.index[1], ("A", "B")].values = np.nan

# you can also create the tables individually
In [517]: store.append_to_multiple(
       "df1_mt": ["A", "B"], "df2_mt": None, dfMt, selector="df1_mt"
       ...

In [518]: store
Out[518]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# individual tables were created
In [519]: store.select("df1_mt")
Out[519]:

(continues on next page)
Delete from a table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then moving the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. To get optimal performance, it’s worthwhile to have the dimension you are deleting be the first of the indexables.

Data is ordered (on the disk) in terms of the indexables. Here’s a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- date_1
  - id_1
  - id_2
  - ...
  - id_n
- date_2
  - id_1
  - ...
  - id_n

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

**Warning:** Please note that HDF5 DOES NOT RECLAIM SPACE in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, WILL TEND TO INCREASE THE FILE SIZE.

To repack and clean the file, use `ptrepack`.

Notes & caveats

Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

- `complevel` specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0<complevel<10` enables compression.
- `complib` specifies which compression library to use. If nothing is specified the default library zlib is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:
  - zlib: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
- lzo: Fast compression and decompression.
- bzip2: Good compression rates.
- blosc: Fast compression and decompression.

Support for alternative blosc compressors:

* blosc:blosclz This is the default compressor for blosc
* blosc:lz4: A compact, very popular and fast compressor.
* blosc:lz4hc: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
* blosc:snappy: A popular compressor used in many places.
* blosc:zlib: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
* blosc:zstd: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

**Note:** If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```python
store_compressed = pd.HDFStore(  
    "store_compressed.h5", complevel=9, complib="blosc:blosclz"
)
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```python
store.append("df", df, complib="zlib", complevel=5)
```

**ptrepack**

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility ptrepack. In addition, ptrepack can change compression levels after the fact.

```bash
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore ptrepack in.h5 out.h5 will *repack* the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.
Caveats

**Warning:** **HDFStore is not-threadsafe for writing.** The underlying PyTables only supports concurrent reads (via threading or processes). If you need reading and writing at the same time, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the [GH2397](https://github.com/pandas-dev/pandas/issues/2397) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsync=True)` to do this for you.
- Once a table is created columns (DataFrame) are fixed; only exactly the same columns can be appended.
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

**Warning:** **PyTables** will show a **NaturalNameWarning** if a column name cannot be used as an attribute selector. **Natural** identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

DataTypes

**HDFStore** will map an object dtype to the **PyTables** underlying dtype. This means the following types are known to work:

<table>
<thead>
<tr>
<th>Type</th>
<th>Represents missing values</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating : float64, float32, float16</td>
<td>np.nan</td>
</tr>
<tr>
<td>integer : int64, int32, int8, uint64, uint32, uint8</td>
<td></td>
</tr>
<tr>
<td>boolean</td>
<td>NaT</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>timedelta64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>categorical</td>
<td>see the section below</td>
</tr>
<tr>
<td>object : strings</td>
<td>np.nan</td>
</tr>
</tbody>
</table>

Unicode columns are not supported, and **WILL FAIL**.

Categorical data

You can write data that contains category dtypes to a **HDFStore**. Queries work the same as if it was an object array. However, the category dtyped data is stored in a more efficient manner.

```
In [522]: dfcat = pd.DataFrame(
       ....:     {"A": pd.Series(list("aabbcdba"))_.astype("category"), "B": np.random.
       .....:         randn(8)})
       ....:     )
```
In [523]: dfcat
Out[523]:
   A    B
0  a  0.477849
1  a  0.283128
2  b -2.045700
3  b -0.338206
4  c -0.423113
5  d  2.314361
6  b -0.033100
7  a -0.965461

In [524]: dfcat.dtypes
Out[524]:
   A    category
   B     float64
dtype: object

In [525]: cstore = pd.HDFStore("cats.h5", mode="w")

In [526]: cstore.append("dfcat", dfcat, format="table", data_columns=["A"])

In [527]: result = cstore.select("dfcat", where="A in ['b', 'c']")

In [528]: result
Out[528]:
   A    B
 2  b -2.045700
 3  b -0.338206
 4  c -0.423113
 6  b -0.033100

In [529]: result.dtypes
Out[529]:
   A    category
   B     float64
dtype: object

String columns

min_itemsize

The underlying implementation of HDFStore uses a fixed column width (itemsize) for string columns. A string column itemsize is calculated as the maximum of the length of data (for that column) that is passed to the HDFStore, in the first append. Subsequent appends, may introduce a string for a column larger than the column can hold, an Exception will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass min_itemsize on the first table creation to a-priori specify the minimum length of a particular string column. min_itemsize can be an integer, or a dict mapping a column name to an integer. You can pass values as a key to allow all indexables or data_columns to have this min_itemsize.

Passing a min_itemsize dict will cause all passed columns to be created as data_columns automatically.
**Note:** If you are not passing any `data_columns`, then the `min_itemsize` will be the maximum of the length of any string passed.

```
In [530]: dfs = pd.DataFrame({"A": "foo", "B": "bar"}, index=list(range(5)))

In [531]: dfs
Out[531]:
   A   B
0  foo  bar
1  foo  bar
2  foo  bar
3  foo  bar
4  foo  bar

# A and B have a size of 30
In [532]: store.append("dfs", dfs, min_itemsize=30)

In [533]: store.get_storer("dfs").table
Out[533]:
/dfs/table (Table(5,)) ''
   description := {
     "index": Int64Col(shape=(), dflt=0, pos=0),
     "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)}
   byteorder := 'little'
   chunkshape := (963,)
   autoindex := True
   colindexes := {
     "index": Index(6, medium, shuffle, zlib(1)).is_csi=False}

# A is created as a data_column with a size of 30
# B is size is calculated
In [534]: store.append("dfs2", dfs, min_itemsize={"A": 30})

In [535]: store.get_storer("dfs2").table
Out[535]:
/dfs2/table (Table(5,)) ''
   description := {
     "index": Int64Col(shape=(), dflt=0, pos=0),
     "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
     "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)}
   byteorder := 'little'
   chunkshape := (1598,)
   autoindex := True
   colindexes := {
     "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
     "A": Index(6, medium, shuffle, zlib(1)).is_csi=False}
```

**nan_rep**

String columns will serialize a `np.nan` (a missing value) with the `nan_rep` string representation. This defaults to the string value `nan`. You could inadvertently turn an actual `nan` value into a missing value.

2.4. IO tools (text, CSV, HDF5, ...)

---

`pandas: powerful Python data analysis toolkit, Release 1.3.4`
```python
In [536]: dfss = pd.DataFrame({"A": ["foo", "bar", "nan"]})

In [537]: dfss
Out[537]:
   A
0  foo
1  bar
2  nan

In [538]: store.append("dfss", dfss)

In [539]: store.select("dfss")
Out[539]:
   A
0  foo
1  bar
2  NaN

# here you need to specify a different nan rep
In [540]: store.append("dfss2", dfss, nan_rep="_nan_")

In [541]: store.select("dfss2")
Out[541]:
   A
0  foo
1  bar
2  nan
```

**External compatibility**

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the rhdf5 library (Package website). Create a table format store like this:

```python
In [542]: df_for_r = pd.DataFrame(
       ...:     {  
       ...:         "first": np.random.rand(100),
       ...:         "second": np.random.rand(100),
       ...:         "class": np.random.randint(0, 2, (100,)),
       ...:     },
       ...:     index=range(100),
       ...: )

In [543]: df_for_r.head()
Out[543]:
   first   second class
0  0.864919  0.852910   0
1  0.030579  0.412962   1
2  0.015226  0.978410   0
```

(continues on next page)
In R this file can be read into a data.frame object using the rhdf5 library. The following example function reads the corresponding column names and data values from the values and assembles them into a data.frame:

```r
# Load values and column names for all datasets from corresponding nodes and # insert them into one data.frame object.
library(rhdf5)
loadhdf5data <- function(h5File) {

listing <- h5ls(h5File)
# Find all data nodes, values are stored in '_values' and corresponding column # titles in '_items'
data_nodes <- grep("_values", listing$names)
name_nodes <- grep("_items", listing$names)
data_paths = paste(listing$group[data_nodes], listing$names[data_nodes], sep = "/")
name_paths = paste(listing$group[name_nodes], listing$names[name_nodes], sep = "/")
columns = list()
for (idx in seq(data_paths)) {
  # NOTE: matrices returned by h5read have to be transposed to obtain # required Fortran order!
data <- data.frame(t(h5read(h5File, data_paths[idx])))
names <- t(h5read(h5File, name_paths[idx]))
entry <- data.frame(data)
colnames(entry) <- names
columns <- append(columns, entry)
}

data <- data.frame(columns)
return(data)
}
```

Now you can import the DataFrame into R:

```r
> data = loadhdf5data("transfer.hdf5")
> head(data)
   first  second class
1 0.4170220047 0.3266449 0
2 0.7203244934 0.5270581 0
```
Note: The R function lists the entire HDF5 file’s contents and assembles the data.frame object from all matching nodes, so use this only as a starting point if you have stored multiple DataFrame objects to a single HDF5 file.

Performance

- **tables** format come with a writing performance penalty as compared to **fixed** stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of rows that PyTables will expect. This will optimize read/write performance.
- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)
- A **PerformanceWarning** will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See Here for more information and some solutions.

2.4.13 Feather

Feather provides binary columnar serialization for dataframes. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize DataFrames, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats:

- The format will NOT write an Index, or MultiIndex for the DataFrame and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.
- Duplicate column names and non-string columns names are not supported
- Actual Python objects in object dtype columns are not supported. These will raise a helpful error message on an attempt at serialization.

See the Full Documentation.

```
In [547]: df = pd.DataFrame(
        ......:   {
        ......:     "a": list("abc"),
        ......:     "b": list(range(1, 4)),
        ......:     "c": np.arange(3, 6).astype("u1"),
        ......:     "d": np.arange(4.0, 7.0, dtype="float64"),
        ......:     "e": [True, False, True],
```

(continues on next page)

......:  "f": pd.Categorical(list("abc")),
......:  "g": pd.date_range("20130101", periods=3),
......:  "h": pd.date_range("20130101", periods=3, tz="US/Eastern"),
......:  "i": pd.date_range("20130101", periods=3, freq="ns"),
......: }
......: )
......:

In [548]: df
Out[548]:
  a  b  c  d  e  f  g  h
  0  a  1  3  4.0  True  a  2013-01-01 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00.

# we preserve dtypes

(continues on next page)
2.4.14 Parquet

Apache Parquet provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize DataFrame s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string columns names are not supported.
- The pyarrow engine always writes the index to the output, but fastparquet only writes non-default indexes. This extra column can cause problems for non-pandas consumers that are not expecting it. You can force including or omitting indexes with the index argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- In the pyarrow engine, categorical dtypes for non-string types can be serialized to parquet, but will de-serialize as their primitive dtype.
- The pyarrow engine preserves the ordered flag of categorical dtypes with string types. fastparquet does not preserve the ordered flag.
- Non supported types include Interval and actual Python object types. These will raise a helpful error message on an attempt at serialization. Period type is supported with pyarrow >= 0.16.0.
- The pyarrow engine preserves extension data types such as the nullable integer and string data type (requiring pyarrow >= 0.16.0, and requiring the extension type to implement the needed protocols, see the extension types documentation).

You can specify an engine to direct the serialization. This can be one of pyarrow, or fastparquet, or auto. If the engine is NOT specified, then the pd.options.io.parquet.engine option is checked; if this is also auto, then pyarrow is tried, and falling back to fastparquet.

See the documentation for pyarrow and fastparquet.

Note: These engines are very similar and should read/write nearly identical parquet format files. Currently pyarrow does not support timedelta data, fastparquet>=0.1.4 supports timezone aware datetimes. These libraries differ by having different underlying dependencies (fastparquet by using numba, while pyarrow uses a c-library).
In [554]: df = pd.DataFrame(
        
        ....:     {  
        ....:         "a": list("abc"),  
        ....:         "b": list(range(1, 4)),  
        ....:         "c": np.arange(3, 6).astype("u1"),  
        ....:         "d": np.arange(4.0, 7.0, dtype="float64"),  
        ....:         "e": [True, False, True],  
        ....:         "f": pd.date_range("20130101", periods=3),  
        ....:         "g": pd.date_range("20130101", periods=3, tz="US/Eastern"),  
        ....:         "h": pd.Categorical(list("abc")),  
        ....:         "i": pd.Categorical(list("abc"), ordered=True),  
        ....:     }
        
        ....: )

In [555]: df
Out[555]:
      a  b  c    d    e        f          g        h        i
0  a  1  3  4.0  True 2013-01-01 2013-01-01 00:00:00-05:00  a  a
1  b  2  4  5.0  False 2013-01-02 2013-01-02 00:00:00-05:00  b  b
2  c  3  5  6.0  True 2013-01-03 2013-01-03 00:00:00-05:00  c  c

In [556]: df.dtypes
Out[556]:
       a          b          c           d           e       f
dtype: object  int64      uint8      float64    bool  datetime64[ns]

Write to a parquet file.

In [557]: df.to_parquet("example_pa.parquet", engine="pyarrow")

In [558]: df.to_parquet("example_fp.parquet", engine="fastparquet")

Read from a parquet file.

In [559]: result = pd.read_parquet("example_fp.parquet", engine="fastparquet")

In [560]: result = pd.read_parquet("example_pa.parquet", engine="pyarrow")

In [561]: result.dtypes
Out[561]:
       a          b          c           d
dtype: object  int64      uint8      float64
(continues on next page)
Read only certain columns of a parquet file.

```python
In [562]: result = pd.read_parquet(
......: "example_fp.parquet",
......: engine="fastparquet",
......: columns=['a', 'b'],
......: )
......:

In [563]: result = pd.read_parquet(
......: "example_pa.parquet",
......: engine="pyarrow",
......: columns=['a', 'b'],
......: )
......:

In [564]: result.dtypes
Out[564]:
a object
b int64
dtype: object
```

### Handling indexes

Serializing a DataFrame to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```python
In [565]: df = pd.DataFrame({"a": [1, 2], "b": [3, 4]})

In [566]: df.to_parquet("test.parquet", engine="pyarrow")
```

creates a parquet file with *three* columns if you use `pyarrow` for serialization: `a`, `b`, and `__index_level_0__`. If you’re using `fastparquet`, the index may or may not be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn’t exist in the target table.

If you want to omit a dataframe’s indexes when writing, pass `index=False` to `to_parquet()`:

```python
In [567]: df.to_parquet("test.parquet", index=False)
```

This creates a parquet file with just the two expected columns, `a` and `b`. If your DataFrame has a custom index, you won’t get it back when you load this file into a DataFrame.

Passing `index=True` will always write the index, even if that’s not the underlying engine’s default behavior.
Partitioning Parquet files

Parquet supports partitioning of data based on the values of one or more columns.

```python
In [568]: df = pd.DataFrame({"a": [0, 0, 1, 1], "b": [0, 1, 0, 1]})
In [569]: df.to_parquet(path="test", engine="pyarrow", partition_cols=["a"],
     compression=None)
```

The path specifies the parent directory to which data will be saved. The `partition_cols` are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
<table>
<thead>
<tr>
<th>test</th>
<th>a=0</th>
<th>a=1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0bac803e32dc42ae83fddfd029cbdebc.parquet</td>
<td>e6ab24a4f45147b49b54a662f0c412a3.parquet</td>
</tr>
<tr>
<td></td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
```

2.4.15 ORC

New in version 1.0.0.

Similar to the `parquet` format, the ORC Format is a binary columnar serialization for data frames. It is designed to make reading data frames efficient. pandas provides only a reader for the ORC format, `read_orc()`. This requires the pyarrow library.

**Warning:**

- It is **highly recommended** to install pyarrow using conda due to some issues occurred by pyarrow.
- `read_orc()` is not supported on Windows yet, you can find valid environments on install optional dependencies.

2.4.16 SQL queries

The pandas.io.sql module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are psycopg2 for PostgreSQL or pymysql for MySQL. For SQLite this is included in Python’s standard library by default. You can find an overview of supported drivers for each SQL dialect in the SQLAlchemy docs.

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the Python DB-API.

See also some **cookbook examples** for some advanced strategies.

The key functions are:
**read_sql_table** (table_name, con[, schema, ...])  
Read SQL database table into a DataFrame.

**read_sql_query** (sql, con[, index_col, ...])  
Read SQL query into a DataFrame.

**read_sql** (sql, con[, index_col, ...])  
Read SQL query or database table into a DataFrame.

**DataFrame.to_sql** (name, con[, schema, ...])  
Write records stored in a DataFrame to a SQL database.

**Note:** The function **read_sql()** is a convenience wrapper around **read_sql_table()** and **read_sql_query()** (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the SQLite SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the **create_engine()** function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on **create_engine()** and the URI formatting, see the examples below and the SQLAlchemy documentation.

```python
In [570]: from sqlalchemy import create_engine

# Create your engine.
In [571]: engine = create_engine("sqlite:///::memory:")
```

If you want to manage your own connections you can pass one of those instead. The example below opens a connection to the database using a Python context manager that automatically closes the connection after the block has completed. See the SQLAlchemy docs for an explanation of how the database connection is handled.

```python
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table("data", conn)
```

**Warning:** When you open a connection to a database you are also responsible for closing it. Side effects of leaving a connection open may include locking the database or other breaking behaviour.

**Writing DataFrames**

Assuming the following data is in a DataFrame `data`, we can insert it into the database using **to_sql()**.

```
<table>
<thead>
<tr>
<th>id</th>
<th>Date</th>
<th>Col_1</th>
<th>Col_2</th>
<th>Col_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>2012-10-18</td>
<td>X</td>
<td>25.7</td>
<td>True</td>
</tr>
<tr>
<td>42</td>
<td>2012-10-19</td>
<td>Y</td>
<td>-12.4</td>
<td>False</td>
</tr>
<tr>
<td>63</td>
<td>2012-10-20</td>
<td>Z</td>
<td>5.73</td>
<td>True</td>
</tr>
</tbody>
</table>
```

```python
In [572]: data
Out[572]:
   id   Date       Col_1  Col_2  Col_3
0  26 2012-10-18   X  25.70  True
1  42 2012-10-19   Y -12.40  False
2  63 2012-10-20   Z  5.730  True

In [573]: data.to_sql("data", engine)
```
With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the chunksize parameter when calling `to_sql`. For example, the following writes data to the database in batches of 1000 rows at a time:

```
In [574]: data.to_sql("data_chunked", engine, chunksize=1000)
```

### SQL data types

`to_sql()` will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype `object`, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchmey `String` type instead of the default `Text` type for string columns:

```
In [575]: from sqlalchemy.types import String
In [576]: data.to_sql("data_dtype", engine, dtype={'Col_1': String})
```

**Note:** Due to the limited support for timedelta’s in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

**Note:** Columns of `category` dtype will be converted to the dense representation as you would get with `np.asarray(categorical)` (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does **not** generate a categorical.

### Datetime data types

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

<table>
<thead>
<tr>
<th>Database</th>
<th>SQL Datetime Types</th>
<th>Timezone Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLite</td>
<td>TEXT</td>
<td>No</td>
</tr>
<tr>
<td>MySQL</td>
<td>TIMESTAMP or DATETIME</td>
<td>No</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>TIMESTAMP or TIMESTAMP WITH TIME ZONE</td>
<td>Yes</td>
</tr>
</tbody>
</table>

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.
Insertion method

The parameter `method` controls the SQL insertion clause used. Possible values are:

- **None**: Uses standard SQL `INSERT` clause (one per row).
- **'multi'**: Pass multiple values in a single `INSERT` clause. It uses a special SQL syntax not supported by all backends. This usually provides better performance for analytic databases like Presto and Redshift, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy documentation.
- **callable with signature (pd_table, conn, keys, data_iter)**: This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL COPY clause:

```python
# Alternative to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    """
    Execute SQL statement inserting data

    Parameters
    ----------
    table : pandas.io.sql.SQLTable
    conn : sqlalchemy.engine.Engine or sqlalchemy.engine.Connection
    keys : list of str
        Column names
    data_iter : Iterable that iterates the values to be inserted
    """
    # gets a DBAPI connection that can provide a cursor
dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        s_buf = StringIO()
        writer = csv.writer(s_buf)
        writer.writerows(data_iter)
        s_buf.seek(0)
        columns = ', '.join('"{}"'.format(k) for k in keys)
        if table.schema:
            table_name = '{},{}'.format(table.schema, table.name)
        else:
            table_name = table.name
        sql = 'COPY {} ({}) FROM STDIN WITH CSV'.format(
            table_name, columns)
        cur.copy_expert(sql=sql, file=s_buf)
```
Reading tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

**Note:** In order to use `read_sql_table()`, you must have the SQLAlchemy optional dependency installed.

```
In [577]: pd.read_sql_table("data", engine)
Out[577]:
   index  id    Date  Col_1  Col_2  Col_3
0       0  26  2010-10-18    X   27.50  True
1       1  42  2010-10-19    Y  -12.50  False
2       2  63  2010-10-20    Z    5.73  True
```

**Note:** Note that pandas infers column dtypes from query outputs, and not by looking up data types in the physical database schema. For example, assume `userid` is an integer column in a table. Then, intuitively, `select userid ..` will return integer-valued series, while `select cast(userid as text) ...` will return object-valued (str) series. Accordingly, if the query output is empty, then all resulting columns will be returned as object-valued (since they are most general). If you foresee that your query will sometimes generate an empty result, you may want to explicitly typecast afterwards to ensure dtype integrity.

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.

```
In [578]: pd.read_sql_table("data", engine, index_col="id")
Out[578]:
  index    Date  Col_1  Col_2  Col_3
id
26    0  2010-10-18    X   27.50  True
42    1  2010-10-19    Y  -12.50  False
63    2  2010-10-20    Z    5.73  True
```

```
In [579]: pd.read_sql_table("data", engine, columns=["Col_1", "Col_2"])
Out[579]:
   Col_1  Col_2
0    X   27.50
1    Y  -12.50
2    Z    5.73
```

And you can explicitly force columns to be parsed as dates:

```
In [580]: pd.read_sql_table("data", engine, parse_dates=["Date"])
Out[580]:
   index  id    Date  Col_1  Col_2  Col_3
0       0  26  2010-10-18    X   27.50  True
1       1  42  2010-10-19    Y  -12.50  False
2       2  63  2010-10-20    Z    5.73  True
```

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```
pd.read_sql_table("data", engine, parse_dates={"Date": "%Y-%m-%d"})
pd.read_sql_table("data",)
```

(continues on next page)
You can check if a table exists using `has_table()`

**Schema support**

Reading from and writing to different schema’s is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema’s). For example:

```python
df.to_sql("table", engine, schema="other_schema")
pd.read_sql_table("table", engine, schema="other_schema")
```

**Querying**

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```python
In [581]: pd.read_sql_query("SELECT * FROM data", engine)
Out[581]:
   index  id          Date         Col_1  Col_2  Col_3
0      0   26  2010-10-18 00:00:00.000000   X   27.50    1
1      1   42  2010-10-19 00:00:00.000000   Y  -12.50    0
2      2   63  2010-10-20 00:00:00.000000   Z    5.73    1
```

Of course, you can specify a more “complex” query.

```python
In [582]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;", engine)
Out[582]:
   id  Col_1  Col_2
0  42      Y  -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```python
In [583]: df = pd.DataFrame(np.random.randn(20, 3), columns=list("abc"))
In [584]: df.to_sql("data_chunks", engine, index=False)
In [585]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks", engine, chunksize=5):
   
   print(chunk)
```

(continues on next page)
You can also run a plain query without creating a DataFrame with `execute()`. This is useful for queries that don’t return values, such as INSERT. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or `db` connection object. Again, you must use the SQL syntax variant appropriate for your database.

```python
from pandas.io import sql

sql.execute("SELECT * FROM table_name", engine)
sql.execute("INSERT INTO table_name VALUES(?, ?, ?)", engine, params=[("id", 1, 12.2, True)])
```

### Engine connection examples

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```python
from sqlalchemy import create_engine

engine = create_engine("postgresql://scott:tiger@localhost:5432/mydatabase")

engine = create_engine("mysql+mysqldb://scott:tiger@localhost/foo")

engine = create_engine("oracle://scott:tiger@127.0.0.1:1521/sidname")

engine = create_engine("mssql+pyodbc://mydsn")

# sqlite://<nohostname>/<path>
# where <path> is relative:
engine = create_engine("sqlite:///foo.db")
```
# or absolute, starting with a slash:

generate = create_engine("sqlite:///absolute/path/to/foo.db")

For more information see the examples the SQLAlchemy documentation

**Advanced SQLAlchemy queries**

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```
In [586]: import sqlalchemy as sa

In [587]: pd.read_sql(
   .....:     sa.text("SELECT * FROM data where Col_1=:col1"),
   .....:     engine, params={"col1": "X "})
```

```
Out[587]:

index id Date Col_1 Col_2 Col_3
0 0 26 2010-10-18 00:00:00.000000 X 27.5 1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```
In [588]: metadata = sa.MetaData()

In [589]: data_table = sa.Table(
   .....:     "data",
   .....:     metadata,
   .....:     sa.Column("index", sa.Integer),
   .....:     sa.Column("Date", sa.DateTime),
   .....:     sa.Column("Col_1", sa.String),
   .....:     sa.Column("Col_2", sa.Float),
   .....:     sa.Column("Col_3", sa.Boolean),
   .....:     )

In [590]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3
   .....:     is True), engine)
```

```
Out[590]:

Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [591]: import datetime as dt

In [592]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam("date"))

In [593]: pd.read_sql(expr, engine, params={"date": dt.datetime(2010, 10, 18)})
```

(continues on next page)
Out[593]:

<table>
<thead>
<tr>
<th>index</th>
<th>Date</th>
<th>Col_1</th>
<th>Col_2</th>
<th>Col_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1 2010-10-19</td>
<td>Y</td>
<td>-12.50</td>
<td>False</td>
</tr>
<tr>
<td>1</td>
<td>2 2010-10-20</td>
<td>Z</td>
<td>5.73</td>
<td>True</td>
</tr>
</tbody>
</table>

### Sqlite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the Python DB-API.

You can create connections like so:

```python
import sqlite3
con = sqlite3.connect(":memory:"
```

And then issue the following queries:

```python
data.to_sql("data", con)
pd.read_sql_query("SELECT * FROM data", con)
```

### 2.4.17 Google BigQuery

**Warning:** Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package pandas-gbq. You can `pip install pandas-gbq` to get it.

The pandas-gbq package provides functionality to read/write from Google BigQuery. pandas integrates with this external package. if pandas-gbq is installed, you can use the pandas methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from pandas-gbq.

Full documentation can be found [here](#).

### 2.4.18 Stata format

#### Writing to stata format

The method `to_stata()` will write a DataFrame into a .dta file. The format version of this file is always 115 (Stata 12).

```python
In [594]: df = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))
In [595]: df.to_stata("stata.dta")
```

Stata data files have limited data type support; only strings with 244 or fewer characters, `int8`, `int16`, `int32`, `float32` and `float64` can be stored in .dta files. Additionally, Stata reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in Stata for a particular data type will retype the variable to the next larger size. For example, `int8` values are restricted to lie between -127 and 100 in Stata, and so variables
with values above 100 will trigger a conversion to int16. nan values in floating points data types are stored as the basic missing data type (. in Stata).

**Note:** It is not possible to export missing data values for integer data types.

The Stata writer gracefully handles other data types including int64, bool, uint8, uint16, uint32 by casting to the smallest supported type that can represent the data. For example, data with a type of uint8 will be cast to int8 if all values are less than 100 (the upper bound for non-missing int8 data in Stata), or, if values are outside of this range, the variable is cast to int16.

**Warning:** Conversion from int64 to float64 may result in a loss of precision if int64 values are larger than $2^{**53}$.

**Warning:** StataWriter and to_stata() only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write Stata dta files with strings longer than 244 characters raises a ValueError.

### Reading from Stata format

The top-level function `read_stata` will read a dta file and return either a DataFrame or a StataReader that can be used to read the file incrementally.

```python
In [596]: pd.read_stata("stata.dta")
Out[596]:
   index  A       B
0       0  0.608228  1.064810
1       1 -0.780506 -2.736887
2       2  0.143539  1.170191
3       3 -1.573076  0.075792
4       4 -1.722223 -0.774650
5       5  0.803627  0.221665
6       6  0.584637  0.147264
7       7  1.057825 -0.284136
8       8  0.912395  1.552808
9       9  0.189376 -0.109830
```

Specifying a chunksize yields a StataReader instance that can be used to read chunksize lines from the file at a time. The StataReader object can be used as an iterator.

```python
In [597]: with pd.read_stata("stata.dta", chunksize=3) as reader:
   ....:     for df in reader:
   ....:         print(df.shape)
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.
Currently the index is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have `object` data type.

**Note:** `read_stata()` and `StataReader` support `.dta` formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

**Note:** Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

### Categorical data

Categorical data can be exported to Stata data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. Stata does not have an explicit equivalent to a `Categorical` and information about whether the variable is ordered is lost when exporting.

**Warning:** Stata only supports string value labels, and so `str` is called on the categories when exporting data. Exporting Categorical variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from Stata data files as `Categorical` variables using the keyword argument `convert_categoricals` (True by default). The keyword argument `order_categoricals` (True by default) determines whether imported Categorical variables are ordered.

**Note:** When importing categorical data, the values of the variables in the Stata data file are not preserved since Categorical variables always use integer data types between -1 and n-1 where n is the number of categories. If the original values in the Stata data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original Stata data values and the category codes of imported Categorical variables: missing values are assigned code -1, and the smallest original value is assigned 0, the second smallest is assigned 1 and so on until the largest original value is assigned the code n-1.

**Note:** Stata supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and numeric categories for values with no label.
2.4.19 SAS formats

The top-level function `read_sas()` can read (but not write) SAS XPORT (.xpt) and (since v0.18.0) SAS7BDAT (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For xport files, there is no automatic type conversion to integers, dates, or categoricals. For SAS7BDAT files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a DataFrame.

Specify a chunksize or use iterator=True to obtain reader objects (XportReader or SAS7BDATReader) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```python
df = pd.read_sas("sas_data.sas7bdat")
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```python
def do_something(chunk):
    pass

with pd.read_sas("sas_xport.xpt", chunk=100000) as rdr:
    for chunk in rdr:
        do_something(chunk)
```

The specification for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

2.4.20 SPSS formats

New in version 0.25.0.

The top-level function `read_spss()` can read (but not write) SPSS SAV (.sav) and ZSAV (.zsav) format files.

SPSS files contain column names. By default the whole file is read, categorical columns are converted into pd.Categorical, and a DataFrame with all columns is returned.

Specify the usecols parameter to obtain a subset of columns. Specify convert_categoricals=False to avoid converting categorical columns into pd.Categorical.

Read an SPSS file:

```python
df = pd.read_spss("spss_data.sav")
```

Extract a subset of columns contained in usecols from an SPSS file and avoid converting categorical columns into pd.Categorical:

```python
df = pd.read_spss(
    "spss_data.sav",
    usecols=["foo", "bar"],
    convert_categoricals=False,
)
```

More information about the SAV and ZSAV file formats is available here.
2.4.21 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

**netCDF**

*xarray* provides data structures inspired by the pandas *DataFrame* for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

2.4.22 Performance considerations

This is an informal comparison of various IO methods, using pandas 0.24.2. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000
In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A 1000000 non-null float64
B 1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

The following test functions will be used below to compare the performance of several IO methods:

```python
import numpy as np
import os

sz = 1000000

sz = 1000000
np.random.seed(42)

def test_sql_write(df):
    if os.path.exists("test.sql"):
        os.remove("test.sql")
    sql_db = sqlite3.connect("test.sql")
    df.to_sql(name="test_table", con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect("test.sql")
    pd.read_sql_query("select * from test_table", sql_db)
```

(continues on next page)
sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf("test_fixed.hdf", "test", mode="w")

def test_hdf_fixed_read():
    pd.read_hdf("test_fixed.hdf", "test")

def test_hdf_fixed_write_compress(df):
    df.to_hdf("test_fixed_compress.hdf", "test", mode="w", complib="blosc")

def test_hdf_fixed_read_compress():
    pd.read_hdf("test_fixed_compress.hdf", "test")

def test_hdf_table_write(df):
    df.to_hdf("test_table.hdf", "test", mode="w", format="table")

def test_hdf_table_read():
    pd.read_hdf("test_table.hdf", "test")

def test_hdf_table_write_compress(df):
    df.to_hdf("test_table_compress.hdf", "test", mode="w", complib="blosc", format="table")

def test_hdf_table_read_compress():
    pd.read_hdf("test_table_compress.hdf", "test")

def test_csv_write(df):
    df.to_csv("test.csv", mode="w")

def test_csv_read():
    pd.read_csv("test.csv", index_col=0)

def test_feather_write(df):
    df.to_feather("test.feather")

def test_feather_read():
    pd.read_feather("test.feather")
def test_pickle_write(df):
    df.to_pickle("test.pkl")

def test_pickle_read():
    pd.read_pickle("test.pkl")

def test_pickle_write_compress(df):
    df.to_pickle("test.pkl.compress", compression="xz")

def test_pickle_read_compress():
    pd.read_pickle("test.pkl.compress", compression="xz")

def test_parquet_write(df):
    df.to_parquet("test.parquet")

def test_parquet_read():
    pd.read_parquet("test.parquet")

When writing, the top three functions in terms of speed are test_feather_write, test_hdf_fixed_write and test_hdf_fixed_write_compress.

In [4]: %timeit test_sql_write(df)
3.29 s ± 43.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [5]: %timeit test_hdf_fixed_write(df)
19.4 ms ± 560 µs per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [6]: %timeit test_hdf_fixed_write_compress(df)
19.6 ms ± 308 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [7]: %timeit test_hdf_table_write(df)
449 ms ± 5.61 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [8]: %timeit test_hdf_table_write_compress(df)
448 ms ± 11.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [9]: %timeit test_csv_write(df)
3.66 s ± 26.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [10]: %timeit test_feather_write(df)
9.75 ms ± 117 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [11]: %timeit test_pickle_write(df)
30.1 ms ± 229 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [12]: %timeit test_pickle_write_compress(df)
When reading, the top three functions in terms of speed are test_feather_read, test_pickle_read and test_hdf_fixed_read.

The files test.pkl.compress, test.parquet and test.feather took the least space on disk (in bytes).
2.5 Indexing and selecting data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides metadata) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

**Note:** The Python and NumPy indexing operators [ ] and attribute operator . provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there’s little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn’t known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

---

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

---

See the MultiIndex / Advanced Indexing for MultiIndex and more advanced indexing documentation.

See the cookbook for some advanced strategies.

### 2.5.1 Different choices for indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. pandas now supports three types of multi-axis indexing.

- **.loc** is primarily label based, but may also be used with a boolean array. .loc will raise KeyError when the items are not found. Allowed inputs are:
  - A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index.).
  - A list or array of labels ['a', 'b', 'c'].
  - A slice object with labels 'a':'f' (Note that contrary to usual Python slices, both the start and the stop are included, when present in the index! See Slicing with labels and Endpoints are inclusive.)
  - A boolean array (any NA values will be treated as False).
  - A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at Selection by Label.

- **.iloc** is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array. .iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy slice semantics). Allowed inputs are:
  - An integer e.g. 5.
– A list or array of integers [4, 3, 0].
– A slice object with ints 1:7.
– A boolean array (any NA values will be treated as False).
– A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at Selection by Position, Advanced Indexing and Advanced Hierarchical.

• .loc, .iloc, and also [] indexing can accept a callable as indexer. See more at Selection By Callable.

Getting values from an object with multi-axes selection uses the following notation (using .loc as an example, but the following applies to .iloc as well). Any of the axes accessors may be the null slice :. Axes left out of the specification are assumed to be :, e.g. p.loc['a'] is equivalent to p.loc['a', :, :].

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Indexers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>s.loc[indexer]</td>
</tr>
<tr>
<td>DataFrame</td>
<td>df.loc[row_indexer, column_indexer]</td>
</tr>
</tbody>
</table>

### 2.5.2 Basics

As mentioned when introducing the data structures in the last section, the primary function of indexing with [] (a.k.a. __getitem__ for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Selection</th>
<th>Return Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>series[label]</td>
<td>scalar value</td>
</tr>
<tr>
<td>DataFrame</td>
<td>frame[colname]</td>
<td>Series corresponding to colname</td>
</tr>
</tbody>
</table>

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```python
In [1]: dates = pd.date_range('1/1/2000', periods=8)

In [2]: df = pd.DataFrame(np.random.randn(8, 4),
                       index=dates, columns=['A', 'B', 'C', 'D'])
```

```
In [3]: df
Out[3]:
       A         B         C         D
2000-01-01 -0.282863 -0.509059  1.135632
2000-01-02 -0.173215  0.119209  1.044236
2000-01-03  0.119209  0.494929  0.671804
2000-01-04 -0.706771  1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232
2000-01-06  0.721555  0.113648  1.478427
2000-01-07  0.567020  0.276232 -1.087401
2000-01-08 -0.370647  0.404705 -0.844885
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:
In [4]: s = df['A']

In [5]: s[dates[5]]
Out[5]: -0.6736907080883706

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

In [6]: df
Out[6]:

   A    B    C    D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885

In [7]: df[['B', 'A']] = df[['A', 'B']]

In [8]: df
Out[8]:

   A    B    C    D
2000-01-01 0.282863  0.469112 -1.509059 -1.135632
2000-01-02 -0.173215  1.212112  0.119209 -1.044236
2000-01-03  2.104569 -0.861849  0.494929  1.071804
2000-01-04 -0.706771  0.721555 -1.039575  0.271860
2000-01-05  0.424972 -0.567020 -0.276232 -1.087401
2000-01-06  0.113648 -0.673690 -1.478427  0.524988
2000-01-07 -0.577046  0.404705 -1.715002 -1.039268
2000-01-08 -1.157892 -0.370647 -1.344312  0.844885

You may find this useful for applying a transform (in-place) to a subset of the columns.

Warning: pandas aligns all AXES when setting Series and DataFrame from .loc, and .iloc.

This will not modify df because the column alignment is before value assignment.

In [9]: df[['A', 'B']]  
Out[9]:

   A    B
2000-01-01 -0.282863  0.469112
2000-01-02 -0.173215  1.212112
2000-01-03  2.104569 -0.861849
2000-01-04 -0.706771  0.721555
2000-01-05  0.567020 -0.424972
2000-01-06  0.113648 -0.673690
2000-01-07  0.577046  0.404705
2000-01-08 -1.157892 -0.370647

In [10]: df.iloc[:, ['B', 'A']] = df[['A', 'B']]

2.5. Indexing and selecting data  411
In [11]: df[['A', 'B']]
Out[11]:
   A       B
0 0.469112 -0.282863
1 1.212112 -0.173215
2 -0.861849 2.104569
3 0.721555 -0.706771
4 -0.673690 0.113648
5 0.577046 0.404705
6 -1.157892 -0.370647

The correct way to swap column values is by using raw values:

In [12]: df.loc[:, ['B', 'A']] = df[['A', 'B']].to_numpy()
In [13]: df[['A', 'B']]
Out[13]:
   A       B
0 0.469112 -0.282863
1 1.212112 -0.173215
2 -0.861849 2.104569
3 0.721555 -0.706771
4 -0.673690 0.113648
5 0.577046 0.404705
6 -1.157892 -0.370647

2.5.3 Attribute access

You may access an index on a Series or column on a DataFrame directly as an attribute:

In [14]: sa = pd.Series([1, 2, 3], index=list('abc'))
In [15]: dfa = df.copy()
In [16]: sa.b
Out[16]: 2
In [17]: dfa.A
Out[17]:
Freq: D, Name: A, dtype: float64
In [18]: sa.a = 5

In [19]: sa
Out[19]:
a 5
b 2
c 3
dtype: int64

In [20]: dfa.A = list(range(len(dfa.index)))  # ok if A already exists

In [21]: dfa
Out[21]:
     A  B        C         D
2000-01-01 0 -0.282863 -1.509059 -1.135632
2000-01-02 1 -0.173215  0.119209 -1.044236
2000-01-03 2 -2.104569 -0.494929  1.071804
2000-01-04 3 -0.706771 -1.039575  0.271860

2000-01-08 7 -1.157892 -1.344312  0.844885

Warning:

• You can use this access only if the index element is a valid Python identifier, e.g. s.1 is not allowed. See here for an explanation of valid identifiers.

• The attribute will not be available if it conflicts with an existing method name, e.g. s.min is not allowed, but s['min'] is possible.

• Similarly, the attribute will not be available if it conflicts with any of the following list: index, major_axis, minor_axis, items.

• In any of these cases, standard indexing will still work, e.g. s['1'], s['min'], and s['index'] will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.
You can also assign a dict to a row of a DataFrame:

2.5. Indexing and selecting data  413
You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a `UserWarning`:

```python
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns - see...
   ...https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In [3]: df
Out[3]:
   one
0  1.0
1  2.0
2  3.0
```

### 2.5.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the Selection by Position section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

```python
In [27]: s[:5]
Out[27]:
2000-01-01  0.469112
2000-01-02  1.212112
2000-01-03  0.861849
2000-01-04  0.721155
2000-01-05 -0.424972
Freq: D, Name: A, dtype: float64
```

```python
In [28]: s[::2]
Out[28]:
2000-01-01  0.469112
2000-01-03  0.861849
2000-01-05 -0.424972
2000-01-07  0.404705
Freq: 2D, Name: A, dtype: float64
```

```python
In [29]: s[::-1]
Out[29]:
```

(continues on next page)
Note that setting works as well:

```
In [30]: s2 = s.copy()
In [31]: s2[:5] = 0
In [32]: s2
Out[32]:
2000-01-01  0.000000
2000-01-02  0.000000
2000-01-03  0.000000
2000-01-04  0.000000
2000-01-05  0.000000
2000-01-06 -0.673690
2000-01-07  0.404705
2000-01-08 -0.370647
Freq: D, Name: A, dtype: float64
```

With DataFrame, slicing inside of `[]` **slices the rows**. This is provided largely as a convenience since it is such a common operation.

```
In [33]: df[:3]
Out[33]:
     A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

```
In [34]: df[::-1]
Out[34]:
     A         B         C         D
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
```

2.5. Indexing and selecting data
2.5.5 Selection by label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy*.

**Warning:**

.loc is strict when you present slicers that are not compatible (or convertible) with the index type. For example using integers in a DatetimeIndex. These will raise a TypeError.

In [35]:
```python
dfl = pd.DataFrame(np.random.randn(5, 4),
                   columns=list('ABCD'),
                   index=pd.date_range('20130101', periods=5))
```

In [36]:
dfl
```
   A   B   C   D
2013-01-01 1.075770 -0.109050 1.643563 -1.469388
2013-01-02 0.357021 -0.674600 -1.776904 -0.968914
2013-01-03 -1.294524 0.413738 0.276662 -0.472035
2013-01-04 -0.013960 -0.362543 -0.006154 -0.923061
2013-01-05 0.895717 0.805244 -1.206412 2.565646
```

In [4]:
dfl.loc[2:3]
```
>>> TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with these indexers [2] of <type 'int'>
```

String likes in slicing can be convertible to the type of the index and lead to natural slicing.

In [37]:
```python
dfl.loc['20130102':'20130104']
```

```
   A   B   C   D
2013-01-02 0.357021 -0.674600 -1.776904 -0.968914
2013-01-03 -1.294524 0.413738 0.276662 -0.472035
2013-01-04 -0.013960 -0.362543 -0.006154 -0.923061
```

**Warning:** Changed in version 1.0.0.

pandas will raise a KeyError if indexing with a list with missing labels. See *list-like Using loc with missing keys in a list is Deprecated*.

pandas provides a suite of methods in order to have purely label based indexing. This is a strict inclusion based protocol. Every label asked for must be in the index, or a KeyError will be raised. When slicing, both the start bound AND the stop bound are included, if present in the index. Integers are valid labels, but they refer to the label and not the position.

The .loc attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index.)
• A list or array of labels ['a', 'b', 'c'].
• A slice object with labels 'a':'f' (Note that contrary to usual Python slices, both the start and the stop are included, when present in the index! See Slicing with labels.
• A boolean array.
• A callable, see Selection By Callable.

In [38]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))

In [39]: s1
Out[39]:
a 1.431256
b 1.340309
c -1.170299
d -0.226169
e 0.410835
f 0.813850
dtype: float64

In [40]: s1.loc['c:']
Out[40]:
c -1.170299
d -0.226169
e 0.410835
f 0.813850
dtype: float64

In [41]: s1.loc['b']
Out[41]: 1.3403088497993827

Note that setting works as well:

In [42]: s1.loc['c:'] = 0
In [43]: s1
Out[43]:
a 1.431256
b 1.340309
c 0.000000
d 0.000000
e 0.000000
f 0.000000
dtype: float64

With a DataFrame:

In [44]: df1 = pd.DataFrame(np.random.randn(6, 4),
                   index=list('abcdef'),
                   columns=list('ABCD'))

In [45]: df1
Out[45]:
(continues on next page)
A B C D
a 0.132003 -0.827317 -0.076467 -1.187678
b 1.130127 -1.436737 -1.413681 1.607920
c 1.024180 0.569605 0.875906 -2.211372
d 0.974466 -2.006747 -0.410001 -0.078638
e 0.545952 -1.219217 -1.226825 0.769804
f -1.281247 -0.727707 -0.121306 -0.097883

In [46]: df1.loc[['a', 'b', 'd'], :]
Out[46]:
A B C D
a 0.132003 -0.827317 -0.076467 -1.187678
b 1.130127 -1.436737 -1.413681 1.607920
d 0.974466 -2.006747 -0.410001 -0.078638

Accessing via label slices:

In [47]: df1.loc['d':, 'A':'C']
Out[47]:
A B C
d 0.974466 -2.006747 -0.410001
e 0.545952 -1.219217 -1.226825
f -1.281247 -0.727707 -0.121306

For getting a cross section using a label (equivalent to df.xs('a')):

In [48]: df1.loc['a']
Out[48]:
A 0.132003
B -0.827317
C -0.076467
D -1.187678
Name: a, dtype: float64

For getting values with a boolean array:

In [49]: df1.loc['a'] > 0
Out[49]:
A   True
B  False
C  False
D  False
Name: a, dtype: bool

In [50]: df1.loc[:, df1.loc['a'] > 0]
Out[50]:
A
a 0.132003
b 1.130127
c 1.024180
d 0.974466
e 0.545952
f -1.281247
NA values in a boolean array propagate as False:

Changed in version 1.0.2.

```python
In [51]: mask = pd.array([True, False, True, False, pd.NA, False], dtype="boolean")
```

```python
In [52]: mask
Out[52]:
<BooleanArray>
[True, False, True, False, <NA>, False]
Length: 6, dtype: boolean
```

```python
In [53]: df1[mask]
Out[53]:
     A   B   C   D
a 0.132003 -0.827317 -0.076467 -1.187678
```

For getting a value explicitly:

```python
# this is also equivalent to `df1.at['a','A']`
In [54]: df1.loc['a', 'A']
Out[54]:
0.13200317033032932
```

## Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```python
In [55]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])
In [56]: s.loc[3:5]
Out[56]:
3  b
2  c
5  d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```python
In [57]: s.sort_index()
Out[57]:
0  a
2  c
3  b
4  e
5  d
dtype: object
```

```python
In [58]: s.sort_index().loc[1:6]
Out[58]:
2  c
```

(continues on next page)
However, if at least one of the two is absent \textit{and} the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, \texttt{s.loc[1:6]} would raise \texttt{KeyError}.

For the rationale behind this behavior, see \textit{Endpoints are inclusive.}

Also, if the index has duplicate labels \textit{and} either the start or the stop label is duplicated, an error will be raised. For instance, in the above example, \texttt{s.loc[2:5]} would raise a \texttt{KeyError}.

For more information about duplicate labels, see \textit{Duplicate Labels}.

### 2.5.6 Selection by position

\textbf{Warning:} Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called \textit{chained assignment} and should be avoided. See \textit{Returning a View versus Copy.}

\texttt{pandas} provides a suite of methods in order to get \textit{purely integer based indexing}. The semantics follow closely Python and NumPy slicing. These are \texttt{0-based} indexing. When slicing, the start bound is \textit{included}, while the upper bound is \textit{excluded}. Trying to use a non-integer, even a \texttt{valid} label will raise an \texttt{IndexError}.

The \texttt{.iloc} attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers \([4, 3, 0]\).
- A slice object with ints \(1:7\).
- A boolean array.
- A \texttt{callable}, see \textit{Selection By Callable}.

\begin{verbatim}
In [61]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2))

In [62]: s1
Out[62]:
0  0.695775
2  0.341734
4  0.959726
6  -1.110336

dtype: object
\end{verbatim}

(continues on next page)
In [63]: s1.iloc[:3]
Out[63]:
 0  0.695775
 2  0.341734
 4  0.959726
dtype: float64

In [64]: s1.iloc[3]
Out[64]:
-1.110336102891167

Note that setting works as well:

In [65]: s1.iloc[:3] = 0

In [66]: s1
Out[66]:
 0  0.000000
 2  0.000000
 4  0.000000
 6 -1.110336
 8 -0.619976
dtype: float64

With a DataFrame:

In [67]: df1 = pd.DataFrame(np.random.randn(6, 4),
                        index=list(range(0, 12, 2)),
                        columns=list(range(0, 8, 2)))

In [68]: df1
Out[68]:
   0  2  4  6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161
6 -0.826591 -0.345352  1.314232  0.690579
8  0.995761  2.396780  0.014871  3.357427
10 -0.317441 -1.236769  0.896171 -0.487602

Select via integer slicing:

In [69]: df1.iloc[:3]
Out[69]:
   0  2  4  6
 0  0.149748 -0.732339  0.687738  0.176444
 2  0.403310 -0.154951  0.301624 -2.179861
 4 -1.369849 -0.954208  1.462696 -1.743161

In [70]: df1.iloc[1:5, 2:4]

(continues on next page)
Select via integer list:

```
In [71]: df1.iloc[[1, 3, 5], [1, 3]]
```

```
Out[71]:
    2       6
   ---     ---
   2 -0.154951 -2.179861
   6 -0.345352  0.690579
   10 -1.236269 -0.487602
```

```
In [72]: df1.iloc[1:3, :]
```

```
Out[72]:
     0  2  4  6
   --- --- --- ---
   2 0.403310 -0.154951 0.301624 -2.179861
   4 -1.369849 -0.954208 1.462696 -1.743161
```

```
In [73]: df1.iloc[:, 1:3]
```

```
Out[73]:
   2  4
   --- ---
   0 -0.732339  0.687738
   2 -0.154951  0.301624
   4 -0.954208  1.462696
   6 -0.345352  1.314232
   8  2.396780  0.014871
   10 -1.236269  0.896171
```

```
# this is also equivalent to 
```
```
In [74]: df1.iat[1, 1]
```

```
Out[74]:
-0.1549507744249032
```

For getting a cross section using an integer position (equiv to df.xs(1)):

```
In [75]: df1.iloc[1]
```

```
Out[75]:
   0  2  4  6
   --- --- --- ---
   2 0.403310 -0.154951 0.301624 -2.179861
   4 -1.369849 -0.954208 1.462696 -1.743161
   Name: 2, dtype: float64
```

Out of range slice indexes are handled gracefully just as in Python/NumPy.

```
# these are allowed in Python/NumPy.
In [76]: x = list('abcdef')

In [77]: x
```

(continues on next page)
Out[77]: ['a', 'b', 'c', 'd', 'e', 'f']

In [78]: x[4:10]
Out[78]: ['e', 'f']

In [79]: x[8:10]
Out[79]: []

In [80]: s = pd.Series(x)

In [81]: s
Out[81]:
0  a
1  b
2  c
3  d
4  e
5  f
dtype: object

In [82]: s.iloc[4:10]
Out[82]:
4  e
5  f
dtype: object

In [83]: s.iloc[8:10]
Out[83]: Series([], dtype: object)

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

In [84]: dfl = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))

In [85]: dfl
Out[85]:
   A          B
0 -0.082240  -2.182937
1  0.380396   0.084844
2  0.432390   1.519970
3 -0.493662   0.600178
4  0.274230   0.132885

In [86]: dfl.iloc[:, 2:3]
Out[86]:
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

In [87]: dfl.iloc[:, 1:3]
Out[87]:
   B
0 -2.182937
In [88]: df1.iloc[4:6]
Out[88]:
   A   B
4 0.27423 0.132885

A single indexer that is out of bounds will raise an IndexError. A list of indexers where any element is out of bounds will raise an IndexError.

>>> df1.loc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> df1.loc[:, 4]
IndexError: single positional indexer is out-of-bounds

2.5.7 Selection by callable

.loc, .iloc, and also [] indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series or DataFrame) that returns valid output for indexing.

In [89]: df1 = pd.DataFrame(np.random.randn(6, 4),
  ....:     index=list('abcdef'),
  ....:     columns=list('ABCD'))

In [90]: df1
Out[90]:
   A   B   C   D
   a -0.023688  2.410179  1.450520  0.206053
   b -0.251905 -2.213588  1.063327  1.266143
   c  0.299368 -0.863838  0.408204 -1.048089
   d -0.025747 -0.988387  0.094055  1.262731
   e  1.289997  0.082423 -0.055758  0.536580
   f -0.489682  0.369374 -0.034571 -2.484478

In [91]: df1.loc[lambda df: df['A'] > 0, :]
Out[91]:
   A   B   C   D
   c  0.299368 -0.863838  0.408204 -1.048089
   e  1.289997  0.082423 -0.055758  0.536580

In [92]: df1.loc[:, lambda df: ['A', 'B']]
Out[92]:
   A   B
   a -0.023688  2.410179
   b -0.251905 -2.213588
   c  0.299368 -0.863838

(continues on next page)
You can use callable indexing in Series.

In [95]: df1['A'].loc[lambda s: s > 0]
Out[95]:
   c   e
0  0.299368  1.289997
Name: A, dtype: float64

Using these methods / indexers, you can chain data selection operations without using a temporary variable.

In [96]: bb = pd.read_csv('data/baseball.csv', index_col='id')
In [97]: (bb.groupby(['year', 'team']).sum()
   ....: .loc[lambda df: df['r'] > 100])
   ....:
Out[97]:
                      year  team  stint  g  ab  r  h  X2b  X3b  hr  rbi  sb  cs  bb  so  ibb  hbp  sh  sf  gidp
                      -->        -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->  -->
2007  CIN  6  379  745  101  203  35  2  36  125.0  10.0  1.0  105  127.0  14.0  1.0  15.0  18.0
  -->  1.0  1.0  15.0  18.0

  -->  HOU  4  311  926  109  218  47  6  14  77.0  10.0  4.0  60  212.0  3.0  9.0  16.0  6.0  17.0
  -->  LAN  11  413  1021  153  293  61  3  36  154.0  7.0  5.0  114  141.0  8.0  9.0  3.0  8.0  29.0
  -->  (continues on next page)
2.5.8 Combining positional and label-based indexing

If you wish to get the 0th and the 2nd elements from the index in the ‘A’ column, you can do:

```
In [98]: dfd = pd.DataFrame({'A': [1, 2, 3],
                          'B': [4, 5, 6],
                          index=list('abc'))

In [99]: dfd
Out[99]:
   A  B
a 1 4
b 2 5
c 3 6

In [100]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[100]:
a 1
b 2
Name: A, dtype: int64
```

This can also be expressed using .iloc, by explicitly getting locations on the indexers, and using positional indexing to select things.

```
In [101]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[101]:
a 1
b 2
Name: A, dtype: int64
```

For getting multiple indexers, using .get_indexer:

```
In [102]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[102]:
   A  B
a 1 4
b 2 5
c 3 6
```
### 2.5.9 Indexing with list with missing labels is deprecated

**Warning:** Changed in version 1.0.0.

Using `.loc` or `[]` with a list with one or more missing labels will no longer reindex, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior was changed and will now raise a `KeyError` if at least one label is missing. The recommended alternative is to use `.reindex()`.

For example,

```python
In [103]: s = pd.Series([1, 2, 3])

In [104]: s
Out[104]:
0   1  
1   2  
2   3  
dtype: int64
```

Selection with all keys found is unchanged.

```python
In [105]: s.loc[[1, 2]]
Out[105]:
1   2  
2   3  
dtype: int64
```

Previous behavior

```python
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1   2.0
2   3.0
3   NaN
dtype: float64
```

Current behavior

```python
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise 
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here: 
```

```python
Out[4]:
1   2.0
2   3.0
3   NaN
dtype: float64
```
Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on `reindexing`.

```python
In [106]: s.reindex([1, 2, 3])
Out[106]:
1  2.0
2  3.0
3  NaN
```

Alternatively, if you want to select only valid keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```python
In [107]: labels = [1, 2, 3]
In [108]: s.loc[s.index.intersection(labels)]
Out[108]:
1  2
2  3
```

Having a duplicated index will raise for a `.reindex()`:

```python
In [109]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
In [110]: labels = ['c', 'd']
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```python
In [111]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[111]:
c  3.0
d  NaN
```

However, this would still raise if your resulting index is duplicated.

```python
In [41]: labels = ['a', 'd']
In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis
```
2.5.10 Selecting random samples

A random selection of rows or columns from a Series or DataFrame with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [112]: s = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1 row.
In [113]: s.sample()
Out[113]:
    4
   ---
dtype: int64

# One may specify either a number of rows:
In [114]: s.sample(n=3)
Out[114]:
      0
     4
     1
   ---
dtype: int64

# Or a fraction of the rows:
In [115]: s.sample(frac=0.5)
Out[115]:
     5
     3
     1
   ---
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [116]: s = pd.Series([0, 1, 2, 3, 4, 5])

# Without replacement (default):
In [117]: s.sample(n=6, replace=False)
Out[117]:
     0
     1
     5
     3
     2
     4
   ---
dtype: int64

# With replacement:
In [118]: s.sample(n=6, replace=True)
Out[118]:
     0
     4
     3
     2
     4
     4
   ---
```

(continues on next page)
dtype: int64

By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```python
In [119]: s = pd.Series([0, 1, 2, 3, 4, 5])

In [120]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [121]: s.sample(n=3, weights=example_weights)
Out[121]:
   5  5
   4  4
   3  3
dtype: int64

# Weights will be re-normalized automatically
In [122]: example_weights2 = [0.5, 0, 0, 0, 0, 0]

In [123]: s.sample(n=1, weights=example_weights2)
Out[123]:
    0
0  0
```
dtype: int64

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```python
In [124]: df2 = pd.DataFrame({
        'col1': [9, 8, 7, 6],
        ....: 'weight_column': [0.5, 0.4, 0.1, 0]})

In [125]: df2.sample(n=3, weights='weight_column')
Out[125]:
   col1  weight_column
   1     8   0.4
   0     9   0.5
   2     7   0.1
```
sample also allows users to sample columns instead of rows using the `axis` argument.

```python
In [126]: df3 = pd.DataFrame({
        'col1': [1, 2, 3], 'col2': [2, 3, 4]})

In [127]: df3.sample(n=1, axis=1)
Out[127]:
  col1
0  1
1  2
2  3
```

Finally, one can also set a seed for `sample`’s random number generator using the `random_state` argument, which will
accept either an integer (as a seed) or a NumPy RandomState object.

```
In [128]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})

# With a given seed, the sample will always draw the same rows.
In [129]: df4.sample(n=2, random_state=2)
Out[129]:
     col1 col2
0     1     2
1     2     3

In [130]: df4.sample(n=2, random_state=2)
Out[130]:
     col1 col2
0     1     2
1     2     3
```

### 2.5.11 Setting with enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis. In the Series case this is effectively an appending operation.

```
In [131]: se = pd.Series([1, 2, 3])
In [132]: se
Out[132]:
0   1
1   2
2   3
dtype: int64

In [133]: se[5] = 5.
In [134]: se
Out[134]:
0  1.0
1  2.0
2  3.0
5  5.0
dtype: float64
```

A DataFrame can be enlarged on either axis via `.loc`.

```
In [135]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
                                  columns=['A', 'B'])

In [136]: dfi
Out[136]:
   A  B
0  0  1
1  2  3
```

(continues on next page)
2 4 5

In [137]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [138]: dfi
Out[138]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4

This is like an append operation on the DataFrame.

In [139]: dfi.loc[3] = 5

In [140]: dfi
Out[140]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5

2.5.12 Fast scalar value getting and setting

Since indexing with [] must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you're asking for. If you only want to access a scalar value, the fastest way is to use the at and iat methods, which are implemented on all of the data structures.

Similarly to loc, at provides label based scalar lookups, while, iat provides integer based lookups analogously to iloc.

In [141]: s.iat[5]
Out[141]: 5

In [142]: df.at[dates[5], 'A']
Out[142]: -0.6736897080883706

In [143]: df.iat[3, 0]
Out[143]: 0.7215551622443669

You can also set using these same indexers.

In [144]: df.at[dates[5], 'E'] = 7

In [145]: df.iat[3, 0] = 7

at may enlarge the object in-place as above if the indexer is missing.

In [146]: df.at[dates[-1] + pd.Timedelta('1 day'), 0] = 7

In [147]: df
2.5.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: | for or, & for and, and ~ for not. These must be grouped by using parentheses, since by default Python will evaluate an expression such as df["A"] > 2 & df["B"] < 3 as df["A"] > (2 & df["B"]) < 3, while the desired evaluation order is (df["A"] > 2) & (df["B"] < 3).

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```python
In [148]: s = pd.Series(range(-3, 4))
In [149]: s
Out[149]:
0   -3
1   -2
2   -1
3    0
4    1
5    2
6    3
dtype: int64
In [150]: s[s > 0]
Out[150]:
4    1
5    2
6    3
dtype: int64
In [151]: (s < -1) | (s > 0.5)
Out[151]:
0   -3
1   -2
4    1
5    2
6    3
dtype: int64
In [152]: ~(s < 0)
```
You may select rows from a DataFrame using a boolean vector the same length as the DataFrame’s index (for example, something derived from one of the columns of the DataFrame):

```python
In [153]: df[df['A'] > 0]
Out[153]:
    A     B     C   D  E
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632 NaN
2000-01-02 1.212112 -0.173215  0.119209 -1.044236 NaN
2000-01-04 7.000000 -0.706771 -1.039575  0.271860 NaN
2000-01-07 0.404705  0.577046 -1.715002 -1.039268 NaN
```

List comprehensions and the `map` method of Series can also be used to produce more complex criteria:

```python
In [155]: criterion = df2['a'].map(lambda x: x.startswith('t'))
In [156]: df2[criterion & (df2['b'] == 'x')]
Out[156]:
     a     b     c
2  two  y  0.041290
3  three  x  0.361719
4   two  y -0.238075
```

With the choice methods *Selection by Label*, *Selection by Position*, and *Advanced Indexing* you may select along more than one axis using boolean vectors combined with other indexing expressions.
2.5.14 Indexing with isin

Consider the *isin()* method of Series, which returns a boolean vector that is true wherever the Series elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```python
In [165]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')
In [166]: s
Out[166]:
   4    0
   3    1
   2    2
   1    3
  0    4
Name: 0, dtype: int64
```
In [167]: s.isin([2, 4, 6])
Out[167]:
4  False
3  False
2  True
1  False
0  True
dtype: bool

In [168]: s[s.isin([2, 4, 6])]
Out[168]:
2 2
0 4
dtype: int64

The same method is available for Index objects and is useful for the cases when you don’t know which of the sought labels are in fact present:

In [169]: s[s.index.isin([2, 4, 6])]
Out[169]:
4 0
2 2
dtype: int64

# compare it to the following
In [170]: s.reindex([2, 4, 6])
Out[170]:
2 2.0
4 0.0
6 Nan
dtype: float64

In addition to that, MultiIndex allows selecting a separate level to use in the membership check:

In [171]: s_mi = pd.Series(np.arange(6),
       index=pd.MultiIndex.from_product(
           [[0, 1], ['a', 'b', 'c']]))

In [172]: s_mi
Out[172]:
0  a  0
   b  1
   c  2
1  a  3
   b  4
   c  5
dtype: int64

In [173]: s_mi.iloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c')])]
Out[173]:
0  c  2
DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```python
In [175]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
                 'ids2': ['a', 'n', 'c', 'n']})
......:
In [176]: values = ['a', 'b', 1, 3]
In [177]: df.isin(values)
Out[177]:
   vals  ids  ids2
0   True  True  True
1   False  True  False
2   True  False  False
3   False  False  False
```

Oftentimes you’ll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```python
In [178]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}
In [179]: df.isin(values)
Out[179]:
   vals  ids  ids2
0   True  True  True
1   False  True  False
2   True  False  False
3   False  False  False
```

Combine DataFrame’s `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```python
In [180]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}
In [181]: row_mask = df.isin(values).all(1)
In [182]: df[row_mask]
Out[182]:
   vals  ids  ids2
0   1    a    a
```

2.5. Indexing and selecting data
2.5.15 The where() Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the where method in Series and DataFrame.

To return only the selected rows:

```
In [183]: s[s > 0]
Out[183]:
   3   1
  2   2
  1   3
  0   4
dtype: int64
```

To return a Series of the same shape as the original:

```
In [184]: s.where(s > 0)
Out[184]:
   4  NaN
  3   1.0
  2   2.0
  1   3.0
  0   4.0
dtype: float64
```

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. where is used under the hood as the implementation. The code below is equivalent to df.where(df < 0).

```
In [185]: df[df < 0]
Out[185]:
     A          B          C          D
2000-01-01 -2.104139 -1.309525   NaN      NaN
2000-01-02 -0.352480   NaN -1.192319   NaN
2000-01-03 -0.864883   NaN   NaN   NaN
2000-01-04   NaN -1.222082 -1.233203   NaN
2000-01-05   NaN -0.605656 -1.169184   NaN
2000-01-06   NaN -0.948458   NaN   NaN
2000-01-07 -2.670153 -0.114722   NaN   NaN
2000-01-08   NaN   NaN -0.048048 -0.808838
```

In addition, where takes an optional other argument for replacement of values where the condition is False, in the returned copy.

```
In [186]: df.where(df < 0, -df)
Out[186]:
     A          B          C          D
2000-01-01 -2.104139 -1.309525 -0.485855 -0.245166
2000-01-02 -0.352480 -0.390389 -1.192319 -1.655824
2000-01-03 -0.864883 -0.299674 -0.227870 -0.281059
2000-01-04 -0.846958 -1.222082   NaN   NaN
2000-01-05 -0.605656 -1.169184   NaN   NaN
2000-01-06 -0.948458 -0.808838 -0.684718 -0.342416
2000-01-07 -2.670153 -0.114722   NaN -0.281059
2000-01-08 -0.801196 -1.392071 -0.048788 -0.808838
```
You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```
In [187]: s2 = s.copy()
In [188]: s2[s2 < 0] = 0
In [189]: s2
Out[189]:
   0  4
   1  3
   2  2
   3  1
   4  0
   5  0
dtype: int64
```

```
In [190]: df2 = df.copy()
In [191]: df2[df2 < 0] = 0
In [192]: df2
Out[192]:
   A  B  C   D
 2000-01-01  0  0  0.485855  0.245166
 2000-01-02  0  0  0.390389  1.655824
 2000-01-03  0  0  0.299674  0.281059
 2000-01-04  0.846958  0.000000  0.600705  0.000000
 2000-01-05  0.669692  0.000000  0.000000  0.342416
 2000-01-06  0.868584  0.000000  2.297780  0.000000
 2000-01-07  0.000000  0.000000  0.168904  0.000000
 2000-01-08  0.801196  1.392071  0.000000  0.000000
```

By default, where returns a modified copy of the data. There is an optional parameter inplace so that the original data can be modified without creating a copy:

```
In [193]: df_orig = df.copy()
In [194]: df_orig.where(df > 0, -df, inplace=True)
In [195]: df_orig
Out[195]:
   A  B  C   D
 2000-01-01  2.104139  1.309525  0.485855  0.245166
 2000-01-02  0.352480  0.390389  1.192319  1.655824
 2000-01-03  0.864883  0.299674  0.227870  0.281059
 2000-01-04  0.864958  0.122082  0.600705  1.233203
 2000-01-05  0.669692  0.299674  1.169184  0.342416
 2000-01-06  0.868584  0.605656  2.297780  0.684718
 2000-01-07  2.670153  0.114722  0.168904  0.048048
 2000-01-08  0.801196  1.392071  0.048788  0.808838
```

Note: The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).
In [196]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[196]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Alignment

Furthermore, where aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via .loc (but on the contents rather than the axis labels).

In [197]: df2 = df.copy()
In [198]: df2[df2[1:4] > 0] = 3
In [199]: df2
Out[199]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-2.104139</td>

</tr>
</tbody>
</table>

This is equivalent to (but faster than) the following.

In [202]: df2 = df.copy()
where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

Mask

mask() is the inverse boolean operation of where.

### Example

```python
In [206]: s.mask(s >= 0)
Out[206]:
4   NaN
3   NaN
2   NaN
1   NaN
0   NaN
dtype: float64
```

```python
In [207]: df.mask(df >= 0)
Out[207]:
          A        B        C        D
2000-01-01 -2.10  -1.31  0.49  0.25
2000-01-02 -0.35  0.39  0.35  1.66
2000-01-03 -0.86  0.29  0.87  0.28
2000-01-04  0.86  0.87  0.61  0.85
2000-01-05  0.67  0.69  0.66  0.34
2000-01-06  0.87  0.87  2.29  0.87
2000-01-07 -2.67 -0.11 -0.05 -0.05
2000-01-08  0.80  1.39  0.80  0.81
```

2.5. Indexing and selecting data
2.5.16 Setting with enlargement conditionally using \texttt{numpy()}

An alternative to \texttt{where()} is to use \texttt{numpy.where()}. Combined with setting a new column, you can use it to enlarge a DataFrame where the values are determined conditionally.

Consider you have two choices to choose from in the following DataFrame. And you want to set a new column color to ‘green’ when the second column has ‘Z’. You can do the following:

\begin{verbatim}
In [208]: df = pd.DataFrame({'col1': list('ABBC'), 'col2': list('ZZXY'))
In [209]: df['color'] = np.where(df['col2'] == 'Z', 'green', 'red')
In [210]: df
Out[210]:
   col1 col2  color
0      A    Z     green
1      B    Z     green
2      B    X      red
3      C    Y      red
\end{verbatim}

If you have multiple conditions, you can use \texttt{numpy.select()} to achieve that. Say corresponding to three conditions there are three choice of colors, with a fourth color as a fallback, you can do the following.

\begin{verbatim}
In [211]: conditions = [
      ...: (df['col2'] == 'Z') & (df['col1'] == 'A'),
      ...: (df['col2'] == 'Z') & (df['col1'] == 'B'),
      ...: (df['col1'] == 'B')
      ...: ]

In [212]: choices = ['yellow', 'blue', 'purple']
In [213]: df['color'] = np.select(conditions, choices, default='black')
In [214]: df
Out[214]:
   col1 col2  color
0      A    Z  yellow
1      B    Z    blue
2      B    X purple
3      C    Y    black
\end{verbatim}

2.5.17 The \texttt{query()} Method

\texttt{DataFrame} objects have a \texttt{query()} method that allows selection using an expression.

You can get the value of the frame where column \texttt{b} has values between the values of columns \texttt{a} and \texttt{c}. For example:

\begin{verbatim}
In [215]: n = 10
In [216]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [217]: df
\end{verbatim}
Out[217]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.438921</td>
<td>0.118680</td>
<td>0.863670</td>
</tr>
<tr>
<td>1</td>
<td>0.138138</td>
<td>0.577363</td>
<td>0.686602</td>
</tr>
<tr>
<td>2</td>
<td>0.595307</td>
<td>0.564592</td>
<td>0.520630</td>
</tr>
<tr>
<td>3</td>
<td>0.913052</td>
<td>0.926075</td>
<td>0.616184</td>
</tr>
<tr>
<td>4</td>
<td>0.078718</td>
<td>0.854477</td>
<td>0.898725</td>
</tr>
<tr>
<td>5</td>
<td>0.076404</td>
<td>0.523211</td>
<td>0.591538</td>
</tr>
<tr>
<td>6</td>
<td>0.792342</td>
<td>0.216974</td>
<td>0.564056</td>
</tr>
<tr>
<td>7</td>
<td>0.397890</td>
<td>0.454131</td>
<td>0.915716</td>
</tr>
<tr>
<td>8</td>
<td>0.074315</td>
<td>0.437913</td>
<td>0.019794</td>
</tr>
<tr>
<td>9</td>
<td>0.559209</td>
<td>0.502065</td>
<td>0.026437</td>
</tr>
</tbody>
</table>

# pure python
In [218]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]

Out[218]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.138138</td>
<td>0.577363</td>
<td>0.686602</td>
</tr>
<tr>
<td>4</td>
<td>0.078718</td>
<td>0.854477</td>
<td>0.898725</td>
</tr>
<tr>
<td>5</td>
<td>0.076404</td>
<td>0.523211</td>
<td>0.591538</td>
</tr>
<tr>
<td>7</td>
<td>0.397890</td>
<td>0.454131</td>
<td>0.915716</td>
</tr>
</tbody>
</table>

# query
In [219]: df.query('(a < b) & (b < c)')

Out[219]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.138138</td>
<td>0.577363</td>
<td>0.686602</td>
</tr>
<tr>
<td>4</td>
<td>0.078718</td>
<td>0.854477</td>
<td>0.898725</td>
</tr>
<tr>
<td>5</td>
<td>0.076404</td>
<td>0.523211</td>
<td>0.591538</td>
</tr>
<tr>
<td>7</td>
<td>0.397890</td>
<td>0.454131</td>
<td>0.915716</td>
</tr>
</tbody>
</table>

Do the same thing but fall back on a named index if there is no column with the name a.

In [220]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
In [221]: df.index.name = 'a'

In [222]: df
Out[222]:

<table>
<thead>
<tr>
<th></th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>9</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
In [223]: df.query('a < b and b < c')
Out[223]:
    b  c
   a 2 3 4

If instead you don’t want to or cannot name your index, you can use the name index in your query expression:

In [224]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
In [225]: df
Out[225]:
   b  c
  0 3 1
  1 3 0
  2 5 6
  3 5 2
  4 7 4
  5 0 1
  6 2 5
  7 0 1
  8 6 0
  9 7 9
In [226]: df.query('index < b < c')
Out[226]:
    b  c
   a 2 5 6

Note: If the name of your index overlaps with a column name, the column name is given precedence. For example,

In [227]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
In [228]: df.index.name = 'a'
In [229]: df.query('a > 2')  # uses the column 'a', not the index
Out[229]:
   a
  1 3
  3 3

You can still use the index in a query expression by using the special identifier ‘index’:

In [230]: df.query('index > 2')
Out[230]:
   a
  a 3 3
  4 2

If for some reason you have a column named index, then you can refer to the index as ilevel_0 as well, but at this

444 Chapter 2. User Guide
point you should consider renaming your columns to something less ambiguous.

**MultiIndex query() Syntax**

You can also use the levels of a DataFrame with a *MultiIndex* as if they were columns in the frame:

```
In [231]: n = 10

In [232]: colors = np.random.choice(['red', 'green'], size=n)

In [233]: foods = np.random.choice(['eggs', 'ham'], size=n)

In [234]: colors
Out[234]: array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green', 'green', 'green'], dtype='<U5')

In [235]: foods
Out[235]: array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs', 'eggs'], dtype='<U4')

In [236]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])

In [237]: df = pd.DataFrame(np.random.randn(n, 2), index=index)

In [238]: df
Out[238]:
   0        1
color food
red  ham  0.194889 -0.381994
      eggs -0.728293 -0.090255
      green -0.748199  1.318931
      eggs -2.029766  0.792652
      ham  0.461007 -0.542749
      ham  0.305384 -0.479195
      eggs 0.095031 -0.270099
      eggs -0.707140 -0.773882
      eggs 0.229453  0.304418

In [239]: df.query('color == "red"')
Out[239]:
   0        1
color food
red  ham  0.194889 -0.381994
      eggs -0.728293 -0.090255
```

If the levels of the *MultiIndex* are unnamed, you can refer to them using special names:
The convention is `ilevel_0`, which means “index level 0” for the 0th level of the `index`.

### query() Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames without having to specify which frame you're interested in querying.
```python
In [247]: expr = '0.0 <= a <= c <= 0.5

In [248]: map(lambda frame: frame.query(expr), [df, df2])
Out[248]: <map at 0x7f42bfbd5490>
```

**query() Python versus pandas Syntax Comparison**

Full numpy-like syntax:

```python
In [249]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))

In [250]: df
Out[250]:
   a  b  c
0  7  8  9
1  1  0  7
2  2  7  2
3  6  2  2
4  2  6  3
5  3  8  2
6  1  7  2
7  5  1  5
8  9  8  0
9  1  5  0

In [251]: df.query('(a < b) & (b < c)')
Out[251]:
   a  b  c
0  7  8  9

In [252]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
Out[252]:
   a  b  c
0  7  8  9
```

Slightly nicer by removing the parentheses (comparison operators bind tighter than & and |):

```
2.5. Indexing and selecting data
```
In [253]: df.query('a < b & b < c')
Out[253]:
   a  b  c
0  7  8  9

Use English instead of symbols:

In [254]: df.query('a < b and b < c')
Out[254]:
   a  b  c
0  7  8  9

Pretty close to how you might write it on paper:

In [255]: df.query('a < b < c')
Out[255]:
   a  b  c
0  7  8  9

The in and not in operators

query() also supports special use of Python's in and not in comparison operators, providing a succinct syntax for calling the isin method of a Series or DataFrame.

# get all rows where columns "a" and "b" have overlapping values
In [256]: df = pd.DataFrame({'a': list('aabbbbcdddeeff'), 'b': list('aaaabbbccccc'), 'c': np.random.randint(5, size=12), 'd': np.random.randint(9, size=12)})

In [257]: df
Out[257]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2

In [258]: df.query('a in b')
Out[258]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3 b a 2 1
4 c b 3 6
5 c b 0 2

# How you'd do it in pure Python
In [259]: df[df['a'].isin(df['b'])]
Out[259]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2

In [260]: df.query('a not in b')
Out[260]:
   a  b  c  d
  6  d  b  3  3
  7  d  b  2  1
  8  c  e  4  3
  9  e  c  2  0
 10  f  c  0  6
 11  f  c  1  2

# pure Python
In [261]: df[~df['a'].isin(df['b'])]
Out[261]:
   a  b  c  d
  6  d  b  3  3
  7  d  b  2  1
  8  c  e  4  3
  9  e  c  2  0
 10  f  c  0  6
 11  f  c  1  2

You can combine this with other expressions for very succinct queries:

# rows where cols a and b have overlapping values
# and col c's values are less than col d's
In [262]: df.query('a in b and c < d')
Out[262]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
4  c  b  3  6
5  c  b  0  2

# pure Python
In [263]: df[df['b'].isin(df['a'])] & (df['c'] < df['d'])
Out[263]:

2.5. Indexing and selecting data 449
Note: Note that in and not in are evaluated in Python, since numexpr has no equivalent of this operation. However, only the in/not in expression itself is evaluated in vanilla Python. For example, in the expression

```python
def.query('a in b + c + d')
```

(b + c + d) is evaluated by numexpr and then the in operation is evaluated in plain Python. In general, any operations that can be evaluated using numexpr will be.

### Special use of the == operator with list objects

Comparing a list of values to a column using ==/!= works similarly to in/not in.

```python
In [264]: df.query('b == ["a", "b", "c"]')
Out[264]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

# pure Python

```python
In [265]: df[df['b'].isin(['a', 'b', 'c'])]
Out[265]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
```
9 e c 2 0
10 f c 0 6
11 f c 1 2

In [266]: df.query('c == [1, 2]')
Out[266]:
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

In [267]: df.query('c != [1, 2]')
Out[267]:
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

# using in/not in
In [268]: df.query('[1, 2] in c')
Out[268]:
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

In [269]: df.query('[1, 2] not in c')
Out[269]:
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

# pure Python
In [270]: df[df['c'].isin([1, 2])]
Out[270]:
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1

(continues on next page)
Boolean operators

You can negate boolean expressions with the word `not` or the `~` operator.

```python
In [271]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [272]: df['bools'] = np.random.rand(len(df)) > 0.5
In [273]: df.query('~bools')
Out[273]:
   a      b      c bools
  2  0.697753  0.212799  0.329209  False
  7  0.275396  0.691034  0.826619  False
  8  0.190649  0.558748  0.262467  False
In [274]: df.query('not bools')
Out[274]:
   a      b      c bools
  2  0.697753  0.212799  0.329209  False
  7  0.275396  0.691034  0.826619  False
  8  0.190649  0.558748  0.262467  False
In [275]: df.query('not bools') == df[~df['bools']]
Out[275]:
   a      b      c bools
 2  True  True  True  True
 7  True  True  True  True
 8  True  True  True  True
```

Of course, expressions can be arbitrarily complex too:

```python
# short query syntax
In [276]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [277]: longer = df[(df['a'] < df['b'])
            ....: & (df['b'] < df['c'])
            ....: & (~df['bools'])
            ....: | (df['bools'] > 2)]

In [278]: shorter
Out[278]:
   a      b      c bools
  7  0.275396  0.691034  0.826619  False
In [279]: longer
```

(continues on next page)
Out[279]:
   a    b    c     bools
7  0.275396  0.691034  0.826619   False

In [280]: shorter == longer
Out[280]:
   a    b    c     bools
7  True  True  True       True

**Performance of query()**

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

![DataFrame.query()](image)

**Note:** You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.
This plot was created using a DataFrame with 3 columns each containing floating point values generated using numpy.random.randn().

### 2.5.18 Duplicate data

If you want to identify and remove duplicate rows in a DataFrame, there are two methods that will help: duplicated and drop_duplicates. Each takes as an argument the columns to use to identify duplicated rows.

- duplicated returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- drop_duplicates removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a keep parameter to specify targets to be kept.

- keep='first' (default): mark / drop duplicates except for the first occurrence.
- keep='last': mark / drop duplicates except for the last occurrence.
- keep=False: mark / drop all duplicates.

```python
In [281]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'three', 'four'],
                        'b': ['x', 'y', 'x', 'y', 'x', 'x'],
                        'c': np.random.randn(7)})
```

```text
Out[282]:
   a    b      c
0  one  x -1.067137
1   one  y  0.309500
2   two  x -0.211056
3   two  y -1.842023
4   two  x -0.390820
```
In [283]: df2.duplicated('a')
Out[283]:
0   False
1    True
2   False
3    True
4    True
5   False
6   False
dtype: bool

In [284]: df2.duplicated('a', keep='last')
Out[284]:
0    True
1   False
2    True
3    True
4   False
5   False
6   False
dtype: bool

In [285]: df2.duplicated('a', keep=False)
Out[285]:
0    True
1    True
2    True
3    True
4    True
5   False
6   False
dtype: bool

In [286]: df2.drop_duplicates('a')
Out[286]:
     a   b   c
0  one  x  -1.067137
2  two  x  -0.211056
5  three  x  -1.964475
6   four  x   1.298329

In [287]: df2.drop_duplicates('a', keep='last')
Out[287]:
     a   b   c
1  one  y   0.309500
4  two  x  -0.390820
5  three  x  -1.964475
6   four  x   1.298329

---

2.5. Indexing and selecting data 455
In [288]: df2.drop_duplicates('a', keep=False)
Out[288]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
<td>c</td>
</tr>
<tr>
<td>5</td>
<td>three</td>
<td>x -1.964475</td>
</tr>
<tr>
<td>6</td>
<td>four</td>
<td>x 1.298329</td>
</tr>
</tbody>
</table>

Also, you can pass a list of columns to identify duplications.

In [289]: df2.duplicated(['a', 'b'])
Out[289]:
<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>6</td>
</tr>
</tbody>
</table>

dtype: bool

In [290]: df2.drop_duplicates(['a', 'b'])
Out[290]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
<td>c</td>
</tr>
<tr>
<td>0</td>
<td>one</td>
<td>x -1.067137</td>
</tr>
<tr>
<td>1</td>
<td>one</td>
<td>y 0.309500</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
<td>x -0.211056</td>
</tr>
<tr>
<td>3</td>
<td>two</td>
<td>y 1.842023</td>
</tr>
<tr>
<td>5</td>
<td>three</td>
<td>x -1.964475</td>
</tr>
<tr>
<td>6</td>
<td>four</td>
<td>x 1.298329</td>
</tr>
</tbody>
</table>

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

In [291]: df3 = pd.DataFrame({'a': np.arange(6), 
                       'b': np.random.randn(6)},
                       index=['a', 'a', 'b', 'c', 'b', 'a'])

In [292]: df3
Out[292]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
</tr>
<tr>
<td>0</td>
<td>1.440455</td>
</tr>
<tr>
<td>1</td>
<td>2.56086</td>
</tr>
<tr>
<td>2</td>
<td>1.038402</td>
</tr>
<tr>
<td>3</td>
<td>-0.894409</td>
</tr>
<tr>
<td>4</td>
<td>0.683536</td>
</tr>
<tr>
<td>5</td>
<td>3.682764</td>
</tr>
</tbody>
</table>

In [293]: df3.index.duplicated()
Out[293]: array([False, True, False, False, True, True])

In [294]: df3[~df3.index.duplicated()]
Out[294]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
<td>c</td>
</tr>
<tr>
<td>0</td>
<td>1.440455</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>2.56086</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1.038402</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>-0.894409</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>0.683536</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>3.682764</td>
<td></td>
</tr>
</tbody>
</table>
```
In [295]: df3[~df3.index.duplicated(keep='last')]
Out[295]:
   a   b
0  a  1.440455
1  b  1.038402
2  c -0.894409

In [296]: df3[~df3.index.duplicated(keep=False)]
Out[296]:
   a   b
0  c -0.894409
1  b  0.683536
2  a  3.082764
```

### 2.5.19 Dictionary-like get() method

Each of Series or DataFrame have a `get()` method which can return a default value.

```
In [297]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [298]: s.get('a')  # equivalent to s['a']
Out[298]: 1
In [299]: s.get('x', default=-1)
Out[299]: -1
```

### 2.5.20 Looking up values by index/column labels

Sometimes you want to extract a set of values given a sequence of row labels and column labels, this can be achieved by pandas.factorize and NumPy indexing. For instance:

```
In [300]: df = pd.DataFrame({'col': ['A', 'A', 'B', 'B'],
                       'A': [80, 23, np.nan, 22],
                       'B': [80, 55, 76, 67]})
In [301]: df
Out[301]:
     col   A   B
0     A  80.0 80
1     A  23.0 55
2     B  NaN  76
3     B  22.0 67
In [302]: idx, cols = pd.factorize(df['col'])
```
In [303]: df.reindex(cols, axis=1).to_numpy()[np.arange(len(df)), idx]
Out[303]: array([80., 23., 76., 67.])

Formerly this could be achieved with the dedicated DataFrame.lookup method which was deprecated in version 1.2.0.

### 2.5.21 Index objects

The pandas Index class and its subclasses can be viewed as implementing an ordered multiset. Duplicates are allowed. However, if you try to convert an Index object with duplicate entries into a set, an exception will be raised.

Index also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an Index directly is to pass a list or other sequence to Index:

In [304]: index = pd.Index(['e', 'd', 'a', 'b'])
In [305]: index
Out[305]: Index(['e', 'd', 'a', 'b'], dtype='O')

In [306]: 'd' in index
Out[306]: True

You can also pass a name to be stored in the index:

In [307]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')
In [308]: index.name
Out[308]: 'something'

The name, if set, will be shown in the console display:

In [309]: index = pd.Index(list(range(5)), name='rows')
In [310]: columns = pd.Index(['A', 'B', 'C'], name='cols')
In [311]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)
In [312]: df
Out[312]:
   cols  A       B       C
  rows
0  1.29599 -1.05169  1.34043
1 -2.36611  0.42824  0.38728
2  0.43306  0.92954  0.27809
3  2.15473 -0.31563  0.26422
4  1.12682  1.13229 -0.35331
In [313]: df['A']
Out[313]:
   rows
0  1.29599
1 -2.36611
2  0.43306
Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their name attribute. You can use the rename, set_names to set these attributes directly, and they default to returning a copy.

See Advanced Indexing for usage of MultiIndexes.

```
In [314]: ind = pd.Index([1, 2, 3])

In [315]: ind.rename("apple")
Out[315]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [316]: ind
Out[316]: Int64Index([1, 2, 3], dtype='int64')

In [317]: ind.set_names(["apple"], inplace=True)

In [318]: ind.name = "bob"

In [319]: ind
Out[319]: Int64Index([1, 2, 3], dtype='int64', name='bob')
```

set_names, set_levels, and set_codes also take an optional level argument

```
In [320]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first', 'second'])

In [321]: index
Out[321]: MultiIndex([(0, 'one'), (0, 'two'), (1, 'one'), (1, 'two'), (2, 'one'), (2, 'two')], names=['first', 'second'])

In [322]: index.levels[1]
Out[322]: Index(['one', 'two'], dtype='object', name='second')

In [323]: index.set_levels(['a', 'b'], level=1)
Out[323]: MultiIndex([(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b'), (2, 'a'), (2, 'b')], names=['first', 'second'])
```
Set operations on Index objects

The two main operations are union and intersection. Difference is provided via the `.difference()` method.

In [324]: a = pd.Index(['c', 'b', 'a'])
In [325]: b = pd.Index(['c', 'e', 'd'])
In [326]: a.difference(b)
Out[326]: Index(['a', 'b'], dtype='object')

Also available is the symmetric_difference operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

In [327]: idx1 = pd.Index([1, 2, 3, 4])
In [328]: idx2 = pd.Index([2, 3, 4, 5])
In [329]: idx1.symmetric_difference(idx2)
Out[329]: Int64Index([1, 5], dtype='int64')

Note: The resulting index from a set operation will be sorted in ascending order.

When performing `Index.union()` between indexes with different dtypes, the indexes must be cast to a common dtype. Typically, though not always, this is object dtype. The exception is when performing a union between integer and float data. In this case, the integer values are converted to float.

In [330]: idx1 = pd.Index([0, 1, 2])
In [331]: idx2 = pd.Index([0.5, 1.5])
In [332]: idx1.union(idx2)
Out[332]: Float64Index([0.0, 0.5, 1.0, 1.5, 2.0], dtype='float64')

Missing values

Important: Even though `Index` can hold missing values (NaN), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

In [333]: idx1 = pd.Index([1, np.nan, 3, 4])

(continues on next page)
In [334]: idx1
Out[334]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')

In [335]: idx1.fillna(2)
Out[335]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')

In [336]: idx2 = pd.DatetimeIndex([pd.Timestamp('2011-01-01'),
                             pd.NaT,
                             pd.Timestamp('2011-01-03')])

In [337]: idx2
Out[337]: DatetimeIndex(['2011-01-01', NaT, '2011-01-03'], dtype='datetime64[ns]',
                        freq=None)

In [338]: idx2.fillna(pd.Timestamp('2011-01-02'))
Out[338]: DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], dtype='datetime64[ns]',
                        freq=None)

### 2.5.22 Set / reset index

Occasionally you will load or create a dataset into a DataFrame and want to add an index after you've already done so. There are a couple of different ways.

#### Set an index

DataFrame has a `set_index()` method which takes a column name (for a regular `Index`) or a list of column names (for a `MultiIndex`). To create a new, re-indexed DataFrame:

In [339]: data
Out[339]:

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>bar</td>
<td>one</td>
<td>z</td>
</tr>
<tr>
<td>1</td>
<td>bar</td>
<td>two</td>
<td>y</td>
</tr>
<tr>
<td>2</td>
<td>foo</td>
<td>one</td>
<td>x</td>
</tr>
<tr>
<td>3</td>
<td>foo</td>
<td>two</td>
<td>w</td>
</tr>
</tbody>
</table>

In [340]: indexed1 = data.set_index('c')

In [341]: indexed1
Out[341]:

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>z</td>
<td>bar</td>
</tr>
<tr>
<td></td>
<td>y</td>
<td>bar</td>
</tr>
<tr>
<td></td>
<td>x</td>
<td>foo</td>
</tr>
<tr>
<td></td>
<td>w</td>
<td>foo</td>
</tr>
</tbody>
</table>

In [342]: indexed2 = data.set_index(['a', 'b'])

(continues on next page)
The `append` keyword option allows you to keep the existing index and append the given columns to a MultiIndex:

```
In [344]: frame = data.set_index('c', drop=False)

In [345]: frame = frame.set_index(['a', 'b'], append=True)

In [346]: frame
```

```
Out[346]:
          c    d
     a  b
  bar  z  1.0
     two  y  2.0
 foo  x  3.0
     two  w  4.0
```

Other options in `set_index` allow you not to drop the index columns or to add the index in-place (without creating a new object):

```
In [347]: data.set_index('c', drop=False)

Out[347]:
           a  b  c    d
     c
  z  bar  one  z  1.0
     y  bar  two  y  2.0
 foo  x  foo  one  x  3.0
     w  foo  two  w  4.0

In [348]: data.set_index(['a', 'b'], inplace=True)

In [349]: data
```

```
Out[349]:
          c    d
     a  b
  bar  z  1.0
     two  y  2.0
 foo  x  3.0
     two  w  4.0
```
Reset the index

As a convenience, there is a new function on DataFrame called \texttt{reset\_index()} which transfers the index values into the DataFrame’s columns and sets a simple integer index. This is the inverse operation of \texttt{set\_index()}.

\begin{verbatim}
In [350]: data
Out[350]:
   c  d
  a  b
  bar one z  1.0
         two y  2.0
  foo one x  3.0
         two w  4.0

In [351]: data.reset_index()
Out[351]:
     a  b  c  d
  0  bar one z  1.0
  1  bar two y  2.0
  2  foo one x  3.0
  3  foo two w  4.0
\end{verbatim}

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the \texttt{names} attribute.

You can use the \texttt{level} keyword to remove only a portion of the index:

\begin{verbatim}
In [352]: frame
Out[352]:
   c  d
  c a b
  z bar one z  1.0
  y bar two y  2.0
  x foo one x  3.0
  w foo two w  4.0

In [353]: frame.reset_index(level=1)
Out[353]:
     a  c  d
  c b
  z one bar z  1.0
  y two bar y  2.0
  x one foo x  3.0
  w two foo w  4.0
\end{verbatim}

\texttt{reset\_index} takes an optional parameter \texttt{drop} which if true simply discards the index, instead of putting index values in the DataFrame’s columns.
Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```python
data.index = index
```

2.5.23 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called chained indexing. Here is an example.

```python
In [354]: dfmi = pd.DataFrame([list('abcd'),
                        ....: list('efgh'),
                        ....: list('ijkl'),
                        ....: list('mnop'),
                        ....:
                        ....: ], columns=pd.MultiIndex.from_product([[ 'one', 'two'], ['first', 'second']]))

In [355]: dfmi
Out[355]:
   one two
first second first second
0   a   b   c   d
1   e   f   g   h
2   i   j   k   l
3   m   n   o   p
```

Compare these two access methods:

```python
In [356]: dfmi['one']['second']
Out[356]:
0   b
1   f
2   j
3   n
Name: second, dtype: object

In [357]: dfmi.loc[:, ('one', 'second')]
Out[357]:
0   b
1   f
2   j
3   n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (.loc) is much preferred over method 1 (chained []).

dfmi['one'] selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation dfmi_with_one['second'] selects the series indexed by 'second'. This is indicated by the variable dfmi_with_one because pandas sees these operations as separate events. e.g. separate calls to __getitem__, so it has to treat them as linear operations, they happen one after another.
Contrast this to `df.loc[:,('one','second')]` which passes a nested tuple of `(slice(None),('one','second'))` to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore this order of operations can be significantly faster, and allows one to index both axes if so desired.

**Why does assignment fail when using chained indexing?**

The problem in the previous section is just a performance issue. What's up with the `SettingWithCopy` warning? We don’t usually throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```python
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```python
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that `__getitem__` in there? Outside of simple cases, it’s very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the `__setitem__` will modify `dfmi` or a temporary object that gets thrown out immediately afterward. That’s what `SettingWithCopy` is warning you about!

**Note:** You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__/dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

Sometimes a `SettingWithCopy` warning will arise at times when there’s no obvious chained indexing going on. These are the bugs that `SettingWithCopy` is designed to catch! pandas is probably trying to warn you that you’ve done this:

```python
def do_something(df):
    foo = df[['bar', 'baz']]  # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    # We don't know whether this will modify df or not!
    foo['quux'] = value
    return foo
```

Yikes!

**Evaluation order matters**

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option mode.chained_assignment` to one of these values:
• 'warn', the default, means a SettingWithCopyWarning is printed.
• 'raise' means pandas will raise a SettingWithCopyException you have to deal with.
• None will suppress the warnings entirely.

```
In [358]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
                           'three', 'two', 'one', 'six'],
                       'c': np.arange(7))

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [359]: dfb['c'][dfb['a'].str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```
>>> pd.set_option('mode.chained_assignment','warn')
>>> dfb[dfb['a'].str.startswith('o')][c] = 42
Traceback (most recent call last)
... SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

A chained assignment can also crop up in setting in a mixed dtype frame.

**Note:** These setting rules apply to all of `.loc/.iloc`.

The following is the recommended access method using `.loc` for multiple items (using mask) and a single item using a fixed index:

```
In [360]: dfc = pd.DataFrame({'a': ['one', 'one', 'two',
                           'three', 'two', 'one', 'six'],
                       'c': np.arange(7))

In [361]: dfd = dfc.copy()

# Setting multiple items using a mask
In [362]: mask = dfd['a'].str.startswith('o')
In [363]: dfd.loc[mask, 'c'] = 42

In [364]: dfd
```

```
a   c
0  one  42
1  one  42
2  two  2
3  three  3
4  two  4
5  one  42
6  six  6
```

(continues on next page)
# Setting a single item

In [365]: dfd = dfc.copy()

In [366]: dfd.loc[2, 'a'] = 11

In [367]: dfd

Out[367]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>one</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>one</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>11</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>two</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>one</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>six</td>
<td>6</td>
</tr>
</tbody>
</table>

The following can work at times, but it is not guaranteed to, and therefore should be avoided:

In [368]: dfd = dfc.copy()

In [369]: dfd['a'][2] = 111

In [370]: dfd

Out[370]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>one</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>one</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>111</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>two</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>one</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>six</td>
<td>6</td>
</tr>
</tbody>
</table>

Last, the subsequent example will not work at all, and so should be avoided:

```python
>>> pd.set_option('mode.chained_assignment', 'raise')
>>> dfd.loc[0]['a'] = 1111
Traceback (most recent call last)
... SettingWithCopyException:
    A value is trying to be set on a copy of a slice from a DataFrame.
    Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.
2.6 MultiIndex / advanced indexing

This section covers indexing with a MultiIndex and other advanced indexing features.

See the Indexing and Selecting Data for general indexing documentation.

Warning: Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

See the cookbook for some advanced strategies.

2.6.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like Series (1d) and DataFrame (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing group by and pivoting and reshaping data, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the cookbook for some advanced strategies.

Creating a MultiIndex (hierarchical index) object

The MultiIndex object is the hierarchical analogue of the standard Index object which typically stores the axis labels in pandas objects. You can think of MultiIndex as an array of tuples where each tuple is unique. A MultiIndex can be created from a list of arrays (using MultiIndex.from_arrays()), an array of tuples (using MultiIndex.from_tuples()), a crossed set of iterables (using MultiIndex.from_product()), or a DataFrame (using MultiIndex.from_frame()). The Index constructor will attempt to return a MultiIndex when it is passed a list of tuples. The following examples demonstrate different ways to initialize MultiIndexes.

In [1]: arrays = [
      ...:     ['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
      ...:     ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'],
      ...: ]

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]: [('bar', 'one'),
        ('bar', 'two'),
        ('baz', 'one'),
        ('baz', 'two'),
        ('foo', 'one'),
        ('foo', 'two'),
        ('qux', 'one'),
        ('qux', 'two')]

(continues on next page)
In [4]: index = pd.MultiIndex.from_tuples(tuples, names=["first", "second"])

In [5]: index
Out[5]:
MultiIndex([('bar', 'one'),
           ('bar', 'two'),
           ('baz', 'one'),
           ('baz', 'two'),
           ('foo', 'one'),
           ('foo', 'two'),
           ('qux', 'one'),
           ('qux', 'two')],
          names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first  second
bar    one    0.469112
      two   -0.282863
baz    one   -1.509059
      two   -1.135632
foo    one    1.212112
      two   -0.173215
qux    one    0.119209
      two  -1.044236
dtype: float64

When you want every pairing of the elements in two iterables, it can be easier to use the MultiIndex. from_product() method:

In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex([('bar', 'one'),
           ('bar', 'two'),
           ('baz', 'one'),
           ('baz', 'two'),
           ('foo', 'one'),
           ('foo', 'two'),
           ('qux', 'one'),
           ('qux', 'two')],
          names=['first', 'second'])

You can also construct a MultiIndex from a DataFrame directly, using the method MultiIndex.from_frame(). This is a complementary method to MultiIndex.to_frame().

In [10]: df = pd.DataFrame(
    ....:     [['bar', 'one'], ['bar', 'two'], ['foo', 'one'], ['foo', 'two']],
    ....:     columns=['first', 'second'])

In [11]: df
Out[11]:
         first  second

two 'bar'  'two'
bar one    'bar'  'one'
...
As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

```python
In [12]: arrays = [
   ....:   np.array(["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"]),
   ....:   np.array(["one", "two", "one", "two", "one", "two", "one", "two"]),
   ....: ]
   ....:

In [13]: s = pd.Series(np.random.randn(8), index=arrays)

In [14]: s
Out[14]:
bar one  -0.861849
   two   -2.104569
baz one  -0.494929
   two    1.071804
foo one   0.721555
   two  -0.706771
qux one  -1.039575
   two   0.271860
dtype: float64

In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)

In [16]: df
Out[16]:
   0   1   2   3
bar one -0.424972  0.567020  0.276232 -1.087401
two  -0.673690  0.113648 -1.478427  0.524988
baz one  0.404705  0.577046 -1.715002 -1.039268
two  -0.370647 -1.157892 -1.344312  0.844885
foo one  1.075770 -0.109050  1.643563 -1.469388
two  -0.357021 -0.674600 -1.776904 -0.968914
qux one -1.294524  0.413738  0.276662 -0.472035
two  -0.013960  0.362543  0.006154  0.923061
```

All of the MultiIndex constructors accept a names argument which stores string names for the levels themselves. If no names are provided, None will be assigned:
In [17]: df.index.names
Out[17]: FrozenList([None, None])

This index can back any axis of a pandas object, and the number of levels of the index is up to you:

In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'], columns=index)

In [19]: df
Out[19]:
   first  bar  baz  foo  qux
second  
A      0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309 -1.170299 -0.226169
B      0.410835  0.813850  0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436737
C     -1.413681  1.607920  1.024180  0.569605  0.875906 -2.211372  0.974466 -2.006747

In [20]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])
Out[20]:
   first  bar  baz  foo
second  
first  
bar   -0.410001 -0.078638  0.545952 -1.219217 -1.226825  0.769804
two   -1.281247 -0.727707 -0.121306 -0.097883  0.695775  0.341734
baz    0.959726 -0.110336 -0.619976  0.149748 -0.732339  0.687738
two    0.176444  0.403310 -0.154951  0.301624 -2.179861 -1.369849
foo    -0.954208  1.462696 -1.743161 -0.826591 -0.345352  1.314232
two    0.690579  0.995761  2.396780  0.014871  3.357427 -0.317441

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the multi_sparse option in pandas.set_options():

In [21]: with pd.option_context("display.multi_sparse", False):
     ....: df
     ....:

It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

In [22]: pd.Series(np.random.randn(8), index=tuples)
Out[22]:
(bar, one)  -1.236269
(bar, two)   0.896171
(baz, one)  -0.487602
(baz, two)  -0.082240
(foo, one)  -2.182937
(foo, two)   0.380396
(qux, one)   0.084844
(qux, two)   0.432390
dtype: float64

The reason that the MultiIndex matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a MultiIndex explicitly yourself. However, when loading data from a file, you may wish to generate your own MultiIndex when preparing the data set.
Reconstructing the level labels

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```python
In [23]: index.get_level_values(0)
Out[23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='O', name='first')

In [24]: index.get_level_values('second')
Out[24]: Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='O', name='second')
```

Basic indexing on axis with MultiIndex

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. Partial selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular DataFrame:

```python
In [25]: df['bar']
Out[25]:
   second  one  two
   A    0.895717  0.805244
   B    0.410835  0.813850
   C   -1.413681  1.607920

In [26]: df['bar', 'one']
Out[26]:
   A    0.895717
   B    0.410835
   C   -1.413681
Name: (bar, one), dtype: float64

In [27]: df['bar']['one']
Out[27]:
   A    0.895717
   B    0.410835
   C   -1.413681
Name: one, dtype: float64

In [28]: s['qux']
Out[28]:
   one   -1.039575
   two    0.271860
dtype: float64
```

See `Cross-section with hierarchical index` for how to select on a deeper level.
Defined levels

The **MultiIndex** keeps all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

```python
In [29]: df.columns.levels  # original MultiIndex
Out[29]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])

In [30]: df[['foo', 'qux']].columns.levels  # sliced
Out[30]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `get_level_values()` method.

```python
In [31]: df[['foo', 'qux']].columns.to_numpy()
Out[31]:
array([(b'foo', b'one'), (b'foo', b'two'), (b'qux', b'one'), (b'qux', b'two')],
      dtype=object)

# for a specific level
In [32]: df[['foo', 'qux']].columns.get_level_values(0)
Out[32]: Index([b'foo', b'foo', b'qux', b'qux'], dtype='O', name='first')
```

To reconstruct the `MultiIndex` with only the used levels, the `remove_unused_levels()` method may be used.

```python
In [33]: new_mi = df[['foo', 'qux']].columns.remove_unused_levels()

In [34]: new_mi.levels
Out[34]: FrozenList([['foo', 'qux'], ['one', 'two']])
```

Data alignment and using reindex

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```python
In [35]: s + s[:-2]
Out[35]:
    bar    one -1.723698
      two -4.209138
    baz    one -0.989859
      two  2.143608
    foo    one  1.443110
      two -1.413542
    qux    one   NaN
      two   NaN
dtype: float64

In [36]: s + s[:2]
Out[36]:
    bar    one -1.723698
      two   NaN
    baz    one -0.989859
      two   NaN
```

(continues on next page)
The `reindex()` method of `Series/DataFrames` can be called with another `MultiIndex`, or even a list or array of tuples:

```python
In [37]: s.reindex(index[:3])
Out[37]:
   first  second
bar   one  -0.861849
       two  -2.104569
baz   one  -0.494929
dtype: float64

In [38]: s.reindex(["foo", "two"], ["bar", "one"], ["qux", "one"], ["baz", "one")]
Out[38]:
   foo  two  -0.706771
    bar  one  -0.861849
    qux  one  -1.039575
    baz  one  -0.494929
dtype: float64
```

### 2.6.2 Advanced indexing with hierarchical index

Syntactically integrating `MultiIndex` in advanced indexing with `.loc` is a bit challenging, but we've made every effort to do so. In general, `MultiIndex` keys take the form of tuples. For example, the following works as you would expect:

```python
In [39]: df = df.T

In [40]: df
Out[40]:
     A   B    C
first second
bar   one  0.895717 0.410835 1.413681
    two  0.805244 0.813850 1.607920
baz   one  1.206412 0.132003 1.024180
    two  2.565646 -0.827317 0.569605
foo   one  1.431256 -0.076467 0.875906
    two  1.340309 -1.187678 -2.211372
qux   one  1.170299 1.130127 0.974466
    two -2.226169 1.436737 -2.006747

In [41]: df.loc["bar", "two"]
Out[41]:
   A  0.805244
   B  0.813850
   C  1.607920
Name: (bar, two), dtype: float64
```
Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:

```python
In [42]: df.loc[('bar', 'two'), 'A']
Out[42]: 0.8052440253863785
```

You don’t have to specify all levels of the `MultiIndex` by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with `bar` in the first level as follows:

```python
In [43]: df.loc["bar"]
Out[43]:
   A    B    C
second
  one  0.895717 0.410835 -1.413681
  two  0.805244 0.813850  1.607920
```

This is a shortcut for the slightly more verbose notation `df.loc[('bar',),]` (equivalent to `df.loc["bar",]` in this example).

“Partial” slicing also works quite nicely.

```python
In [44]: df.loc["baz":"foo"]
Out[44]:
   A    B    C
first second
baz one -1.206412 0.132003  1.024180
  two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
  two  1.340309 -1.187678 -2.211372
```

You can slice with a ‘range’ of values, by providing a slice of tuples.

```python
In [45]: df.loc[('baz', 'two'):('qux', 'one')]
Out[45]:
   A    B    C
first second
baz two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
  two  1.340309 -1.187678 -2.211372
qux one -1.170299  1.130127  0.974466
```

```python
In [46]: df.loc[('baz', 'two'):'foo']
Out[46]:
   A    B    C
first second
baz two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
  two  1.340309 -1.187678 -2.211372
```

Passing a list of labels or tuples works similar to reindexing:

```python
In [47]: df.loc[['bar', 'two'], ['qux', 'one']]  
Out[47]:
```

(continues on next page)
A | B | C
---|---|---
bar two | 0.805244 | 0.813850 | 1.607920
qux one | -1.170299 | 1.130127 | 0.974466

**Note:** It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

In [48]: s = pd.Series([1, 2, 3, 4, 5, 6], index=pd.MultiIndex.from_product([['A', 'B'], ['c', 'd', 'e']]),)

In [49]: s.loc[('A', 'c'), ('B', 'd')]
   # list of tuples
Out[49]:
A c 1
B d 5

dtype: int64

In [50]: s.loc[['A', 'B'], ['c', 'd']]    # tuple of lists
Out[50]:
A c 1
d 2
B c 4
d 5

dtype: int64

**Using slicers**

You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see Selection by Label, including slices, lists of labels, labels, and boolean indexers.

You can use slice(None) to select all the contents of that level. You do not need to specify all the deeper levels, they will be implied as slice(None).

As usual, both sides of the slicers are included as this is label indexing.

**Warning:** You should specify all axes in the .loc specifier, meaning the indexer for the index and for the columns. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the MultiIndex for the rows.

You should do this:

df.loc[[slice("A1", "A3"), ...], :]

# noqa: E999
You should **not** do this:

```python
df.loc[(slice("A1", "A3"), ...)]  # noqa: E999
```

```python
In [51]: def mklbl(prefix, n):
    ....:     return ["%s%s" % (prefix, i) for i in range(n)]

In [52]: miindex = pd.MultiIndex.from_product(
    ....:     [mklbl("A", 4), mklbl("B", 2), mklbl("C", 4), mklbl("D", 2)]
    ....: )

In [53]: micolumns = pd.MultiIndex.from_tuples(
    ....:     [("a", "foo"), ("a", "bar"), ("b", "foo"), ("b", "bah")],
    ....:     names=["lvl0", "lvl1"]
    ....: )

In [54]: dfmi = (pd.DataFrame(
    ....:     np.arange(len(miindex) * len(micolumns)).reshape(
    ....:         (len(miindex), len(micolumns))
    ....:     ),
    ....:     index=miindex,
    ....:     columns=micolumns,
    ....: ).sort_index().sort_index(axis=1)

In [55]: dfmi
```

```
Out[55]:

<table>
<thead>
<tr>
<th></th>
<th>lvl0</th>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>lvl1</td>
<td></td>
<td>b</td>
<td>foo</td>
</tr>
<tr>
<td>A0</td>
<td>B0</td>
<td>C0</td>
<td>D0</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>D1</td>
<td>5</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>A1</td>
<td>B1</td>
<td>C1</td>
<td>D0</td>
<td>9</td>
</tr>
<tr>
<td>C0</td>
<td>D0</td>
<td>13</td>
<td>12</td>
<td>15</td>
</tr>
<tr>
<td>C1</td>
<td>D1</td>
<td>17</td>
<td>16</td>
<td>19</td>
</tr>
</tbody>
</table>
```

Basic MultiIndex slicing using slices, lists, and labels.

2.6. MultiIndex / advanced indexing 477
You can use `pandas.IndexSlice` to facilitate a more natural syntax using 

displayed here}

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```python
In [59]: dfmi.loc["A1", (slice(None), "foo")]
```

```output
lvl0 a b
lvl1 foo foo
B0 C0 D0 64 66
  D1 68 70
C1 D0 72 74
  D1 76 78
C2 D0 80 82
...
B1 C1 D1 108 110
```

(continues on next page)
Using a boolean indexer you can provide selection related to the values.

In [61]: mask = dfmi["a", "foo"] > 200

In [62]: dfmi.loc[idx[mask, :, ["C1", "C3"]], idx[:, "foo"]]

Out[62]:

Using a boolean indexer you can provide selection related to the values.

```python
In [61]: mask = dfmi["a", "foo"] > 200

In [62]: dfmi.loc[idx[mask, :, ["C1", "C3"]], idx[:, "foo"]]
```

You can also specify the axis argument to .loc to interpret the passed slicers on a single axis.

In [63]: dfmi.loc(axis=0)[; :, ["C1", "C3"]]

Out[63]:

---

2.6. MultiIndex / advanced indexing
Furthermore, you can set the values using the following methods.

```
In [64]: df2 = dfmi.copy()

In [65]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [66]: df2
```

```
Out[66]:
        a    b
   lvl0
   lvl1     bar  foo  bah  foo
A0 B0 C0 D0 1  0  3  2
   D1  5  4  7  6
   C1 D0 -10 -10 -10 -10
   D1 -10 -10 -10 -10
   C2 D0 17  16 19  18

... ... ... ...
A3 B1 C1 D1 -10 -10 -10 -10
   C2 D0 241 240 243 242
   D1 245 244 247 246

[64 rows x 4 columns]
```

You can use a right-hand-side of an alignable object as well.

```
In [67]: df2 = dfmi.copy()

In [68]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000

In [69]: df2
```

```
Out[69]:
        a    b
   lvl0
   lvl1     bar  foo  bah  foo
A0 B0 C0 D0 1  0  3  2
   D1  5  4  7  6
   C1 D0  9000  8000 11000 10000
   D1 13000 12000 15000 14000
   C2 D0 17  16 19  18

... ... ... ...
A3 B1 C1 D1 237000 236000 239000 238000
   C2 D0  241  240  243  242
   D1  245  244  247  246
```

(continues on next page)
Cross-section

The `xs()` method of `DataFrame` additionally takes a level argument to make selecting data at a particular level of a `MultiIndex` easier.

```
In [70]: df
Out[70]:
   A    B    C
first  
bar    0.895717 0.410835 -1.413681
two   0.805244 0.813850  1.607920
baz   -1.206412 0.132003  1.024180
two   2.565646 -0.827317  0.569605
foo    1.431256 -0.076467  0.875906
two   1.340309 -1.187678 -2.211372
qux   -1.170299 1.130127  0.974466
two   -0.226169 -1.436737 -2.006747

In [71]: df.xs("one", level="second")
Out[71]:
   A    B    C
first  
bar    0.895717 0.410835 -1.413681
baz   -1.206412 0.132003  1.024180
foo    1.431256 -0.076467  0.875906
qux   -1.170299 1.130127  0.974466

# using the slicers
In [72]: df.loc[(slice(None), "one"), :]
Out[72]:
   A    B    C
first  
bar    0.895717 0.410835 -1.413681
baz   -1.206412 0.132003  1.024180
foo    1.431256 -0.076467  0.875906
qux   -1.170299 1.130127  0.974466

In [73]: df = df.T
In [74]: df.xs("one", level="second", axis=1)
Out[74]:
   first   bar   baz   foo   qux
A  0.895717 -1.206412  1.431256 -1.170299
```

You can also select on the columns with `xs`, by providing the axis argument.

```
In [75]: df.xs("one", level="second", axis=1)
Out[75]:
   first   bar   baz   foo   qux
A  0.895717 -1.206412  1.431256 -1.170299
```
# using the slicers

```python
In [75]: df.loc[:, (slice(None), "one")]
Out[75]:
```

<table>
<thead>
<tr>
<th>first</th>
<th>bar</th>
<th>baz</th>
<th>foo</th>
<th>qux</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.895717</td>
<td>-1.206412</td>
<td>1.431256</td>
<td>-1.170299</td>
</tr>
<tr>
<td>B</td>
<td>0.410835</td>
<td>0.132003</td>
<td>-0.076467</td>
<td>1.130127</td>
</tr>
<tr>
<td>C</td>
<td>-1.413681</td>
<td>1.024180</td>
<td>0.875906</td>
<td>0.974466</td>
</tr>
</tbody>
</table>

- xs also allows selection with multiple keys.

```python
In [76]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out[76]:
```

<table>
<thead>
<tr>
<th>first</th>
<th>bar</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.895717</td>
</tr>
<tr>
<td>B</td>
<td>0.410835</td>
</tr>
<tr>
<td>C</td>
<td>-1.413681</td>
</tr>
</tbody>
</table>

# using the slicers

```python
In [77]: df.loc[:, ('bar', 'one')]
Out[77]:
```

A 0.895717  
B 0.410835  
C -1.413681 
Name: (bar, one), dtype: float64

- You can pass `drop_level=False` to `xs` to retain the level that was selected.

```python
In [78]: df.xs("one", level="second", axis=1, drop_level=False)
Out[78]:
```

<table>
<thead>
<tr>
<th>first</th>
<th>bar</th>
<th>baz</th>
<th>foo</th>
<th>qux</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.895717</td>
<td>-1.206412</td>
<td>1.431256</td>
<td>-1.170299</td>
</tr>
<tr>
<td>B</td>
<td>0.410835</td>
<td>0.132003</td>
<td>-0.076467</td>
<td>1.130127</td>
</tr>
<tr>
<td>C</td>
<td>-1.413681</td>
<td>1.024180</td>
<td>0.875906</td>
<td>0.974466</td>
</tr>
</tbody>
</table>

- Compare the above with the result using `drop_level=True` (the default value).

```python
In [79]: df.xs("one", level="second", axis=1, drop_level=True)
Out[79]:
```

<table>
<thead>
<tr>
<th>first</th>
<th>bar</th>
<th>baz</th>
<th>foo</th>
<th>qux</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.895717</td>
<td>-1.206412</td>
<td>1.431256</td>
<td>-1.170299</td>
</tr>
<tr>
<td>B</td>
<td>0.410835</td>
<td>0.132003</td>
<td>-0.076467</td>
<td>1.130127</td>
</tr>
<tr>
<td>C</td>
<td>-1.413681</td>
<td>1.024180</td>
<td>0.875906</td>
<td>0.974466</td>
</tr>
</tbody>
</table>
Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```python
In [80]: midx = pd.MultiIndex(
        ....:     levels=["zero", "one"], ["x", "y"], codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
        ....:

In [81]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)
In [82]: df
Out[82]:
    0   1
one y 1.519970 -0.493662
     x 0.600178  0.274230
zero y 0.132885 -0.023688
      x 2.410179  1.450520

In [83]: df2 = df.groupby(level=0).mean()
In [84]: df2
Out[84]:
    0   1
one y 1.060074 -0.109716
     x 1.060074 -0.109716
zero y 1.271532  0.713416
      x 1.271532  0.713416

In [85]: df2.reindex(df.index, level=0)
Out[85]:
    0   1
one y 1.519970 -0.493662
     x 0.600178  0.274230
zero y 0.132885 -0.023688
      x 2.410179  1.450520

# aligning
In [86]: df_aligned, df2_aligned = df.align(df2, level=0)
In [87]: df_aligned
Out[87]:
    0   1
one y 1.519970 -0.493662
     x 0.600178  0.274230
zero y 0.132885 -0.023688
      x 2.410179  1.450520
In [88]: df2_aligned
Out[88]:
    0   1
one y 1.060074 -0.109716
     x 1.060074 -0.109716
zero y 1.271532  0.713416
      x 1.271532  0.713416
```
Swapping levels with `swaplevel`

The `swaplevel()` method can switch the order of two levels:

```python
In [89]: df[:5]
Out[89]:
         0  1
one y  1.519970 -0.493662
      x  0.600178  0.274230
zero y  0.132885 -0.023688
      x  2.410179  1.450520

In [90]: df[:5].swaplevel(0, 1, axis=0)
Out[90]:
         0  1
   y one  1.519970 -0.493662
   x one  0.600178  0.274230
   y zero  0.132885 -0.023688
   x zero  2.410179  1.450520
```

Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```python
In [91]: df[:5].reorder_levels([1, 0], axis=0)
Out[91]:
         0  1
   y one  1.519970 -0.493662
   x one  0.600178  0.274230
   y zero  0.132885 -0.023688
   x zero  2.410179  1.450520
```

Renaming names of an Index or MultiIndex

The `rename()` method is used to rename the labels of a MultiIndex, and is typically used to rename the columns of a DataFrame. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```python
In [92]: df.rename(columns={0: "col0", 1: "col1"})
Out[92]:
       col0  col1
one y  1.519970 -0.493662
      x  0.600178  0.274230
zero y  0.132885 -0.023688
      x  2.410179  1.450520
```

This method can also be used to rename specific labels of the main index of the DataFrame.

```python
In [93]: df.rename(index={"one": "two", "y": "z"})
Out[93]:
         0  1
```
The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a `MultiIndex` can be specified, which is useful if `reset_index()` is later used to move the values from the `MultiIndex` to a column.

```
In [94]: df.rename_axis(index=["abc", "def"])
Out[94]:
     0     1
  abc  def
one  y   1.519970 -0.493662
     x   0.600178  0.274230
zero y   0.132885 -0.023688
     x   2.410179  1.450520
```

Note that the columns of a `DataFrame` are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```
In [95]: df.rename_axis(columns="Cols").columns
Out[95]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```

Both `rename` and `rename_axis` support specifying a dictionary, `Series` or a mapping function to map labels/names to new values.

When working with an `Index` object directly, rather than via a `DataFrame`, `Index.set_names()` can be used to change the names.

```
In [96]: mi = pd.MultiIndex.from_product([[1, 2], ["a", "b"]], names=["x", "y"])
In [97]: mi
Out[97]: FrozenList(["x", "y"])
In [98]: mi2 = mi.rename("new name", level=0)
In [99]: mi2
Out[99]: MultiIndex(((1, 'a'),
             (1, 'b'),
             (2, 'a'),
             (2, 'b')),
             names=['new name', 'y'])
```

You cannot set the names of the `MultiIndex` via a level.

```
In [100]: mi.levels[0].name = "name via level"
---------------------------------------------------------------------------
RuntimeError                                Traceback (most recent call last)
<ipython-input-100-35d32a9a5218> in <module>
-----> 1 mi.levels[0].name = "name via level"
```

---

2.6. MultiIndex / advanced indexing
Use `Index.set_names()` instead.

### 2.6.3 Sorting a MultiIndex

For `MultiIndex`-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```python
In [101]: import random

In [102]: random.shuffle(tuples)

In [103]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))

In [104]: s
Out[104]:
foo one  0.206053
qux one -0.251905
two -2.213588
bar one  1.063327
two  1.266143
baz one  0.299368
foo two  0.863838
two  0.408204
dtype: float64

In [105]: s.sort_index()
Out[105]:
bar one  1.063327
two  1.266143
baz one  0.299368
two  0.408204
foo one  0.206053
two  0.863838
qux one -0.251905
two -2.213588
dtype: float64

In [106]: s.sort_index(level=0)
Out[106]:
bar one  1.063327
two  1.266143
```
You may also pass a level name to `sort_index` if the MultiIndex levels are named.

```
In [108]: s.index.set_names(["L1", "L2"], inplace=True)
```

```
In [109]: s.sort_index(level="L1")
```

```
   L1  L2
bar  one  1.063327
    two  1.266143
baz  one  0.299368
    two  0.408204
foo  one  0.206053
    two -0.863838
qux  one -0.251905
    two -2.213588
dtype: float64
```

```
In [110]: s.sort_index(level="L2")
```

```
   L1  L2
bar  one  1.063327
baz  one  0.299368
foo  one  0.206053
qux  one -0.251905
bar  two  1.266143
baz  two  0.408204
foo  two -0.863838
qux  two -2.213588
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a MultiIndex:
Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```python
In [112]: dfm = pd.DataFrame(
.....:   {"jim": [0, 0, 1, 1], "joe": ["x", "x", "z", "y"], "jolie": np.random.rand(4)}
.....: )

In [113]: dfm = dfm.set_index(["jim", "joe"])

In [114]: dfm
Out[114]:
     jolie
     jim  joe
0    x  0.490671
     x  0.120248
1    z  0.537020
     y  0.110968
```

Furthermore, if you try to index something that is not fully lexsorted, this can raise:

```python
In [5]: dfm.loc[(0, 'y'): (1, 'z')]
UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'
```

The `is_monotonic_increasing()` method on a `MultiIndex` shows if the index is sorted:

```python
In [115]: dfm.index.is_monotonic_increasing
Out[115]: False
```

```python
In [116]: dfm = dfm.sort_index()

In [117]: dfm
Out[117]:
     jolie
     jim  joe
0    x  0.490671
     x  0.120248
```

(continues on next page)
In [118]: dfm.index.is_monotonic_increasing
Out[118]: True

And now selection works as expected.

In [119]: dfm.loc[(0, "y"): (1, "z")]
Out[119]:
   1 y  0.110968
   z  0.537020

2.6.4 Take methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

In [120]: index = pd.Index(np.random.randint(0, 1000, 10))
In [121]: index
Out[121]: Int64Index([214, 502, 712, 567, 786, 175, 993, 133, 758, 329], dtype='int64')
In [122]: positions = [0, 9, 3]
In [123]: index[positions]
Out[123]: Int64Index([214, 329, 567], dtype='int64')
In [124]: index.take(positions)
Out[124]: Int64Index([214, 329, 567], dtype='int64')

In [125]: ser = pd.Series(np.random.randn(10))
In [126]: ser.iloc[positions]
Out[126]:
   0  -0.179666
   9   1.824375
   3   0.392149
dtype: float64
In [127]: ser.take(positions)
Out[127]:
   0  -0.179666
   9   1.824375
   3   0.392149
dtype: float64

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.
In [128]: frm = pd.DataFrame(np.random.randn(5, 3))

In [129]: frm.take([1, 4, 3])
Out[129]:
    0  1  2
0 -1.237881 0.106854 -1.276829
1  0.629675 -1.425966  1.857704
3  0.979542 -1.633678  0.615855

In [130]: frm.take([0, 2], axis=1)
Out[130]:
    0  2
0  0.595974 0.601544
1 -1.237881 -1.276829
2 -0.767101  1.499591
3  0.979542  0.615855
4  0.629675  1.857704

It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

In [131]: arr = np.random.randn(10)

In [132]: arr.take([False, False, True, True])
Out[132]: array([-1.1935, -1.1935,  0.6775,  0.6775])

In [133]: arr[[0, 1]]
Out[133]: array([-1.1935,  0.6775])

In [134]: ser = pd.Series(np.random.randn(10))

In [135]: ser.take([False, False, True, True])
Out[135]:
    0  0.233141
    0  0.233141
    1 -0.223540
    1 -0.223540
dtype: float64

In [136]: ser.iloc[[0, 1]]
Out[136]:
    0  0.233141
    1 -0.223540
dtype: float64

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

In [137]: arr = np.random.randn(10000, 5)

In [138]: indexer = np.arange(10000)

In [139]: random.shuffle(indexer)

(continues on next page)
In [140]: %timeit arr[indexer]
   ......: %timeit arr.take(indexer, axis=0)
   ......:
150 us +- 9.75 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
46.1 us +- 6.08 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)

In [141]: ser = pd.Series(arr[:, 0])

In [142]: %timeit ser.iloc[indexer]
   ......: %timeit ser.take(indexer)
   ......:
76.1 us +- 1.79 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
67.6 us +- 2.63 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)

2.6.5 Index types

We have discussed MultiIndex in the previous sections pretty extensively. Documentation about DatetimeIndex and PeriodIndex are shown here, and documentation about TimedeltaIndex is found here.

In the following sub-sections we will highlight some other index types.

CategoricalIndex

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements.

In [143]: from pandas.api.types import CategoricalDtype

In [144]: df = pd.DataFrame({"A": np.arange(6), "B": list("aabbc")})

In [145]: df["B"] = df["B"].astype(CategoricalDtype(list("cab")))

In [146]: df
Out[146]:
   A   B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a

In [147]: df.dtypes
Out[147]:
A     int64
B   category
dtype: object

In [148]: df["B"].cat.categories
Out[148]: Index(['c', 'a', 'b'], dtype='object')
Setting the index will create a CategoricalIndex.

```python
In [149]: df2 = df.set_index("B")
In [150]: df2.index
Out[150]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'], ordered=False, dtype='category', name='B')
```

Indexing with `__getitem__`/.iloc/.loc works similarly to an Index with duplicates. The indexers must be in the category or the operation will raise a KeyError.

```python
In [151]: df2.loc["a"]
Out[151]:
     A   B
a 0  a
a 1  a
a 5
```

The CategoricalIndex is preserved after indexing:

```python
In [152]: df2.loc["a"].index
Out[152]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False, dtype='category', name='B')
```

Sorting the index will sort by the order of the categories (recall that we created the index with CategoricalDtype(list('cab')), so the sorted order is cab).

```python
In [153]: df2.sort_index()
Out[153]:
     A   B
c 4  a
a 0  a
a 1  a
a 5  a
b 2  b
b 3  b
```

Groupby operations on the index will preserve the index nature as well.

```python
In [154]: df2.groupby(level=0).sum()
Out[154]:
     A   B
c 4  a
a 6  a
b 5  b

In [155]: df2.groupby(level=0).sum().index
Out[155]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False, dtype='category', name='B')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories.
of the passed `Categorical` dtype. This allows one to arbitrarily index these even with values not in the categories, similarly to how you can reindex any pandas index.

```python
In [156]: df3 = pd.DataFrame(
    ...:     {"A": np.arange(3), "B": pd.Series(list("abc")).astype("category")}
    ...: )
    ...:
In [157]: df3 = df3.set_index("B")
In [158]: df3
Out[158]:
   A
B  
a 0
b 1
c 2

In [159]: df3.reindex(["a", "e"])
Out[159]:
   A
B  
a 0
b 1
c 2
e NaN

In [160]: df3.reindex(["a", "e"]).index
Out[160]: Index(["a", "e"], dtype='object', name='B')

In [161]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe")))
Out[161]:
   A
B  
a 0
b 1
c 2
e NaN

In [162]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe"))).index
Out[162]: CategoricalIndex(["a", "e"], categories=['a', 'b', 'e'], ordered=False, dtype='category', name='B')
```

**Warning:** Reshaping and Comparison operations on a `CategoricalIndex` must have the same categories or a TypeError will be raised.

```python
In [163]: df4 = pd.DataFrame({"A": np.arange(2), "B": list("ba")})
In [164]: df4["B"] = df4["B"].astype(CategoricalDtype(list("ab")))
In [165]: df4 = df4.set_index("B")
In [166]: df4.index
Out[166]: CategoricalIndex(['a', 'b'], categories=['a', 'b'], ordered=False, dtype='category', name='B')
In [167]: df5 = pd.DataFrame({"A": np.arange(2), "B": list("bc")})

```

### 2.6. MultiIndex / advanced indexing
In [168]: df5["B"] = df5["B"].astype(CategoricalDtype(list("bc")))

In [169]: df5 = df5.set_index("B")

In [170]: df5.index
Out[170]: CategoricalIndex(
'b'
', 'c'), categories=['b', 'c'], ordered=False, dtype=
˓→'category', name='B')

In [1]: pd.concat([df4, df5])
TypeError: categories must match existing categories when appending

### Int64Index and RangeIndex

*Int64Index* is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set.

*RangeIndex* is a sub-class of *Int64Index* that provides the default index for all *NDFrame* objects. *RangeIndex* is an optimized version of *Int64Index* that can represent a monotonic ordered set. These are analogous to Python range types.

#### Float64Index

By default a *Float64Index* will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes [], *ix, loc* for scalar indexing and slicing work exactly the same.

In [171]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])

In [172]: indexf
Out[172]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [173]: sf = pd.Series(range(5), index=indexf)

In [174]: sf
Out[174]:
1.5 0
2.0 1
3.0 2
4.5 3
5.0 4
dtype: int64

Scalar selection for [], .loc will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

In [175]: sf[3]
Out[175]: 2

In [176]: sf[3.0]
Out[176]: 2

(continues on next page)
In [177]: sf.loc[3]
Out[177]: 2

In [178]: sf.loc[3.0]
Out[178]: 2

The only positional indexing is via `iloc`.

In [179]: sf.iloc[3]
Out[179]: 3

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and always positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

In [180]: sf[2:4]
Out[180]:
   2.0  1  
   3.0  2  
   dtype: int64

In [181]: sf.loc[2:4]
Out[181]:
   2.0  1  
   3.0  2  
   dtype: int64

In [182]: sf.iloc[2:4]
Out[182]:
   3.0  2  
   4.5  3  
   dtype: int64

In float indexes, slicing using floats is allowed.

In [183]: sf[2.1:4.6]
Out[183]:
   3.0  2  
   4.5  3  
   dtype: int64

In [184]: sf.loc[2.1:4.6]
Out[184]:
   3.0  2  
   4.5  3  
   dtype: int64

In non-float indexes, slicing using floats will raise a `TypeError`.

In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)
In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type (Int64Index)

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

In [185]: dfir = pd.concat(
......: [np.random.randn(5, 2), index=np.arange(5) * 250.0, columns=list("AB")],
......: np.random.randn(6, 2),
......: index=np.arange(4, 10) * 250.1,
......: columns=list("AB")),
......: )

In [186]: dfir
Out[186]:
    A         B
0.0  -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243487  0.514704
1000.0  1.162969 -0.287725
1000.4 -0.179734  0.993962
1250.5 -0.212673  0.909872
1500.6 -0.733333 -0.349893
1750.7  0.456434 -0.306735
2000.8  0.553396  0.166221
2250.9 -0.101684 -0.734907

Selection operations then will always work on a value basis, for all selection operators.

In [187]: dfir[0:1000.4]
Out[187]:
    A         B
0.0  -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243487  0.514704
1000.0  1.162969 -0.287725
1000.4 -0.179734  0.993962

In [188]: dfir.loc[0:1001, "A"]
Out[188]:
    0.0  -0.435772
     250.0 -0.808286
In [189]: dfir.loc[1000.4]
Out[189]:
A  -0.179734
B   0.993962
Name: 1000.4, dtype: float64

You could retrieve the first 1 second (1000 ms) of data as such:

In [190]: dfir[0:1000]
Out[190]:
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0</td>
<td>-0.435772</td>
</tr>
<tr>
<td>250.0</td>
<td>-0.808286</td>
</tr>
<tr>
<td>500.0</td>
<td>-1.815703</td>
</tr>
<tr>
<td>750.0</td>
<td>-0.243487</td>
</tr>
<tr>
<td>1000.0</td>
<td>1.162969</td>
</tr>
</tbody>
</table>

If you need integer based selection, you should use `iloc`:

In [191]: dfir.iloc[0:5]
Out[191]:
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0</td>
<td>-0.435772</td>
</tr>
<tr>
<td>250.0</td>
<td>-0.808286</td>
</tr>
<tr>
<td>500.0</td>
<td>-1.815703</td>
</tr>
<tr>
<td>750.0</td>
<td>-0.243487</td>
</tr>
<tr>
<td>1000.0</td>
<td>1.162969</td>
</tr>
</tbody>
</table>

**IntervalIndex**

`IntervalIndex` together with its own dtype, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

2.6. MultiIndex / advanced indexing
Indexing with an IntervalIndex

An IntervalIndex can be used in Series and in DataFrame as the index.

```
In [192]: df = pd.DataFrame(
    ....:     {"A": [1, 2, 3, 4]}, index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4])
    ....: )
    ....:

In [193]: df
Out[193]:
     A
(0, 1]  1
(1, 2]  2
(2, 3]  3
(3, 4]  4
```

Label based indexing via .loc along the edges of an interval works as you would expect, selecting that particular interval.

```
In [194]: df.loc[2]
Out[194]:
     A
Name: (1, 2], dtype: int64

In [195]: df.loc[[2, 3]]
Out[195]:
     A
(1, 2]  2
(2, 3]  3
```

If you select a label contained within an interval, this will also select the interval.

```
In [196]: df.loc[2.5]
Out[196]:
     A
Name: (2, 3], dtype: int64

In [197]: df.loc[[2.5, 3.5]]
Out[197]:
     A
(2, 3]  3
(3, 4]  4
```

Selecting using an Interval will only return exact matches (starting from pandas 0.25.0).

```
In [198]: df.loc[pd.Interval(1, 2)]
Out[198]:
     A
Name: (1, 2], dtype: int64
```

Trying to select an Interval that is not exactly contained in the IntervalIndex will raise a KeyError.
In [7]: df.loc[pd.Interval(0.5, 2.5)]
---------------------------------------------------------------------------
KeyError: Interval(0.5, 2.5, closed='right')

Selecting all Intervals that overlap a given Interval can be performed using the \texttt{overlaps()} method to create a boolean indexer.

In [199]: idxr = df.index.overlaps(pd.Interval(0.5, 2.5))

In [200]: idxr
Out[200]: array([ True,  True,  True, False])

In [201]: df[idxr]
Out[201]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

**Binning data with \texttt{cut} and \texttt{qcut}**

\texttt{cut()} and \texttt{qcut()} both return a \texttt{Categorical} object, and the bins they create are stored as an \texttt{IntervalIndex} in its \texttt{.categories} attribute.

In [202]: c = pd.cut(range(4), bins=2)

In [203]: c
Out[203]:

([-0.003, 1.5], [-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64, right]): [-0.003, 1.5] < (1.5, 3.0]]

In [204]: c.categories
Out[204]: IntervalIndex([-0.003, 1.5], (1.5, 3.0]], dtype='interval[float64, right]')

\texttt{cut()} also accepts an \texttt{IntervalIndex} for its \texttt{bins} argument, which enables a useful pandas idiom. First, we call \texttt{cut()} with some data and \texttt{bins} set to a fixed number, to generate the bins. Then, we pass the values of \texttt{.categories} as the \texttt{bins} argument in subsequent calls to \texttt{cut()}, supplying new data which will be binned into the same bins.

In [205]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[205]:

([-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64, right]): [-0.003, 1.5] < (1.5, 3.0]]

Any value which falls outside all bins will be assigned a \texttt{NaN} value.
Generating ranges of intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an `IntervalIndex` using various combinations of `start`, `end`, and `periods`. The default frequency for `interval_range` is 1 for numeric intervals, and calendar day for datetime-like intervals:

```python
In [206]: pd.interval_range(start=0, end=5)
Out[206]: IntervalIndex([[0, 1], (1, 2), (2, 3), (3, 4), (4, 5]], dtype='interval[int64, right]')
```

```python
In [207]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4)
Out[207]: IntervalIndex([(2017-01-01, 2017-01-02), (2017-01-02, 2017-01-03), (2017-01-03, 2017-01-04), (2017-01-04, 2017-01-05]], dtype='interval[datetime64[ns], right]')
```

```python
In [208]: pd.interval_range(end=pd.Timedelta("3 days"), periods=3)
Out[208]: IntervalIndex([(0 days 00:00:00, 1 days 00:00:00), (1 days 00:00:00, 2 days 00:00:00), (2 days 00:00:00, 3 days 00:00:00]], dtype='interval[timedelta64[ns], right]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of `frequency aliases` with datetime-like intervals:

```python
In [209]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[209]: IntervalIndex([[0, 1.5], (1.5, 3.0), (3.0, 4.5), (4.5, 6.0), (6.0, 7.5]], dtype='interval[float64, right]')
```

```python
In [210]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4, freq="W")
```

```python
In [211]: pd.interval_range(start=pd.Timedelta("0 days"), periods=3, freq="9H")
Out[211]: IntervalIndex([(0 days 00:00:00, 0 days 09:00:00), (0 days 09:00:00, 0 days 18:00:00), (0 days 18:00:00, 1 days 03:00:00]], dtype='interval[timedelta64[ns], right]')
```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```python
In [212]: pd.interval_range(start=0, end=4, closed="both")
Out[212]: IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]], dtype='interval[int64, both]')
```

```python
In [213]: pd.interval_range(start=0, end=4, closed="neither")
Out[213]: IntervalIndex([[0, 1), (1, 2), (2, 3), (3, 4)], dtype='interval[int64, neither]')
```

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```python
In [214]: pd.interval_range(start=0, end=6, periods=4)
Out[214]: IntervalIndex([[0.0, 1.5], (1.5, 3.0), (3.0, 4.5), (4.5, 6.0]], dtype='interval[float64, right]')
```

```python
In [215]: pd.interval_range(pd.Timestamp("2018-01-01"), pd.Timestamp("2018-02-28"), periods=3)
Out[215]: IntervalIndex([(2018-01-01, 2018-01-20 08:00:00), (2018-01-20 08:00:00, 2018-02-08 16:00:00), (2018-02-08 16:00:00, 2018-02-28)], dtype='interval[datetime64[ns], right]')
```

(continues on next page)
2.6.6 Miscellaneous indexing FAQ

Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index only label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```python
In [216]: s = pd.Series(range(5))
In [217]: s[-1]
---------------------------------------------------------------------------
ValueError Traceback (most recent call last)
/pandas/pandas/core/indexes/range.py in get_loc(self, key, method, tolerance)
    384     try:
--> 385         return self._range.index(new_key)
    386     except ValueError as err:

ValueError: -1 is not in range
```

The above exception was the direct cause of the following exception:

```python
KeyError Traceback (most recent call last)
<ipython-input-217-76c3dce40054> in <module>
----> 1 s[-1]
/pandas/pandas/core/series.py in __getitem__(self, key)
    940         elif key_is_scalar:
--> 942             return self._get_value(key)
    943         if is_hashable(key):

/pandas/pandas/core/series.py in _get_value(self, label, takeable)
   1049 # Similar to Index.get_value, but we do not fall back to positional
--> 1050     loc = self.index.get_loc(label)
    1051     return self.index._get_values_for_loc(self, loc, label)
    1053
/pandas/pandas/core/indexes/range.py in get_loc(self, key, method, tolerance)
    385     return self._range.index(new_key)
--> 386     except ValueError as err:
    387     raise KeyEr
```

KeyError: -1
In [218]: df = pd.DataFrame(np.random.randn(5, 4))

In [219]: df
Out[219]:
     0    1    2    3
0 -1.30121 -0.476046 0.759104 0.213379
1 -0.082641 0.448008 0.656420 -1.051443
2  0.594956 -0.151360 -0.069303 1.221431
3 -0.182832 0.791235 0.042745 2.069775
4  1.446552 0.019814 -1.389212 -0.702312

In [220]: df.loc[-2:]
Out[220]:
    0    1    2    3
0 -1.30121 -0.476046 0.759104 0.213379
1 -0.082641 0.448008 0.656420 -1.051443
2  0.594956 -0.151360 -0.069303 1.221431
3 -0.182832 0.791235 0.042745 2.069775
4  1.446552 0.019814 -1.389212 -0.702312

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

Non-monotonic indexes require exact matches

If the index of a `Series` or `DataFrame` is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

In [223]: df.loc[0:4, :]
Out[223]:
    data
2   0
3   1
4   3

On the other hand, if the index is not monotonic, then both slice bounds must be _unique_ members of the index.

In [224]: df.loc[13:15, :]
Out[224]:
Empty DataFrame
Columns: [data]
Index: []
In [225]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5], columns=['data'],
   ...:            data=list(range(6)))

In [226]: df.index.is_monotonic_increasing
Out[226]: False

# OK because 2 and 4 are in the index
In [227]: df.loc[2:4, :]
Out[227]:
   data
2   0
3   1
1   2
4   3

# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'

Index.is_monotonic_increasing and Index.is_monotonic_decreasing only check that an index is weakly
monotonic. To check for strict monotonicity, you can combine one of those with the is_unique() attribute.

In [228]: weakly_monotonic = pd.Index(['a', 'b', 'c', 'c'])

In [229]: weakly_monotonic
Out[229]: Index(['a', 'b', 'c', 'c'], dtype=object)

In [230]: weakly_monotonic.is_monotonic_increasing
Out[230]: True

In [231]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique
Out[231]: False

Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in
pandas is inclusive. The primary reason for this is that it is often not possible to easily determine the “successor” or
next element after a particular label in an index. For example, consider the following Series:

In [232]: s = pd.Series(np.random.randn(6), index=list('abcdef'))

In [233]: s
Out[233]:
   a   0.301379
   b   1.240445
   c  -0.846068
   d  -0.043312
   e  -1.658747

(continues on next page)
Suppose we wished to slice from c to e, using integers this would be accomplished as such:

```
In [234]: s[2:5]
Out[234]:
  c   -0.846068
  d   -0.043312
  e   -1.658747
dtype: float64
```

However, if you only had c and e, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```
s.loc['c':'e' + 1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design choice to make label-based slicing include both endpoints:

```
In [235]: s.loc['c':'e']
Out[235]:
  c   -0.846068
  d   -0.043312
  e   -1.658747
dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

**Indexing potentially changes underlying Series dtype**

The different indexing operation can potentially change the dtype of a Series.

```
In [236]: series1 = pd.Series([1, 2, 3])

In [237]: series1.dtype
Out[237]: dtype('int64')

In [238]: res = series1.reindex([0, 4])

In [239]: res.dtype
Out[239]: dtype('float64')

In [240]: res
Out[240]:
0    1.0
4    NaN
dtype: float64
```

```
In [241]: series2 = pd.Series([True])
```
This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as numpy.logical_and.

See the this old issue for a more detailed discussion.

### 2.7 Merge, join, concatenate and compare

pandas provides various facilities for easily combining together Series or DataFrame with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

In addition, pandas also provides utilities to compare two Series or DataFrame and summarize their differences.

#### 2.7.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:
Like its sibling function on ndarrays, numpy.concatenate, pandas.concat takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```python
pd.concat(  
objs,  
   )
```
axis=0,
join="outer",
ignore_index=False,
keys=None,
levels=None,
names=None,
verify_integrity=False,
copy=True,
)

- **objs**: a sequence or mapping of Series or DataFrame objects. If a dict is passed, the sorted keys will be used as the keys argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- **axis**: {0, 1, ...}, default 0. The axis to concatenate along.

- **join**: {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.

- **ignore_index**: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **keys**: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.

- **levels**: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

- **names**: list, default None. Names for the levels in the resulting hierarchical index.

- **verify_integrity**: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

- **copy**: boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don’t make much sense. Let’s revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the keys argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```
As you can see (if you’ve read the rest of the documentation), the resulting object’s index has a **hierarchical index**. This means that we can now select out each chunk by key:

In [7]: result.loc["y"]

Out[7]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>A4</td>
<td>B4</td>
<td>C4</td>
<td>D4</td>
</tr>
<tr>
<td>5</td>
<td>A5</td>
<td>B5</td>
<td>C5</td>
<td>D5</td>
</tr>
<tr>
<td>6</td>
<td>A6</td>
<td>B6</td>
<td>C6</td>
<td>D6</td>
</tr>
<tr>
<td>7</td>
<td>A7</td>
<td>B7</td>
<td>C7</td>
<td>D7</td>
</tr>
</tbody>
</table>

It’s not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```python
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```

**Note:** When concatenating DataFrames with named axes, pandas will attempt to preserve these index/column names whenever possible. In the case where all inputs share a common name, this name will be assigned to the result. When the input names do not all agree, the result will be unnamed. The same is true for `MultiIndex`, but the logic is applied separately on a level-by-level basis.
Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following two ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```python
In [8]: df4 = pd.DataFrame(  
    ...:     {  
    ...:         "B": ["B2", "B3", "B6", "B7"],  
    ...:         "D": ["D2", "D3", "D6", "D7"],  
    ...:         "F": ["F2", "F3", "F6", "F7"],  
    ...:     },  
    ...:     index=[2, 3, 6, 7],  
    ...: )
```

```python
In [9]: result = pd.concat([df1, df4], axis=1)
```

Here is the same thing with `join='inner'`:

```python
In [10]: result = pd.concat([df1, df4], axis=1, join="inner")
```

Lastly, suppose we just wanted to reuse the exact index from the original DataFrame:

```python
In [11]: result = pd.concat([df1, df4], axis=1).reindex(df1.index)
```

Similarly, we could index before the concatenation:

2.7. Merge, join, concatenate and compare 509
In [12]: pd.concat([df1, df4.reindex(df1.index)], axis=1)

Out[12]:
   A  B  C  D  B  D  F
0  A0  B0  C0  D0  NaN NaN NaN
1  A1  B1  C1  D1  NaN NaN NaN
2  A2  B2  C2  D2  B2  D2  F2
3  A3  B3  C3  D3  B3  D3  F3

Concatenating using `append`

A useful shortcut to `concat()` are the `append()` instance methods on `Series` and `DataFrame`. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

In [13]: result = df1.append(df2)

In the case of `DataFrame`, the indexes must be disjoint but the columns do not need to be:

In [14]: result = df1.append(df4, sort=False)
append may take multiple objects to concatenate:

```
In [15]: result = df1.append([df2, df3])
```

Note: Unlike the append() method, which appends to the original list and returns None, append() here does not modify df1 and returns its copy with df2 appended.
Ignoring indexes on the concatenation axis

For DataFrame objects which don’t have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the ignore_index argument:

In [16]: result = pd.concat([df1, df4], ignore_index=True, sort=False)

This is also a valid argument to DataFrame.append():

In [17]: result = df1.append(df4, ignore_index=True, sort=False)
Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame objects. The Series will be transformed to DataFrame with the column name as the name of the Series.

```python
In [18]: s1 = pd.Series(["X0", "X1", "X2", "X3"], name="X")
In [19]: result = pd.concat([df1, s1], axis=1)
```

<table>
<thead>
<tr>
<th>df1</th>
<th>s1</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>

Note: Since we're concatenating a Series to a DataFrame, we could have achieved the same result with DataFrame.assign(). To concatenate an arbitrary number of pandas objects (DataFrame or Series), use concat.

If unnamed Series are passed they will be numbered consecutively.

```python
In [20]: s2 = pd.Series(["_0", "_1", "_2", "_3")
In [21]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

<table>
<thead>
<tr>
<th>df1</th>
<th>s2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>

Passing ignore_index=True will drop all name references.

```python
In [22]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

<table>
<thead>
<tr>
<th>df1</th>
<th>s1</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>
More concatenating with group keys

A fairly common use of the keys argument is to override the column names when creating a new DataFrame based on existing Series. Notice how the default behaviour consists on letting the resulting DataFrame inherit the parent Series’ name, when these existed.

```python
In [23]: s3 = pd.Series([0, 1, 2, 3], name="foo")
In [24]: s4 = pd.Series([0, 1, 2, 3])
In [25]: s5 = pd.Series([0, 1, 4, 5])
In [26]: pd.concat([s3, s4, s5], axis=1)
Out[26]:
\[
\begin{array}{ccc}
0 & 0 & 0 \\
1 & 1 & 1 \\
2 & 2 & 4 \\
3 & 3 & 5 \\
\end{array}
\]

Through the keys argument we can override the existing column names.

```python
In [27]: pd.concat([s3, s4, s5], axis=1, keys=["red", "blue", "yellow"])
Out[27]:
\[
\begin{array}{ccc}
red & blue & yellow \\
0 & 0 & 0 \\
1 & 1 & 1 \\
2 & 2 & 4 \\
3 & 3 & 5 \\
\end{array}
\]
```

Let’s consider a variation of the very first example presented:

```python
In [28]: result = pd.concat(frames, keys=["x", "y", "z"])
```
You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```python
In [29]: pieces = {"x": df1, "y": df2, "z": df3}
In [30]: result = pd.concat(pieces)
```
The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:
If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```
In [33]: result = pd.concat(...
                   pieces, keys=['x', 'y', 'z'], levels=[['z', 'y', 'x', 'w']], names=['group_...
                   key'])
                   ...
```

```
In [34]: result.index.levels
Out[34]: FrozenList([['z', 'y'], [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]])
```

This is fairly esoteric, but it is actually necessary for implementing things like GroupBy where the order of a categorical variable is meaningful.
Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a DataFrame by passing a Series or dict to `append`, which returns a new DataFrame as above.

```python
In [35]: s2 = pd.Series(["X0", "X1", "X2", "X3"], index=["A", "B", "C", "D"])
In [36]: result = df1.append(s2, ignore_index=True)
```

You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

You can also pass a list of dicts or Series:

```python
In [37]: dicts = [{"A": 1, "B": 2, "C": 3, "X": 4}, {"A": 5, "B": 6, "C": 7, "Y": 8}]
In [38]: result = df1.append(dicts, ignore_index=True, sort=False)
```
2.7.2 Database-style DataFrame or named Series joining/merging

pandas has full-featured, high performance in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like base::merge.data.frame in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the cookbook for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a comparison with SQL.

pandas provides a single function, merge(), as the entry point for all standard database join operations between DataFrame or named Series objects:

```python
pd.merge(
    left,
    right,
    how="inner",
    on=None,
    left_on=None,
    right_on=None,
    left_index=False,
    right_index=False,
    sort=True,
    suffixes=('_x', '_y'),
    copy=True,
    indicator=False,
    validate=None,
)
```

- **left**: A DataFrame or named Series object.
- **right**: Another DataFrame or named Series object.
- **on**: Column or index level names to join on. Must be found in both the left and right DataFrame and/or Series objects. If not passed and left_index and right_index are False, the intersection of the columns in the DataFrames and/or Series will be inferred to be the join keys.
- **left_on**: Columns or index levels from the left DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **right_on**: Columns or index levels from the right DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **left_index**: If True, use the index (row labels) from the left DataFrame or Series as its join key(s). In the case of a DataFrame or Series with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame or Series.
- **right_index**: Same usage as left_index for the right DataFrame or Series
- **how**: One of 'left', 'right', 'outer', 'inner', 'cross'. Defaults to inner. See below for more detailed description of each method.
- **sort**: Sort the result DataFrame by the join keys in lexicographical order. Defaults to True, setting to False will improve performance substantially in many cases.
- **suffixes**: A tuple of string suffixes to apply to overlapping columns. Defaults to ('_x', '_y').
- **copy**: Always copy data (default True) from the passed DataFrame or named Series objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
• indicator: Add a column to the output DataFrame called _merge with information on the source of each row. _merge is Categorical-type and takes on a value of left_only for observations whose merge key only appears in 'left' DataFrame or Series, right_only for observations whose merge key only appears in 'right' DataFrame or Series, and both if the observation's merge key is found in both.

• validate: string, default None. If specified, checks if merge is of specified type.
  – “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
  – “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
  – “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
  – “many_to_many” or “m:m”: allowed, but does not result in checks.

Note: Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0. Support for merging named Series objects was added in version 0.24.0.

The return type will be the same as left. If left is a DataFrame or named Series and right is a subclass of DataFrame, the return type will still be DataFrame.

merge is a function in the pandas namespace, and it is also available as a DataFrame instance method merge(), with the calling DataFrame being implicitly considered the left object in the join.

The related join() method, uses merge internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use DataFrame.join to save yourself some typing.

**Brief primer on merge methods (relational algebra)**

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (DataFrame objects). There are several cases to consider which are very important to understand:

• one-to-one joins: for example when joining two DataFrame objects on their indexes (which must contain unique values).

• many-to-one joins: for example when joining an index (unique) to one or more columns in a different DataFrame.

• many-to-many joins: joining columns on columns.

Note: When joining columns on columns (potentially a many-to-many join), any indexes on the passed DataFrame objects will be discarded.

It is worth spending some time understanding the result of the many-to-many join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the Cartesian product of the associated data. Here is a very basic example with one unique key combination:

```
In [39]: left = pd.DataFrame(
    ....:     {
    ....:         "key": ["K0", "K1", "K2", "K3"],
    ....:         "B": ["B0", "B1", "B2", "B3"],
    ....:     }
    ....: )
```

(continues on next page)
In [40]: right = pd.DataFrame(
   ....:     {
   ....:         "key": ["K0", "K1", "K2", "K3"],
   ....:         "C": ["C0", "C1", "C2", "C3"],
   ....:         "D": ["D0", "D1", "D2", "D3"],
   ....:     }
   ....: )
   ....:

In [41]: result = pd.merge(left, right, on="key")

Here is a more complicated example with multiple join keys. Only the keys appearing in left and right are present (the intersection), since how='inner' by default.

In [42]: left = pd.DataFrame(
   ....:     {
   ....:         "key1": ["K0", "K0", "K1", "K2"],
   ....:         "key2": ["K0", "K1", "K0", "K1"],
   ....:         "B": ["B0", "B1", "B2", "B3"],
   ....:     }
   ....: )
   ....:

In [43]: right = pd.DataFrame(
   ....:     {
   ....:         "key1": ["K0", "K1", "K1", "K2"],
   ....:         "key2": ["K0", "K0", "K0", "K0"],
   ....:         "C": ["C0", "C1", "C2", "C3"],
   ....:         "D": ["D0", "D1", "D2", "D3"],
   ....:     }
   ....: )
   ....:

In [44]: result = pd.merge(left, right, on=["key1", "key2"])

2.7. Merge, join, concatenate and compare
The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be **NA**. Here is a summary of the `how` options and their SQL equivalent names:

<table>
<thead>
<tr>
<th>Merge method</th>
<th>SQL Join Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>LEFT OUTER JOIN</td>
<td>Use keys from left frame only</td>
</tr>
<tr>
<td>right</td>
<td>RIGHT OUTER JOIN</td>
<td>Use keys from right frame only</td>
</tr>
<tr>
<td>outer</td>
<td>FULL OUTER JOIN</td>
<td>Use union of keys from both frames</td>
</tr>
<tr>
<td>inner</td>
<td>INNER JOIN</td>
<td>Use intersection of keys from both frames</td>
</tr>
<tr>
<td>cross</td>
<td>CROSS JOIN</td>
<td>Create the cartesian product of rows of both frames</td>
</tr>
</tbody>
</table>

In [45]: result = pd.merge(left, right, how="left", on=['key1', 'key2'])

In [46]: result = pd.merge(left, right, how="right", on=['key1', 'key2'])

In [47]: result = pd.merge(left, right, how="outer", on=['key1', 'key2'])
You can merge a multi-indexed Series and a DataFrame, if the names of the MultiIndex correspond to the columns from
the DataFrame. Transform the Series to a DataFrame using `Series.reset_index()` before merging, as shown in the following example.

```
In [50]: df = pd.DataFrame({"Let": ["A", "B", "C"], "Num": [1, 2, 3]})
In [51]: df
Out[51]:
   Let  Num
0    A    1
1    B    2
2    C    3

In [52]: ser = pd.Series(
    ....:     ["a", "b", "c", "d", "e", "f"],
    ....:     index=pd.MultiIndex.from_arrays(
    ....:         [["A", "B", "C"] * 2, [1, 2, 3, 4, 5, 6]],
    ....:         names=["Let", "Num"]
    ....:     ),
    ....:)

In [53]: ser
Out[53]:
   Let  Num
A    1    a
B    2    b
C    3    c
A    4    d
B    5    e
C    6    f
dtype: object

In [54]: pd.merge(df, ser.reset_index(), on="Let", "Num")
Out[54]:
   Let  Num  0
0    A    1    a
1    B    2    b
2    C    3    c

Here is another example with duplicate join keys in DataFrames:

```
In [55]: left = pd.DataFrame({"A": [1, 2], "B": [2, 2]})
In [56]: right = pd.DataFrame({"A": [4, 5, 6], "B": [2, 2, 2]})
In [57]: result = pd.merge(left, right, on="B", how="outer")
```
Warning: Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user’s responsibility to manage duplicate values in keys before joining large DataFrames.

Checking for duplicate keys

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of `B` in the right DataFrame. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```
In [58]: left = pd.DataFrame({"A": [1, 2], "B": [1, 2]})
In [59]: right = pd.DataFrame({"A": [4, 5, 6], "B": [2, 2, 2]})

In [53]: result = pd.merge(left, right, on="B", how="outer", validate="one_to_one")
...: MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```
In [60]: pd.merge(left, right, on="B", how="outer", validate="one_to_many")
Out[60]:
   A_x B  A_y
0  0  1  1.0
1  1  2  4.0
2  2  3  NaN
3  3  4  NaN
4  4  5  NaN
5  5  6  NaN
```
The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

<table>
<thead>
<tr>
<th>Observation Origin</th>
<th>_merge value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td>right_only</td>
</tr>
<tr>
<td>Merge key in both frames</td>
<td>both</td>
</tr>
</tbody>
</table>

```
In [61]: df1 = pd.DataFrame({"col1": [0, 1], "col_left": ["a", "b"]})
In [62]: df2 = pd.DataFrame({"col1": [1, 2, 2], "col_right": [2, 2, 2]})
In [63]: pd.merge(df1, df2, on="col1", how="outer", indicator=True)
Out[63]:
col1  col_left  col_right  _merge
      0      a       NaN   left_only
      1      b       2.0   both
      2      NaN      2.0   right_only
      3      NaN      2.0   right_only
```

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```
In [64]: pd.merge(df1, df2, on="col1", how="outer", indicator="indicator_column")
Out[64]:
col1  col_left  col_right  indicator_column
      0      a       NaN   left_only
      1      b       2.0   both
      2      NaN      2.0   right_only
      3      NaN      2.0   right_only
```

Merge dtypes

Merging will preserve the dtype of the join keys.

```
In [65]: left = pd.DataFrame({"key": [1], "v1": [10]})
In [66]: left
Out[66]:
   key  v1
0   1  10
In [67]: right = pd.DataFrame({"key": [1, 2], "v1": [20, 30]})
In [68]: right
Out[68]:
   key  v1
0   1  20
1   2  30
```
We are able to preserve the join keys:

```python
In [69]: pd.merge(left, right, how="outer")
Out[69]:
   key  v1
0   1   10
1   2   20
2   2   30
```

```python
In [70]: pd.merge(left, right, how="outer").dtypes
Out[70]:
key    int64
v1     int64
dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```python
In [71]: pd.merge(left, right, how="outer", on="key")
Out[71]:
   key  v1_x  v1_y
0   1   10.0  20
1   2   NaN   30
```

```python
In [72]: pd.merge(left, right, how="outer", on="key").dtypes
Out[72]:
key    int64
v1_x   float64
v1_y   int64
dtype: object
```

Merging will preserve category dtypes of the mergands. See also the section on `categoricals`.

The left frame.

```python
In [73]: from pandas.api.types import CategoricalDtype
In [74]: X = pd.Series(np.random.choice(["foo", "bar"], size=(10,)))
In [75]: X = X.astype(CategoricalDtype(categories=["foo", "bar"]))
In [76]: left = pd.DataFrame(
       ....:     {"X": X, "Y": np.random.choice(["one", "two", "three"], size=(10,))}
       ....:     )
       ....:
In [77]: left
Out[77]:
   X   Y
0  bar  one
1  foo  one
2  foo  three
3  bar  three
4  foo  one
5  bar  one
```

(continues on next page)
6 bar three
7 bar three
8 bar three
9 foo three

In [78]: left.dtypes
Out[78]:
X  category
Y  object
dtype: object

The right frame.

In [79]: right = pd.DataFrame(
      ...
      "X": pd.Series(["foo", "bar"], dtype=CategoricalDtype(["foo", "bar"])),
      ....:
      "Z": [1, 2],
      ....:
      )
      ....:

In [80]: right
Out[80]:
   X  Z
0  foo 1
1  bar 2

In [81]: right.dtypes
Out[81]:
X  category
Z  int64
dtype: object

The merged result:

In [82]: result = pd.merge(left, right, how="outer")

In [83]: result
Out[83]:
   X  Y  Z
0  bar one 2
1  bar three 2
2  bar one 2
3  bar three 2
4  bar three 2
5  bar three 2
6  foo one 1
7  foo three 1
8  foo one 1
9  foo one 1

In [84]: result.dtypes
(continues on next page)
Out[84]:
X category
Y object
Z int64
dtype: object

Note: The category dtypes must be exactly the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to the categories' dtype.

Note: Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed `DataFrames` into a single result `DataFrame`. Here is a very basic example:

```python
In [85]: left = pd.DataFrame(
    .....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"],
    .....:     index=["K0", "K1", "K2"]
    .....: )
    .....:
In [86]: right = pd.DataFrame(
    .....:     {"C": ["C0", "C2", "C3"], "D": ["D0", "D2", "D3"],
    .....:     index=["K0", "K2", "K3"]
    .....: )
    .....:
In [87]: result = left.join(right)
```

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>A</td>
</tr>
<tr>
<td>K0</td>
<td>A0</td>
<td>K0</td>
</tr>
<tr>
<td>K1</td>
<td>A1</td>
<td>K1</td>
</tr>
<tr>
<td>K2</td>
<td>A2</td>
<td>K2</td>
</tr>
<tr>
<td></td>
<td>B0</td>
<td>B0</td>
</tr>
<tr>
<td></td>
<td>B1</td>
<td>B1</td>
</tr>
<tr>
<td></td>
<td>B2</td>
<td>B2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C</td>
</tr>
<tr>
<td></td>
<td></td>
<td>K0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>D0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>B0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>D0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>B1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>D1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>B2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>D2</td>
</tr>
</tbody>
</table>

In [88]: result = left.join(right, how="outer")
The same as above, but with how='inner'.

```
In [89]: result = left.join(right, how="inner")
```

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [90]: result = pd.merge(left, right, left_index=True, right_index=True, how="outer")
```

```
In [91]: result = pd.merge(left, right, left_index=True, right_index=True, how="inner")
```
Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(
    left, right, left_on=key_or_keys, right_index=True, how="left", sort=False
)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame’s is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [92]: left = pd.DataFrame(
    ...:
    ...:
    ...:
    "B": ["B0", "B1", "B2", "B3"],
    ...:
    "key": ["K0", "K1", "K0", "K1"],
    ...:
    ...
)
```

```
In [93]: right = pd.DataFrame({"C": ["C0", "C1"], "D": ["D0", "D1"]}, index=["K0", "K1"])
```

```
In [94]: result = left.join(right, on="key")
```

```
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>key</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0</td>
<td>B0</td>
<td>K0</td>
</tr>
<tr>
<td>A1</td>
<td>B1</td>
<td>K1</td>
</tr>
<tr>
<td>A2</td>
<td>B2</td>
<td>K0</td>
</tr>
<tr>
<td>A3</td>
<td>B3</td>
<td>K1</td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>C1</td>
<td>D1</td>
</tr>
</tbody>
</table>
```

```
In [95]: result = pd.merge(
    ...:
    left, right, left_on="key", right_index=True, how="left", sort=False
    ...:
)
```

```
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>key</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0</td>
<td>B0</td>
<td>K0</td>
</tr>
<tr>
<td>A1</td>
<td>B1</td>
<td>K1</td>
</tr>
<tr>
<td>A2</td>
<td>B2</td>
<td>K0</td>
</tr>
<tr>
<td>A3</td>
<td>B3</td>
<td>K1</td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>C1</td>
<td>D1</td>
</tr>
</tbody>
</table>
```

the passed DataFrame must have a MultiIndex:

```
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>key</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0</td>
<td>B0</td>
<td>K0</td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>C0</td>
<td>D0</td>
</tr>
</tbody>
</table>
```

To join on multiple keys,
In [96]: left = pd.DataFrame(
    ....:     {
    ....:         "B": ["B0", "B1", "B2", "B3"],
    ....:         "key1": ["K0", "K0", "K1", "K2"],
    ....:         "key2": ["K0", "K1", "K0", "K1"],
    ....:     }
    ....: )
    ....:
In [97]: index = pd.MultiIndex.from_tuples(
    ....:     [("K0", "K0"), ("K1", "K0"), ("K2", "K0"), ("K2", "K1")]
    ....: )
    ....:
In [98]: right = pd.DataFrame(
    ....:     {
    ....:         "C": ["C0", "C1", "C2", "C3"],
    ....:         "D": ["D0", "D1", "D2", "D3"],
    ....:     }, index=index
    ....: )
    ....:

Now this can be joined by passing the two key column names:

In [99]: result = left.join(right, on="key1", "key2")

The default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

In [100]: result = left.join(right, on="key1", "key2", how="inner")

As you can see, this drops any rows where there was no match.
Joining a single Index to a MultiIndex

You can join a singly-indexed DataFrame with a level of a MultiIndexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

In [101]: left = pd.DataFrame(
    ....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"]},
    ....:     index=pd.Index(["K0", "K1", "K2"], name="key"),
    ....:     )
    ....:
In [102]: index = pd.MultiIndex.from_tuples(
    ....:     [("K0", "Y0"), ("K1", "Y1"), ("K2", "Y2"), ("K2", "Y3")],
    ....:     names=["key", "Y"],
    ....:     )
    ....:
In [103]: right = pd.DataFrame(
    ....:     {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"]},
    ....:     index=index,
    ....:     )
    ....:
In [104]: result = left.join(right, how="inner")

This is equivalent but less verbose and more memory efficient / faster than this.

In [105]: result = pd.merge(
    ....:     left.reset_index(), right.reset_index(), on="key", how="inner"
    ....: ).set_index(["key", "Y1"])
    ....:

2.7. Merge, join, concatenate and compare
Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```python
In [106]: leftindex = pd.MultiIndex.from_product(
        ....:     [list("abc"), list("xy"), [1, 2]], names=["abc", "xy", "num"]
        ....: )
        ....:

In [107]: left = pd.DataFrame({"v1": range(12)}, index=leftindex)

In [108]: left
Out[108]:
   v1
  abc xy num
   a  x 1  0
       2  1
       3  0
   b  x 1  2
       2  3
       4  0
   c  x 1  6
       2  7
       8  0

In [109]: rightindex = pd.MultiIndex.from_product(
        ....:     [list("abc"), list("xy")], names=["abc", "xy"]
        ....: )
        ....:

In [110]: right = pd.DataFrame({"v2": [100 * i for i in range(1, 7)]}, index=rightindex)

In [111]: right
Out[111]:
   v2
  abc xy
   a  x 100
       y 200
   b  x 300
       y 400
   c  x 500
       y 600

In [112]: left.join(right, on="abc", "xy", how="inner")
Out[112]:
   v1   v2
a x  1  0  100
    2  1  100
(continues on next page)
If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

```python
In [113]: leftindex = pd.MultiIndex.from_tuples(
    .....:     ["K0", "X0"], ["K0", "X1"], ["K1", "X2"], names=["key", "X"]
    .....: )
    .....:
In [114]: left = pd.DataFrame(
    .....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"]}, index=leftindex
    .....: )
    .....:
In [115]: rightindex = pd.MultiIndex.from_tuples(
    .....:     ["K0", "Y0"], ["K1", "Y1"], ["K2", "Y2"], ["K2", "Y3"], names=["key", "Y"]
    .....: )
    .....:
In [116]: right = pd.DataFrame(
    .....:     {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"]},
    .....:     index=rightindex
    .....: )
    .....:
In [117]: result = pd.merge(
    .....:     left.reset_index(), right.reset_index(), on=["key"], how="inner"
    .....: ).set_index(["key", "X", "Y"])
    .....:
```

```
2.7. Merge, join, concatenate and compare
```
Merging on a combination of columns and index levels

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes.

In [118]: `left_index = pd.Index(["K0", "K0", "K1", "K2"], name="key1")`

In [119]: `left = pd.DataFrame(
    .....:
    .....:
    .....:
    .....:
    .....:
    .....:
    .....:
    .....:
    .....:

precedence. This will result in an ambiguity error in a future version.

### Overlapping value columns

The merge suffixes argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

```
In [123]: left = pd.DataFrame({"k": ["K0", "K1", "K2"], "v": [1, 2, 3]})
In [124]: right = pd.DataFrame({"k": ["K0", "K0", "K3"], "v": [4, 5, 6]})
In [125]: result = pd.merge(left, right, on="k")
```

```
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>k</td>
<td>v</td>
<td></td>
</tr>
<tr>
<td>K0</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>K1</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>K2</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td>K0</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>K0</td>
<td>5</td>
<td></td>
</tr>
<tr>
<td>K3</td>
<td>6</td>
<td></td>
</tr>
</tbody>
</table>
```

```
In [126]: result = pd.merge(left, right, on="k", suffixes=('_l', '_r'))
```

```
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>k</td>
<td>v_i</td>
<td>v_r</td>
</tr>
<tr>
<td>K0</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>K0</td>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>K3</td>
<td>6</td>
<td>6</td>
</tr>
</tbody>
</table>
```

`DataFrame.join()` has lsuffix and rsuffix arguments which behave similarly.

```
In [127]: left = left.set_index("k")
In [128]: right = right.set_index("k")
In [129]: result = left.join(right, lsuffix="_l", rsuffix="_r")
```

```
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td></td>
<td>v_l</td>
</tr>
<tr>
<td>K0</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>K1</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>K2</td>
<td>3</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```

2.7. Merge, join, concatenate and compare

537
Joining multiple DataFrames

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```
In [130]: right2 = pd.DataFrame({'v': [7, 8, 9], 'index': ['K1', 'K1', 'K2']})
In [131]: result = left.join([right, right2])
```

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>right2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>v</td>
<td>v</td>
<td>v.x</td>
</tr>
<tr>
<td>K0</td>
<td>K0</td>
<td>K3</td>
<td>1</td>
</tr>
<tr>
<td>K1</td>
<td>K0</td>
<td>K3</td>
<td>2</td>
</tr>
<tr>
<td>K2</td>
<td>K3</td>
<td>K2</td>
<td>3</td>
</tr>
</tbody>
</table>

Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [132]: df1 = pd.DataFrame(
           ....:   [[np.nan, 3.0, 5.0], [-4.6, np.nan, np.nan], [np.nan, 7.0, np.nan]],
           ....:   index=[1, 2, 3])
In [133]: df2 = pd.DataFrame([[42.6, np.nan, -8.2], [-5.0, 1.6, 4]], index=[1, 2])

In [134]: result = df1.combine_first(df2)
```

For this, use the `combine_first()` method:

```
In [135]: result = df1.combine_first(df2)
```

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values in place:

```
In [136]: df1.update(df2)
```
2.7.3 Timeseries friendly merging

Merging ordered data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [136]: left = pd.DataFrame(
    ....:     {"k": ["K0", "K1", "K1", "K2"], "lv": [1, 2, 3, 4], "s": ["a", "b", "c", "d"])
    ....: )
    ....: 

In [137]: right = pd.DataFrame({"k": ["K1", "K2", "K4"], "rv": [1, 2, 3]})

In [138]: pd.merge_ordered(left, right, fill_method="ffill", left_by="s")
```

```
<table>
<thead>
<tr>
<th>k</th>
<th>lv</th>
<th>s</th>
<th>rv</th>
</tr>
</thead>
<tbody>
<tr>
<td>K0</td>
<td>1.0</td>
<td>a</td>
<td>NaN</td>
</tr>
<tr>
<td>K1</td>
<td>1.0</td>
<td>a</td>
<td>1.0</td>
</tr>
<tr>
<td>K2</td>
<td>1.0</td>
<td>a</td>
<td>2.0</td>
</tr>
<tr>
<td>K4</td>
<td>1.0</td>
<td>a</td>
<td>3.0</td>
</tr>
<tr>
<td>K1</td>
<td>2.0</td>
<td>b</td>
<td>1.0</td>
</tr>
<tr>
<td>K2</td>
<td>2.0</td>
<td>b</td>
<td>2.0</td>
</tr>
<tr>
<td>K4</td>
<td>2.0</td>
<td>b</td>
<td>3.0</td>
</tr>
<tr>
<td>K1</td>
<td>3.0</td>
<td>c</td>
<td>1.0</td>
</tr>
<tr>
<td>K2</td>
<td>3.0</td>
<td>c</td>
<td>2.0</td>
</tr>
<tr>
<td>K4</td>
<td>3.0</td>
<td>c</td>
<td>3.0</td>
</tr>
<tr>
<td>K1</td>
<td>NaN</td>
<td>d</td>
<td>1.0</td>
</tr>
<tr>
<td>K2</td>
<td>4.0</td>
<td>d</td>
<td>2.0</td>
</tr>
<tr>
<td>K4</td>
<td>4.0</td>
<td>d</td>
<td>3.0</td>
</tr>
</tbody>
</table>
```

Merging asof

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `left DataFrame`, we select the last row in the `right DataFrame` whose `on` key is less than the left’s key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the by key equally, in addition to the nearest match on the on key.

For example; we might have trades and quotes and we want to asof merge them.

```
In [139]: trades = pd.DataFrame(
    ....:     {
```

(continues on next page)
In [140]: quotes = pd.DataFrame(
    ...:     {
    ...:         "time": pd.to_datetime(
    ...:             [
    ...:                 "2016-05-25 13:30:00.023",
    ...:                 "2016-05-25 13:30:00.023",
    ...:                 "2016-05-25 13:30:00.030",
    ...:                 "2016-05-25 13:30:00.041",
    ...:                 "2016-05-25 13:30:00.048",
    ...:                 "2016-05-25 13:30:00.049",

2.7.4 Comparing objects

The `compare()` and `compare()` methods allow you to compare two DataFrame or Series, respectively, and summarize their differences.

This feature was added in **V1.1.0**.

For example, you might want to compare two DataFrame and stack their differences side by side.

```python
In [146]: df = pd.DataFrame(
    .....:     {  
    .....:         "col1": ["a", "a", "b", "b", "a"],  
    .....:         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],  
    .....:         "col3": [1.0, 2.0, 3.0, 4.0, 5.0],  
    .....:     },  
    .....:     columns=['col1', 'col2', 'col3'],  
    .....: )

In [147]: df
Out[147]:
   col1  col2  col3
0   a    1.0  1.0
1   a    2.0  2.0
2   b    3.0  3.0
3   b   NaN  4.0
4   a    5.0  5.0

In [148]: df2 = df.copy()

In [149]: df2.loc[0, "col1"] = "c"

In [150]: df2.loc[2, "col3"] = 4.0

In [151]: df2
Out[151]:
   col1  col2  col3
0   c    1.0  1.0
1   a    2.0  2.0
2   b    3.0  4.0
3   b   NaN  4.0
4   a    5.0  5.0

In [152]: df.compare(df2)
Out[152]:
   col1  col3 
  self other  self other
0   a    c    NaN  NaN
2   NaN  NaN    3.0  4.0
```

By default, if two corresponding values are equal, they will be shown as NaN. Furthermore, if all values in an entire row / column, the row / column will be omitted from the result. The remaining differences will be aligned on columns.

If you wish, you may choose to stack the differences on rows.
In [153]: df.compare(df2, align_axis=0)
Out[153]:

<table>
<thead>
<tr>
<th></th>
<th>col1</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>self</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>other</td>
<td>c</td>
</tr>
<tr>
<td>2</td>
<td>self</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>other</td>
<td>NaN</td>
</tr>
</tbody>
</table>

If you wish to keep all original rows and columns, set keep_shape argument to True.

In [154]: df.compare(df2, keep_shape=True)
Out[154]:

<table>
<thead>
<tr>
<th></th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>self</td>
<td>other</td>
<td>self</td>
</tr>
<tr>
<td>0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

You may also keep all the original values even if they are equal.

In [155]: df.compare(df2, keep_shape=True, keep_equal=True)
Out[155]:

<table>
<thead>
<tr>
<th></th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>self</td>
<td>other</td>
<td>self</td>
</tr>
<tr>
<td>0</td>
<td>a</td>
<td>c</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>a</td>
<td>a</td>
<td>2.0</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
<td>b</td>
<td>3.0</td>
</tr>
<tr>
<td>3</td>
<td>b</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>4</td>
<td>a</td>
<td>a</td>
<td>5.0</td>
</tr>
</tbody>
</table>
2.8 Reshaping and pivot tables

2.8.1 Reshaping by pivoting DataFrame objects

Data is often stored in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
   date     variable  value
0 2000-01-03       A   0.469112
1 2000-01-04       A  -0.282863
2 2000-01-05       A  -1.509059
3 2000-01-03       B  -1.135632
4 2000-01-04       B   1.212112
5 2000-01-05       B  -0.173215
6 2000-01-03       C   0.119209
7 2000-01-04       C  -1.044236
8 2000-01-05       C  -0.861849
9 2000-01-03       D  -2.104569
10 2000-01-04      D  -0.494929
11 2000-01-05      D   1.071804
```

For the curious here is how the above DataFrame was created:

```python
import pandas._testing as tm
def unpivot(frame):
    N, K = frame.shape
data = {
        "value": frame.to_numpy().ravel("F"),
        "variable": np.asarray(frame.columns).repeat(N),
    }
```
To select out everything for variable A we could do:

```python
In [2]: df[df["variable"] == "A"]
Out[2]:
   date  variable  value
0 2000-01-03     A  0.469112
1 2000-01-04     A -0.282863
2 2000-01-05     A -1.509059
```

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```python
In [3]: df.pivot(index="date", columns="variable", values="value")
Out[3]:
   variable A   B   C   D
date
2000-01-03  0.469112 -1.135632 0.119209 -2.104569
2000-01-04 -0.282863  1.212112 -1.044236 -0.494929
2000-01-05 -1.509059 -0.173215 -0.861849  1.071804
```

If the `values` argument is omitted, and the input DataFrame has more than one column of values which are not used as column or index inputs to `pivot`, then the resulting “pivoted” DataFrame will have hierarchical columns whose topmost level indicates the respective value column:

```python
In [4]: df["value2"] = df["value"] * 2
In [5]: pivoted = df.pivot(index="date", columns="variable")
In [6]: pivoted
Out[6]:
   value   value2
variable
   A   B   C   D   A   B   C   D
date
2000-01-03  0.469112 -1.135632 0.119209 -2.104569 0.938225 -2.271265 0.238417 -4.209138
2000-01-04 -0.282863  1.212112 -1.044236 -0.494929 -0.565727  2.424224 -2.088472 -0.989859
2000-01-05 -1.509059 -0.173215 -0.861849  1.071804 -3.018117 -0.346429 -1.723698  2.143608
```

You can then select subsets from the pivoted DataFrame:
In [7]: pivoted["value2"]

Out[7]:

<table>
<thead>
<tr>
<th>variable</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.938225</td>
<td>-2.271265</td>
<td>0.238417</td>
<td>-4.209138</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.565727</td>
<td>2.424224</td>
<td>-2.088472</td>
<td>-0.989859</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-3.018117</td>
<td>-0.346429</td>
<td>-1.723698</td>
<td>2.143608</td>
</tr>
</tbody>
</table>

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

Note: `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape` if the index/column pair is not unique. In this case, consider using `pivot_table()` which is a generalization of pivot that can handle duplicate values for one index/column pair.

2.8.2 Reshaping by stacking and unstacking

**Stack**

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on hierarchical indexing). Here are essentially what these methods do:

- `stack`: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.

- `unstack`: (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.
The clearest way to explain is by example. Let’s take a prior example data set from the hierarchical indexing section:

```python
In [8]: tuples = list(
    ...:     zip(["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
    ...:     ["one", "two", "one", "two", "one", "two", "one", "two"],
    ...:     ))

In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [11]: df2 = df[:4]

Out[12]:
          A         B
first second       
bar   one  0.721555 -0.706771
       two -1.039575  0.271860
baz   one -0.424972  0.567020
       two  0.276232 -1.087401
```

The stack function “compresses” a level in the DataFrame’s columns to produce either:

- A Series, in the case of a simple column Index.
• A DataFrame, in the case of a MultiIndex in the columns.

If the columns have a MultiIndex, you can choose which level to stack. The stacked level becomes the new lowest level in a MultiIndex on the columns:

```
In [13]: stacked = df2.stack()

In [14]: stacked
Out[14]:
first     second
bar  one     A  0.721555
       B  -0.706771
   two     A  -1.039575
       B   0.271860
baz  one     A  -0.424972
       B   0.567020
   two     A   0.276232
       B  -1.087401

dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack is unstack, which by default unstacks the last level:

```
In [15]: stacked.unstack()
Out[15]:
first  second
bar    one    A  0.721555
       B  -0.706771
   two    A  -1.039575
       B   0.271860
baz    one    A  -0.424972
       B   0.567020
   two    A   0.276232
       B  -1.087401

In [16]: stacked.unstack(1)
Out[16]:
second  one     two
first
bar    A  0.721555   -1.039575
       B  -0.706771    0.271860
baz    A  -0.424972   0.276232
       B   0.567020   -1.087401

In [17]: stacked.unstack(0)
Out[17]:
first  bar     baz
second
one    A  0.721555  -0.424972
       B  -0.706771  -0.567020
two    A  -1.039575  0.276232
       B  -1.087401  -0.271860
```
## Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [18]: stacked.unstack("second")
Out[18]:
   first   second  one   two
bar    A     0.721555 -1.039575
       B    -0.706771  0.271860
two    A     0.424972  0.276232
       B    -0.567020 -1.087401
baz    A     0.024497  0.276232
       B     0.567020 -0.567020
```

```
In [18]: stacked.unstack('second')
```

If the indexes have names, you can use the level names instead of specifying the level numbers:
Unstack(0)

Notice that the stack and unstack methods implicitly sort the index levels involved. Hence a call to stack and then unstack, or vice versa, will result in a sorted copy of the original DataFrame or Series:

```
In [19]: index = pd.MultiIndex.from_product([[2, 1], ["a", "b"]])

In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=["A"])

In [21]: df
Out[21]:
       A
2  a -0.370647
   b -1.157892
1  a -1.344312
   b  0.844885

In [22]: all(df.unstack().stack() == df.sort_index())
Out[22]: True
```

The above code will raise a TypeError if the call to sort_index is removed.

Multiple levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [23]: columns = pd.MultiIndex.from_tuples(
    ....:     ["A", "cat", "long"),
    ....:     ["B", "cat", "long"),
    ....:     ["A", "dog", "short")
```

(continues on next page)
.....:  ("B", "dog", "short"),
.....:  ],
.....:  names=['exp', 'animal', 'hair_length'],
.....:  )
.....:

In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)

In [25]: df
Out[25]:
 exp A    B   A    B
animal  cat  cat  dog  dog
hair_length  long  long  short  short
0       1.075770 -0.109050 1.643563 -1.469388
1       0.357021 -0.674600 -1.776904 -0.968914
2      -1.294524  0.413738  0.276662 -0.472035
3      -0.013960 -0.362543 -0.006154 -0.923061

In [26]: df.stack(level=['animal', 'hair_length'])
Out[26]:
 exp A    B
animal hair_length
0       cat  long  1.075770 -0.109050
       dog  short  1.643563 -1.469388
1       cat  long  0.357021 -0.674600
       dog  short -1.776904 -0.968914
2       cat  long -1.294524  0.413738
       dog  short  0.276662 -0.472035
3       cat  long -0.013960 -0.362543
       dog  short -0.006154 -0.923061

The list of levels can contain either level names or level numbers (but not a mixture of the two).

# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:

In [27]: df.stack(level=[1, 2])
Out[27]:
 exp A    B
animal hair_length
0       cat  long  1.075770 -0.109050
       dog  short  1.643563 -1.469388
1       cat  long  0.357021 -0.674600
       dog  short -1.776904 -0.968914
2       cat  long -1.294524  0.413738
       dog  short  0.276662 -0.472035
3       cat  long -0.013960 -0.362543
       dog  short -0.006154 -0.923061
Missing data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling sort_index, of course). Here is a more complex example:

```
In [28]: columns = pd.MultiIndex.from_tuples(
    ....:     ["A", "cat"],
    ....:     ["B", "dog"],
    ....:     ["C", "cat"],
    ....:     ["D", "dog"],
    ....:     ),
    ....:     names=["exp", "animal"],
    ....:     )
    ....: 

In [29]: index = pd.MultiIndex.from_product(
    ....:     ["bar", "baz", "foo", "qux"], ["one", "two"],
    ....:     names=["first", "second"]
    ....:     )
    ....: 

In [30]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [32]: df2
Out[32]:

<table>
<thead>
<tr>
<th>exp</th>
<th>A</th>
<th>B</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>animal</td>
<td>cat</td>
<td>dog</td>
<td>cat</td>
</tr>
<tr>
<td>bar</td>
<td>0.895717</td>
<td>0.805244</td>
<td>-1.206412</td>
</tr>
<tr>
<td>two</td>
<td>1.431256</td>
<td>1.340309</td>
<td>-1.170299</td>
</tr>
<tr>
<td>baz</td>
<td>0.410835</td>
<td>0.813850</td>
<td>0.132003</td>
</tr>
<tr>
<td>foo</td>
<td>-1.413681</td>
<td>1.607920</td>
<td>1.024180</td>
</tr>
<tr>
<td>two</td>
<td>0.875906</td>
<td>-2.211372</td>
<td>0.974466</td>
</tr>
<tr>
<td>qux</td>
<td>-1.226825</td>
<td>0.769804</td>
<td>-1.281247</td>
</tr>
</tbody>
</table>
```

As mentioned above, stack can be called with a level argument to select which level in the columns to stack:

```
In [33]: df2.stack("exp")
Out[33]:

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
<th>exp</th>
</tr>
</thead>
<tbody>
<tr>
<td>animal</td>
<td>cat</td>
<td>dog</td>
</tr>
<tr>
<td>bar</td>
<td>one</td>
<td>0.895717</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>-1.206412</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>1.431256</td>
</tr>
<tr>
<td></td>
<td></td>
<td>-1.170299</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>0.410835</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>0.132003</td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
<td>-1.413681</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>1.024180</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.875906</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0.974466</td>
</tr>
</tbody>
</table>
```

(continues on next page)
Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types, by default data will converted to float and missing values will be set to NaN.

Alternatively, unstack takes an optional fill_value argument, for specifying the value of missing data.
With a MultiIndex

Unstacking when the columns are a MultiIndex is also careful about doing the right thing:

```
In [39]: df[:3].unstack(0)
Out[39]:
   exp  A       B       A
animal  first  bar  baz  animal  first  bar  baz
second   one    0.89572 0.41084    0.80524    0.81385 -1.20641 -1.17030
        two   1.43126      NaN   1.34031    -1.20641  0.13200  2.56565

In [40]: df2.unstack(1)
Out[40]:
   exp  A       B       A
animal  second  one  two  animal  first  bar  baz
first   one    0.89572 1.43126    0.80524    -1.20641  2.56565 -0.22617
    two   0.41084      NaN   0.81385    0.13200    0.82731    NaN
    bar  -1.41368  0.87591  1.60792  -2.21137  1.02418  0.97447  0.56961
    baz  NaN        0.76980    NaN      0.82731  0.56961 -0.72771
```
2.8.3 Reshaping by melt

Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a DataFrame into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```
In [41]: cheese = pd.DataFrame(
    .....:     {  
    .....:         "first": ["John", "Mary"],  
    .....:         "last": ["Doe", "Bo"],  
    .....:         "height": [5.5, 6.0],  
    .....:         "weight": [130, 150],  
    .....:     }  
    .....: )
    .....:

In [42]: cheese
Out[42]:
   first  last  height  weight
0  John   Doe    5.5      130
1  Mary     Bo    6.0       150

In [43]: cheese.melt(id_vars=["first", "last"])
Out[43]:
   first  last variable  value
0  John   Doe   height    5.5
1  Mary     Bo   height    6.0
2  John   Doe   weight   130.0
3  Mary     Bo   weight   150.0
```

(continues on next page)
When transforming a DataFrame using `melt()`, the index will be ignored. The original index values can be kept around by setting the `ignore_index` parameter to `False` (default is `True`). This will however duplicate them.

New in version 1.1.0.

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.
2.8.4 Combining with stats and GroupBy

It should be no shock that combining pivot / stack / unstack with GroupBy and the basic Series and DataFrame statistical functions can produce some very expressive and fast data manipulations.
Out[55]:
animal  cat  dog
first  second
bar  one  -0.155347  1.685445
two  0.130479  0.557070
baz  one  0.271419  -0.006733
two  0.526830  -1.312207

qux  one  0.067976  -0.648927
two  -1.254036  0.021048

In [57]: df.stack().groupby(level=1).mean()
Out[57]:
exp  A  B
second
one  0.071448  0.455513
two  -0.424186  -0.204486

In [58]: df.mean().unstack()
Out[58]:
exp  A  B
animal
cat  0.060843  0.018596
dog  -0.413580  0.232430

2.8.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the [cookbook](https://pandas.pydata.org/pandas-docs/stable/user_guide/categorical.html) for some advanced strategies.

It takes a number of arguments:

- `data`: a DataFrame object.
- `values`: a column or a list of columns to aggregate.
Consider a data set like this:

```python
import datetime

df = pd.DataFrame(
    {
        "A": ["one", "one", "two", "three"] * 6,
        "B": ["A", "B", "C"] * 8,
        "C": ["foo", "foo", "foo", "bar", "bar"] * 4,
        "D": np.random.randn(24),
        "E": np.random.randn(24),
        "F": [datetime.datetime(2013, i, 1) + datetime.datetime(2013, i, 15) for i in range(1, 13)],
    }
)
```

We can produce pivot tables from this data very easily:

```python
pd.pivot_table(df, values="D", index=["A", "B"], columns=["C"])
```

2.8. Reshaping and pivot tables
```python
In [63]:
pd.pivot_table(df, values="D", index=["B"], columns=["A", "C"], aggfunc=np.sum)
Out[63]:

<table>
<thead>
<tr>
<th></th>
<th>A one</th>
<th>three</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>C bar</td>
<td>NaN</td>
<td>foo</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>bar</td>
<td>foo</td>
</tr>
<tr>
<td>B</td>
<td>A 2.241830</td>
<td>-1.028115</td>
<td>-2.363137</td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>NaN</td>
<td>2.001971</td>
</tr>
<tr>
<td>C -1.077692</td>
<td>1.399070</td>
<td>1.177566</td>
<td>NaN</td>
</tr>
</tbody>
</table>

In [64]:
pd.pivot_table(df, values=["D", "E"], index=["B"], columns=["A", "C"], aggfunc=np.sum)

<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>A one</td>
<td></td>
<td></td>
</tr>
<tr>
<td>three</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C bar</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

B
A 2.241830 | -1.028115 | -2.363137 | NaN | NaN | 2.001971 | 2.786113 | -0.043211 | 1.922577 | NaN | 0.128491 |
B -0.676843 | 0.005518 | NaN | 0.867024 | 0.316495 | NaN | 1.368280 | -1.103384 | NaN | 0.352360 |
C -1.077692 | 1.399070 | 1.177566 | NaN | NaN | 0.352360 | -1.976883 | 1.495717 | -0.263660 | NaN | 0.872482 |

The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:
```
```
Also, you can use `Grouper` for index and columns keywords. For detail of `Grouper`, see *Grouping with a Grouper specification*.

```python
In [66]: pd.pivot_table(df, values="D", index=pd.Grouper(freq="M", key="F"), columns="C")
Out[66]:
                  C   bar   foo
F
2013-01-31     NaN -0.514058
2013-02-28     NaN  0.002759
2013-03-31     NaN  0.176180
2013-04-30    -1.181568   NaN
2013-05-31    -0.338421  0.002759
2013-06-30    -0.538846   NaN
2013-07-31     NaN  0.158248
2013-08-31     NaN  0.176180
2013-09-30    -0.338421  0.002759
2013-10-31    -0.538846   NaN
2013-11-30     NaN  0.588783
2013-12-31     NaN  0.436241
```

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```python
In [67]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
In [68]: print(table.to_string(na_rep=''))
```

```bash
D       E
C        bar   foo     bar   foo
A
one     A  1.120915 -0.514058  1.393057 -0.021605
       B  0.338421  0.002759  0.684140 -0.551692
       C  0.538846  0.699535 -0.988442  0.747859
three   A -1.181568  0.961289
       B  0.538846  0.433512 -1.064372
       C  0.588783  0.131830
two     A  1.000985  0.064245
       B  0.158248 -0.097147
       C  0.176180  0.436241
```

Note that `pivot_table` is also available as an instance method on DataFrame, i.e. `DataFrame.pivot_table()`.
Adding margins

If you pass `margins=True` to `pivot_table`, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [69]: df.pivot_table(index=["A", "B"], columns="C", margins=True, aggfunc=np.std)
Out[69]:
    D  E
   bar  foo  All  bar  foo  All
  A
  B
  C
  one
  two
```

### 2.8.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments:

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.
- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.
- `margins`: boolean, default `False`, Add row/column margins (subtotals)
- `normalize`: boolean, `{all`, `index`, `columns`}, or `{0,1}`, default `False`. Normalize by dividing all values by the sum of values.

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

For example:

```
In [70]: foo, bar, dull, shiny, one, two = "foo", "bar", "dull", "shiny", "one", "two"
In [71]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [72]: b = np.array([one, one, two, one, two, one], dtype=object)
In [73]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
```

(continues on next page)
If `crosstab` receives only two Series, it will provide a frequency table.

```python
In [75]: df = pd.DataFrame(
.....:   {"A": [1, 2, 2, 2, 2], "B": [3, 3, 4, 4, 4], "C": [1, 1, np.nan, 1, 1]}
.....: )
.....:

In [76]: df
Out[76]:
   A  B  C
0  1  3  1.0
1  2  3  1.0
2  2  4  NaN
3  2  4  1.0
4  2  4  1.0

In [77]: pd.crosstab(df["A"], df["B"])
Out[77]:
   B 3  4
A  
  1  1  0
  2  1  3
```

crosstab can also be implemented to Categorical data.

```python
In [78]: foo = pd.Categorical(["a", "b"], categories=["a", "b", "c"])
In [79]: bar = pd.Categorical(["d", "e"], categories=["d", "e", "f"])

In [80]: pd.crosstab(foo, bar)
Out[80]:
   col_0  d  e
row_0  
   a     1  0
   b     0  1
```

If you want to include **all** of data categories even if the actual data does not contain any instances of a particular category, you should set `dropna=False`.

For example:

```python
In [81]: pd.crosstab(foo, bar, dropna=False)
Out[81]:
   col_0  d  e  f
row_0  
   a     1  0  0
   b     0  1  0
```

---

2.8. Reshaping and pivot tables
Normalization

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```
In [82]: pd.crosstab(df["A"], df["B"], normalize=True)
Out[82]:
   B  3  4
A
  1  0.2  0.0
  2  0.2  0.6
```

`normalize` can also normalize values within each row or within each column:

```
In [83]: pd.crosstab(df["A"], df["B"], normalize="columns")
Out[83]:
   B  3  4
A
  1  0.5  0.0
  2  0.5  1.0
```

crosstab can also be passed a third Series and an aggregation function (aggfunc) that will be applied to the values of the third Series within each group defined by the first two Series:

```
In [84]: pd.crosstab(df["A"], df["B"], values=df["C"], aggfunc=np.sum)
Out[84]:
   B  3  4
A
  1  1.0  NaN
  2  1.0  2.0
```

Adding margins

Finally, one can also add margins or normalize this output.

```
In [85]: pd.crosstab(
   ...: df["A"], df["B"], values=df["C"], aggfunc=np.sum, normalize=True,
   ...:   margins=True)
   ...
Out[85]:
   B  3  4  All
A
  1  0.25  0.0  0.25
  2  0.25  0.5  0.75
 All  0.50  0.5  1.00
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

2.8.7 Tiling
The cut() function computes groupings for the values of the input array and is often used to transform continuous
variables to discrete or categorical variables:
In [86]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])
In [87]: pd.cut(ages, bins=3)
Out[87]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95,␣
˓→26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64, right]): [(9.95, 26.667] < (26.667, 43.333] < (43.333,␣
˓→60.0]]
If the bins keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:
In [88]: c = pd.cut(ages, bins=[0, 18, 35, 70])
In [89]: c
Out[89]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]]
Categories (3, interval[int64, right]): [(0, 18] < (18, 35] < (35, 70]]
If the bins keyword is an IntervalIndex, then these will be used to bin the passed data.:
pd.cut([25, 20, 50], bins=c.categories)

2.8.8 Computing indicator / dummy variables
To convert a categorical variable into a “dummy” or “indicator” DataFrame, for example a column in a DataFrame
(a Series) which has k distinct values, can derive a DataFrame containing k columns of 1s and 0s using
get_dummies():
In [90]: df = pd.DataFrame({"key": list("bbacab"), "data1": range(6)})
In [91]:
Out[91]:
a b
0 0 1
1 0 1
2 1 0
3 0 0
4 1 0
5 0 1

pd.get_dummies(df["key"])
c
0
0
0
1
0
0

Sometimes it’s useful to prefix the column names, for example when merging the result with the original DataFrame:
In [92]: dummies = pd.get_dummies(df["key"], prefix="key")
In [93]: dummies
Out[93]:
key_a key_b key_c
0
0
1

2.8. Reshaping and pivot tables

565


In [94]: df["data1"].join(dummies)
Out[94]:
   data1  key_a  key_b  key_c
0      0      0      1      0
1      1      0      1      0
2      2      1      0      0
3      3      0      0      1
4      4      0      0      1
5      5      0      1      0

This function is often used along with discretization functions like cut:

In [95]: values = np.random.randn(10)

In [96]: values
Out[96]:
array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29 ,
       0.0824, -0.0558,  0.5366])

In [97]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]

In [98]: pd.get_dummies(pd.cut(values, bins))
Out[98]:
(0.0, 0.2] (0.2, 0.4] (0.4, 0.6] (0.6, 0.8] (0.8, 1.0]
 0  0  0  1  0  0
 1  0  0  0  0  0
 2  0  0  0  0  0
 3  0  0  0  0  0
 4  1  0  0  0  0
 5  0  0  0  0  0
 6  0  0  0  0  0
 7  1  0  0  0  0
 8  0  0  0  0  0
 9  0  0  1  0  0

See also Series.str.get_dummies.

get_dummies() also accepts a DataFrame. By default all categorical variables (categorical in the statistical sense, those with object or categorical dtype) are encoded as dummy variables.

In [99]: df = pd.DataFrame({"A": ["a", "b", "a"], "B": ["c", "c", "b"], "C": [1, 2, 3]})

In [100]: pd.get_dummies(df)
Out[100]:
   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

```python
In [101]: pd.get_dummies(df, columns=["A"])
Out[101]:
       B  C  A_a  A_b
0  c  1   1   0
1  c  2   0   1
2  b  3   1   0
```

Notice that the `B` column is still included in the output, it just hasn’t been encoded. You can drop `B` before calling `get_dummies` if you don’t want to include it in the output.

As with the `Series` version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and `_` as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```python
In [102]: simple = pd.get_dummies(df, prefix="new_prefix")
In [103]: simple
Out[103]:
           C  new_prefix_a  new_prefix_b  new_prefix_b  new_prefix_c
0  1  1  0  0  1
1  2  0  1  0  1
2  3  1  0  1  0
In [104]: from_list = pd.get_dummies(df, prefix=["from_A", "from_B")
In [105]: from_list
Out[105]:
            C  from_A_a  from_A_b  from_B_b  from_B_c
0  1  1  0  0  1
1  2  0  1  0  1
2  3  1  0  1  0
In [106]: from_dict = pd.get_dummies(df, prefix={"B": "from_B", "A": "from_A")
In [107]: from_dict
Out[107]:
            C  from_A_a  from_A_b  from_B_b  from_B_c
0  1  1  0  0  1
1  2  0  1  0  1
2  3  1  0  1  0
```

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

## 2.8. Reshaping and pivot tables

567
In [108]: s = pd.Series(list("abcaa"))

In [109]: pd.get_dummies(s)
Out[109]:
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
4  1  0  0

In [110]: pd.get_dummies(s, drop_first=True)
Out[110]:
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0

When a column contains only one level, it will be omitted in the result.

In [111]: df = pd.DataFrame({"A": list("aaaaa"), "B": list("ababc")})

In [112]: pd.get_dummies(df)
Out[112]:
   A_a  B_a  B_b  B_c
0   1  1  0  0
1   1  0  1  0
2   1  1  0  0
3   1  0  1  0
4   1  0  0  1

In [113]: pd.get_dummies(df, drop_first=True)
Out[113]:
   B_b  B_c
0   0  0
1   1  0
2   0  0
3   1  0
4   0  1

By default new columns will have \texttt{np.uint8} dtype. To choose another dtype, use the \texttt{dtype} argument:

In [114]: df = pd.DataFrame({"A": list("abc"), "B": [1.1, 2.2, 3.3]})

In [115]: pd.get_dummies(df, dtype=bool).dtypes
Out[115]:
B    float64
A_a  bool
A_b  bool
A_c  bool
dtype: object
2.8.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```

In [117]: x
Out[117]:
0   A
1   A
2  NaN
3   B
4  3.14
5    inf
dtype: object

In [118]: labels, uniques = pd.factorize(x)

In [119]: labels
Out[119]: array([ 0, 0, -1, 1, 2, 3])

In [120]: uniques
Out[120]: Index(['A', 'B', 3.14, inf], dtype=object)
```

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

```
Note: The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also here.
```

```
In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([2, 2, -1, 3, 0, 1]),
 Index([3.14, inf, 'A', 'B'], dtype='object'))

In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

Note: If you just want to handle one column as a categorical variable (like R’s factor), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on `Categorical`, see the `Categorical introduction` and the `API documentation`.
2.8.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

In [121]: np.random.seed([3, 1415])

In [122]: n = 20

In [123]: cols = np.array(['key', 'row', 'item', 'col'])

In [124]: df = cols + pd.DataFrame((np.random.randint(5, size=(n, 4)) // [2, 1, 2, 1]).astype(str))

In [125]: df.columns = cols

In [126]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix("val"))

In [127]: df

Out[127]:
    key row item col val0  val1
0  key0 row3 item1 col3  0.81  0.04
1  key1 row2 item1 col2  0.44  0.07
2  key1 row0 item1 col0  0.77  0.01
3  key0 row4 item0 col2  0.15  0.59
4  key1 row0 item2 col1  0.81  0.64
..   ...   ...   ...  ...   ...
15 key0 row3 item1 col1  0.31  0.23
16 key0 row0 item2 col3  0.86  0.01
17 key0 row4 item0 col3  0.64  0.21
18 key2 row2 item2 col0  0.13  0.45
19 key0 row2 item0 col4  0.37  0.70
[20 rows x 6 columns]

Pivoting with single aggregations

Suppose we wanted to pivot df such that the col values are columns, row values are the index, and the mean of val0 are the values? In particular, the resulting DataFrame should look like:

<table>
<thead>
<tr>
<th>col</th>
<th>col0</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row0</td>
<td>0.77</td>
<td>0.605</td>
<td>NaN</td>
<td>0.860</td>
<td>0.65</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
<td>NaN</td>
<td>0.395</td>
<td>0.500</td>
<td>0.25</td>
</tr>
<tr>
<td>row3</td>
<td>NaN</td>
<td>0.310</td>
<td>NaN</td>
<td>0.545</td>
<td>NaN</td>
</tr>
<tr>
<td>row4</td>
<td>NaN</td>
<td>0.100</td>
<td>0.395</td>
<td>0.760</td>
<td>0.24</td>
</tr>
</tbody>
</table>

This solution uses pivot_table(). Also note that aggfunc='mean' is the default. It is included here to be explicit.

In [128]: df.pivot_table(values="val0", index="row", columns="col", aggfunc="mean")

Out[128]:

(continues on next page)
Note that we can also replace the missing values by using the `fill_value` parameter.

```
In [129]: df.pivot_table(
.....:     values="val0",
.....:     index="row",
.....:     columns="col",
.....:     aggfunc="mean",
.....:     fill_value=0,
.....:     )
```

```
Out[129]:
   col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65
row2  0.13  NaN   0.395  0.500  0.25
row3  NaN  0.310  NaN  0.545  NaN
row4  NaN  0.100  0.395  0.760  0.24
```

Also note that we can pass in other aggregation functions as well. For example, we can also pass in `sum`.

```
In [130]: df.pivot_table(
.....:     values="val0",
.....:     index="row",
.....:     columns="col",
.....:     aggfunc="sum",
.....:     fill_value=0,
.....:     )
```

```
Out[130]:
   col  col0  col1  col2  col3  col4
row
row0  0.77  1.21  0.00  0.86  0.65
row2  0.13  0.00  0.395  0.500  0.25
row3  0.00  0.310  0.00  0.545  0.00
row4  0.00  0.100  0.395  0.760  0.24
```

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass `size` to the `aggfunc` parameter.

```
In [131]: df.pivot_table(index="row", columns="col", fill_value=0, aggfunc="size")
```

```
Out[131]:
   col  col0  col1  col2  col3  col4
row
row0  1   2   0   1   1
row2  1   0   2   1   2
```
Pivoting with multiple aggregations

We can also perform multiple aggregations. For example, to perform both a `sum` and `mean`, we can pass in a list to the `aggfunc` argument.

```
In [132]: df.pivot_table(
    .....:       values="val0",
    .....:       index="row",
    .....:       columns="col",
    .....:       aggfunc=["mean", "sum"],
    .....:   )
```

```
Out[132]:

<table>
<thead>
<tr>
<th></th>
<th>col0</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>row0</td>
<td>0.77</td>
<td>0.605</td>
<td>NaN</td>
<td>0.860</td>
<td>0.65</td>
<td>0.77</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
<td>NaN</td>
<td>0.395</td>
<td>0.500</td>
<td>0.25</td>
<td>0.13</td>
</tr>
<tr>
<td>row3</td>
<td>NaN</td>
<td>0.310</td>
<td>NaN</td>
<td>0.545</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>row4</td>
<td>NaN</td>
<td>0.100</td>
<td>0.395</td>
<td>0.760</td>
<td>0.24</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```

Note to aggregate over multiple value columns, we can pass in a list to the `values` parameter.

```
In [133]: df.pivot_table(
    .....:       values=["val0", "val1"],
    .....:       index="row",
    .....:       columns="col",
    .....:       aggfunc=["mean"],
    .....:   )
```

```
Out[133]:

<table>
<thead>
<tr>
<th></th>
<th>val0</th>
<th>val1</th>
</tr>
</thead>
<tbody>
<tr>
<td>col</td>
<td>col0</td>
<td>col1</td>
</tr>
<tr>
<td>row0</td>
<td>0.77</td>
<td>0.605</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
<td>NaN</td>
</tr>
<tr>
<td>row3</td>
<td>NaN</td>
<td>0.310</td>
</tr>
<tr>
<td>row4</td>
<td>NaN</td>
<td>0.100</td>
</tr>
</tbody>
</table>
```

Note to subdivide over multiple columns we can pass in a list to the `columns` parameter.

```
In [134]: df.pivot_table(
    .....:       values=["val0"],
    .....:       index="row",
    .....:       columns=["item", "col"],
    .....:       aggfunc=["mean"],
    .....:   )
```

(continues on next page)
2.8.11 Exploding a list-like column

New in version 0.25.0.

Sometimes the values in a column are list-like.

```python
In [135]: keys = ['panda1', 'panda2', 'panda3']
In [136]: values = [['eats', 'shoots'], ['shoots', 'leaves'], ['eats', 'leaves']]
In [137]: df = pd.DataFrame({'keys': keys, 'values': values})
In [138]: df
```

We can ‘explode’ the `values` column, transforming each list-like to a separate row, by using `explode()`. This will replicate the index values from the original row:

```python
In [139]: df['values'].explode()
Out[139]:
    0  panda1  eats
    0  panda1  shoots
    1  panda2  shoots
    1  panda2  leaves
    2  panda3  eats
    2  panda3  leaves
Name: values, dtype: object
```

You can also explode the column in the `DataFrame`.

```python
In [140]: df.explode('values')
Out[140]:
    keys values
    0  panda1  eats
    0  panda1  shoots
    1  panda2  shoots
```

(continues on next page)
Series.explode() will replace empty lists with np.nan and preserve scalar entries. The dtype of the resulting Series is always object.

```
In [141]: s = pd.Series([[1, 2, 3], "foo", [], ["a", "b"]])

In [142]: s
Out[142]:
0   [1, 2, 3]
1     foo
2      []
3   [a, b]
dtype: object

In [143]: s.explode()
Out[143]:
0   1
  2
  3
1   foo
2   NaN
3     a
3     b
dtype: object
```

Here is a typical usecase. You have comma separated strings in a column and want to expand this.

```
In [144]: df = pd.DataFrame(["var1": "a,b,c", "var2": 1}, {"var1": "d,e,f", "var2": 2}]

In [145]: df
Out[145]:
   var1 var2
0  a,b,c   1
1  d,e,f   2

Creating a long form DataFrame is now straightforward using explode and chained operations

```
In [146]: df.assign(var1=df.var1.str.split(",")].explode("var1")
Out[146]:
   var1 var2
0     a   1
0     b   1
0     c   1
1     d   2
1     e   2
1     f   2
```
## 2.9 Working with text data

### 2.9.1 Text data types

New in version 1.0.0.

There are two ways to store text data in pandas:

1. **object**-dtype NumPy array.
2. **StringDtype** extension type.

We recommend using **StringDtype** to store text data.

Prior to pandas 1.0, **object** dtype was the only option. This was unfortunate for many reasons:

1. You can accidentally store a mixture of strings and non-strings in an **object** dtype array. It’s better to have a dedicated dtype.
2. **object** dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn’t a clear way to select just text while excluding non-text but still object-dtype columns.
3. When reading code, the contents of an **object** dtype array is less clear than 'string'.

Currently, the performance of **object** dtype arrays of strings and `arrays.StringArray` are about the same. We expect future enhancements to significantly increase the performance and lower the memory overhead of `StringArray`.

*Warning*: `StringArray` is currently considered experimental. The implementation and parts of the API may change without warning.

For backwards-compatibility, **object** dtype remains the default type we infer a list of strings to

```python
In [1]: pd.Series(["a", "b", "c")
Out[1]:
0   a
1   b
2   c
dtype: object
```

To explicitly request string dtype, specify the dtype

```python
In [2]: pd.Series(["a", "b", "c"], dtype="string")
Out[2]:
0   a
1   b
2   c
dtype: string

In [3]: pd.Series(["a", "b", "c"], dtype=pd.StringDtype())
Out[3]:
0   a
1   b
2   c
dtype: string
```

Or astype after the Series or DataFrame is created
In [4]: s = pd.Series(["a", "b", "c"])

In [5]: s  
Out[5]:  
0   a  
1   b  
2   c  
dtype: object

In [6]: s.astype("string")  
Out[6]:  
0   a  
1   b  
2   c  
dtype: string

Changed in version 1.1.0.

You can also use StringDtype/"string" as the dtype on non-string data and it will be converted to string dtype:

In [7]: s = pd.Series(["a", 2, np.nan], dtype="string")

In [8]: s  
Out[8]:  
0   a  
1   2  
2   <NA>  
dtype: string

In [9]: type(s[1])  
Out[9]: str

or convert from existing pandas data:

In [10]: s1 = pd.Series([1, 2, np.nan], dtype="Int64")

In [11]: s1  
Out[11]:  
0   1  
1   2  
2   <NA>  
dtype: Int64

In [12]: s2 = s1.astype("string")

In [13]: s2  
Out[13]:  
0   1  
1   2  
2   <NA>  
dtype: string

In [14]: type(s2[0])  
Out[14]: str
Behavior differences

These are places where the behavior of `StringDtype` objects differ from `object` dtype

1. For `StringDtype`, `string accessor methods` that return numeric output will always return a nullable integer dtype, rather than either int or float dtype, depending on the presence of NA values. Methods returning boolean output will return a nullable boolean dtype.

```
In [15]: s = pd.Series(['a', None, 'b'], dtype='string')
In [16]: s
Out[16]:
0    a
1   <NA>
2    b
dtype: string

In [17]: s.str.count('a')
Out[17]:
0    1
1   <NA>
2    0
dtype: Int64

In [18]: s.dropna().str.count('a')
Out[18]:
0    1
2    0
dtype: Int64
```

Both outputs are `Int64` dtype. Compare that with object-dtype

```
In [19]: s2 = pd.Series(['a', None, 'b'], dtype='object')
In [20]: s2.str.count('a')
Out[20]:
0   1.0
1  NaN
2   0.0
dtype: float64

In [21]: s2.dropna().str.count('a')
Out[21]:
0    1
2    0
dtype: int64
```

When NA values are present, the output dtype is float64. Similarly for methods returning boolean values.

```
In [22]: s.str.isdigit()
Out[22]:
0   False
1   <NA>
2   False
```

(continues on next page)
dtype: boolean

In [23]: s.str.match("a")
Out[23]:
0   True
1  <NA>
2  False
dtype: boolean

2. Some string methods, like Series.str.decode() are not available on StringArray because StringArray only holds strings, not bytes.

3. In comparison operations, arrays.StringArray and Series backed by a StringArray will return an object with BooleanDtype, rather than a bool dtype object. Missing values in a StringArray will propagate in comparison operations, rather than always comparing unequal like numpy.nan.

Everything else that follows in the rest of this document applies equally to string and object dtype.

2.9.2 String methods

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the str attribute and generally have names matching the equivalent (scalar) built-in string methods:

```python
In [24]: s = pd.Series(
    ....:     dtype="string")

In [25]: s.str.lower()
Out[25]:
0   a
1   b
2   c
3  aaba
4   baca
5  <NA>
6  caba
7   dog
8   cat
dtype: string
```

```python
In [26]: s.str.upper()
Out[26]:
0    A
1    B
2    C
3  AABA
4  BACA
5  <NA>
6  CABA
```
7  DOG
8  CAT
dtype: string

In [27]: s.str.len()
Out[27]:
0 1
1 1
2 1
3 4
4 4
5 <NA>
6 4
7 3
8 3
dtype: Int64

In [28]: idx = pd.Index([' jack', ' jill ', ' jesse ', 'frank'])
In [29]: idx.str.strip()
Out[29]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
In [30]: idx.str.lstrip()
Out[30]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
In [31]: idx.str.rstrip()
Out[31]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

In [32]: df = pd.DataFrame(np.random.randn(3, 2), columns=[' Column A ', ' Column B '], index=range(3))
In [33]: df
Out[33]:
   Column A   Column B
0  0.469112  -0.282863
1 -1.509059  -1.135632
2  1.212112  -0.173215

Since df.columns is an Index object, we can use the .str accessor

In [34]: df.columns.str.strip()
Out[34]: Index(['Column A', 'Column B'], dtype='object')
In [35]: df.columns.str.lower()
Out[35]: Index(['column a', 'column b'], dtype='object')

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lower casing all names, and replacing any remaining whitespaces with underscores:

2.9. Working with text data
In [36]: df.columns = df.columns.str.strip().str.lower().str.replace(" ", "_")

In [37]: df
Out[37]:
   column_a  column_b
0   0.469112  -0.282863
1  -1.509059  -1.135632
2   1.212112   -0.173215

Note: If you have a Series where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series), it can be faster to convert the original Series to one of type category and then use .str.<method> or .dt.<property> on that. The performance difference comes from the fact that, for Series of type category, the string operations are done on the .categories and not on each element of the Series.

Please note that a Series of type category with string .categories has some limitations in comparison to Series of type string (e.g. you can’t add strings to each other: s +"" + s won’t work if s is a Series of type category). Also, .str methods which operate on elements of type list are not available on such a Series.

Warning: Before v.0.25.0, the .str-accessor did only the most rudimentary type checks. Starting with v.0.25.0, the type of the Series is inferred and the allowed types (i.e. strings) are enforced more rigorously.

Generally speaking, the .str accessor is intended to work only on strings. With very few exceptions, other uses are not supported, and may be disabled at a later point.

2.9.3 Splitting and replacing strings

Methods like split return a Series of lists:

In [38]: s2 = pd.Series(["a_b_c", "c_d_e", np.nan, "f_g_h"], dtype="string")

In [39]: s2.str.split("_")
Out[39]:
   0     [a, b, c]
   1     [c, d, e]
   2       <NA>
   3     [f, g, h]

Elements in the split lists can be accessed using get or [] notation:

In [40]: s2.str.split("_").str.get(1)
Out[40]:
   0     b
   1     d
   2       <NA>
   3     g

In [41]: s2.str.split("_").str[1]
Out[41]:
It is easy to expand this to return a DataFrame using `expand`.

```python
In [42]: s2.str.split("_", expand=True)
Out[42]:
   0  1  2
0  a  b  c
1  c  d  e
2 <NA> <NA> <NA>
3  f  g  h
```

When original `Series` has `StringDtype`, the output columns will all be `StringDtype` as well.

It is also possible to limit the number of splits:

```python
In [43]: s2.str.split("_", expand=True, n=1)
Out[43]:
   0  1
0  a  b_c
1  c  d_e
2 <NA> <NA>
3  f  g_h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```python
In [44]: s2.str.rsplit("_", expand=True, n=1)
Out[44]:
   0  1
0  a_b  c
1  c_d  e
2 <NA> <NA>
3  f_g  h
```

`replace` optionally uses regular expressions:

```python
In [45]: s3 = pd.Series(
   ....:     dtype="string",
   ....: )
   ....:

In [46]: s3
Out[46]:
   0  A
   1  B
   2  C
   3  Aaba
```

(continues on next page)
Warning: Some caution must be taken when dealing with regular expressions! The current behavior is to treat single character patterns as literal strings, even when regex is set to True. This behavior is deprecated and will be removed in a future version so that the regex keyword is always respected.

Changed in version 1.2.0.

If you want literal replacement of a string (equivalent to str.replace()), you can set the optional regex parameter to False, rather than escaping each character. In this case both pat and repl must be strings:

```python
In [48]: dollars = pd.Series(["12", "-$10", "$10,000"], dtype="string")
# These lines are equivalent
In [49]: dollars.str.replace(r"-\$", "-", regex=True)
Out[49]:
0   12
1  -10
2  $10,000
dtype: string
```

```python
In [50]: dollars.str.replace("-$", "-", regex=False)
Out[50]:
0   12
1  -10
2  $10,000
dtype: string
```

The replace method can also take a callable as replacement. It is called on every pat using re.sub(). The callable should expect one positional argument (a regex object) and return a string.
# Reverse every lowercase alphabetic word
In [51]: pat = r"^[a-z]+$"

In [52]: def repl(m):
       ....:     return m.group(0)[::-1]
       ....:

In [53]: pd.Series( ["foo 123", "bar baz", np.nan], dtype="string" ).str.replace(  
       ....:     pat, repl, regex=True  
       ....: )

Out[53]:
0  oof 123
1  rab zab
2  <NA>
dtype: string

# Using regex groups
In [54]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [55]: def repl(m):
       ....:     return m.group("two").swapcase()
       ....:

In [56]: pd.Series(["Foo Bar Baz", np.nan], dtype="string" ).str.replace(  
       ....:     pat, repl, regex=True  
       ....: )

Out[56]:
0  bAR
1  <NA>
dtype: string

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

In [57]: import re

In [58]: regex_pat = re.compile(r"^[a|.a|dog]", flags=re.IGNORECASE)

In [59]: s3.str.replace(regex_pat, "XX-XX ", regex=True)

Out[59]:
0    A
1    B
2    C
3  XX-XX ba
4  XX-XX ca
5  
6  <NA>
7  XX-XX BA
8  XX-XX
9  XX-XX t
dtype: string

2.9. Working with text data
Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```python
In [60]: s3.str.replace(regex_pat, 'XX-XX', flags=re.IGNORECASE)
---------------------------------------------------------------------------
ValueError: case and flags cannot be set when pat is a compiled regex
```

### 2.9.4 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

#### Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:

```python
In [61]: s = pd.Series(['a', 'b', 'c', 'd'], dtype='string')
In [62]: s.str.cat(sep=',')
Out[62]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=''`:

```python
In [63]: s.str.cat()  # sep='' by default
Out[63]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```python
In [64]: t = pd.Series(['a', 'b', np.nan, 'd'], dtype='string')
In [65]: t.str.cat(sep=',')  # na_rep=None by default
Out[65]: 'a,b,d'
In [66]: t.str.cat(sep=',', na_rep='-')
Out[66]: 'a,b,-,d'
```

#### Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling `Series` (or `Index`).

```python
In [67]: s.str.cat(['A', 'B', 'C', 'D'])
Out[67]:
   0   aA
   1   bB
   2   cC
   3   dD

   dtype: string
```

Missing values on either side will result in missing values in the result as well, `unless na_rep` is specified:
Concatenating a Series and something array-like into a Series

The parameter `others` can also be two-dimensional. In this case, the number or rows must match the lengths of the calling `Series` (or `Index`).

```
In [70]: d = pd.concat([t, s], axis=1)

In [71]: s
Out[71]:
0  a
1  b
2  c
3  d
dtype: string

In [72]: d
Out[72]:
        0  1
0  a  a
1  b  b
2 <NA> c
3  d  d

In [73]: s.str.cat(d, na_rep="-")
Out[73]:
0  aaa
1  bbb
2  c-c
3  d-c
dtype: string
```
Concatenating a Series and an indexed object into a Series, with alignment

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the join-keyword.

```
In [74]: u = pd.Series(["b", "d", "a", "c"], index=[1, 3, 0, 2], dtype="string")

In [75]: s
Out[75]:
0  a
1  b
2  c
3  d
dtype: string

In [76]: u
Out[76]:
1  b
3  d
0  a
2  c
dtype: string

In [77]: s.str.cat(u)
Out[77]:
0  aa
1  bb
2  cc
3  dd
dtype: string

In [78]: s.str.cat(u, join="left")
Out[78]:
0  aa
1  bb
2  cc
3  dd
dtype: string
```

**Warning:** If the join keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for join (one of 'left', 'outer', 'inner', 'right'). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [79]: v = pd.Series(["z", "a", "b", "d", "e"], index=[-1, 0, 1, 3, 4], dtype="string")

In [80]: s
Out[80]:
0  a
1  b
```

(continues on next page)
The same alignment can be used when `others` is a DataFrame:

```python
In [84]: f = d.loc[[3, 2, 1, 0], :]
In [85]: s
Out[85]:
0 a
1 b
2 c
3 d
dtype: string
In [86]: f
Out[86]:
0 1
3 d d
2 <NA> c
1 b b
0 a a
In [87]: s.str.cat(f, join="left", na_rep="-")
```
Concatenating a Series and many objects into a Series

Several array-like items (specifically: Series, Index, and 1-dimensional variants of np.ndarray) can be combined in a list-like container (including iterators, dict-views, etc.).

```
In [88]: s
Out[88]:
0  a
1  b
2  c
3  d
dtype: string

In [89]: u
Out[89]:
0  a
1  b
2  c
0  a
2  c
dtype: string

In [90]: s.str.cat([u, u.to_numpy()], join="left")
Out[90]:
0  aab
1  bbd
2  cca
3  ddc
dtype: string
```

All elements without an index (e.g. np.ndarray) within the passed list-like must match in length to the calling Series (or Index), but Series and Index may have arbitrary length (as long as alignment is not disabled with join=None):

```
In [91]: v
Out[91]:
-1  z
0  a
1  b
3  d
4  e
dtype: string

In [92]: s.str.cat([v, u, u.to_numpy()], join="outer", na_rep="-")
Out[92]:
-1  -z--
```
If using `join='right'` on a list-like of others that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```python
In [93]: u.loc[[3]]
Out[93]:
3   d
dtype: string

In [94]: v.loc[[-1, 0]]
Out[94]:
-1  z
  0  a
dtype: string

In [95]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join="right", na_rep="-")
Out[95]:
-1  --z
  0  a-a
  3  dd-
dtype: string
```

### 2.9.5 Indexing with `.str`

You can use `[]` notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```python
In [96]: s = pd.Series(
        ...:     dtype="string"
        ...
    )

In [97]: s.str[0]
Out[97]:
0   A
1   B
2   C
3   A
4   B
5  <NA>
6   C
7   d
8   c
dtype: string
```
2.9.6 Extracting substrings

Extract first match in each subject (extract)

Warning: Before version 0.23, argument expand of the extract method defaulted to False. When expand=False, expand returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern. When expand=True, it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user. expand=True has been the default since version 0.23.0.

The extract method accepts a regular expression with at least one capture group.

Extracting a regular expression with more than one group returns a DataFrame with one column per group.

Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating get() to access tuples or re.match objects. The dtype of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

```
In [100]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(
              r"(?P<letter>[ab])(?P<digit>\d)", expand=False
```

(continues on next page)
and optional groups like

```python
In [101]: pd.Series(  
              .....:      ['a1', 'b2', '3'],  
              .....:      dtype='string',  
              .....: ).str.extract(r'([ab])?\d', expand=False)
       0   1
       0   a  1
       1   b  2
       2  <NA>  3
```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if expand=True.

```python
In [102]: pd.Series(['a1', 'b2', 'c3'], dtype='string').str.extract(r'([ab])\d', expand=True)
Out [102]:
          0
       0   1
       1   2
       2  <NA>
```

It returns a Series if expand=False.

```python
In [103]: pd.Series(['a1', 'b2', 'c3'], dtype='string').str.extract(r'([ab])\d', expand=False)
Out [103]:
       0
       0   1
       1   2
       2  <NA>

dtype: string
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if expand=True.

```python
In [104]: s = pd.Series(['a1', 'b2', 'c3'], ['A11', 'B22', 'C33'], dtype='string')
In [105]: s
Out [105]:
          A11  a1
          B22  b2
          C33  c3

dtype: string
```

2.9. Working with text data
In [106]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[106]:
<table>
<thead>
<tr>
<th>letter</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
</tr>
<tr>
<td>B</td>
</tr>
<tr>
<td>C</td>
</tr>
</tbody>
</table>

It returns an Index if expand=False.

In [107]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[107]:
Index(['A', 'B', 'C'], dtype='object', name='letter')

Calling on an Index with a regex with more than one capture group returns a DataFrame if expand=True.

In [108]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[108]:
<table>
<thead>
<tr>
<th>letter</th>
<th>digit</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>11</td>
</tr>
<tr>
<td>B</td>
<td>22</td>
</tr>
<tr>
<td>C</td>
<td>33</td>
</tr>
</tbody>
</table>

It raises ValueError if expand=False.

>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index

The table below summarizes the behavior of extract(expand=False) (input subject in first column, number of groups in regex in first row)

<table>
<thead>
<tr>
<th></th>
<th>1 group</th>
<th>&gt;1 group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>Index</td>
<td>ValueError</td>
</tr>
<tr>
<td>Series</td>
<td>Series</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

**Extract all matches in each subject (extractall)**

Unlike extract (which returns only the first match),

In [109]: s = pd.Series(['a1a2', 'b1', 'c1'], index=['A', 'B', 'C'], dtype='string')

In [110]: s
Out[110]:
A  a1a2
B  b1
C  c1
dtype: string

In [111]: two_groups = "(?P<letter>[a-z])(?P<digit>[0-9])"

In [112]: s.str.extract(two_groups, expand=True)
Out[112]:
<table>
<thead>
<tr>
<th>letter</th>
<th>digit</th>
</tr>
</thead>
<tbody>
<tr>
<td>A1</td>
<td>11</td>
</tr>
<tr>
<td>B1</td>
<td>22</td>
</tr>
<tr>
<td>C1</td>
<td>33</td>
</tr>
</tbody>
</table>
the `extractall` method returns every match. The result of `extractall` is always a DataFrame with a `MultiIndex` on its rows. The last level of the `MultiIndex` is named `match` and indicates the order in the subject.

```python
In [113]: s.str.extractall(two_groups)
Out[113]:
          letter digit
match
A 0     a  1
   1     a  2
B 0     b  1
C 0     c  1
```

When each subject string in the Series has exactly one match,

```python
In [114]: s = pd.Series(["a3", "b3", "c2"], dtype="string")
In [115]: s
Out[115]:
0   a3
1   b3
2   c2
dtype: string
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```python
In [116]: extract_result = s.str.extract(two_groups, expand=True)
In [117]: extract_result
Out[117]:
          letter digit
0       a     3
1       b     3
2       c     2
In [118]: extractall_result = s.str.extractall(two_groups)
In [119]: extractall_result
Out[119]:
          letter digit
match
0   0     a     3
1   0     b     3
2   0     c     2
In [120]: extractall_result.xs(0, level='match')
Out[120]:
          letter digit
0   0     a     3
```

(continues on next page)
Index also supports `.str.extractall`. It returns a DataFrame which has the same result as a Series.str.extractall with a default index (starts from 0).

```
In [121]: pd.Index(["a1a2", "b1", "c1"]).str.extractall(two_groups)
Out[121]:
     letter  digit
   0     a     1
   1     a     2
   2     b     1
   3     c     1
```

```
In [122]: pd.Series(["a1a2", "b1", "c1"], dtype="string").str.extractall(two_groups)
Out[122]:
     letter  digit
   0     a     1
   1     a     2
   2     b     1
   3     c     1
```

### 2.9.7 Testing for strings that match or contain a pattern

You can check whether elements contain a pattern:

```
In [123]: pattern = r"\[0-9]\[a-z"]
```

```
In [124]: pd.Series(["1", "2", "3a", "3b", "03c", "4dx"],
   dtypes='string').str.contains(pattern)
Out[124]:
0   False
1   False
2   True
3   True
4   True
5   True
dtype: bool
```

Or whether elements match a pattern:

```
In [125]: pd.Series(["1", "2", "3a", "3b", "03c", "4dx"],
   dtypes='string').str.match(pattern)
```

(continues on next page)
Out[125]:
0    False
1    False
2     True
3     True
4    False
5     True
dtype: boolean

New in version 1.1.0.

In [126]: pd.Series(
     ...:     ["1", "2", "3a", "3b", "ö3c", "4dx"],
     ...:     dtype="string",
     ...: ).str.fullmatch(pattern)
     ...
Out[126]:
0    False
1    False
2     True
3     True
4    False
5    False
dtype: boolean

Note: The distinction between match, fullmatch, and contains is strictness: fullmatch tests whether the entire string matches the regular expression; match tests whether there is a match of the regular expression that begins at the first character of the string; and contains tests whether there is a match of the regular expression at any position within the string. The corresponding functions in the re package for these three match modes are re.fullmatch, re.match, and re.search, respectively.

Methods like match, fullmatch, contains, startswith, and endswith take an extra na argument so missing values can be considered True or False:

In [127]: s4 = pd.Series(
     ...
"string"
     ...: )
     ...

In [128]: s4.str.contains("A", na=False)
Out[128]:
0     True
1    False
2    False
3     True
4    False
5    False
6     True

(continues on next page)
2.9.8 Creating indicator variables

You can extract dummy variables from string columns. For example if they are separated by a `'|'`:

```python
In [129]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'], dtype='string')

In [130]: s.str.get_dummies(sep='|')
Out[130]:
   a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1
```

String Index also supports `get_dummies` which returns a `MultiIndex`.

```python
In [131]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])

In [132]: idx.str.get_dummies(sep='|')
Out[132]:
MultiIndex([(1, 0, 0),
            (1, 1, 0),
            (0, 0, 0),
            (1, 0, 1)],
           names=['a', 'b', 'c'])
```

See also `get_dummies()`.

2.9.9 Method summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cat()</code></td>
<td>Concatenate strings</td>
</tr>
<tr>
<td><code>split()</code></td>
<td>Split strings on delimiter</td>
</tr>

2.10 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

Note: The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. Starting from pandas 1.0, some optional data types start experimenting with a native NA scalar using a mask-based approach. See here for more.

See the cookbook for some advanced strategies.

2.10.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python None will arise and we wish to also consider that “missing” or “not available” or “NA”.

Note: If you want to consider inf and -inf to be “NA” in computations, you can set pandas.options.mode.use_inf_as_na = True.

In [1]: df = pd.DataFrame(
   ...:   np.random.randn(5, 3),
   ...:   index=["a", "c", "e", "f", "h"],
   ...:   columns=["one", "two", "three"],
   ...: )
   ...

In [2]: df["four"] = "bar"

In [3]: df["five"] = df["one"] > 0

In [4]: df

Out[4]:
   one   two   three   four   five
a  0.469112 -0.282863 -1.509059   bar   True
   c -1.135632  1.212112 -0.173215   bar   False
   e  0.119209 -1.044236 -0.861849   bar   True
   f -2.104569 -0.494929  1.071804   bar   False
   h  0.721555 -0.706771 -1.039575   bar   True

In [5]: df2 = df.reindex(["a", "b", "c", "d", "e", "f", "g", "h"])

In [6]: df2

Out[6]:
   one    two    three    four    five
a  0.469112 -0.282863 -1.509059   bar   True
b    NaN     NaN     NaN     NaN   NaN
c -1.135632  1.212112 -0.173215   bar   False
d    NaN     NaN     NaN     NaN   NaN

(continues on next page)
To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```python
In [7]: df2["one"]
Out[7]:
a    0.469112
b     NaN
c -1.135632
d     NaN
e   0.119209
f  -2.104569
g    NaN
h   0.721555
Name: one, dtype: float64

In [8]: pd.isna(df2["one"])
Out[8]:
a   False
b  True
c  False
d  True
e  False
f  False
g   True
h  False
Name: one, dtype: bool

In [9]: df2["four"].notna()
Out[9]:
a   True
b  False
c   True
d  False
e   True
f   True
g  False
h   True
Name: four, dtype: bool

In [10]: df2.isna()
Out[10]:
      one    two    three    four    five
a  False  False  False  False  False
b  True   True   True   True   True
c  False  False  False  False  False
d  True   True   True   True   True
e  False  False  False  False  False
f  True   True   True   True   True
g  False  False  False  False  False
h  True   True   True   True   True
```
Warning: One has to be mindful that in Python (and NumPy), the nan’s don’t compare equal, but None’s do. Note that pandas/NumPy uses the fact that np.nan != np.nan, and treats None like np.nan.

<table>
<thead>
<tr>
<th>f</th>
<th>False</th>
<th>False</th>
<th>False</th>
<th>False</th>
<th>False</th>
</tr>
</thead>
<tbody>
<tr>
<td>g</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>h</td>
<td>False</td>
<td>False</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

So as compared to above, a scalar equality comparison versus a None/np.nan doesn’t provide useful information.

| In [13]: df2["one"] == np.nan |
| Out[13]: |
| a | False |
| b | False |
| c | False |
| d | False |
| e | False |
| f | False |
| g | False |
| h | False |
Name: one, dtype: bool

**Integer dtypes and missing data**

Because NaN is a float, a column of integers with even one missing values is cast to floating-point dtype (see [Support for integer NA](#) for more). pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

| In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype()) |
| Out[14]: |
| 0  | 1 |
| 1  | 2 |
| 2  | <NA> |
| 3  | 4 |
dtype: Int64

Alternatively, the string alias dtype='Int64' (note the capital "I") can be used.

See [Nullable integer data type](#) for more.
Datetimes

For datetime64[ns] types, NaT represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (datetime64[ns]). pandas objects provide compatibility between NaT and NaN.

```
In [15]: df2 = df.copy()

In [16]: df2["timestamp"] = pd.Timestamp("20120101")

In [17]: df2
Out[17]:
     one    two    three    four    five  timestamp
a  0.469112 -0.282863 -1.509059    bar      True  2012-01-01
b  1.135632  1.212112 -0.173215    bar     False  2012-01-01
c  0.119209 -1.044236  0.861849    bar      True  2012-01-01
f  2.104569 -0.494929  1.071804    bar     False  2012-01-01
h  0.721555 -0.706771 -1.039575    bar      True  2012-01-01

In [18]: df2.loc["a", "c", "h"], ["one", "timestamp"] = np.nan

In [19]: df2
Out[19]:
     one    two    three    four    five  timestamp
a  NaN   -0.282863 -1.509059    bar      True   NaN
b  NaN    1.212112 -0.173215    bar     False   NaN
c  NaN  1.135632 -0.861849    bar      True   NaN
f  NaN  2.104569  1.071804    bar     False   NaN
h  NaN   0.721555 -1.039575    bar      True   NaN

In [20]: df2.dtypes.value_counts()
Out[20]:
float64    3
object     1
bool       1
datetime64[ns]  1
dtype: int64
```

2.10.2 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])

In [22]: s.loc[0] = None

In [23]: s
Out[23]:
0    NaN
1    2.0
```

(continues on next page)
Likewise, datetime containers will always use \texttt{NaT}.

For object containers, pandas will use the value given:

```python
In [24]: s = pd.Series(["a", "b", "c"])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan
In [27]: s
```

```
Out[27]:
0   None
1   NaN
2   c
dtype: object
```

### 2.10.3 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```python
In [28]: a
Out[28]:
    one  two
   a  NaN  -0.282863
   c  NaN   1.212112
   e  0.119209 -1.044236
   f -2.104569  -0.494929
   h -2.104569  -0.706771
In [29]: b
Out[29]:
    one  two  three
   a  NaN  NaN  -1.509059
   c  NaN  NaN  -0.173215
   e  0.119209 -1.044236  -0.861849
   f -2.104569  -0.494929  1.071804
   h  NaN  NaN  -1.039575
In [30]: a + b
Out[30]:
    one  three  two
   a  NaN  NaN  -0.565727
   c  NaN  NaN   2.424224
   e  0.238417  NaN  -2.088472
   f -4.209138  NaN   -0.989859
   h  NaN  NaN  -1.413542
```

The descriptive statistics and computational methods discussed in the \textit{data structure overview} (and listed \texttt{here} and \texttt{here})
are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```
In [31]: df
Out[31]:
   one  two  three
a  NaN  -0.282863  -1.509059
b  NaN   1.212112   -0.173215
c  0.119209  -1.844236   -0.861849
d -2.104569   -0.494929    1.071804
e  NaN    -0.706771   -1.039575
f  NaN   -1.9853605075978744
```

```
In [32]: df["one"].sum()
Out[32]:
-1.9853605075978744
```

```
In [33]: df.mean(1)
Out[33]:
   a   -0.895961
   c    0.519449
   e   -0.595625
   f   -0.509232
   h  -0.873173
   dtype: float64
```

```
In [34]: df.cumsum()
Out[34]:
   one  two  three
a  NaN  -0.282863  -1.509059
b  NaN   0.929249   -1.682273
c  0.119209  -0.114987  -2.544122
d -1.985361    -0.609917  -1.472318
e  NaN    -1.316688  -2.511893
```

```
In [35]: df.cumsum(skipna=False)
Out[35]:
   one  two  three
a  NaN  -0.282863  -1.509059
b  NaN   0.929249  -1.682273
c  NaN  -0.114987  -2.544122
d  NaN  -0.609917  -1.472318
e  NaN  -1.316688  -2.511893
```

2.10. Working with missing data
2.10.4 Sum/prod of empties/nans

**Warning:** This behavior is now standard as of v0.22.0 and is consistent with the default in numpy; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See v0.22.0 whatsnw for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```python
In [36]: pd.Series([np.nan]).sum()
Out[36]: 0.0

In [37]: pd.Series([], dtype="float64").sum()
Out[37]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```python
In [38]: pd.Series([np.nan]).prod()
Out[38]: 1.0

In [39]: pd.Series([], dtype="float64").prod()
Out[39]: 1.0
```

2.10.5 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```python
In [40]: df
Out[40]:
       one   two    three
a   NaN  -0.282863 -1.509059
c   NaN   1.212112  -0.173215
e   0.119209  -0.844236  -0.861849
f  -2.104569  -0.494929   1.071804
h   NaN   -0.706771  -1.039575

In [41]: df.groupby("one").mean()
Out[41]:
        two     three
one
-2.104569 -0.494929   1.071804
  0.119209  -0.844236  -0.861849
```

See the groupby section [here](#) for more information.
Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

2.10.6 Filling missing values: fillna

fillna() can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

Replace NA with a scalar value

```python
In [42]: df2
Out[42]:
   one   two  three  four   five         timestamp
  a  NaN -0.282863 -1.509059  bar  True       NaT
  c  NaN   1.212112  -0.173215  bar  False       NaT
  e  0.119209 -1.044236  -0.861849  bar  True 2012-01-01
  f -2.104569  -0.494929   1.071804  bar  False 2012-01-01
  h  NaN  -0.706771 -1.039575  bar  True       NaT

In [43]: df2.fillna(0)
Out[43]:
   one   two  three  four   five         timestamp
  a   0.0 -0.282863 -1.509059  bar  True        0
  c  NaN   1.212112  -0.173215  bar  False        0
  e  0.119209 -1.044236  -0.861849  bar  True 2012-01-01 00:00:00
  f -2.104569  -0.494929   1.071804  bar  False 2012-01-01 00:00:00
  h  NaN  -0.706771 -1.039575  bar  True        0

In [44]: df2["one"].fillna("missing")
Out[44]:
   a  missing
   c  missing
   e  missing
   f -2.104569
   h  missing

Name: one, dtype: object
```

Fill gaps forward or backward

Using the same filling arguments as reindexing, we can propagate non-NA values forward or backward:

```python
In [45]: df
Out[45]:
   one   two  three
  a  NaN -0.282863 -1.509059
  c  NaN  1.212112  -0.173215
  e  0.119209 -1.044236  -0.861849
  f -2.104569  -0.494929   1.071804
  h  NaN  -0.706771 -1.039575

In [46]: df.fillna(method="pad")
Out[46]:
   one   two  three
  a  NaN -0.282863 -1.509059
```

(continues on next page)
Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the `limit` keyword:

```
In [47]: df
Out[47]:
   one    two    three
a  NaN   -0.282863 -1.509059
c  NaN   1.212112 -0.173215
e  NaN     NaN      NaN
f  NaN     NaN      NaN
h  NaN  -0.706771 -1.039575
```

```
In [48]: df.fillna(method="pad", limit=1)
Out[48]:
   one    two    three
a  NaN   -0.282863 -1.509059
c  NaN   1.212112 -0.173215
e  NaN  1.212112 -0.173215
f  NaN     NaN      NaN
h  NaN  -0.706771 -1.039575
```

To remind you, these are the available filling methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
</tbody>
</table>

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

### 2.10.7 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list("ABC"))
In [50]: dff.iloc[3:5, 0] = np.nan
In [51]: dff.iloc[4:6, 1] = np.nan
In [52]: dff.iloc[5:8, 2] = np.nan
In [53]: dff
(continues on next page)
In [53]:

       A        B         C

8 -0.968914 -1.294524   0.413738
9  0.276662  -0.472035  -0.013960

In [54]:

dff.fillna(dff.mean())

Out[54]:

       A        B         C
0   0.271860 -0.424972   0.567020
1   0.276232 -1.087401  -0.673690
2   0.113648 -1.478427   0.524988
3  -0.140857  0.577046  -1.715002
4  -0.140857  -0.401419  -0.293543
5  -1.344312  -0.401419  -0.293543
6 -0.109050  1.643563   0.413738
7   0.357021  -0.674600   NaN
8 -0.968914 -1.294524  -0.293543
9  0.276662  -0.472035  -0.013960

In [55]:

dff.fillna(dff.mean()[:"B":"C"])

Out[55]:

       A        B         C
0   0.271860 -0.424972   0.567020
1   0.276232 -1.087401  -0.673690
2   0.113648 -1.478427   0.524988
3  -0.140857  0.577046  -1.715002
4  -0.140857  -0.401419  -0.293543
5  -1.344312  -0.401419  -0.293543
6 -0.109050  1.643563   0.413738
7   0.357021  -0.674600   NaN
8 -0.968914 -1.294524  -0.293543
9  0.276662  -0.472035  -0.013960

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

In [56]:

dff.where(pd.notna(dff), dff.mean(), axis="columns")

Out[56]:

       A        B         C
0   0.271860 -0.424972   0.567020
1   0.276232 -1.087401  -0.673690
2   0.113648 -1.478427   0.524988
3     NaN         0.577046 -1.715002

5  -1.344312  -0.401419  -0.293543
6 -0.109050  1.643563   0.413738
7   0.357021  -0.674600   NaN
8 -0.968914 -1.294524  -0.293543
9  0.276662  -0.472035  -0.013960

(continues on next page)
2.10.8 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```
In [57]: df
Out[57]:
     one      two      three
   a  NaN  -0.282863 -1.509059
   b  NaN       NaN       NaN
   c  NaN  1.212112  -0.173215
   d  NaN  0.000000   0.000000
   e  NaN  0.000000   0.000000
   f  NaN  0.000000   0.000000
   g  NaN  0.000000   0.000000
   h  NaN -0.706771  -1.039575
```

```
In [58]: df.dropna(axis=0)
Out[58]:
Empty DataFrame
Columns: [one, two, three]
Index: []
```

```
In [59]: df.dropna(axis=1)
Out[59]:
         two      three
   a -0.282863 -1.509059
   c  1.212112  -0.173215
   e  0.000000   0.000000
   f  0.000000   0.000000
   h -0.706771  -1.039575
```

```
In [60]: df["one"].dropna()
Out[60]: Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. DataFrame.dropna has considerably more options than Series.dropna, which can be examined in the API.

2.10.9 Interpolation

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.

```
In [61]: ts
Out[61]:
2000-01-31  0.469112
2000-02-29  NaN
data       2000-03-31  NaN
          2000-04-28  NaN
```

(continues on next page)
2000-05-31 NaN
2007-12-31 -6.950267
2008-01-31 -7.904475
2008-02-29 -6.441779
2008-03-31 -8.184940
2008-04-30 -9.011531
Freq: BM, Length: 100, dtype: float64

In [62]: ts.count()
Out[62]: 66

In [63]: ts.plot()
Out[63]: <AxesSubplot:>

In [64]: ts.interpolate()
Out[64]:
2000-01-31 0.469112
2000-02-29 0.434469
2000-03-31 0.399826
2000-04-28 0.365184
2000-05-31 0.330541

(continues on next page)
Index aware interpolation is available via the `method` keyword:

```
In [67]: ts2
Out[67]:
2000-01-31    0.469112
2000-02-29    NaN
2002-07-31    -5.785037
2005-01-31    NaN
```
In 
Out:

In [68]: ts2.interpolate()
Out [68]:

2000-01-31  0.469112
2000-02-29  0.270241
2002-07-31  -5.785037
2005-01-31  -7.190866
2008-04-30  -9.011531

dtype: float64

In [69]: ts2.interpolate(method="time")
Out [69]:

2000-01-31  0.469112
2000-02-29  0.270241
2002-07-31  -5.785037
2005-01-31  -7.190866
2008-04-30  -9.011531

dtype: float64

For a floating-point index, use method='values':

In [70]: ser
Out [70]:

0.0  0.0
1.0  NaN
10.0 10.0

dtype: float64

In [71]: ser.interpolate()
Out [71]:

0.0  0.0
1.0  5.0
10.0 10.0

dtype: float64

In [72]: ser.interpolate(method="values")
Out [72]:

0.0  0.0
1.0  1.0
10.0 10.0

dtype: float64

You can also interpolate with a DataFrame:

In [73]: df = pd.DataFrame(
       .....:    
       .....:        "A": [1, 2.1, np.nan, 4.7, 5.6, 6.8],
       .....:        "B": [0.25, np.nan, np.nan, 4, 12.2, 14.4],
       .....:    }
       .....: )

2.10. Working with missing data
The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the name of a 1-d interpolation routine to `method`. You'll want to consult the full scipy interpolation documentation and reference [guide](#) for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

**Warning:** These methods require `scipy`.
When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```python
In [79]: df.interpolate(method="spline", order=2)
Out[79]:
   A     B
0  1.000000  0.250000
1  2.100000 -0.428598
2  3.404545  1.206900
3  4.700000  4.000000
4  5.600000  12.200000
5  6.800000  14.400000
```

```python
In [80]: df.interpolate(method="polynomial", order=2)
Out[80]:
   A     B
0  1.000000  0.250000
1  2.100000 -2.703846
2  3.451351 -1.453846
3  4.700000  4.000000
4  5.600000  12.200000
5  6.800000  14.400000
```

Compare several methods:

```python
In [81]: np.random.seed(2)
In [82]: ser = pd.Series(np.arange(1, 10.1, 0.25) ** 2 + np.random.randn(37))
In [83]: missing = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])
In [84]: ser[missing] = np.nan
In [85]: methods = ["linear", "quadratic", "cubic"]
In [86]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
In [87]: df.plot()
Out[87]: <AxesSubplot:>
```

2.10. Working with missing data
Another use case is interpolation at new values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```python
In [88]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [89]: new_index = ser.index.union(pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75]))

In [90]: interp_s = ser.reindex(new_index).interpolate(method="pchip")

In [91]: interp_s[49:51]
Out[91]:
   49.00    0.471410
   49.25    0.476841
   49.50    0.481780
   49.75    0.485998
   50.00    0.489266
   50.25    0.491814
   50.50    0.493995
   50.75    0.495763
   51.00    0.497074

   dtype: float64
```
Interpolation limits

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```
In [92]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])

In [93]: ser
Out[93]:
0   NaN
1   NaN
2    5.0
3   NaN
4   NaN
5   NaN
6   13.0
7   NaN
8   NaN
dtype: float64

# fill all consecutive values in a forward direction
In [94]: ser.interpolate()
Out[94]:
0   NaN
1   NaN
2    5.0
3    7.0
4    9.0
5   11.0
6   13.0
7   13.0
8   13.0
dtype: float64

# fill one consecutive value in a forward direction
In [95]: ser.interpolate(limit=1)
Out[95]:
0   NaN
1   NaN
2    5.0
3    7.0
4   NaN
5   NaN
6   13.0
7   13.0
8   NaN
dtype: float64
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

```
# fill one consecutive value backwards
In [96]: ser.interpolate(limit=1, limit_direction="backward")
Out[96]:
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.4

0    NaN
1     5.0
2     5.0
3    NaN
4    NaN
5    11.0
6    13.0
7    NaN
8    NaN
dtype: float64

# fill one consecutive value in both directions
In [97]: ser.interpolate(limit=1, limit_direction="both")
Out[97]:
0    NaN
1     5.0
2     5.0
3     7.0
4    NaN
5    11.0
6    13.0
7    13.0
8    NaN
dtype: float64

# fill all consecutive values in both directions
In [98]: ser.interpolate(limit_direction="both")
Out[98]:
0     5.0
1     5.0
2     5.0
3     7.0
4     9.0
5    11.0
6    13.0
7    13.0
8    13.0
dtype: float64

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. The limit_area parameter restricts filling to either inside or outside values.

# fill one consecutive inside value in both directions
In [99]: ser.interpolate(limit_direction="both", limit_area="inside", limit=1)
Out[99]:
0    NaN
1    NaN
2     5.0
3     7.0
4    NaN
5    11.0
6    13.0
7    13.0
8    13.0
(continues on next page)
# fill all consecutive outside values backward
In [100]: ser.interpolate(limit_direction="backward", limit_area="outside")
Out[100]:
0  5.0
1  5.0
2  5.0
3  NaN
4  NaN
5  NaN
6  13.0
7  NaN
8  NaN
dtype: float64

# fill all consecutive outside values in both directions
In [101]: ser.interpolate(limit_direction="both", limit_area="outside")
Out[101]:
0  5.0
1  5.0
2  5.0
3  NaN
4  NaN
5  NaN
6  13.0
7  13.0
8  13.0
dtype: float64

## 2.10.10 Replacing generic values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

In [102]: ser = pd.Series([0.0, 1.0, 2.0, 3.0, 4.0])

In [103]: ser.replace(0, 5)
Out[103]:
0  5.0
1  1.0
2  2.0
3  3.0
4  4.0
dtype: float64

You can replace a list of values by a list of other values:
In [104]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])
Out[104]:
0  4.0
1  3.0
2  2.0
3  1.0
4  0.0
dtype: float64

You can also specify a mapping dict:

In [105]: ser.replace({0: 10, 1: 100})
Out[105]:
0   10.0
1  100.0
2   2.0
3   3.0
4   4.0
dtype: float64

For a DataFrame, you can specify individual values by column:

In [106]: df = pd.DataFrame({"a": [0, 1, 2, 3, 4], "b": [5, 6, 7, 8, 9]})
In [107]: df.replace({"a": 0, "b": 5}, 100)
Out[107]:
a  b
0  100  100
1   1   6
2   2   7
3   3   8
4   4   9

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

In [108]: ser.replace([1, 2, 3], method="pad")
Out[108]:
0   0.0
1   0.0
2   0.0
3   0.0
4   4.0
dtype: float64
2.10.11 String/regular expression replacement

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\' == '```. You should read about them if this is unclear.

Replace the `.` with `NaN` (str -> str):

```
In [109]: d = {"a": list(range(4)), "b": list("ab.."), "c": ["a", "b", np.nan, "d"]}
In [110]: df = pd.DataFrame(d)
In [111]: df.replace( ".", np.nan)
```

```
Out[111]:
   a   b   c
0  0   a   a
1  1   b   b
2  NaN NaN
3  NaN  d
```

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```
In [112]: df.replace(r"\s*\..\s*", np.nan, regex=True)
```

```
Out[112]:
   a   b   c
0  0   a   a
1  1   b   b
2  NaN NaN
3  NaN  d
```

Replace a few different values (list -> list):

```
In [113]: df.replace(["a", "."], ["b", np.nan])
```

```
Out[113]:
   a   b   c
0  0   b   b
1  1   b   b
2  NaN NaN
3  NaN  d
```

List of regex -> list of regex:

```
In [114]: df.replace([r"\..", r"(a)"], ["dot", r"\1stuff"], regex=True)
```

```
Out[114]:
   a   b   c
0  0   stuff stuff
1  1   b   b
2  dot NaN
3  dot  d
```

Only search in column 'b' (dict -> dict):

```
```
In [115]: df.replace({"b": "."}, {"b": np.nan})
Out[115]:
   a  b  c
0  0  a  a
1  1  b  b
2  Na\N  Na\N
3  Na\N  d

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

In [116]: df.replace({"b": r"\s*\.\s*"}, {"b": np.nan}, regex=True)
Out[116]:
   a  b  c
0  0  a  a
1  1  b  b
2  Na\N  Na\N
3  Na\N  d

You can pass nested dictionaries of regular expressions that use regex=True:

In [117]: df.replace({"b": {"b": r""}}, regex=True)
Out[117]:
   a  b  c
0  0  a  a
1  1  b  b
2  .  Na\N
3  .  d

Alternatively, you can pass the nested dictionary like so:

In [118]: df.replace(regex={"b": {r"\s*\.\s*": np.nan}})
Out[118]:
   a  b  c
0  0  a  a
1  1  b  b
2  2  .  Na\N
3  3  .  d

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

In [119]: df.replace({"b": r"\s*(\.\s*)\s*"}, {"b": r"\1ty"}, regex=True)
Out[119]:
   a  b  c
0  0  a  a
1  1  b  b
2  2  .ty  Na\N
3  3  .ty  d

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

In [120]: df.replace([r"\s*\.\s*", r"a|b"], np.nan, regex=True)
Out[120]:

(continues on next page)
All of the regular expression examples can also be passed with the \texttt{to_replace} argument as the \texttt{regex} argument. In this case the value argument must be passed explicitly by name or \texttt{regex} must be a nested dictionary. The previous example, in this case, would then be:

\begin{verbatim}
In [121]: df.replace(regex=[r"s*\s*", r"a|b"], value=np.nan)
Out[121]:
a  b  c
0  NaN NaN
1  NaN NaN
2  NaN NaN
3  NaN  d
\end{verbatim}

This can be convenient if you do not want to pass \texttt{regex=True} every time you want to use a regular expression.

\textbf{Note:} Anywhere in the above \texttt{replace} examples that you see a regular expression a compiled regular expression is valid as well.

### 2.10.12 Numeric replacement

\texttt{replace()} is similar to \texttt{fillna()}.

\begin{verbatim}
In [122]: df = pd.DataFrame(np.random.randn(10, 2))
In [123]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
In [124]: df.replace(1.5, np.nan)
Out[124]:
          a    b
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4        NaN  NaN
5        NaN  NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9        NaN  NaN
\end{verbatim}

Replacing more than one value is possible by passing a list.

\begin{verbatim}
In [125]: df00 = df.iloc[0, 0]
In [126]: df.replace([1.5, df00], [np.nan, "a"])
\end{verbatim}
Out[126]:

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>-1.021415</td>
</tr>
<tr>
<td>1</td>
<td>0.432396</td>
<td>-0.32358</td>
</tr>
<tr>
<td>2</td>
<td>0.423825</td>
<td>0.79918</td>
</tr>
<tr>
<td>3</td>
<td>1.262614</td>
<td>0.751965</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>5</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>6</td>
<td>-0.498174</td>
<td>-1.060799</td>
</tr>
<tr>
<td>7</td>
<td>0.591667</td>
<td>-0.183257</td>
</tr>
<tr>
<td>8</td>
<td>1.019855</td>
<td>-1.482465</td>
</tr>
<tr>
<td>9</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

In [127]: df[1].dtype
Out[127]: dtype('float64')

You can also operate on the DataFrame in place:

In [128]: df.replace(1.5, np.nan, inplace=True)

### Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

<table>
<thead>
<tr>
<th>data type</th>
<th>Cast to</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>float</td>
</tr>
<tr>
<td>boolean</td>
<td>object</td>
</tr>
<tr>
<td>float</td>
<td>no cast</td>
</tr>
<tr>
<td>object</td>
<td>no cast</td>
</tr>
</tbody>
</table>

For example:

In [129]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [130]: s > 0
Out[130]:

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>6</td>
</tr>
<tr>
<td>7</td>
</tr>
</tbody>
</table>

dtype: bool

In [131]: (s > 0).dtype
Out[131]: dtype('bool')

In [132]: crit = (s > 0).reindex(list(range(8)))
Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```python
In [135]: reindexed = s.reindex(list(range(8))).fillna(0)

In [136]: reindexed[crit]
---------------------------------------------------------------------------
ValueError Traceback (most recent call last)
<ipython-input-136-0dac417a4890> in <module>
----> 1 reindexed[crit]

/pandas/pandas/core/series.py in __getitem__(self, key)
   959     key = self._check_indexer(key)
   960     if com.is_bool_indexer(key):
-> 961         key = check_bool_indexer(key)
   962     key = np.asarray(key, dtype=bool)
   963
/pandas/pandas/core/common.py in is_bool_indexer(key)
   137       # Don't raise on e.g. ["A", "B", np.nan], see
   138       # test_loc_getitem_list_of_labels_categoricalindex_with_na
--> 139       raise ValueError(na_msg)
   140       return False
   141     return True

ValueError: Cannot mask with non-boolean array containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

```python
In [137]: reindexed[crit.fillna(False)]
Out[137]:
   0   0.126504
   2   0.696198
   4   0.697416
   6   0.601516
   7   0.003659
```

2.10. Working with missing data
pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital ‘I’ in the dtype="Int64".

```
In [139]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")
```

```
In [140]: s
Out[140]:
0   0
1   1
2  <NA>
3   3
4   4
dtype: Int64
```

See Nullable integer data type for more.

### 2.10.13 Experimental NA scalar to denote missing values

**Warning:** Experimental: the behaviour of `pd.NA` can still change without warning.

New in version 1.0.0.

Starting from pandas 1.0, an experimental `pd.NA` value (singleton) is available to represent scalar missing values. At this moment, it is used in the nullable integer, boolean and dedicated string data types as the missing value indicator.

The goal of `pd.NA` is provide a “missing” indicator that can be used consistently across data types (instead of np.nan, None or pd.NaT depending on the data type).

For example, when having missing values in a Series with the nullable integer dtype, it will use `pd.NA`:

```
In [141]: s = pd.Series([1, 2, None], dtype="Int64")
```

```
In [142]: s
Out[142]:
0   1
1   2
2  <NA>
```

(continues on next page)
Currently, pandas does not yet use those data types by default (when creating a DataFrame or Series, or when reading in data), so you need to specify the dtype explicitly. An easy way to convert to those dtypes is explained here.

### Propagation in arithmetic and comparison operations

In general, missing values propagate in operations involving pd.NA. When one of the operands is unknown, the outcome of the operation is also unknown.

For example, pd.NA propagates in arithmetic operations, similarly to np.nan:

```python
In [145]: pd.NA + 1
Out[145]: <NA>
```

```
In [146]: "a" * pd.NA
Out[146]: <NA>
```

There are a few special cases when the result is known, even when one of the operands is NA.

```python
In [147]: pd.NA ** 0
Out[147]: 1
```

```
In [148]: 1 ** pd.NA
Out[148]: 1
```

In equality and comparison operations, pd.NA also propagates. This deviates from the behaviour of np.nan, where comparisons with np.nan always return False.

```python
In [149]: pd.NA == 1
Out[149]: <NA>
```

```
In [150]: pd.NA == pd.NA
Out[150]: <NA>
```

```
In [151]: pd.NA < 2.5
Out[151]: <NA>
```

To check if a value is equal to pd.NA, the `isna()` function can be used:

```python
In [152]: pd.isna(pd.NA)
Out[152]: True
```

An exception on this basic propagation rule are reductions (such as the mean or the minimum), where pandas defaults to skipping missing values. See above for more.

### 2.10. Working with missing data
Logical operations

For logical operations, `pd.NA` follows the rules of the three-valued logic (or Kleene logic, similarly to R, SQL and Julia). This logic means to only propagate missing values when it is logically required.

For example, for the logical “or” operation (`|`), if one of the operands is `True`, we already know the result will be `True`, regardless of the other value (so regardless the missing value would be `True` or `False`). In this case, `pd.NA` does not propagate:

```
In [153]: True | False
Out[153]: True

In [154]: True | pd.NA
Out[154]: True

In [155]: pd.NA | True
Out[155]: True
```

On the other hand, if one of the operands is `False`, the result depends on the value of the other operand. Therefore, in this case `pd.NA` propagates:

```
In [156]: False | True
Out[156]: True

In [157]: False | False
Out[157]: False

In [158]: False | pd.NA
Out[158]: <NA>
```

The behaviour of the logical “and” operation (`&`) can be derived using similar logic (where now `pd.NA` will not propagate if one of the operands is already `False`):

```
In [159]: False & True
Out[159]: False

In [160]: False & False
Out[160]: False

In [161]: False & pd.NA
Out[161]: False

In [162]: True & True
Out[162]: True

In [163]: True & False
Out[163]: False

In [164]: True & pd.NA
Out[164]: <NA>
```
**NA in a boolean context**

Since the actual value of an NA is unknown, it is ambiguous to convert NA to a boolean value. The following raises an error:

```python
In [165]: bool(pd.NA)
---------------------------------------------------------------------------
TypeError                                 Traceback (most recent call last)
<ipython-input-165-5477a57d5abb> in <module>
----> 1 bool(pd.NA)
/pandas/pandas/_libs/missing.pyx in pandas._libs.missing.NAType.__bool__()

TypeError: boolean value of NA is ambiguous
```

This also means that `pd.NA` cannot be used in a context where it is evaluated to a boolean, such as `if condition:`. ... where `condition` can potentially be `pd.NA`. In such cases, `isna()` can be used to check for `pd.NA` or `condition` being `pd.NA` can be avoided, for example by filling missing values beforehand.

A similar situation occurs when using Series or DataFrame objects in `if` statements, see *Using if/truth statements with pandas*.

**NumPy ufuncs**

`pandas.NA` implements NumPy's `__array_ufunc__` protocol. Most ufuncs work with `NA`, and generally return `NA`:

```python
In [166]: np.log(pd.NA)
Out[166]: <NA>

In [167]: np.add(pd.NA, 1)
Out[167]: <NA>
```

**Warning:** Currently, ufuncs involving an ndarray and `NA` will return an object-dtype filled with `NA` values.

```python
In [168]: a = np.array([1, 2, 3])

In [169]: np.greater(a, pd.NA)
Out[169]: array([<NA>, <NA>, <NA>], dtype=object)
```

The return type here may change to return a different array type in the future.

See *DataFrame interoperability with NumPy functions* for more on ufuncs.
Conversion

If you have a DataFrame or Series using traditional types that have missing data represented using `np.nan`, there are convenience methods `convert_dtypes()` in Series and `convert_dtypes()` in DataFrame that can convert data to use the newer dtypes for integers, strings and booleans listed here. This is especially helpful after reading in data sets when letting the readers such as `read_csv()` and `read_excel()` infer default dtypes.

In this example, while the dtypes of all columns are changed, we show the results for the first 10 columns.

```
In [170]: bb = pd.read_csv("data/baseball.csv", index_col="id")

In [171]: bb[bb.columns[:10]].dtypes
Out[171]:
player  object
year    int64
stint   int64
team    object
lg      object
g       int64
ab      int64
r       int64
h       int64
X2b     int64
dtype: object

In [172]: bbn = bb.convert_dtypes()

In [173]: bbn[bbn.columns[:10]].dtypes
Out[173]:
player  string
year    Int64
stint   Int64
team    string
lg      string
g       Int64
ab      Int64
r       Int64
h       Int64
X2b     Int64
dtype: object
```

2.11 Duplicate Labels

Index objects are not required to be unique; you can have duplicate row or column labels. This may be a bit confusing at first. If you’re familiar with SQL, you know that row labels are similar to a primary key on a table, and you would never want duplicates in a SQL table. But one of pandas’ roles is to clean messy, real-world data before it goes to some downstream system. And real-world data has duplicates, even in fields that are supposed to be unique.

This section describes how duplicate labels change the behavior of certain operations, and how prevent duplicates from arising during operations, or to detect them if they do.
2.11.1 Consequences of Duplicate Labels

Some pandas methods (Series.reindex() for example) just don’t work with duplicates present. The output can’t be determined, and so pandas raises.

```python
In [3]: s1 = pd.Series([0, 1, 2], index=['a', 'b', 'b'])
In [4]: s1.reindex(['a', 'b', 'c'])
ValueError: Traceback (most recent call last)
<ipython-input-4-18a38f6978fe> in <module>
----> 1 s1.reindex(['a', 'b', 'c'])
/pandas/pandas/core/series.py in reindex(self, index, **kwargs)
   4578     def reindex(self, index=None, **kwargs):
   4579         return super().reindex(index=index, **kwargs)
   4580     @deprecate_nonkeyword_arguments(version=None, allowed_args=['self', 'labels', ...])
/pandas/pandas/core/generic.py in reindex(self, *args, **kwargs)
   4816     # perform the reindex on the axes
   4817     axes, level, limit, tolerance, method, fill_value, copy
   4818     return self._reindex_axes(axes, level, limit, tolerance, method, fill_value, copy)
/pandas/pandas/core/generic.py in _reindex_axes(self, axes, level, limit, tolerance, method, fill_value, copy)
   4837     axis = self._get_axis_number(a)
   4838     obj = obj._reindex_with_indexers({axis: [new_index, indexer]}, axis, fill_value=fill_value,)
   4840     fill_value=fill_value,
/pandas/pandas/core/generic.py in _reindex_with_indexers(self, reindexers, fill_value, copy)
   4881     new_data = new_data.reindex_indexer(index, indexer, axis, fill_value, allow_dups, copy, consolidate, only_slice)
```

(continues on next page)

2.11. Duplicate Labels
Other methods, like indexing, can give very surprising results. Typically indexing with a scalar will reduce dimensionality. Slicing a DataFrame with a scalar will return a Series. Slicing a Series with a scalar will return a scalar. But with duplicates, this isn’t the case.

![Code snippets]

We have duplicates in the columns. If we slice 'B', we get back a Series

- If we slice 'A', we get back a DataFrame.

This applies to row labels as well

(continues on next page)
In [11]: df2.loc["b", "A"]  # a scalar
Out[11]: 2

In [12]: df2.loc["a", "A"]  # a Series
Out[12]:
a  0
a  1
Name: A, dtype: int64

### 2.11.2 Duplicate Label Detection

You can check whether an Index (storing the row or column labels) is unique with `Index.is_unique`:

In [13]: df2
Out[13]:
   A
  a  0
  a  1
  b  2

In [14]: df2.index.is_unique
Out[14]: False

In [15]: df2.columns.is_unique
Out[15]: True

**Note:** Checking whether an index is unique is somewhat expensive for large datasets. pandas does cache this result, so re-checking on the same index is very fast.

`Index.duplicated()` will return a boolean ndarray indicating whether a label is repeated.

In [16]: df2.index.duplicated()
Out[16]: array([False, True, False])

Which can be used as a boolean filter to drop duplicate rows.

In [17]: df2.loc[~df2.index.duplicated(), :]
Out[17]:
   A
  a  0
  b  2

If you need additional logic to handle duplicate labels, rather than just dropping the repeats, using `groupby()` on the index is a common trick. For example, we’ll resolve duplicates by taking the average of all rows with the same label.

In [18]: df2.groupby(level=0).mean()
Out[18]:
   A
  a  0.5
  b  2.0
2.11.3 Disallowing Duplicate Labels

New in version 1.2.0.

As noted above, handling duplicates is an important feature when reading in raw data. That said, you may want to avoid introducing duplicates as part of a data processing pipeline (from methods like `pandas.concat()`, `rename()`, etc.). Both Series and DataFrame disallow duplicate labels by calling `.set_flags(allows_duplicate_labels=False)`. (the default is to allow them). If there are duplicate labels, an exception will be raised.

```
In [19]: pd.Series([0, 1, 2], index=['a', 'b', 'b']).set_flags(allows_duplicate_labels=False)
```

```
DuplicateLabelError Traceback (most recent call last)
<ipython-input-19-11af4ee9738e> in <module>
----> 1 pd.Series([0, 1, 2], index=['a', 'b', 'b']).set_flags(allows_duplicate_labels=False)

/pandas/pandas/core/generic.py in set_flags(self, copy, allows_duplicate_labels)
    432         df = self.copy(deep=copy)
    433         if allows_duplicate_labels is not None:
--> 434             df.flags['allows_duplicate_labels'] = allows_duplicate_labels
    435         return df
    436

/pandas/pandas/core/flags.py in __setitem__(self, key, value)
    103             raise ValueError(f"Unknown flag {key}. Must be one of {self._keys}")
--> 105             setattr(self, key, value)
    106     107     def __repr__(self):

/pandas/pandas/core/flags.py in allows_duplicate_labels(self, value)
    90             self._allows_duplicate_labels = value
    91     92             for ax in obj.axes:
--> 93                 ax._maybe_check_unique()
    94

/pandas/pandas/core/indexes/base.py in _maybe_check_unique(self)
    649             msg += f"\n{duplicates}"
    650
--> 651             raise DuplicateLabelError(msg)
    652     653 @final

DuplicateLabelError: Index has duplicates.
```

This applies to both row and column labels for a DataFrame.

```
In [20]: pd.DataFrame([[0, 1, 2], [3, 4, 5]], columns=['A', 'B', 'C']).set_flags(
```

allows_duplicate_labels=False

In [21]: df = pd.DataFrame({"A": [0, 1, 2, 3]}, index=["x", "y", "X", "Y"]).set_flags(
   allows_duplicate_labels=False
   
   
In [22]: df
Out[22]:
   A
  x  0
  y  1
  X  2
  Y  3

In [23]: df.flags.allows_duplicate_labels
Out[23]: False

DataFrame.set_flags() can be used to return a new DataFrame with attributes like allows_duplicate_labels set to some value.

In [24]: df2 = df.set_flags(allows_duplicate_labels=True)
In [25]: df2.flags.allows_duplicate_labels
Out[25]: True

The new DataFrame returned is a view on the same data as the old DataFrame. Or the property can just be set directly on the same object.

In [26]: df2.flags.allows_duplicate_labels = False
In [27]: df2.flags.allows_duplicate_labels
Out[27]: False

When processing raw, messy data you might initially read in the messy data (which potentially has duplicate labels), deduplicate, and then disallow duplicates going forward, to ensure that your data pipeline doesn’t introduce duplicates.

```python
>>> raw = pd.read_csv("...")
>>> deduplicated = raw.groupby(level=0).first()  # remove duplicates
>>> deduplicated.flags.allows_duplicate_labels = False  # disallow going forward
```

Setting allows_duplicate_labels=True on a Series or DataFrame with duplicate labels or performing an operation that introduces duplicate labels on a Series or DataFrame that disallows duplicates will raise an errors. DuplicateLabelError.

2.11. Duplicate Labels 633

    653     @final

DuplicateLabelError: Index has duplicates.
                positions

(continues on next page)
This error message contains the labels that are duplicated, and the numeric positions of all the duplicates (including the “original”) in the Series or DataFrame

**Duplicate Label Propagation**

In general, disallowing duplicates is “sticky”. It’s preserved through operations.

```python
In [29]: s1 = pd.Series(0, index=["a", "b"]).set_flags(allows_duplicate_labels=False)
```

```python
In [30]: s1
Out[30]:
    a 0
    b 0
Name: 0, dtype: int64
```

```python
In [31]: s1.head().rename({"a": "b"})
```

```
---------------------------------------------------------------------------
DuplicateLabelError Traceback (most recent call last)
   <ipython-input-31-8f09bda3af1a> in
     1 s1.head().rename({"a": "b"})
```

```
/pandas/pandas/core/series.py in rename(self, index, axis, copy, inplace, level, errors)
   4576         if callable(index) or is_dict_like(index):
   4577             return super().rename(
->   4578                 index, copy=copy, inplace=inplace, level=level, errors=errors
   4579             )
   4580         # For subclasses using _metadata.
```

```
pandas/pandas/core/generic.py in rename(self, mapper, index, columns, axis, copy, inplace, level, errors)
   1162     return None
   1163 else:
->   1164     return result.__finalize__(self, method="rename")
   1165
   1166 @rewrite_axis_style_signature("mapper", [("copy", True), ("inplace", False)])
```

```
pandas/pandas/core/generic.py in __finalize__(self, other, method, **kwargs)
    5457     self.attrs[name] = other.attrs[name]
    5458->   5459     self.flags.allows_duplicate_labels = other.flags.allows_duplicate_labels
    5460     # For subclasses using _metadata.
    5461     for name in set(self._metadata) & set(other._metadata):
```

```
pandas/pandas/core/flags.py in allows_duplicate_labels(self, value)
    90         if not value:
    91     for ax in obj.axes:
```

(continues on next page)
Warning: This is an experimental feature. Currently, many methods fail to propagate the allows_duplicate_labels value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate allows_duplicate_labels.

2.12 Categorical data

This is an introduction to pandas categorical data type, including a short comparison with R’s factor.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (categories; levels in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, …) are not possible.

All values of categorical data are either in categories or np.nan. Order is defined by the order of categories, not lexical order of the values. Internally, the data structure consists of a categories array and an integer array of codes which point to the real value in the categories array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see here.

- The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see here.

- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the API docs on categoricals.
2.12.1 Object creation

Series creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying dtype="category" when constructing a Series:

```
In [1]: s = pd.Series(['a', 'b', 'c', 'a'], dtype='category')
In [2]: s
Out[2]:
     0 a
     1 b
     2 c
     3 a
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

By converting an existing Series or column to a category dtype:

```
In [3]: df = pd.DataFrame({'A': ['a', 'b', 'c', 'a']})
In [4]: df['B'] = df['A'].astype('category')
In [5]: df
Out[5]:
   A  B
  0 a  a
  1 b  b
  2 c  c
  3 a  a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the example on tiling in the docs.

```
In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})
In [7]: labels = ['{} - {}'.format(i, i + 9) for i in range(0, 100, 10)]
In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)
In [9]: df.head(10)
Out[9]:
   value  group
  0  65  60 - 69
  1  49  40 - 49
  2  56  50 - 59
  3  43  40 - 49
  4  43  40 - 49
  5  91  90 - 99
  6  32  30 - 39
  7  87  80 - 89
  8  36  30 - 39
  9   8   0 - 9
```
By passing a `pandas.Categorical` object to a Series or assigning it to a DataFrame.

```python
In [10]: raw_cat = pd.Categorical(
   ....:     ["a", "b", "c", "a"], categories=["b", "c", "d"], ordered=False
   ....: )
   ....:
In [11]: s = pd.Series(raw_cat)
   ...
In [12]: s
Out[12]:
0    NaN
1    b
2    c
3    NaN
dtype: category
Categories (3, object): [b', 'c', 'd']
In [13]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})

In [14]: df["B"] = raw_cat
   ...
In [15]: df
Out[15]:
   A  B
0  a  NaN
1  b  b
2  c  c
3  a  NaN
```

Categorical data has a specific category `dtype`:

```python
In [16]: df.dtypes
Out[16]:
A    object
B  category
dtype: object
```

**DataFrame creation**

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the DataFrame constructor:

```python
In [17]: df = pd.DataFrame({"A": list("abca"), "B": list("bccd"), dtypes="category")
   ...
In [18]: df.dtypes
Out[18]:
A  category
B  category
dtype: object
```
Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```python
In [19]: df['A']
Out[19]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [20]: df['B']
Out[20]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): ['b', 'c', 'd']
```

Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```python
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [22]: df_cat = df.astype('category')
In [23]: df_cat.dtypes
Out[23]:
A    category
B    category
dtype: object
```

This conversion is likewise done column by column:

```python
In [24]: df_cat['A']
Out[24]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [25]: df_cat['B']
Out[25]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): ['b', 'c', 'd']
```
Controlling behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing 'category', use an instance of `CategoricalDtype`.

```python
In [26]: from pandas.api.types import CategoricalDtype

In [27]: s = pd.Series(['a', 'b', 'c', 'a'])

In [28]: cat_type = CategoricalDtype(categories=['b', 'c', 'd'], ordered=True)

In [29]: s_cat = s.astype(cat_type)

In [30]: s_cat
Out[30]:
0   NaN
1     b
2     c
3   NaN
dtype: category
Categories (3, object): ['b' < 'c' < 'd']
```

Similarly, a `CategoricalDtype` can be used with a DataFrame to ensure that categories are consistent among all columns.

```python
In [31]: from pandas.api.types import CategoricalDtype

In [32]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd'))

In [33]: cat_type = CategoricalDtype(categories=list('abcd'), ordered=True)

In [34]: df_cat = df.astype(cat_type)

In [35]: df_cat['A']
Out[35]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']

In [36]: df_cat['B']
Out[36]:
0  b
1  c
2  c
3  d
Name: B, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']
```
Note: To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the categories parameter can be determined programmatically by:

categories = pd.unique(df.to_numpy().ravel()).

If you already have codes and categories, you can use the \texttt{from_codes()} constructor to save the factorize step during normal constructor mode:

In [37]: splitter = np.random.choice([0, 1], 5, p=[0.5, 0.5])
In [38]: s = pd.Series(pd.Categorical.from_codes(splitter, categories=["train", "test"]))

Regaining original data

To get back to the original Series or NumPy array, use \texttt{Series.astype(original
dtype)} or \texttt{np.asarray(categorical)}:

In [39]: s = pd.Series(["a", "b", "c", "a"])
In [40]: s
Out[40]:
0  a
1  b
2  c
3  a

dtype: object
In [41]: s2 = s.astype("category")
In [42]: s2
Out[42]:
0  a
1  b
2  c
3  a

dtype: category
Categories (3, object): ['a', 'b', 'c']
In [43]: s2.astype(str)
Out[43]:
0  a
1  b
2  c
3  a

dtype: object
In [44]: np.asarray(s2)
Out[44]: array(['a', 'b', 'c', 'a'], dtype=object)

Note: In contrast to R's \texttt{factor} function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.
Note: In contrast to R’s factor function, there is currently no way to assign/change labels at creation time. Use categories to change the categories after creation time.

### 2.12.2 CategoricalDtype

A categorical’s type is fully described by

1. **categories**: a sequence of unique values and no missing values
2. **ordered**: a boolean

This information can be stored in a CategoricalDtype. The categories argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the pandas.Categorical is created. The categories are assumed to be unordered by default.

```python
In [45]: from pandas.api.types import CategoricalDtype

In [46]: CategoricalDtype(['a', 'b', 'c'])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)

In [47]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=False)
```

A CategoricalDtype can be used in any place pandas expects a dtype. For example pandas.read_csv(), pandas.DataFrame.astype(), or in the Series constructor.

Note: As a convenience, you can use the string 'category' in place of a CategoricalDtype when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, dtype='category' is equivalent to dtype=CategoricalDtype().

#### Equality semantics

Two instances of CategoricalDtype compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```python
In [49]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)

# Equal, since order is not considered when ordered=False
In [50]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[50]: True

# Unequal, since the second CategoricalDtype is ordered
In [51]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[51]: False
```

All instances of CategoricalDtype compare equal to the string 'category'.
In [52]: c1 == "category"
Out[52]: True

Warning: Since dtype='category' is essentially CategoricalDtype(None, False), and since all instances
CategoricalDtype compare equal to 'category', all instances of CategoricalDtype compare equal to a
CategoricalDtype(None, False), regardless of categories or ordered.

2.12.3 Description

Using describe() on categorical data will produce similar output to a Series or DataFrame of type string.

In [53]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])
In [54]: df = pd.DataFrame({"cat": cat, "s": ["a", "c", "c", np.nan]})
In [55]: df.describe()
Out[55]:
   cat  s
  count 3  3
  unique 2  2
  top  c  c
  freq 2  2
In [56]: df["cat"].describe()
Out[56]:
   count 3
   unique 2
   top  c
   freq 2
Name: cat, dtype: object

2.12.4 Working with categories

Categorical data has a categories and a ordered property, which list their possible values and whether the ordering
matters or not. These properties are exposed as s.cat.categories and s.cat.ordered. If you don’t manually
specify categories and ordering, they are inferred from the passed arguments.

In [57]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [58]: s.cat.categories
Out[58]: Index(['a', 'b', 'c'], dtype='object')
In [59]: s.cat.ordered
Out[59]: False

It’s also possible to pass in the categories in a specific order:

In [60]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], categories=["c", "b", "a"}))

(continues on next page)
Note: New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered Categorical.

Note: The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```python
In [63]: s = pd.Series(list("babc"))
```

```python
In [64]: s
Out[64]:
0  b
1  a
2  b
3  c
dtype: category
Categories (4, object): ["a", "b", "c", "d"]
```

```python
# categories
In [65]: s.cat.categories
Out[65]: Index(['a', 'b', 'c', 'd'], dtype='object')
```

```python
# uniques
In [66]: s.unique()
Out[66]:
['b', 'a', 'c']
```

Categories (4, object): ["a", "b", "c", "d"]

### Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```python
In [67]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
```

```python
In [68]: s
Out[68]:
0  a
1  b
2  c
3  a
dtype: category
```
Categories (3, object): ['a', 'b', 'c']

In [69]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]

In [70]: s
Out[70]:
0  Group a
1  Group b
2  Group c
3  Group a

dtype: category
Categories (3, object): ['Group a', 'Group b', 'Group c']

In [71]: s = s.cat.rename_categories([1, 2, 3])

In [72]: s
Out[72]:
0  1
1  2
2  3
3  1

dtype: category
Categories (3, int64): [1, 2, 3]

# You can also pass a dict-like object to map the renaming
In [73]: s = s.cat.rename_categories({1: "x", 2: "y", 3: "z"})

In [74]: s
Out[74]:
0  x
1  y
2  z
3  x

dtype: category
Categories (3, object): ['x', 'y', 'z']

---

**Note:** In contrast to R’s `factor`, categorical data can have categories of other types than string.

**Note:** Be aware that assigning new categories is an in-place operation, while most other operations under `Series.cat` per default return a new `Series` of `dtype category`.

Categories must be unique or a `ValueError` is raised:

In [75]: try:
   ....:     s.cat.categories = [1, 1, 1]
   ....: except ValueError as e:
   ....:     print("ValueError:", str(e))
   ....:
ValueError: Categorical categories must be unique

---

2.12. Categorical data 645
Categories must also not be NaN or a ValueError is raised:

```python
In [76]: try:
    ....: s.cat.categories = [1, 2, np.nan]
    ....: except ValueError as e:
    ....:     print("ValueError:", str(e))
ValueError: Categorical categories cannot be null
```

### Appending new categories

Appending new categories can be done by using the `add_categories()` method:

```python
In [77]: s = s.cat.add_categories([4])
```

```python
In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')
```

```python
In [79]: s
Out[79]:
0 x
1 y
2 z
3 x
dtype: category
Categories (4, object): ['x', 'y', 'z', 4]
```

### Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```python
In [80]: s = s.cat.remove_categories([4])
```

```python
In [81]: s
Out[81]:
0 x
1 y
2 z
3 x
dtype: category
Categories (3, object): ['x', 'y', 'z']
```
Removing unused categories

Removing unused categories can also be done:

```python
In [82]: s = pd.Series(pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c', 'd']))
In [83]: s
Out[83]:
0    a
1    b
2    a
dtype: category
Categories (4, object): ['a', 'b', 'c', 'd']

In [84]: s.cat.remove_unused_categories()
Out[84]:
0    a
1    b
2    a
dtype: category
Categories (2, object): ['a', 'b']
```

Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```python
In [85]: s = pd.Series(['one', 'two', 'four', '-'], dtype='category')
In [86]: s
Out[86]:
0    one
1    two
2    four
3    -
dtype: category
Categories (4, object): ['-', 'four', 'one', 'two']

In [87]: s = s.cat.set_categories(['one', 'two', 'three', 'four'])
In [88]: s
Out[88]:
0    one
1    two
2    four
3    NaN
dtype: category
Categories (4, object): ['one', 'two', 'three', 'four']
```

Note: Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This
can result in surprising behaviour!

## 2.12.5 Sorting and order

If categorical data is ordered (s.cat.ordered == True), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, .min()/.max() will raise a TypeError.

```python
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))
In [90]: s.sort_values(inplace=True)
In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(CategoricalDtype(ordered=True))
In [92]: s.sort_values(inplace=True)
In [93]: s
Out[93]:
0   a
3   a
1   b
2   c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']

In [94]: s.min(), s.max()
Out[94]: ('a', 'c')
```

You can set categorical data to be ordered by using `as_ordered()` or unordered by using `as_unordered()`. These will by default return a new object.

```python
In [95]: s.cat.as_ordered()
Out[95]:
0   a
3   a
1   b
2   c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']

In [96]: s.cat.as_unordered()
Out[96]:
0   a
3   a
1   b
2   c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:
Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```python
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")
In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)
In [105]: s
Out[105]:
0  1
1  2
2  3
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]
In [106]: s.sort_values(inplace=True)
In [107]: s
Out[107]:
1  2
2  3
0  1
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]
(continues on next page)```
Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the Series, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the Series are changed.

Note: If the Categorical is not ordered, Series.min() and Series.max() will raise TypeError. Numeric operations like +, -, *, / and operations based on them (e.g. Series.median(), which would need to compute the mean between two values if the length of an array is even) do not work and raise a TypeError.

Multi column sorting

A categorical typed column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

Reordering the categories changes a future sort.
```python
In [111]: dfs['A'] = dfs['A'].cat.reorder_categories(['a', 'b', 'e'])

In [112]: dfs.sort_values(by=['A', 'B'])
```

```
Out[112]:
A  B
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
2  e  1
3  e  2
```

### 2.12.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (== and !=) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (==, !=, >, >=, <, and <=) of categorical data to another categorical Series, when ordered==True and the categories are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

**Note:** Any “non-equality” comparisons of categorical data with a `Series`, `np.array`, `list` or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```python
In [113]: cat = pd.Series([1, 2, 3]).astype(CategoricalDtype([3, 2, 1], ordered=True))

In [114]: cat_base = pd.Series([2, 2, 2]).astype(CategoricalDtype([3, 2, 1],
                       ordered=True))

In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(CategoricalDtype(ordered=True))

In [116]: cat
```

```
Out[116]:
0  1
1  2
2  3
dtype: category
Categories (3, int64): [3 < 2 < 1]
```

```python
In [117]: cat_base
```

```
Out[117]:
0  2
1  2
```
Comparing to a categorical with the same categories and ordering or to a scalar works:

```
In [119]: cat > cat_base
Out[119]:
0   True
1   False
2  False
dtype: bool
```

```
In [120]: cat > 2
Out[120]:
0  True
1  False
2  False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```
In [121]: cat == cat_base
Out[121]:
0   False
1    True
2   False
dtype: bool
```

```
In [122]: cat == np.array([1, 2, 3])
Out[122]:
0    True
1    True
2    True
dtype: bool
```

```
In [123]: cat == 2
Out[123]:
0   False
1    True
2   False
dtype: bool
```

This doesn’t work because the categories are not the same:
In [124]: try:
.....:    cat > cat_base2
.....: except TypeError as e:
.....:    print("TypeError:", str(e))
TypeError: Categoricals can only be compared if 'categories' are the same.

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

In [125]: base = np.array([1, 2, 3])

In [126]: try:
.....:    cat > base
.....: except TypeError as e:
.....:    print("TypeError:", str(e))
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [127]: np.asarray(cat) > base
Out[127]: array([False, False, False])

When you compare two unordered categoricals with the same categories, the order is not considered:

In [128]: c1 = pd.Categorical(["a", "b"], categories=["a", "b"], ordered=False)
In [129]: c2 = pd.Categorical(["a", "b"], categories=["b", "a"], ordered=False)
In [130]: c1 == c2
Out[130]: array([ True, True])

2.12.7 Operations

Apart from Series.min(), Series.max() and Series.mode(), the following operations are possible with categorical data:

Series methods like Series.value_counts() will use all categories, even if some categories are not present in the data:

In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"], categories=["c", "a", "b", "d"]))
In [132]: s.value_counts()
Out[132]:
c  2
a  1
b  1
d  0
dtype: int64

DataFrame methods like DataFrame.sum() also show “unused” categories.
In [133]: columns = pd.Categorical(
          ....:     ["One", "One", "Two"], categories=["One", "Two", "Three"], ordered=True
          ....: )
          ....:

In [134]: df = pd.DataFrame(
          ....:     data=[[1, 2, 3], [4, 5, 6]],
          ....:     columns=pd.MultiIndex.from_arrays([["A", "B", "B"], columns]),
          ....: )
          ....:

In [135]: df.groupby(axis=1, level=1).sum()
Out[135]:

   One  Two  Three
0   3     3     0
1   9     6     0

Groupby will also show “unused” categories:

In [136]: cats = pd.Categorical(
          ....:     ["a", "b", "b", "b", "c", "c", "c"], categories=["a", "b", "c", "d"]
          ....: )
          ....:

In [137]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 2, 3, 4, 5]})

In [138]: df.groupby("cats").mean()
Out[138]:

   values
cats
a   1.0
b   2.0
c   4.0
d  NaN

In [139]: cats2 = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [140]: df2 = pd.DataFrame(
          ....:     {
          ....:         "cats": cats2,
          ....:         "B": ["c", "d", "c", "d"],
          ....:         "values": [1, 2, 3, 4],
          ....:     }
          ....: )
          ....:

In [141]: df2.groupby(["cats", "B"]).mean()
Out[141]:

   values
cats  B
a  c   1.0
d   2.0
b  c   3.0

(continues on next page)
Pivot tables:

```python
In [142]: raw_cat = pd.Categorical(['a', 'a', 'b', 'b'], categories=['a', 'b', 'c'])
In [143]: df = pd.DataFrame({'A': raw_cat, 'B': ['c', 'd', 'c', 'd'], 'values': [1, 2, 3, 4]})
In [144]: pd.pivot_table(df, values='values', index=['A', 'B'])
```

```
Out[144]:
             values
A B
a c 1
   d 2
b c 3
   d 4
```

### 2.12.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat` work as normal. The only difference is the return type (for getting) and that only values already in `categories` can be assigned.

**Getting**

If the slicing operation returns either a `DataFrame` or a column of type `Series`, the `category` dtype is preserved.

```python
In [145]: idx = pd.Index(['h', 'i', 'j', 'k', 'l', 'm', 'n'])
In [146]: cats = pd.Series(['a', 'b', 'b', 'b', 'c', 'c', 'c'], dtype='category', index=idx)
In [147]: values = [1, 2, 2, 2, 3, 4, 5]
In [148]: df = pd.DataFrame({'cats': cats, 'values': values}, index=idx)
In [149]: df.iloc[2:4, :]
```

```
   cats  values
j  b  2
k  b  2
```

```python
In [150]: df.iloc[2:4, :].dtypes
```

```
cats category
values int64
dtype: object
```
In [151]: df.loc["h":"j", "cats"]
Out[151]:
h a
i b
j b
Name: cats, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [152]: df[df["cats"] == "b"]
Out[152]:
cats values
i b 2
j b 2
k b 2

An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

# get the complete "h" row as a Series
In [153]: df.loc["h", :]
Out[153]:
cats   a
values 1
Name: h, dtype: object

Returning a single item from categorical data will also return the value, not a categorical of length “1”:

In [154]: df.iat[0, 0]
Out[154]: 'a'

In [155]: df["cats"].cat.categories = ["x", "y", "z"]

In [156]: df.at["h", "cats"]  # returns a string
Out[156]: 'x'

Note: The is in contrast to R’s factor function, where `factor(c(1,2,3))[1]` returns a single value factor.

To get a single value Series of type category, you pass in a list with a single value:

In [157]: df.loc[["h"], "cats"]
Out[157]:
h x
Name: cats, dtype: category
Categories (3, object): ['x', 'y', 'z']
String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```
In [158]: str_s = pd.Series(list("aabb"))
In [159]: str_cat = str_s.astype("category")
In [160]: str_cat
Out[160]:
0 a
1 a
2 b
3 b
dtype: category
Categories (2, object): ['a', 'b']
In [161]: str_cat.str.contains("a")
Out[161]:
0   True
1   True
2  False
3  False
dtype: bool
In [162]: date_s = pd.Series(pd.date_range("1/1/2015", periods=5))
In [163]: date_cat = date_s.astype("category")
In [164]: date_cat
Out[164]:
0  2015-01-01
1  2015-01-02
2  2015-01-03
3  2015-01-04
4  2015-01-05
dtype: category
In [165]: date_cat.dt.day
Out[165]:
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

Note: The returned `Series` (or `DataFrame`) is of the same type as if you used the `.str.<method>` / `.dt.<method>` on a `Series` of that type (and not of type `category`).

That means, that the returned values from methods and properties on the accessors of a `Series` and the returned values
from methods and properties on the accessors of this Series transformed to one of type category will be equal:

```python
In [166]: ret_s = str_s.str.contains("a")
In [167]: ret_cat = str_cat.str.contains("a")
In [168]: ret_s.dtype == ret_cat.dtype
Out[168]: True
In [169]: ret_s == ret_cat
Out[169]:
0   True
1   True
2   True
3   True
dtype: bool
```

**Note:** The work is done on the categories and then a new Series is constructed. This has some performance implication if you have a Series of type string, where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series). In this case it can be faster to convert the original Series to one of type category and use .str.<method> or .dt.<property> on that.

---

### Setting

Setting values in a categorical column (or Series) works as long as the value is included in the categories:

```python
In [170]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])
In [171]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"], categories=["a", "b "])
In [172]: values = [1, 1, 1, 1, 1, 1, 1]
In [173]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
In [174]: df.iloc[2:4, :] = [["b", 2], ["b", 2]]
In [175]: df
Out[175]:
   cats  values
  h    a       1
  i    a       1
  j    b       2
  k    b       2
  l    a       1
  m    a       1
  n    a       1
```

```python
In [176]: try:
    ...:     df.iloc[2:4, :] = [["c", 3], ["c", 3]]
    ...:     except ValueError as e:
    ...:
```

(continues on next page)
Setting values by assigning categorical data will also check that the categories match:

```
In [177]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])

In [178]: df
Out[178]:
cats  values
  h a    1
  i a    1
  j a    2
  k a    2
  l a    1
  m a    1
  n a    1

In [179]: try:
       ......: df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"], categories=["a", "b", "c"])
       ......: except ValueError as e:
       ......:     print("ValueError:", str(e))
       ......:     print("ValueError: Cannot set a Categorical with another, without identical categories")

Assigning a Categorical to parts of a column of other types will use the values:

```
In [180]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})

In [181]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [182]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [183]: df
Out[183]:
a  b
0 1  a
1 b  a
2 b  b
3 l  b
4 l  a

In [184]: df.dtypes
Out[184]:
a  object
b  object
dtype: object
```
Merging / concatenation

By default, combining Series or DataFrames which contain the same categories results in category dtype, otherwise results will depend on the dtype of the underlying categories. Merges that result in non-categorical dtypes will likely have higher memory usage. Use .astype or union_categoricals to ensure category results.

```
In [185]: from pandas.api.types import union_categoricals

# same categories
In [186]: s1 = pd.Series(['a', 'b'], dtype='category')
In [187]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')
In [188]: pd.concat([s1, s2])
Out[188]:
   0  a
   1  b
   0  a
   1  b
   2  a
dtype: category
Categories (2, object): ['a', 'b']

# different categories
In [189]: s3 = pd.Series(['b', 'c'], dtype='category')
In [190]: pd.concat([s1, s3])
Out[190]:
   0  a
   1  b
   0  b
   1  c
dtype: object

# Output dtype is inferred based on categories values
In [191]: int_cats = pd.Series([1, 2], dtype='category')
In [192]: float_cats = pd.Series([3.0, 4.0], dtype='category')
In [193]: pd.concat([int_cats, float_cats])
Out[193]:
   0  1.0
   1  2.0
   0  3.0
   1  4.0
dtype: float64
In [194]: pd.concat([s1, s3]).astype('category')
Out[194]:
   0  a
   1  b
   0  b
   1  c
```

(continues on next page)
The following table summarizes the results of merging Categoricals:

<table>
<thead>
<tr>
<th>arg1</th>
<th>arg2</th>
<th>identical</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>category</td>
<td>True</td>
<td>category</td>
</tr>
<tr>
<td>category (object)</td>
<td>category (object)</td>
<td>False</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category (int)</td>
<td>category (float)</td>
<td>False</td>
<td>float (dtype is inferred)</td>
</tr>
</tbody>
</table>

See also the section on *merge dtypes* for notes about preserving merge dtypes and performance.

**Unioning**

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python
In [196]: from pandas.api.types import union_categoricals
In [197]: a = pd.Categorical(['b', 'c'])
In [198]: b = pd.Categorical(['a', 'b'])
In [199]: union_categoricals([a, b])
Out[199]: ['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python
In [200]: union_categoricals([a, b], sort_categories=True)
Out[200]: ['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```python
In [201]: a = pd.Categorical(['a', 'b'], ordered=True)
In [202]: b = pd.Categorical(['a', 'b', 'a'], ordered=True)
In [203]: union_categoricals([a, b])
Out[203]: ['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```
The below raises `TypeError` because the categories are ordered and not identical.

```python
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
In [204]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [205]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [206]: union_categoricals([a, b], ignore_order=True)
Out[206]:
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```python
In [207]: a = pd.Series(["b", "c"], dtype="category")
In [208]: b = pd.Series(["a", "b"], dtype="category")
In [209]: union_categoricals([a, b])
Out[209]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```python
In [210]: c1 = pd.Categorical(["b", "c"])
In [211]: c2 = pd.Categorical(["a", "b"])
In [212]: c1
Out[212]:
['b', 'c']
Categories (2, object): ['b', 'c']
# "b" is coded to 0
In [213]: c1.codes
Out[213]: array([0, 1], dtype=int8)
In [214]: c2
Out[214]:
['a', 'b']
Categories (2, object): ['a', 'b']
```
(continues on next page)
# "b" is coded to 1
In [215]: c2.codes
Out[215]: array([0, 1], dtype=int8)

In [216]: c = union_categoricals([c1, c2])
In [217]: c
Out[217]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']

# "b" is coded to 0 throughout, same as c1, different from c2
In [218]: c.codes
Out[218]: array([0, 1, 2, 0], dtype=int8)

2.12.9 Getting data in/out

You can write data that contains category dtypes to a HDFStore. See [here](https://pandas.pydata.org/pandas-docs/stable/reference/api/pandas.HDFStore.html) for an example and caveats.

It is also possible to write data to and reading data from Stata format files. See [here](https://pandas.pydata.org/pandas-docs/stable/reference/api/pandas.io stata.read.html) for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to category and assign the right categories and categories ordering.

In [219]: import io
In [220]: s = pd.Series(pd.Categorical(["a", "b", "b", "a", "a", "d"]))

# rename the categories
In [221]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [222]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [223]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})
In [224]: csv = io.StringIO()
In [225]: df.to_csv(csv)
In [226]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))

In [227]: df2.dtypes
Out[227]:
Unname: 0    int64
cats        object
vals        int64
dtype: object
In [228]: df2["cats"]
Out[228]:
0 very good
1 good
2 good
3 very good
4 very good
5 bad
Name: cats, dtype: object

# Redo the category
In [229]: df2['cats'] = df2['cats'].astype('category')

In [230]: df2['cats'].cat.set_categories(['very bad', 'bad', 'medium', 'good', 'very good'], inplace=True)

In [231]: df2.dtypes
Out[231]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Unnamed: 0</td>
<td>int64</td>
</tr>
<tr>
<td>cats</td>
<td>category</td>
</tr>
<tr>
<td>vals</td>
<td>int64</td>
</tr>
<tr>
<td>dtype:</td>
<td>object</td>
</tr>
</tbody>
</table>

In [232]: df2['cats']
Out[232]:
0 very good
1 good
2 good
3 very good
4 very good
5 bad
Name: cats, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

The same holds for writing to a SQL database with `to_sql`.

### 2.12.10 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the Missing Data section.

Missing values should **not** be included in the Categorical’s `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical’s `codes`, missing values will always have a code of -1.

In [233]: s = pd.Series(['a', 'b', np.nan, 'a'], dtype='category')

# only two categories
In [234]: s
Out[234]:
0 a
Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```python
In [236]: s = pd.Series(["a", "b", np.nan], dtype="category")

In [237]: s
Out[237]:
0   a
1   b
2  NaN
dtype: category
Categories (2, object): ['a', 'b']

In [238]: pd.isna(s)
Out[238]:
0  False
1   False
2    True
dtype: bool

In [239]: s.fillna("a")
Out[239]:
0   a
1   b
2   a
dtype: category
Categories (2, object): ['a', 'b']
```

### 2.12.11 Differences to R’s factor

The following differences to R’s factor functions can be observed:

- R’s levels are named categories.
- R’s levels are always of type string, while categories in pandas can be of any dtype.
- It’s not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R’s `factor` function, using categorical data as the sole input to create a new categorical series will *not* remove unused categories but create a new categorical series which is equal to the passed in one!
• R allows for missing values to be included in its levels (pandas’ categories). pandas does not allow NaN categories, but missing values can still be in the values.

2.12.12 Gotchas

Memory usage

The memory usage of a Categorical is proportional to the number of categories plus the length of the data. In contrast, an object dtype is a constant times the length of the data.

In [240]: s = pd.Series(["foo", "bar"] * 1000)

# object dtype
In [241]: s.nbytes
Out[241]: 16000

# category dtype
In [242]: s.astype("category").nbytes
Out[242]: 2016

Note: If the number of categories approaches the length of the data, the Categorical will use nearly the same or more memory than an equivalent object dtype representation.

In [243]: s = pd.Series(["foo%04d" % i for i in range(2000)])

# object dtype
In [244]: s.nbytes
Out[244]: 16000

# category dtype
In [245]: s.astype("category").nbytes
Out[245]: 20000

Categorical is not a numpy array

Currently, categorical data and the underlying Categorical is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn’t know about the new dtype:

In [246]: try:
       ....:     np.dtype("category")
       ....:     except TypeError as e:
       ....:         print("TypeError:", str(e))
       ....:
TypeError: data type 'category' not understood

In [247]: dtype = pd.Categorical(["a"]).dtype

In [248]: try:
Dtype comparisons work:

```python
In [249]: dtype == np.str_
Out[249]: False

In [250]: np.str_ == dtype
Out[250]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```python
In [251]: hasattr(pd.Series(["a"], dtype="category"), "cat")
Out[251]: True

In [252]: hasattr(pd.Series(["a"]), "cat")
Out[252]: False
```

Using NumPy functions on a Series of type `category` should not work as Categoricals are not numeric data (even in the case that `.categories` is numeric).

```python
In [253]: s = pd.Series(pd.Categorical([1, 2, 3, 4]))

In [254]: try:
   ....:     np.sum(s)
   ....: except TypeError as e:
   ....:     print("TypeError:", str(e))
   ....:
TypeError: 'Categorical' does not implement reduction 'sum'
```

**Note:** If such a function works, please file a bug at https://github.com/pandas-dev/pandas!

### dtype in apply

pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a Series of object dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use `fillna` to handle missing values before applying a function.

```python
In [255]: df = pd.DataFrame(
   ....:     {
   ....:         "a": [1, 2, 3, 4],
   ....:         "b": ["a", "b", "c", "d"],
   ....:         "cats": pd.Categorical([1, 2, 3, 2]),
   ....:     },
   ....: )
```

(continues on next page)
In [256]: df.apply(lambda row: type(row["cats"]), axis=1)
Out[256]:
0  <class 'int'>
1  <class 'int'>
2  <class 'int'>
3  <class 'int'>
dtype: object

In [257]: df.apply(lambda col: col.dtype, axis=0)
Out[257]:
a  int64
b  object
cats  category
dtype: object

Categorical index

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements. See the advanced indexing docs for a more detailed explanation.

Setting the index will create a CategoricalIndex:

In [258]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])

In [259]: strings = ["a", "b", "c", "d"]

In [260]: values = [4, 2, 3, 1]

In [261]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)

In [262]: df.index
Out[262]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype=category)

# This now sorts by the categories order
In [263]: df.sort_index()
Out[263]:
   strings  values
4       d      1
2       b      2
3       c      3
1       a      4
Side effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```python
In [264]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [265]: s = pd.Series(cat, name="cat")
In [266]: cat
Out[266]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [267]: s.iloc[0:2] = 10
In [268]: cat
Out[268]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [269]: df = pd.DataFrame(s)
In [270]: df["cat"].cat.categories = [1, 2, 3, 4, 5]
In [271]: cat
Out[271]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

Use copy=True to prevent such a behaviour or simply don’t reuse Categoricals:

```python
In [272]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [273]: s = pd.Series(cat, name="cat", copy=True)
In [274]: cat
Out[274]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [275]: s.iloc[0:2] = 10
In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

**Note:** This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. np.array([1,2,3,4])) will exhibit the same behavior, while using a string array (e.g. np.array(["a","b","c","a"])) will not.
2.13 Nullable integer data type

**Note:** IntegerArray is currently experimental. Its API or implementation may change without warning.

Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

In *Working with missing data*, we saw that pandas primarily uses NaN to represent missing data. Because NaN is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

### 2.13.1 Construction

pandas can represent integer data with possibly missing values using arrays.IntegerArray. This is an extension types implemented within pandas.

```python
In [1]: arr = pd.array([1, 2, None], dtype=pd.Int64Dtype())
In [2]: arr
Out[2]: <IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

Or the string alias "Int64" (note the capital "I", to differentiate from NumPy’s 'int64' dtype):

```python
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out[3]: <IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

All NA-like values are replaced with pandas.NA.

```python
In [4]: pd.array([1, 2, np.nan, None, pd.NA], dtype="Int64")
Out[4]: <IntegerArray>
[1, 2, <NA>, <NA>, <NA>]
Length: 5, dtype: Int64
```

This array can be stored in a DataFrame or Series like any NumPy array.

```python
In [5]: pd.Series(arr)
Out[5]:
0   1
1   2
2  <NA>
dtype: Int64
```

You can also pass the list-like object to the Series constructor with the dtype.
Warning: Currently `pandas.array()` and `pandas.Series()` use different rules for dtype inference. `pandas.array()` will infer a nullable-integer dtype.

```
In [6]: pd.array([1, None])
Out[6]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [7]: pd.array([1, 2])
Out[7]:
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

For backwards-compatibility, `Series` infers these as either integer or float dtype.

```
In [8]: pd.Series([1, None])
Out[8]:
0    1.0
1    NaN
dtype: float64

In [9]: pd.Series([1, 2])
Out[9]:
0    1
1    2
dtype: int64
```

We recommend explicitly providing the dtype to avoid confusion.

```
In [10]: pd.array([1, None], dtype="Int64")
Out[10]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [11]: pd.Series([1, None], dtype="Int64")
Out[11]:
0    1
1    <NA>
dtype: Int64
```

In the future, we may provide an option for `Series` to infer a nullable-integer dtype.
2.13.2 Operations

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and the
data will be coerced to another dtype if needed.

```python
In [12]: s = pd.Series([1, 2, None], dtype="Int64")

# arithmetic
In [13]: s + 1
Out[13]:
0  2
1  3
2  <NA>
dtype: Int64

# comparison
In [14]: s == 1
Out[14]:
0  True
1  False
2  <NA>
dtype: boolean

# indexing
In [15]: s.iloc[1:3]
Out[15]:
1  2
2  <NA>
dtype: Int64

# operate with other dtypes
In [16]: s + s.iloc[1:3].astype("Int8")
Out[16]:
0  <NA>
1  4
2  <NA>
dtype: Int64

# coerce when needed
In [17]: s + 0.01
Out[17]:
0  1.01
1  2.01
2  <NA>
dtype: Float64
```

These dtypes can operate as part of DataFrame.

```python
In [18]: df = pd.DataFrame({"A": s, "B": [1, 1, 3], "C": list("aab")})

In [19]: df
Out[19]:
       A  B  C
0  1.01  1  a
```
In [20]: df.dtypes
Out[20]:
A   Int64
B   int64
C  object
dtype: object

These dtypes can be merged & reshaped & casted.

In [21]: pd.concat([df["A"], df["B", "C"]], axis=1).dtypes
Out[21]:
A   Int64
B   int64
C  object
dtype: object

In [22]: df["A"].astype(float)
Out[22]:
0  1.0
1  2.0
2  NaN
Name: A, dtype: float64

Reduction and groupby operations such as ‘sum’ work as well.

In [23]: df.sum()
Out[23]:
A  3
B  5
C  aab
dtype: object

In [24]: df.groupby("B").A.sum()
Out[24]:
B
1  3
3  0
Name: A, dtype: Int64

2.13.3 Scalar NA Value

arrays.IntegerArray uses pandas.NA as its scalar missing value. Slicing a single element that’s missing will return pandas.NA

In [25]: a = pd.array([1, None, dtype="Int64")
In [26]: a[1]
Out[26]: <NA>
2.14 Nullable Boolean data type

Note: BooleanArray is currently experimental. Its API or implementation may change without warning.

New in version 1.0.0.

2.14.1 Indexing with NA values

pandas allows indexing with NA values in a boolean array, which are treated as False.

Changed in version 1.0.2.

```
In [1]: s = pd.Series([1, 2, 3])
In [2]: mask = pd.array([True, False, pd.NA], dtype="boolean")
In [3]: s[mask]
Out[3]:
0  1
dtype: int64
```

If you would prefer to keep the NA values you can manually fill them with fillna(True).

```
In [4]: s[mask.fillna(True)]
Out[4]:
0  1
2  3
dtype: int64
```

2.14.2 Kleene logical operations

arrays.BooleanArray implements Kleene Logic (sometimes called three-value logic) for logical operations like & (and), | (or) and ^ (exclusive-or).

This table demonstrates the results for every combination. These operations are symmetrical, so flipping the left- and right-hand side makes no difference in the result.
When an NA is present in an operation, the output value is NA only if the result cannot be determined solely based on the other input. For example, True | NA is True, because both True | True and True | False are True. In that case, we don’t actually need to consider the value of the NA.

On the other hand, True & NA is NA. The result depends on whether the NA really is True or False, since True & True is True, but True & False is False, so we can’t determine the output.

This differs from how np.nan behaves in logical operations. pandas treated np.nan is always false in the output.

In or

```python
In [5]: pd.Series([True, False, np.nan], dtype="object") | True
Out[5]:
0   True
1   True
2  False
dtype: bool
```

```python
In [6]: pd.Series([True, False, np.nan], dtype="boolean") | True
Out[6]:
0   True
1   True
2   True
dtype: boolean
```

In and

```python
In [7]: pd.Series([True, False, np.nan], dtype="object") & True
Out[7]:
0   True
1   False
2   False
dtype: bool
```
In [8]: pd.Series([True, False, np.nan], dtype="boolean") & True
Out[8]:
0   True
1   False
2     <NA>
dtype: boolean

2.15 Chart Visualization

This section demonstrates visualization through charting. For information on visualization of tabular data please see the section on Table Visualization.

We use the standard convention for referencing the matplotlib API:

In [1]: import matplotlib.pyplot as plt
In [2]: plt.close("all")

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

Note: All calls to np.random are seeded with 123456.

2.15.1 Basic plotting: plot

We will demonstrate the basics, see the cookbook for some advanced strategies.

The plot method on Series and DataFrame is just a simple wrapper around plt.plot():

In [3]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
In [4]: ts = ts.cumsum()
In [5]: ts.plot();
If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On DataFrame, `plot()` is a convenience to plot all of the columns with labels:

In [6]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD"))

In [7]: df = df.cumsum()

In [8]: plt.figure();

In [9]: df.plot();
You can plot one column versus another using the x and y keywords in `plot()`:

```python
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
In [11]: df3['A'] = pd.Series(list(range(len(df))))
In [12]: df3.plot(x='A', y='B');  
```
2.15.2 Other plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- `bar` or `barh` for bar plots
- `hist` for histogram
- `box` for boxplot
- `kde` or `density` for density plots
- `area` for area plots
- `scatter` for scatter plots
- `hexbin` for hexagonal bin plots
- `pie` for pie plots

For example, a bar plot can be created the following way:
In [13]: plt.figure();
In [14]: df.iloc[5].plot(kind="bar");

You can also create these other plots using the methods DataFrame.plot.<kind> instead of providing the kind keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

In [15]: df = pd.DataFrame()
In [16]: df.plot.<TAB>  # noqa: E225, E999
df.plot.area  df.plot.barh  df.plot.density  df.plot.hist  df.plot.line  df.
    →plot.scatter
df.plot.bar  df.plot.box  df.plot.hexbin  df.plot.kde  df.plot.pie

In addition to these kind s, there are the DataFrame.hist(), and DataFrame.boxplot() methods, which use a separate interface.

Finally, there are several plotting functions in pandas.plotting that take a Series or DataFrame as an argument. These include:

- Scatter Matrix
- Andrews Curves
- Parallel Coordinates
• Lag Plot
• Autocorrelation Plot
• Bootstrap Plot
• RadViz

Plots may also be adorned with errorbars or tables.

Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [17]: plt.figure();
In [18]: df.iloc[5].plot.bar();
In [19]: plt.axhline(0, color="k");
```

![Bar plot example]

Calling a DataFrame’s `plot.bar()` method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [21]: df2.plot.bar();
```
To produce a stacked bar plot, pass `stacked=True`:

```
In [22]: df2.plot.bar(stacked=True);
```
To get horizontal bar plots, use the `barh` method:

```python
In [23]: df2.plot.barh(stacked=True);
```
Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```python
In [24]: df4 = pd.DataFrame(
    ...:     {
    ...:         "a": np.random.randn(1000) + 1,
    ...:         "b": np.random.randn(1000),
    ...:         "c": np.random.randn(1000) - 1,
    ...:     },
    ...:     columns=['a', 'b', 'c'],
    ...: )

In [25]: plt.figure();

In [26]: df4.plot.hist(alpha=0.5);
```
A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```
In [27]: plt.figure();
In [28]: df4.plot.hist(stacked=True, bins=20);
```
You can pass other keywords supported by matplotlib **hist**. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```python
In [29]: plt.figure();

In [30]: df4["a"].plot.hist(orientation="horizontal", cumulative=True);
```
See the `hist` method and the `matplotlib` hist documentation for more.

The existing interface DataFrame.hist to plot histogram still can be used.

```python
In [31]: plt.figure();

In [32]: df['A'].diff().hist();
```
DataFrame.hist() plots the histograms of the columns on multiple subplots:

In [33]: plt.figure();

In [34]: df.diff().hist(color="k", alpha=0.5, bins=50);
The `by` keyword can be specified to plot grouped histograms:

```python
In [35]: data = pd.Series(np.random.randn(1000))

In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4));
```
Box plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```python
In [37]: df = pd.DataFrame(np.random.rand(10, 5), columns=["A", "B", "C", "D", "E"])
In [38]: df.plot.box();
```
Boxplot can be colorized by passing `color` keyword. You can pass a dict whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the dict, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```python
In [39]: color = {
           .....:   "boxes": "DarkGreen",
           .....:   "whiskers": "DarkOrange",
           .....:   "medians": "DarkBlue",
           .....:   "caps": "Gray",
           .....: }
           .....:
In [40]: df.plot.box(color=color, sym="r+"),
```
Also, you can pass other keywords supported by matplotlib boxplot. For example, horizontal and custom-positioned boxplot can be drawn by vert=False and positions keywords.

In [41]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8]);
See the `boxplot` method and the matplotlib boxplot documentation for more. The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```python
In [42]: df = pd.DataFrame(np.random.rand(10, 5))

In [43]: plt.figure();

In [44]: bp = df.boxplot()
```
You can create a stratified boxplot using the by keyword argument to create groupings. For instance,

```python
In [45]: df = pd.DataFrame(np.random.rand(10, 2), columns=["Col1", "Col2"])
```

```python
```

```python
In [47]: plt.figure();
```

```python
In [48]: bp = df.boxplot(by="X")
```
You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [49]: df = pd.DataFrame(np.random.rand(10, 3), columns=['Col1', 'Col2', 'Col3'])
In [52]: plt.figure();
In [53]: bp = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```
In `boxplot`, the return type can be controlled by the `return_type` keyword. The valid choices are \{"axes", "dict", "both", None\}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

<table>
<thead>
<tr>
<th>return_type</th>
<th>Faceted</th>
<th>Output type</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>None</td>
<td>Yes</td>
<td>2-D ndarray of axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>Yes</td>
<td>Series of axes</td>
</tr>
<tr>
<td>'dict'</td>
<td>No</td>
<td>dict of artists</td>
</tr>
<tr>
<td>'dict'</td>
<td>Yes</td>
<td>Series of dicts of artists</td>
</tr>
<tr>
<td>'both'</td>
<td>No</td>
<td>namedtuple</td>
</tr>
<tr>
<td>'both'</td>
<td>Yes</td>
<td>Series of namedtuples</td>
</tr>
</tbody>
</table>

Groupby.boxplot always returns a Series of return_type.

In [54]: np.random.seed(1234)

In [55]: df_box = pd.DataFrame(np.random.randn(50, 2))

In [56]: df_box["g"] = np.random.choice(["A", "B"], size=50)

In [57]: df_box.loc[df_box["g"] == "B", 1] += 3

(continues on next page)
The subplots above are split by the numeric columns first, then the value of the g column. Below the subplots are first split by the value of g, then by the numeric columns.

```
In [59]: bp = df_box.groupby("g").boxplot()
```
Area plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains NaN, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```python
In [60]: df = pd.DataFrame(np.random.rand(10, 4), columns=["a", "b", "c", "d"])

In [61]: df.plot.area();
```
To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [62]: df.plot.area(stacked=False);
```
Scatter plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```python
In [63]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])

In [64]: df['species'] = pd.Categorical('setosa' * 20 + 'versicolor' * 20 + 'virginica' * 10)

In [65]: df.plot.scatter(x='a', y='b');
```
To plot multiple column groups in a single axes, repeat plot method specifying target ax. It is recommended to specify color and label keywords to distinguish each groups.

```python
In [66]: ax = df.plot.scatter(x="a", y="b", color="DarkBlue", label="Group 1")
In [67]: df.plot.scatter(x="c", y="d", color="DarkGreen", label="Group 2", ax=ax);
```
The keyword `c` may be given as the name of a column to provide colors for each point:

In [68]: df.plot.scatter(x="a", y="b", c="c", s=50);
If a categorical column is passed to `c`, then a discrete colorbar will be produced:

New in version 1.3.0.

```
In [69]: df.plot.scatter(x="a", y="b", c="species", cmap="viridis", s=50);
```
You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```
In [70]: df.plot.scatter(x="a", y="b", s=df["c"] * 200);
```
See the `scatter` method and the `matplotlib scatter documentation` for more.

**Hexagonal bin plot**

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```python
In [71]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [72]: df['b'] = df['b'] + np.arange(1000)
In [73]: df.plot.hexbin(x='a', y='b', gridsize=25);
```
A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each \((x, y)\) point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each \((x, y)\) point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. `mean`, `max`, `sum`, `std`). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy’s `max` function.

```python
In [74]: df = pd.DataFrame(np.random.randn(1000, 2), columns=["a", "b"])
In [75]: df["b"] = df["b"] + np.arange(1000)
In [76]: df["z"] = np.random.uniform(0, 3, 1000)
In [77]: df.plot.hexbin(x="a", y="b", C="z", reduce_C_function=np.max, gridsize=25);
```
See the `hexbin` method and the matplotlib hexbin documentation for more.

**Pie plot**

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any NaN, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```python
In [78]: series = pd.Series(3 * np.random.rand(4), index=["a", "b", "c", "d"], name="series")
In [79]: series.plot.pie(figsize=(6, 6));
```
For pie plots it’s best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

In [80]: `df = pd.DataFrame(`
   3 * np.random.rand(4, 2), index=["a", "b", "c", "d"], columns=["x", "y"]
   )

In [81]: `df.plot.pie(subplots=True, figsize=(8, 4));`
You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```python
In [82]: series.plot.pie(
    ....:     labels=['AA', 'BB', 'CC', 'DD'],
    ....:     colors=['r', 'g', 'b', 'c'],
    ....:     autopct='%.2f',
    ....:     fontsize=20,
    ....:     figsize=(6, 6),
    ....: );
```
If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [83]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
In [84]: series.plot.pie(figsize=(6, 6));
```
See the matplotlib pie documentation for more.

2.15.3 Plotting with missing data

pandas tries to be pragmatic about plotting DataFrames or Series that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.
If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

### 2.15.4 Plotting tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

**Scatter matrix plot**

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```python
In [85]: from pandas.plotting import scatter_matrix

In [86]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [87]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde');
```
Density plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```python
In [88]: ser = pd.Series(np.random.randn(1000))
In [89]: ser.plot.kde();
```
Andrews curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the Wikipedia entry for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

Note: The “Iris” dataset is available here.

```python
In [90]: from pandas.plotting import andrews_curves

In [91]: data = pd.read_csv("data/iris.data")

In [92]: plt.figure();

In [93]: andrews_curves(data, "Name");
```
Parallel coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the Wikipedia entry for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```python
In [94]: from pandas.plotting import parallel_coordinates

In [95]: data = pd.read_csv("data/iris.data")

In [96]: plt.figure();

In [97]: parallel_coordinates(data, "Name");
```
Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```python
In [98]: from pandas.plotting import lag_plot

In [99]: plt.figure();

In [100]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)

In [101]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))

In [102]: lag_plot(data);
```
Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the Wikipedia entry for more about autocorrelation plots.

```python
In [103]: from pandas.plotting import autocorrelation_plot

In [104]: plt.figure();

In [105]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)

In [106]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))

In [107]: autocorrelation_plot(data);
```
Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [108]: from pandas.plotting import bootstrap_plot

In [109]: data = pd.Series(np.random.rand(1000))

In [110]: bootstrap_plot(data, size=50, samples=500, color="grey");
```
RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package Radviz for more information.

Note: The “Iris” dataset is available here.

```python
In [111]: from pandas.plotting import radviz

In [112]: data = pd.read_csv("data/iris.data")

In [113]: plt.figure();

In [114]: radviz(data, "Name");
```
2.15.5 Plot formatting

Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it’s very easy to try them out.

General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [115]: plt.figure();
In [116]: ts.plot(style="k--", label="Series");
```
For each kind of plot (e.g. line, bar, scatter) any additional arguments keywords are passed along to the corresponding matplotlib function (ax.plot(), ax.bar(), ax.scatter()). These can be used to control additional styling, beyond what pandas provides.

**Controlling the legend**

You may set the legend argument to False to hide the legend, which is shown by default.

```python
In [117]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD "))
In [118]: df = df.cumsum()
In [119]: df.plot(legend=False);
```
Controlling the labels

New in version 1.1.0.

You may set the xlabel and ylabel arguments to give the plot custom labels for x and y axis. By default, pandas will pick up index name as xlabel, while leaving it empty for ylabel.

```
In [120]: df.plot();

In [121]: df.plot(xlabel="new x", ylabel="new y");
```
Scales

You may pass logy to get a log-scale Y axis.

```python
In [122]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))

In [123]: ts = np.exp(ts.cumsum())

In [124]: ts.plot(logy=True);
```
See also the logx and loglog keyword arguments.

**Plotting on a secondary y-axis**

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```python
In [125]: df["A"].plot();
In [126]: df["B"].plot(secondary_y=True, style="g");
```
To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```python
In [127]: plt.figure();
In [128]: ax = df.plot(secondary_y=['A', 'B'])
In [129]: ax.set_ylabel("CD scale");
In [130]: ax.right_ax.set_ylabel("AB scale");
```
Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```python
In [131]: plt.figure();

In [132]: df.plot(secondary_y=['A', 'B'], mark_right=False);
```
Custom formatters for timeseries plots

Changed in version 1.0.0.

pandas provides custom formatters for timeseries plots. These change the formatting of the axis labels for dates and times. By default, the custom formatters are applied only to plots created by pandas with DataFrame.plot() or Series.plot(). To have them apply to all plots, including those made by matplotlib, set the option pd.options.plotting.matplotlib.register_converters = True or use pandas.plotting.register_matplotlib_converters().

Suppressing tick resolution adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created twinx), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```python
In [133]: plt.figure();
In [134]: df["A"].plot();
```
Using the `x_compat` parameter, you can suppress this behavior:

```python
In [135]: plt.figure();
In [136]: df['A'].plot(x_compat=True);
```
If you have more than one plot that needs to be suppressed, the use method in pandas.plotting.plot_params can be used in a with statement:

```python
In [137]: plt.figure();

In [138]: with pd.plotting.plot_params.use("x_compat", True):
   ....:     df["A"].plot(color="r")
   ....:     df["B"].plot(color="g")
   ....:     df["C"].plot(color="b")
   ....:```

2.15. Chart Visualization
**Automatic date tick adjustment**

`TimedeltaIndex` now uses the native `matplotlib` tick locator methods, it is useful to call the automatic date tick adjustment from `matplotlib` for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the `matplotlib` documentation for more.
Subplots

Each Series in a DataFrame can be plotted on a different axis with the subplots keyword:

```python
In [139]: df.plot(subplots=True, figsize=(6, 6));
```
Using layout and targeting multiple axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array’s `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [140]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```
In [141]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).
You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don’t affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```python
In [142]: fig, axes = plt.subplots(4, 4, figsize=(9, 9))
In [143]: plt.subplots_adjust(wspace=0.5, hspace=0.5)
In [144]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
In [145]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]
In [146]: df.plot(subplots=True, ax=target1, legend=False, sharex=False, sharey=False);
In [147]: (-df).plot(subplots=True, ax=target2, legend=False, sharex=False, sharey=False);
```
Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```python
In [148]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [149]: plt.subplots_adjust(wspace=0.2, hspace=0.5)
In [150]: df["A"].plot(ax=axes[0, 0]);
In [151]: axes[0, 0].set_title("A");
In [152]: df["B"].plot(ax=axes[0, 1]);
In [153]: axes[0, 1].set_title("B");
```
Plotting with error bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or dict of errors with column names matching the columns attribute of the plotting `DataFrame` or matching the name attribute of the `Series`.
- As a str indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (list, tuple, or np.ndarray). Must be the same length as the plotting `DataFrame/Series`.

Here is an example of one way to easily plot group means with standard deviations from the raw data.
# Generate the data

```python
In [158]: ix3 = pd.MultiIndex.from_arrays(
        ....:     [
        ....:         ["a", "a", "a", "a", "b", "b", "b", "b"],
        ....:         ["foo", "foo", "foo", "bar", "foo", "foo", "bar", "bar"],
        ....:     ],
        ....:     names=["letter", "word"],
        ....: )
```

```python
In [159]: df3 = pd.DataFrame(
        ....:     {
        ....:         "data1": [9, 3, 2, 4, 3, 2, 4, 6, 3, 2],
        ....:         "data2": [9, 6, 5, 7, 5, 4, 5, 6, 5, 1],
        ....:     },
        ....:     index=ix3,
        ....: )
```

# Group by index labels and take the means and standard deviations for each group

```python
In [160]: gp3 = df3.groupby(level=("letter", "word"))
```

```python
In [161]: means = gp3.mean()
```

```python
In [162]: errors = gp3.std()
```

```python
In [163]: means
```

```
<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>3.500000</td>
<td>6.000000</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>4.666667</td>
<td>6.666667</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>3.666667</td>
<td>4.000000</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>3.000000</td>
<td>4.500000</td>
</tr>
</tbody>
</table>
```

```python
In [164]: errors
```

```
<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>0.707107</td>
<td>1.414214</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>3.785939</td>
<td>2.081666</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>2.081666</td>
<td>2.645751</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>1.414214</td>
<td>0.707107</td>
</tr>
</tbody>
</table>
```

# Plot

```python
In [165]: fig, ax = plt.subplots()
```

```python
In [166]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
```
Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a \( N \) length \texttt{Series}, a \( 2 \times N \) array should be provided indicating lower and upper (or left and right) errors. For a \( M \times N \) \texttt{DataFrame}, asymmetrical errors should be in a \( M \times 2 \times N \) array.

Here is an example of one way to plot the min/max range using asymmetrical error bars.

```python
In [167]: mins = gp3.min()

In [168]: maxs = gp3.max()

# errors should be positive, and defined in the order of lower, upper
In [169]: errors = [[means[c] - mins[c], maxs[c] - means[c]] for c in df3.columns]

# Plot
In [170]: fig, ax = plt.subplots()

In [171]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
```
Plotting tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a table keyword. The table keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib’s default layout.

```
In [172]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.5))

In [173]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [174]: ax.xaxis.tick_top()  # Display x-axis ticks on top.

In [175]: df.plot(table=True, ax=ax);
```
Also, you can pass a different :class:`DataFrame` or :class:`Series` to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```python
In [176]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.75))

In [177]: ax.xaxis.tick_top()  # Display x-axis ticks on top.

In [178]: df.plot(table=np.round(df.T, 2), ax=ax);
```
There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to a matplotlib.Axes instance. This function can accept keywords which the matplotlib `table` has.

```python
In [179]: from pandas.plotting import table

In [180]: fig, ax = plt.subplots(1, 1)

In [181]: table(ax, np.round(df.describe(), 2), loc="upper right", colWidths=[0.2, 0.2, 0.2]);

In [182]: df.plot(ax=ax, ylim=(0, 2), legend=None);
```
**Colormaps**

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, DataFrame plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available here.

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the DataFrame. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```
In [183]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
In [184]: df = df.cumsum()
In [185]: plt.figure();
In [186]: df.plot(colormap="cubehelix");
```
Alternatively, we can pass the colormap itself:

```python
In [187]: from matplotlib import cm
In [188]: plt.figure();
In [189]: df.plot(colormap=cm.cubehelix);
```
Colormaps can also be used other plot types, like bar charts:

In [190]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)

In [191]: dd = dd.cumsum()

In [192]: plt.figure();

In [193]: dd.plot.bar(colormap="Greens");
Parallel coordinates charts:

```python
In [194]: plt.figure();
```

```python
In [195]: parallel_coordinates(data, "Name", colormap="gist_rainbow");
```
Andrews curves charts:

```python
In [196]: plt.figure();

In [197]: andrews_curves(data, "Name", colormap="winter");
```
2.15.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. `Series` and `DataFrame` objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```python
In [198]: price = pd.Series(
    ...:     np.random.randn(150).cumsum(),
    ...:     index=pd.date_range("2000-1-1", periods=150, freq="B"),
    ...: )

In [199]: ma = price.rolling(20).mean()

In [200]: mstd = price.rolling(20).std()

In [201]: plt.figure();
```

(continues on next page)
2.15.7 Plotting backends

Starting in version 0.25, pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib.

This can be done by passing `backend.module` as the argument `backend` in `plot` function. For example:

```python
>>> Series([1, 2, 3]).plot(backend="backend.module")
```

Alternatively, you can also set this option globally, do you don’t need to specify the keyword in each `plot` call. For example:

```python
>>> pd.set_option("plottingbackend", "backend.module")
>>> pd.Series([1, 2, 3]).plot()
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

Or:

```python
>>> pd.options.plotting.backend = "backend.module"
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair, hvplot…) to generate the plots. Some libraries implementing a backend for pandas are listed on the ecosystem ecosystem.visualization page.

Developers guide can be found at https://pandas.pydata.org/docs/dev/development/extending.html#plotting-backends

## 2.16 Table Visualization

This section demonstrates visualization of tabular data using the `Styler` class. For information on visualization with charting please see Chart Visualization. This document is written as a Jupyter Notebook, and can be viewed or downloaded here.

### 2.16.1 Styler Object and HTML

Styling should be performed after the data in a DataFrame has been processed. The `Styler` creates an HTML `<table>` and leverages CSS styling language to manipulate many parameters including colors, fonts, borders, background, etc. See here for more information on styling HTML tables. This allows a lot of flexibility out of the box, and even enables web developers to integrate DataFrames into their existing user interface designs.

The DataFrame.style attribute is a property that returns a `Styler` object. It has a `_repr_html_` method defined on it so they are rendered automatically in Jupyter Notebook.

```python
[2]: import pandas as pd
[2]: import numpy as np

df = pd.DataFrame([[38.0, 2.0, 18.0, 22.0, 21, np.nan], [19, 439, 6, 452, 226, 232]],
                  index=pd.Index(['Tumour (Positive)', 'Non-Tumour (Negative)'], name='Actual Label:'),
                  columns=pd.MultiIndex.from_product([['Decision Tree', 'Regression'], ['Tumour', 'Non-Tumour']], names=['Model:', 'Predicted:']))

[2]: df.style
```

The above output looks very similar to the standard DataFrame HTML representation. But the HTML here has already attached some CSS classes to each cell, even if we haven’t yet created any styles. We can view these by calling the `render()` method, which returns the raw HTML as string, which is useful for further processing or adding to a file - read on in More about CSS and HTML. Below we will show how we can use these to format the DataFrame to be more communicative. For example how we can build `s`:

```python
[4]: s
[4]: <pandas.io.formats.style.Styler at 0x7f07acdb5670>
```
### 2.16.2 Formatting the Display

#### Formatting Values

Before adding styles it is useful to show that the Styler can distinguish the display value from the actual value. To control the display value, the text is printed in each cell, and we can use the `.format()` method to manipulate this according to a format spec string or a callable that takes a single value and returns a string. It is possible to define this for the whole table or for individual columns.

Additionally, the format function has a precision argument to specifically help formatting floats, as well as decimal and thousands separators to support other locales, an na_rep argument to display missing data, and an escape argument to help displaying safe-HTML or safe-LaTeX. The default formatter is configured to adopt pandas' regular display. precision option, controllable using with `pd.option_context('display.precision', 2):

Here is an example of using the multiple options to control the formatting generally and with specific column formatters.

```
[5]: df.style.format(precision=0, na_rep='MISSING', thousands=" ",
    formatter={('Decision Tree', 'Tumour'): "{:2f}",
               ('Regression', 'Non-Tumour'): lambda x: "$ {:,.1f}\times10^6\)"
    })
```

#### Hiding Data

The index and column headers can be completely hidden, as well subselecting rows or columns that one wishes to exclude. Both these options are performed using the same methods.

The index can be hidden from rendering by calling `.hide_index()` without any arguments, which might be useful if your index is integer based. Similarly column headers can be hidden by calling `.hide_columns()` without any arguments.

Specific rows or columns can be hidden from rendering by calling the same `.hide_index()` or `.hide_columns()` methods and passing in a row/column label, a list-like or a slice of row/column labels to for the subset argument.

Hiding does not change the integer arrangement of CSS classes, e.g. hiding the first two columns of a DataFrame means the column class indexing will start at `col2`, since `col0` and `col1` are simply ignored.

We can update our Styler object to hide some data and format the values.

```
[6]: s = df.style.format('{:.0f}').hide_columns([('Random', 'Tumour'), ('Random', 'Non-Tumour')])
```

#### 2.16.3 Methods to Add Styles

There are 3 primary methods of adding custom CSS styles to Styler:

- Using `.set_table_styles()` to control broader areas of the table with specified internal CSS. Although table styles allow the flexibility to add CSS selectors and properties controlling all individual parts of the table, they are unwieldy for individual cell specifications. Also, note that table styles cannot be exported to Excel.

- Using `.set_td_classes()` to directly link either external CSS classes to your data cells or link the internal CSS classes created by `.set_table_styles()`. See here. These cannot be used on column header rows or indexes, and also won't export to Excel.
• Using the .apply() and .applymap() functions to add direct internal CSS to specific data cells. See here. These cannot be used on column header rows or indexes, but only these methods add styles that will export to Excel. These methods work in a similar way to DataFrame.apply() and DataFrame.applymap().

2.16.4 Table Styles

Table styles are flexible enough to control all individual parts of the table, including column headers and indexes. However, they can be unwieldy to type for individual data cells or for any kind of conditional formatting, so we recommend that table styles are used for broad styling, such as entire rows or columns at a time.

Table styles are also used to control features which can apply to the whole table at once such as creating a generic hover functionality. The :hover pseudo-selector, as well as other pseudo-selectors, can only be used this way.

To replicate the normal format of CSS selectors and properties (attribute value pairs), e.g.

```css
tr:hover {
    background-color: #ffff99;
}
```

the necessary format to pass styles to .set_table_styles() is as a list of dicts, each with a CSS-selector tag and CSS-properties. Properties can either be a list of 2-tuples, or a regular CSS-string, for example:

```python
[8]: cell_hover = {
    # for row hover use <tr> instead of <td>
    'selector': 'td:hover',
    'props': [('background-color', '#ffffb3')]
}
index_names = {
    'selector': '.index_name',
    'props': 'font-style: italic; color: darkgrey; font-weight:normal;'
}
headers = {
    'selector': 'th:not(.index_name)',
    'props': 'background-color: #000066; color: white;'
}
s.set_table_styles([cell_hover, index_names, headers])
```

Next we just add a couple more styling artifacts targeting specific parts of the table. Be careful here, since we are chaining methods we need to explicitly instruct the method not to overwrite the existing styles.

```python
[10]: s.set_table_styles([
    {'selector': 'th.col_heading', 'props': 'text-align: center;'},
    {'selector': 'th.col_heading.level0', 'props': 'font-size: 1.5em;'},
    {'selector': 'td', 'props': 'text-align: center; font-weight: bold;'},
], overwrite=False)
```

As a convenience method (since version 1.2.0) we can also pass a dict to .set_table_styles() which contains row or column keys. Behind the scenes Styler just indexes the keys and adds relevant .col<n> or .row<n> classes as necessary to the given CSS selectors.

```python
[12]: s.set_table_styles({
    'Regression', 'Tumour': [{'selector': 'th', 'props': 'border-left: 1px solid white'}]
})
```
2.16.5 Setting Classes and Linking to External CSS

If you have designed a website then it is likely you will already have an external CSS file that controls the styling of table and cell objects within it. You may want to use these native files rather than duplicate all the CSS in python (and duplicate any maintenance work).

Table Attributes

It is very easy to add a class to the main <table> using .set_table_attributes(). This method can also attach inline styles - read more in CSS Hierarchies.

```
[14]: out = s.set_table_attributes('class="my-table-cls"').render()
     print(out[out.find('"table"'):][:109])
```

```
<table id="T_xyz01" class="my-table-cls">
  <thead>
    <tr>
      <th class="index_name level0" >Model:</th>
```

Data Cell CSS Classes

New in version 1.2.0

The .set_td_classes() method accepts a DataFrame with matching indices and columns to the underlying Styler’s DataFrame. That DataFrame will contain strings as css-classes to add to individual data cells: the <td> elements of the <table>. Rather than use external CSS we will create our classes internally and add them to table style. We will save adding the borders until the section on tooltips.

```
[15]: s.set_table_styles([  # create internal CSS classes
    {'selector': '.true', 'props': 'background-color: #e6ffe6;'},
    {'selector': '.false', 'props': 'background-color: #ffe6e6;'},
], overwrite=False)
cell_color = pd.DataFrame([[true, false, true, false],
                           [false, true, false, true]],
                          index=dfs.index,
                          columns=dfs.columns[:4])
```

```
s.set_td_classes(cell_color)
```

[15]: <pandas.io.formats.style.Styler at 0x7f07acd279a0>
2.16.6 Styler Functions

We use the following methods to pass your style functions. Both of those methods take a function (and some other keyword arguments) and apply it to the DataFrame in a certain way, rendering CSS styles.

- `.applymap()` (elementwise): accepts a function that takes a single value and returns a string with the CSS attribute-value pair.
- `.apply()` (column-/row-/table-wise): accepts a function that takes a Series or DataFrame and returns a Series, DataFrame, or numpy array with an identical shape where each element is a string with a CSS attribute-value pair. This method passes each column or row of your DataFrame one-at-a-time or the entire table at once, depending on the axis keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

This method is powerful for applying multiple, complex logic to data cells. We create a new DataFrame to demonstrate this.

```
[17]: np.random.seed(0)
df2 = pd.DataFrame(np.random.randn(10,4), columns=['A','B','C','D'])
df2.style
[17]: <pandas.io.formats.style.Styler at 0x7f07ac4493a0>
```

For example we can build a function that colors text if it is negative, and chain this with a function that partially fades cells of negligible value. Since this looks at each element in turn we use `applymap`.

```
[18]: def style_negative(v, props=''): return props if v < 0 else None
s2 = df2.style.applymap(style_negative, props='color:red;')
    .applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)
s2
[18]: <pandas.io.formats.style.Styler at 0x7f07acd25e80>
```

We can also build a function that highlights the maximum value across rows, cols, and the DataFrame all at once. In this case we use `apply`. Below we highlight the maximum in a column.

```
[20]: def highlight_max(s, props=''): return np.where(s == np.nanmax(s.values), props, '')
s2.apply(highlight_max, props='color:white;background-color:darkblue', axis=0)
[20]: <pandas.io.formats.style.Styler at 0x7f07acd25e80>
```

We can use the same function across the different axes, highlighting here the DataFrame maximum in purple, and row maximums in pink.

```
[22]: s2.apply(highlight_max, props='color:white;background-color:pink;', axis=1)
    .apply(highlight_max, props='color:white;background-color:purple', axis=None)
[22]: <pandas.io.formats.style.Styler at 0x7f07acd25e80>
```

This last example shows how some styles have been overwritten by others. In general the most recent style applied is active but you can read more in the section on CSS hierarchies. You can also apply these styles to more granular parts of the DataFrame - read more in section on subset slicing.

It is possible to replicate some of this functionality using just classes but it can be more cumbersome. See item 3) of Optimization.
Debugging Tip: If you’re having trouble writing your style function, try just passing it into DataFrame.apply. Internally, Styler.apply uses DataFrame.apply so the result should be the same, and with DataFrame.apply you will be able to inspect the CSS string output of your intended function in each cell.

2.16.7 Tooltips and Captions

Table captions can be added with the .set_caption() method. You can use table styles to control the CSS relevant to the caption.

```
[23]: s.set_caption("Confusion matrix for multiple cancer prediction models.")
    .set_table_styles([{ 'selector': ':caption', 'props': 'caption-side: bottom; font-size:1.25em;' }], overwrite=False)
[23]: <pandas.io.formats.style.Styler at 0x7f07acd279a0>
```

Adding tooltips (since version 1.3.0) can be done using the .set_tooltips() method in the same way you can add CSS classes to data cells by providing a string based DataFrame with intersecting indices and columns. You don’t have to specify a css_class name or any css props for the tooltips, since there are standard defaults, but the option is there if you want more visual control.

```
[25]: tt = pd.DataFrame([['This model has a very strong true positive rate', 'This model's total number of false negatives is too high']], index=['Tumour (Positive)'], columns=df.columns[[0,3]])
    s.set_tooltips(tt, props='visibility: hidden; position: absolute; z-index: 1; border: 1px solid #000066; background-color: white; color: #000066; font-size: 0.8em; transform: translate(0px, -24px); padding: 0.6em; border-radius: 0.5em;')
[25]: <pandas.io.formats.style.Styler at 0x7f07acd279a0>
```

The only thing left to do for our table is to add the highlighting borders to draw the audience attention to the tooltips. We will create internal CSS classes as before using table styles. Setting classes always overwrites so we need to make sure we add the previous classes.

```
[27]: s.set_table_styles([{'selector': '.border-red', 'props': 'border: 2px dashed red;'},
                        {'selector': '.border-green', 'props': 'border: 2px dashed green;'},
                      ], overwrite=False)
    cell_border = pd.DataFrame([['border-green'], [''], [''], [''], ['border-red']],[[''], [''], [''], ['']], index=df.index, columns=df.columns[:4])
    s.set_td_classes(cell_color + cell_border)
[27]: <pandas.io.formats.style.Styler at 0x7f07acd279a0>
```
2.16.8 Finer Control with Slicing

The examples we have shown so far for the Styler.apply and Styler.applymap functions have not demonstrated the use of the subset argument. This is a useful argument which permits a lot of flexibility: it allows you to apply styles to specific rows or columns, without having to code that logic into your style function.

The value passed to subset behaves similar to slicing a DataFrame;

- A scalar is treated as a column label
- A list (or Series or NumPy array) is treated as multiple column labels
- A tuple is treated as (row_indexer, column_indexer)

Consider using pd.IndexSlice to construct the tuple for the last one. We will create a MultiIndexed DataFrame to demonstrate the functionality.

```
[29]: df3 = pd.DataFrame(np.random.randn(4,4),
               pd.MultiIndex.from_product([[['A', 'B'], ['r1', 'r2']]],
                                      columns=['c1','c2','c3','c4']))
[29]:
c1   c2   c3   c4
A r1 -1.048553 -1.420018 -1.706270  1.950775
    r2 -0.509652 -0.438074 -1.252795  0.777490
B r1 -1.613898 -0.212740 -0.895467  0.386902
    r2 -0.510805 -1.180632 -0.028182  0.428332
```

We will use subset to highlight the maximum in the third and fourth columns with red text. We will highlight the subset sliced region in yellow.

```
[30]: slice_ = ['c3', 'c4']
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_)
   .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
[30]: <pandas.io.formats.style.Styler at 0x7f07acd23730>
```

If combined with the IndexSlice as suggested then it can index across both dimensions with greater flexibility.

```
[31]: idx = pd.IndexSlice
slice_ = idx[idx[:, 'r1'], idx['c2':'c4']]
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_)
   .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
[31]: <pandas.io.formats.style.Styler at 0x7f07acd14640>
```

This also provides the flexibility to sub select rows when used with the axis=1.

```
[32]: slice_ = idx[idx[:, 'r2'], :]
df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)
   .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
[32]: <pandas.io.formats.style.Styler at 0x7f07128bb0d0>
```

There is also scope to provide conditional filtering.

Suppose we want to highlight the maximum across columns 2 and 4 only in the case that the sum of columns 1 and 3 is less than -2.0 (essentially excluding rows (:, 'r2')).
```
[33]: slice_ = idx[idx[(df3['c1'] + df3['c3']) < -2.0], ['c2', 'c4']]
df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)
    .set_properties(**{"background-color": '#ffffff'}, subset=slice_)
```

```
[33]: <pandas.io.formats.style.Styler at 0x7f07acc53250>
```

Only label-based slicing is supported right now, not positional, and not callables.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```
my_func2 = functools.partial(my_func, subset=42)
```

### 2.16.9 Optimization

Generally, for smaller tables and most cases, the rendered HTML does not need to be optimized, and we don’t really recommend it. There are two cases where it is worth considering:

- If you are rendering and styling a very large HTML table, certain browsers have performance issues.
- If you are using `Styler` to dynamically create part of online user interfaces and want to improve network performance.

Here we recommend the following steps to implement:

1. **Remove UUID and cell_ids**

Ignore the uuid and set `cell_ids` to False. This will prevent unnecessary HTML.

```
This is sub-optimal:
```

```
[34]: df4 = pd.DataFrame([[1,2],[3,4]])
s4 = df4.style
```

```
This is better:
```

```
[35]: from pandas.io.formats.style import Styler
    s4 = Styler(df4, uuid_len=0, cell_ids=False)
```

2. **Use table styles**

Use table styles where possible (e.g. for all cells or rows or columns at a time) since the CSS is nearly always more efficient than other formats.

```
This is sub-optimal:
```

```
[36]: props = 'font-family: "Times New Roman", Times, serif; color: #e83e8c; font-size:1.3em;' 
    df4.style.applymap(lambda x: props, subset=[1])
```

2.16. Table Visualization
3. Set classes instead of using Styler functions

For large DataFrames where the same style is applied to many cells it can be more efficient to declare the styles as classes and then apply those classes to data cells, rather than directly applying styles to cells. It is, however, probably still easier to use the Styler function api when you are not concerned about optimization.

This is sub-optimal:

```python
[38]: df2.style.apply(highlight_max, props='color:white;background-color:darkblue;', axis=0)\n    .apply(highlight_max, props='color:white;background-color:pink;', axis=1)\n    .apply(highlight_max, props='color:white;background-color:purple', axis=None)
```

This is better:

```python
[39]: build = lambda x: pd.DataFrame(x, index=df2.index, columns=df2.columns)
cls1 = build(df2.apply(highlight_max, props='cls-1', axis=0))
cls2 = build(df2.apply(highlight_max, props='cls-2', axis=1, result_type='expand').\n    .values)
cls3 = build(highlight_max(df2, props='cls-3 '))
df2.style.set_table_styles([\n    {'selector': '.cls-1', 'props': 'color:white;background-color:darkblue;'},\n    {'selector': '.cls-2', 'props': 'color:white;background-color:pink;'},\n    {'selector': '.cls-3', 'props': 'color:white;background-color:purple;'}\n]).set_td_classes(cls1 + cls2 + cls3)
```

4. Don’t use tooltips

Tooltips require cell_ids to work and they generate extra HTML elements for every data cell.
5. If every byte counts use string replacement

You can remove unnecessary HTML, or shorten the default class names with string replace functions.

```python
html = Styler(df4, uuid_len=0, cell_ids=False)
        .set_table_styles([{
            'selector': 'td', 'props': props,
            'selector': '.col1', 'props': 'color:green;',
            'selector': '.level0', 'props': 'color:blue;'}])
        .render()
        .replace('blank', '')
        .replace('data', '')
        .replace('level0', 'l0')
        .replace('col_heading', '')
        .replace('row_heading', '')
```

```python
import re
html = re.sub(r'col[0-9]+', lambda x: x.group().replace('col', 'c'), html)
html = re.sub(r'row[0-9]+', lambda x: x.group().replace('row', 'r'), html)
print(html)
```

```html
<style type="text/css">
#T__ td {
  font-family: "Times New Roman", Times, serif;
  color: #e83e8c;
  font-size: 1.3em;
}
#T__ .c1 {
  color: green;
}
#T__ .l0 {
  color: blue;
}
</style>
<table id="T__">
<thead>
<tr>
  <th class=" l0">&nbsp;</th>
  <th class=" l0 c0" >0</th>
  <th class=" l0 c1" >1</th>
</tr>
</thead>
<tbody>
<tr>
  <th id="T__l0_r0" class=" l0 r0" >0</th>
  <td class=" r0 c0" >1</td>
  <td class=" r0 c1" >2</td>
</tr>
<tr>
  <th id="T__l0_r1" class=" l0 r1" >1</th>
  <td class=" r1 c0" >3</td>
  <td class=" r1 c1" >4</td>
</tr>
</tbody>
</table>
```

(continues on next page)

2.16. Table Visualization 757
2.16.10 Builtin Styles

Some styling functions are common enough that we’ve “built them in” to the Styler, so you don’t have to write them and apply them yourself. The current list of such functions is:

- `.highlight_null`: for use with identifying missing data.
- `.highlight_min` and `.highlight_max`: for use with identifying extremeties in data.
- `.highlight_between` and `.highlight_quantile`: for use with identifying classes within data.
- `.background_gradient`: a flexible method for highlighting cells based on their, or other, values on a numeric scale.
- `.text_gradient`: similar method for highlighting text based on their, or other, values on a numeric scale.
- `.bar`: to display mini-charts within cell backgrounds.

The individual documentation on each function often gives more examples of their arguments.

**Highlight Null**

```python
[42]: df2.iloc[0,2] = np.nan
df2.iloc[4,3] = np.nan
df2.loc[:4].style.highlight_null(null_color='yellow')
```

**Highlight Min or Max**

```python
[43]: df2.loc[:4].style.highlight_max(axis=1, props='color:white; font-weight:bold; background-color:darkblue;')
```

**Highlight Between**

This method accepts ranges as float, or NumPy arrays or Series provided the indexes match.

```python
[44]: left = pd.Series([1.0, 0.0, 1.0], index=['A', 'B', 'D'])
df2.loc[:4].style.highlight_between(left=left, right=1.5, axis=1, props='color:white;background-color:purple;')
```

---

---
highlight quantile

Useful for detecting the highest or lowest percentile values

```
[45]: df2.loc[:4].style.highlight_quantile(q_left=0.85, axis=None, color='yellow')
[45]: <pandas.io.formats.style.Styler at 0x7f07acc5f790>
```

background gradient and text gradient

You can create “heatmaps” with the background_gradient and text_gradient methods. These require matplotlib, and we’ll use Seaborn to get a nice colormap.

```
[46]: import seaborn as sns
cm = sns.light_palette("green", as_cmap=True)
df2.style.background_gradient(cmap=cm)
[46]: <pandas.io.formats.style.Styler at 0x7f07f071fe52b0>

[47]: df2.style.text_gradient(cmap=cm)
[47]: <pandas.io.formats.style.Styler at 0x7f07acd23e20>
```

`.background_gradient` and `.text_gradient` have a number of keyword arguments to customise the gradients and colors. See the documentation.

set properties

Use Styler.set_properties when the style doesn’t actually depend on the values. This is just a simple wrapper for .applymap where the function returns the same properties for all cells.

```
[48]: df2.loc[:4].style.set_properties(**{'background-color': 'black',
                     'color': 'lawngreen',
                     'border-color': 'white'})
[48]: <pandas.io.formats.style.Styler at 0x7f07f07adfb8e0>
```

bar charts

You can include “bar charts” in your DataFrame.

```
[49]: df2.style.bar(subset=['A', 'B'], color='#d65f5f')
[49]: <pandas.io.formats.style.Styler at 0x7f0f70f72520>
```

In version 0.20.0 the ability to customize the bar chart further was given. You can now have the df.style.bar be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of [color_negative, color_positive].

Here’s how you can change the above with the new align='mid' option:

```
[50]: df2.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
```
The following example aims to give a highlight of the behavior of the new align options:

```python
style1 = df2.style.applymap(style_negative, props='color:red;')
     applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)
```

Notice that you're able to share the styles even though they're data aware. The styles are re-evaluated on the new DataFrame they've been used upon.

### 2.16.12 Limitations

- DataFrame only (use Series.to_frame().style)
- The index and columns must be unique
- No large repr, and construction performance isn't great; although we have some HTML optimizations
- You can only style the values, not the index or columns (except with table_styles above)
- You can only apply styles, you can't insert new HTML entities

Some of these might be addressed in the future.

### 2.16.13 Other Fun and Useful Stuff

Here are a few interesting examples.

**Widgets**

Styler interacts pretty well with widgets. If you're viewing this online instead of running the notebook yourself, you're missing out on interactively adjusting the color palette.

```python
from ipywidgets import widgets
@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0., 359), s=(0., 99.9), l=(0., 99.9)):
    return df2.style.background_gradient(cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l),
(continues on next page)
```
Magnify

```python
[56]: def magnify():
    return [dict(selector="th",
                 props=[("font-size", "4pt")]),
            dict(selector="td",
                 props=[('padding', "0em 0em")]),
            dict(selector="th:hover",
                 props=[("font-size", "12pt")]),
            dict(selector="tr:hover td:hover",
                 props=[('max-width', '200px'),
                         ('font-size', '12pt')])
]
```

```python
[57]: np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigrf = pd.DataFrame(np.random.randn(20, 25)).cumsum()
bigrf.style.background_gradient(cmap, axis=1)
    .set_properties(**{"max-width": '80px', 'font-size': '1pt'
                         'caption': 'Hover to magnify'
                         'format': 'precision=2'
                         .set_table_styles(magnify())
```

Sticky Headers

If you display a large matrix or DataFrame in a notebook, but you want to always see the column and row headers you can use the `.set_sticky` method which manipulates the table styles CSS.

```python
[58]: bigdf = pd.DataFrame(np.random.randn(16, 100))
bigrf.style.set_sticky(axis="index")
```

It is also possible to stick MultiIndexes and even only specific levels.

```python
[59]: bigdf.index = pd.MultiIndex.from_product(["A","B"],[0,1],[0,1,2,3])
bigrf.style.set_sticky(axis = "index", pixel_size=18, levels=[1,2])
```
**HTML Escaping**

Suppose you have to display HTML within HTML, that can be a bit of pain when the renderer can’t distinguish. You can use the escape formatting option to handle this, and even use it within a formatter that contains HTML itself.

```
[60]: df4 = pd.DataFrame([['<div></div>', '"other"', '<span></span']])
   df4.style
[60]: <pandas.io.formats.style.Styler at 0x7f07a1cc0eb0>

[61]: df4.style.format(escape="html")
[61]: <pandas.io.formats.style.Styler at 0x7f07a1dc3910>

[62]: df4.style.format('a href="https://pandas.pydata.org" target="_blank">{}</a>', escape="html")
[62]: <pandas.io.formats.style.Styler at 0x7f07a1cc0250>
```

### 2.16.14 Export to Excel

Some support (*since version 0.20.0*) is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap

Currently broken: border-style, border-width, border-color and their {top, right, bottom, left variants}

Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.

The following pseudo CSS properties are also available to set excel specific style properties:

- number-format

Table level styles, and data cell CSS-classes are not included in the export to Excel: individual cells must have their properties mapped by the Styler.apply and/or Styler.applymap methods.

```
[63]: df2.style.applymap(style_negative, props='color:red;').highlight_max(axis=0).to_excel('styled.xlsx', engine='openpyxl')
```
A screenshot of the output:

### 2.16.15 Export to LaTeX

There is support (*since version 1.3.0*) to export **Styler** to LaTeX. The documentation for the `.to_latex` method gives further detail and numerous examples.

### 2.16.16 More About CSS and HTML

Cascading Style Sheet (CSS) language, which is designed to influence how a browser renders HTML elements, has its own peculiarities. It never reports errors: it just silently ignores them and doesn’t render your objects how you intend so can sometimes be frustrating. Here is a very brief primer on how **Styler** creates HTML and interacts with CSS, with advice on common pitfalls to avoid.

#### CSS Classes and Ids

The precise structure of the CSS class attached to each cell is as follows.

- Cells with Index and Column names include `index_name` and `level<k>` where `k` is its level in a MultiIndex
- Index label cells include
  - `row_heading`
  - `level<k>` where `k` is the level in a MultiIndex
  - `row<m>` where `m` is the numeric position of the row
- Column label cells include
  - `col_heading`
  - `level<k>` where `k` is the level in a MultiIndex
  - `col<n>` where `n` is the numeric position of the column
- Data cells include
  - `data`
  - `row<m>`, where `m` is the numeric position of the cell.
pandas: powerful Python data analysis toolkit, Release 1.3.4

- col<n>, where n is the numeric position of the cell.

- Blank cells include blank

The structure of the id is T_uuid_level<k>_row<m>_col<n> where level<k> is used only on headings, and headings will only have either row<m> or col<n> whichever is needed. By default we’ve also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn’t collide with the styling from another within the same notebook or page. You can read more about the use of UUIDs in Optimization.

We can see example of the HTML by calling the .render() method.

```python
[64]: print(pd.DataFrame([[[1,2],[3,4]], index=['i1', 'i2'], columns=['c1', 'c2']]).style.
    ...:     .render())
    ...
<style type="text/css">
</style>
<table id="T_0ffe8_">
<thead>
    <tr>
        <th class="blank level0" >&nbsp;</th>
        <th class="col_heading level0 col0" >c1</th>
        <th class="col_heading level0 col1" >c2</th>
    </tr>
</thead>
<tbody>
    <tr>
        <th id="T_0ffe8_level0_row0" class="row_heading level0 row0" >i1</th>
        <td id="T_0ffe8_row0_col0" class="data row0 col0" >1</td>
        <td id="T_0ffe8_row0_col1" class="data row0 col1" >2</td>
    </tr>
    <tr>
        <th id="T_0ffe8_level0_row1" class="row_heading level0 row1" >i2</th>
        <td id="T_0ffe8_row1_col0" class="data row1 col0" >3</td>
        <td id="T_0ffe8_row1_col1" class="data row1 col1" >4</td>
    </tr>
</tbody>
</table>
```

CSS Hierarchies

The examples have shown that when CSS styles overlap, the one that comes last in the HTML render, takes precedence. So the following yield different results:

```python
[65]: df4 = pd.DataFrame([['text']])
    ...: df4.style.applymap(lambda x: 'color:green;')
    ...:     .applymap(lambda x: 'color:red;')
    ...
    <pandas.io.formats.style.Styler at 0x7f07a0c2fe80>
[66]: df4.style.applymap(lambda x: 'color:red;')
    ...:     .applymap(lambda x: 'color:green;')
    ...
    <pandas.io.formats.style.Styler at 0x7f07a1cc0580>
```
This is only true for CSS rules that are equivalent in hierarchy, or importance. You can read more about CSS specificity here but for our purposes it suffices to summarize the key points:

A CSS importance score for each HTML element is derived by starting at zero and adding:

- 1000 for an inline style attribute
- 100 for each ID
- 10 for each attribute, class or pseudo-class
- 1 for each element name or pseudo-element

Let's use this to describe the action of the following configurations

```
[67]: df4.style.set_uuid('a_')
    .set_table_styles([{
        'selector': 'td', 'props': 'color:red;'}])
    .applymap(lambda x: 'color:green;')
[67]: <pandas.io.formats.style.Styler at 0x7f07a0c48880>
```

This text is red because the generated selector #T_a_ td is worth 101 (ID plus element), whereas #T_a_row0_col0 is only worth 100 (ID), so is considered inferior even though in the HTML it comes after the previous.

```
[68]: df4.style.set_uuid('b_')
    .set_table_styles([{
        'selector': 'td', 'props': 'color:red;'},
        {'selector': '.cls-1', 'props': 'color:blue;'}])
    .applymap(lambda x: 'color:green;')
    .set_td_classes(pd.DataFrame([['cls-1']]))
[68]: <pandas.io.formats.style.Styler at 0x7f07a0c2c1f0>
```

In the above case the text is blue because the selector #T_b_ .cls-1 is worth 110 (ID plus class), which takes precedence.

```
[69]: df4.style.set_uuid('c_')
    .set_table_styles([{
        'selector': 'td', 'props': 'color:red;'},
        {'selector': '.cls-1', 'props': 'color:blue;'},
        {'selector': 'td.data', 'props': 'color:yellow;'}])
    .applymap(lambda x: 'color:green !important;')
    .set_td_classes(pd.DataFrame([['cls-1']]))
[69]: <pandas.io.formats.style.Styler at 0x7f07a0c480a0>
```

Now we have created another table style this time the selector T_c_ td.data (ID plus element plus class) gets bumped up to 111.

If your style fails to be applied, and is really frustrating, try the !important trump card.

```
[70]: df4.style.set_uuid('d_')
    .set_table_styles([{
        'selector': 'td', 'props': 'color:red;'},
        {'selector': '.cls-1', 'props': 'color:blue;'},
        {'selector': 'td.data', 'props': 'color:yellow;'}])
    .applymap(lambda x: 'color:green !important;')
    .set_td_classes(pd.DataFrame([['cls-1']]))
[70]: <pandas.io.formats.style.Styler at 0x7f07a0c3e610>
```

Finally got that green text after all!
2.16.17 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that DataFrame.style accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll link to it.

Subclassing

If the default template doesn’t quite suit your needs, you can subclass Styler and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```python
from jinja2 import Environment, ChoiceLoader, FileSystemLoader
from IPython.display import HTML
from pandas.io.formats.style import Styler

We'll use the following template:

```
with open("templates/myhtml.tpl") as f:
    print(f.read())

{% extends "html_table.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we’ve created a template, we need to set up a subclass of Styler that knows about it.

```python
class MyStyler(Styler):
    env = Environment(
        loader=ChoiceLoader([
            FileSystemLoader("templates"), # contains ours
            Styler.loader, # the default
        ])
    )
    template_html_table = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment’s loader. That’s because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It’s __init__ takes a DataFrame.

```python
MyStyler(df3)
```

```
<__main__.MyStyler at 0x7f07a0c259a0>
```

Our custom template accepts a table_title keyword. We can provide the value in the .render method.

```python
HTML(MyStyler(df3).render(table_title="Extending Example"))
```

```
<IPython.core.display.HTML object>
```
For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.

```python
[76]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
    HTML(EasyStyler(df3).render(table_title="Another Title"))
[76]: <IPython.core.display.HTML object>
```

### Template Structure

Here’s the template structure for the both the style generation template and the table generation template:

**Style template:**

```python
[78]: HTML(style_structure)
[78]: <IPython.core.display.HTML object>
```

**Table template:**

```python
[80]: HTML(table_structure)
[80]: <IPython.core.display.HTML object>
```

See the template in the [GitHub repo](https://github.com/pandas-dev/pandas) for more details.

## 2.17 Computational tools

### 2.17.1 Statistical functions

#### Percent change

Series and DataFrame have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values *before* computing the percent change).

```python
In [1]: ser = pd.Series(np.random.randn(8))
In [2]: ser.pct_change()
Out[2]:
0   NaN
1  -1.602976
2   4.334938
3  -0.247456
4  -2.067345
5  -1.142903
6  -1.688214
7  -9.759729
dtype: float64

In [3]: df = pd.DataFrame(np.random.randn(10, 4))
In [4]: df.pct_change(periods=3)
Out[4]:
```

(continues on next page)
Covariance

*Series.cov()* can be used to compute covariance between series (excluding missing values).

df = pd.DataFrame(np.random.randn(1000, 5), columns=["a", "b", "c", "d", "e"])
df.cov()

Analogously, *DataFrame.cov()* to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

DataFrame.cov also supports an optional min_periods keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.
In [13]: frame.cov()
Out[13]:
   a     b     c
  a 1.12367 -0.412751  0.018169
  b -0.412751  1.15414  0.305261
  c  0.018169  0.305261  1.301149

In [14]: frame.cov(min_periods=12)
Out[14]:
   a     b     c
  a 1.12367 NaN  0.018169
  b NaN  1.15414  0.305261
  c 0.018169  0.305261  1.301149

Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

<table>
<thead>
<tr>
<th>Method name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pearson</td>
<td>Standard correlation coefficient</td>
</tr>
<tr>
<td>kendall</td>
<td>Kendall Tau correlation coefficient</td>
</tr>
<tr>
<td>spearman</td>
<td>Spearman rank correlation coefficient</td>
</tr>
</tbody>
</table>

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman’s rank correlation coefficient

Note: Please see the caveats associated with this method of calculating correlation matrices in the covariance section.
In [19]: frame.corr()
Out[19]:
    a    b    c    d    e
a  1.000000 -0.013479 -0.049269 -0.042239 -0.028525
b  0.013479  1.000000 -0.020433 -0.011139  0.005654
c -0.049269 -0.020433  1.000000  0.018587 -0.054269
d -0.042239 -0.011139  0.018587  1.000000 -0.017060
e -0.028525  0.005654 -0.054269 -0.017060  1.000000

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like cov, corr also supports the optional min_periods keyword:

In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [21]: frame.loc[frame.index[:5], 'a'] = np.nan
In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [23]: frame.corr()
Out[23]:
    a     b      c
a  1.000000 NaN  0.069544
b  NaN  1.000000  0.051742
c  0.069544  0.051742  1.000000

In [24]: frame.corr(min_periods=12)
Out[24]:
    a     b      c
a  1.000000 NaN  0.069544
b  NaN  1.000000  0.051742
c  0.069544  0.051742  1.000000

The method argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

# histogram intersection
In [25]: def histogram_intersection(a, b):
    return np.minimum(np.true_divide(a, a.sum()), np.true_divide(b, b.sum())).sum()

In [26]: frame.corr(method=histogram_intersection)
Out[26]:
    a     b      c
a  1.000000 -6.404882 -2.058431
b -6.404882  1.000000 -19.255743
c -2.058431 -19.255743  1.000000

A related method corrwith() is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.
In [27]: index = ["a", "b", "c", "d", "e"]

In [28]: columns = ["one", "two", "three", "four"]

In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)

In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)

In [31]: df1.corrwith(df2)
Out[31]:
    one  -0.125501
    two  -0.493244
    three  0.344056
    four   0.004183

In [32]: df2.corrwith(df1, axis=1)
Out[32]:
     a   -0.675817
     b    0.458296
     c    0.190809
     d   -0.186275
     e      NaN

Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

In [33]: s = pd.Series(np.random.randn(5), index=list("abcde"))

In [34]: s["d"] = s["b"]  # so there's a tie

In [35]: s.rank()
Out[35]:
    a   5.0
    b   2.5
    c   1.0
    d   2.5
    e   4.0

`rank()` is also a DataFrame method and can rank either the rows (axis=0) or the columns (axis=1). NaN values are excluded from the ranking.

In [36]: df = pd.DataFrame(np.random.randn(10, 6))

In [38]: df
Out[38]:
   0  1  2  3  4  5
(continues on next page)
rank optionally takes a parameter ascending which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

rank supports different tie-breaking methods, specified with the method parameter:

- **average**: average rank of tied group
- **min**: lowest rank in the group
- **max**: highest rank in the group
- **first**: ranks assigned in the order they appear in the array

## Windowing functions

See the window operations user guide for an overview of windowing functions.

### 2.18 Group by: split-apply-combine

By "group by" we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to do one of the following:
• **Aggregation**: compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.

• **Transformation**: perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.

• **Filtration**: discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.

• Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name `GroupBy` should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```sql
SELECT Column1, Column2, mean(Column3), sum(Column4) 
FROM SomeTable 
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the `cookbook` for some advanced strategies.

### 2.18.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a `GroupBy` object (more on what the `GroupBy` object is later), you may do the following:

```python
In [1]: df = pd.DataFrame(  
    ...:     [  
    ...:         ("bird", "Falconiformes", 389.0),  
    ...:         ("bird", "Psittaciformes", 24.0),  
    ...:         ("mammal", "Carnivora", 80.2),  
    ...:         ("mammal", "Primates", np.nan),  
    ...:         ("mammal", "Carnivora", 58),  
    ...:     ],  
    ...:     index=["falcon", "parrot", "lion", "monkey", "leopard"],  
    ...:     columns=("class", "order", "max speed"),  
    ...: )  
Out[2]:
```

<table>
<thead>
<tr>
<th>class</th>
<th>order</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>Falconiformes 389.0</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>Psittaciformes 24.0</td>
</tr>
</tbody>
</table>
lion mammal Carnivora 80.2
monkey mammal Primates NaN
leopard mammal Carnivora 58.0

# default is axis=0
In [3]: grouped = df.groupby("class")

In [4]: grouped = df.groupby("order", axis="columns")

In [5]: grouped = df.groupby(["class", "order"])

The mapping can be specified many different ways:

• A Python function, to be called on each of the axis labels.
• A list or NumPy array of the same length as the selected axis.
• A dict or Series, providing a label -> group name mapping.
• For DataFrame objects, a string indicating either a column name or an index level name to be used to group.
• df.groupby('A') is just syntactic sugar for df.groupby(df['A']).
• A list of any of the above things.

Collectively we refer to the grouping objects as the keys. For example, consider the following DataFrame:

Note: A string passed to groupby may refer to either a column or an index level. If a string matches both a column name and an index level name, a ValueError will be raised.

In [6]: df = pd.DataFrame(
    ...:     {  
    ...:         "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],  
    ...:         "B": ["one", "one", "two", "three", "two", "two", "one", "three"],  
    ...:         "C": np.random.randn(8),  
    ...:         "D": np.random.randn(8),  
    ...:     })
    ...: )
    ...

In [7]: df

Out[7]:

</tr>
</tbody>
</table>

On a DataFrame, we obtain a GroupBy object by calling groupby(). We could naturally group by either the A or B columns, or both:
If we also have a MultiIndex on columns A and B, we can group by all but the specified columns:

```python
In [10]: df2 = df.set_index(['A', 'B'])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(['B']))
In [12]: grouped.sum()
Out[12]:
            C         D
A  bar -1.591710 -1.739537
   foo  -0.752861  -1.402938
```

These will split the DataFrame on its index (rows). We could also split by the columns:

```python
In [13]: def get_letter_type(letter):
   ....:     if letter.lower() in 'aeiou':
   ....:         return 'vowel'
   ....:     else:
   ....:         return 'consonant'
   ....:
In [14]: grouped = df.groupby(get_letter_type, axis=1)
```

**pandas** Index objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```python
In [15]: lst = [1, 2, 3, 1, 2, 3]
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [17]: grouped = s.groupby(level=0)
In [18]: grouped.first()
Out[18]:
   1  1
   2  2
   3  3
   dtype: int64
In [19]: grouped.last()
Out[19]:
   1  10
   2  20
   3   30
   dtype: int64
In [20]: grouped.sum()
```

(continues on next page)
Note that no splitting occurs until it’s needed. Creating the GroupBy object only verifies that you’ve passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can’t be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

### GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```
in [21]: df2 = pd.DataFrame({"X": ["B", "B", "A", "A"], "Y": [1, 2, 3, 4]})

in [22]: df2.groupby(["X"]).sum()
out[22]:
   Y
X
A 7
B 3

in [23]: df2.groupby(["X"], sort=False).sum()
out[23]:
   Y
X
B 3
A 7
```

Note that `groupby` will preserve the order in which observations are sorted within each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

```
in [24]: df3 = pd.DataFrame({"X": ["A", "B", "A", "B"], "Y": [1, 4, 3, 2]})

in [25]: df3.groupby(["X"]).get_group("A")
out[25]:
   X   Y
0  A   1
2  A   3

in [26]: df3.groupby(["X"]).get_group("B")
out[26]:
   X   Y
1  B   4
3  B   2
```

New in version 1.1.0.
GroupBy dropna

By default NA values are excluded from group keys during the groupby operation. However, in case you want to include NA values in group keys, you could pass dropna=False to achieve it.

```python
In [27]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
In [28]: df_dropna = pd.DataFrame(df_list, columns=['a', 'b', 'c'])
In [29]: df_dropna
Out[29]:
   a  b  c
0  1  2.0 3
1  1   NaN 4
2  2  1.0 3
3  1  2.0 2
```

# Default `dropna` is set to True, which will exclude NaNs in keys

```python
In [30]: df_dropna.groupby(by=['b'], dropna=True).sum()
Out[30]:
   a  c
   b
1.0 2 3
2.0 2 5
```

# In order to allow NaN in keys, set `dropna` to False

```python
In [31]: df_dropna.groupby(by=['b'], dropna=False).sum()
Out[31]:
   a  c
   b
1.0 2 3
2.0 2 5
NaN 1 4
```

The default setting of dropna argument is True which means NA are not included in group keys.

GroupBy object attributes

The groups attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```python
In [32]: df.groupby("A").groups
Out[32]: {'bar': [1, 3, 5], 'foo': [0, 2, 4, 6, 7]}
In [33]: df.groupby(get_letter_type, axis=1).groups
Out[33]: {'consonant': ['B', 'C', 'D'], 'vowel': ['A']}
```

Calling the standard Python len function on the GroupBy object just returns the length of the groups dict, so it is largely just a convenience:

```python
In [34]: grouped = df.groupby(['A', 'B'])
(continues on next page)
```

2.18. Group by: split-apply-combine
In [35]: grouped.groups
Out[35]: {'bar', 'one': [1], ('bar', 'three'): [3], ('bar', 'two'): [5], ('foo', 'one'): [0, 6], ('foo', 'three'): [7], ('foo', 'two'): [2, 4]}

In [36]: len(grouped)
Out[36]: 6

GroupBy will tab complete column names (and other attributes):

In [37]: df
Out[37]:

<table>
<thead>
<tr>
<th></th>
<th>height</th>
<th>weight</th>
<th>gender</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>42.849980</td>
<td>157.500553</td>
<td>male</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>49.607315</td>
<td>177.340407</td>
<td>male</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>56.293531</td>
<td>171.524640</td>
<td>male</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>48.421077</td>
<td>144.251986</td>
<td>female</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>46.556882</td>
<td>152.526206</td>
<td>male</td>
</tr>
<tr>

<td>70.757698</td>
<td>136.431469</td>
<td>male</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>58.909500</td>
<td>176.499753</td>
<td>female</td>
</tr>
<tr>
<td>2000-01-09</td>
<td>76.435631</td>
<td>174.094104</td>
<td>female</td>
</tr>
<tr>
<td>2000-01-10</td>
<td>45.306120</td>
<td>177.540920</td>
<td>male</td>
</tr>
</tbody>
</table>

In [38]: gb = df.groupby("gender")

GroupBy with MultiIndex

With \textit{hierarchically-indexed data}, it’s quite natural to group by one of the levels of the hierarchy. Let’s create a Series with a two-level MultiIndex.

In [40]: arrays = [
    ....:     ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
    ....:     ["one", "two", "one", "two", "one", "two", "one", "two"],
    ....: ]
    ....: 

In [41]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])

In [42]: s = pd.Series(np.random.randn(8), index=index)
In [43]: s

Out[43]:
first  second
bar    one   -0.919854
       two    -0.042379
baz    one    1.247642
       two   -0.009920
foo    one    0.290213
       two    0.495767
qux    one    0.362949
       two    1.548106
dtype: float64

We can then group by one of the levels in s.

In [44]: grouped = s.groupby(level=0)

In [45]: grouped.sum()

Out[45]:
first
bar   -0.962232
baz    1.237723
foo    0.785980
qux    1.911055
dtype: float64

If the MultiIndex has names specified, these can be passed instead of the level number:

In [46]: s.groupby(level="second").sum()

Out[46]:
second
one    0.980950
two    1.991575
dtype: float64

Grouping with multiple levels is supported.

In [47]: s

Out[47]:
first  second  third
bar    doo    one   -1.131345
       two    -0.089329
baz    bee    one    0.337863
       two   -0.945867
foo    bop    one   -0.932132
       two    1.956030
qux    bop    one    0.017587
       two   -0.016692
dtype: float64

In [48]: s.groupby(level=["first", "second"]).sum()

Out[48]:
(continues on next page)
Index level names may be supplied as keys.

```
In [49]: s.groupby(["first", "second"]).sum()
Out[49]:
   first  second
  bar    doo    -1.220674
  baz    bee    -0.608004
  foo    bop     1.023898
  qux    bop     0.000895
dtype: float64
```

More on the `sum` function and aggregation later.

**Grouping DataFrame with Index levels and columns**

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```
In [50]: arrays = [
   ....:     ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
   ....:     ["one", "two", "one", "two", "one", "two", "one", "two"],
   ....:     ["one", "two", "one", "two", "one", "two", "one", "two"]
   ....:
   ....: ]

In [51]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])

In [52]: df = pd.DataFrame({"A": [1, 1, 1, 1, 2, 2, 3, 3], "B": np.arange(8)},
   ....:         index=index)

In [53]: df
Out[53]:
   A  B
first second
bar   one  1  0
     two  1  1
baz   one  1  2
     two  1  3
foo   one  2  4
     two  2  5
qux   one  3  6
     two  3  7
```

The following example groups `df` by the second index level and the A column.
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
In [54]: df.groupby([pd.Grouper(level=1), "A"]).sum()
Out[54]:
   B
  second A
 one  1 2
    2 4
    3 6
 two  1 4
    2 5
    3 7
```

Index levels may also be specified by name.

```python
In [55]: df.groupby([pd.Grouper(level="second"), "A"]).sum()
Out[55]:
   B
  second A
 one  1 2
    2 4
    3 6
 two  1 4
    2 5
    3 7
```

Index level names may be specified as keys directly to `groupby`.

```python
In [56]: df.groupby(["second", "A"]).sum()
Out[56]:
   B
  second A
 one  1 2
    2 4
    3 6
 two  1 4
    2 5
    3 7
```

### DataFrame column selection in GroupBy

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a DataFrame, you can do:

```python
In [57]: grouped = df.groupby(["A"])  
In [58]: grouped_C = grouped["C"]  
In [59]: grouped_D = grouped["D"]
```

This is mainly syntactic sugar for the alternative and much more verbose:

```python
In [60]: df["C"].groupby(df["A"])  
Out[60]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7f4305e377f0>
```

2.18. Group by: split-apply-combine

781
Additionally this method avoids recomputing the internal grouping information derived from the passed key.

### 2.18.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```python
In [61]: grouped = df.groupby('A')

In [62]: for name, group in grouped:
    ...:     print(name)
    ...:     print(group)
    ...:
bar
   A  B  C  D
  1  bar one  0.254161  1.511763
  3  bar three  0.215897  -0.990582
  5  bar two  -0.077118   1.211526
foo
   A  B  C  D
  0  foo one  -0.575247   1.346061
  2  foo two  -1.143704   1.627081
  4  foo two   1.193555  -0.441652
  6  foo one  -0.408530   0.268520
  7  foo three  -0.862495   0.024580
```

In the case of grouping by multiple keys, the group name will be a tuple:

```python
In [63]: for name, group in df.groupby(['A', 'B']):
    ...:     print(name)
    ...:     print(group)
    ...:
('bar', 'one')
   A  B  C  D
  1  bar one  0.254161  1.511763
('bar', 'three')
   A  B  C  D
  3  bar three  0.215897  -0.990582
('bar', 'two')
   A  B  C  D
  5  bar two  -0.077118   1.211526
('foo', 'one')
   A  B  C  D
  0  foo one  -0.575247   1.346061
('foo', 'two')
   A  B  C  D
  6  foo two  -0.408530   0.268520
('foo', 'three')
   A  B  C  D
  7  foo three  -0.862495   0.024580
('foo', 'two')
   A  B  C  D
  2  foo two  -1.143704   1.627081
  4  foo two   1.193555  -0.441652
```

See [Iterating through groups](#).
2.18.3 Selecting a group

A single group can be selected using `get_group()`:

```
In [64]: grouped.get_group("bar")
Out[64]:
   A   B   C   D
1  bar one 0.254161 1.511763
3  bar three 0.215897 -0.990582
5  bar two -0.077118 1.211526
```

Or for an object grouped on multiple columns:

```
In [65]: df.groupby(["A", "B"]).get_group(("bar", "one"))
Out[65]:
   A   B   C   D
1  bar one 0.254161 1.511763
```

2.18.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the aggregating API, window API, and resample API.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```
In [66]: grouped = df.groupby("A")
In [67]: grouped.aggregate(np.sum)
Out[67]:
   C   D
A
bar 0.392940 1.732707
foo -1.796421 2.824590
```

```
In [68]: grouped = df.groupby(["A", "B"])
In [69]: grouped.aggregate(np.sum)
Out[69]:
   C   D
A B
bar one 0.254161 1.511763
   three 0.215897 -0.990582
   two -0.077118 1.211526
foo one -0.983776 1.614581
   three -0.862495 0.024580
   two 0.049851 1.185429
```

As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a `MultiIndex` by default, though this can be changed by using the `as_index` option:

```
In [70]: grouped = df.groupby(["A", "B"], as_index=False)
In [71]: grouped.aggregate(np.sum)
```

(continues on next page)
Out[71]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>bar</td>
<td>one</td>
<td>0.254161</td>
<td>1.511763</td>
</tr>
<tr>
<td>1</td>
<td>bar</td>
<td>three</td>
<td>0.215897</td>
<td>-0.990582</td>
</tr>
<tr>
<td>2</td>
<td>bar</td>
<td>two</td>
<td>-0.077118</td>
<td>1.211526</td>
</tr>
<tr>
<td>3</td>
<td>foo</td>
<td>one</td>
<td>-0.983776</td>
<td>1.614581</td>
</tr>
<tr>
<td>4</td>
<td>foo</td>
<td>three</td>
<td>-0.862495</td>
<td>0.024580</td>
</tr>
<tr>
<td>5</td>
<td>foo</td>
<td>two</td>
<td>0.049851</td>
<td>1.185429</td>
</tr>
</tbody>
</table>

In [72]: df.groupby("A", as_index=False).sum()

Out[72]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>bar</td>
<td>0.392940</td>
<td>1.732707</td>
</tr>
<tr>
<td>1</td>
<td>foo</td>
<td>-1.796421</td>
<td>2.824590</td>
</tr>
</tbody>
</table>

Note that you could use the reset_index DataFrame function to achieve the same result as the column names are stored in the resulting MultiIndex:

In [73]: df.groupby(["A", "B"]).sum().reset_index()

Out[73]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>bar</td>
<td>one</td>
<td>0.254161</td>
<td>1.511763</td>
</tr>
<tr>
<td>1</td>
<td>bar</td>
<td>three</td>
<td>0.215897</td>
<td>-0.990582</td>
</tr>
<tr>
<td>2</td>
<td>bar</td>
<td>two</td>
<td>-0.077118</td>
<td>1.211526</td>
</tr>
<tr>
<td>3</td>
<td>foo</td>
<td>one</td>
<td>-0.983776</td>
<td>1.614581</td>
</tr>
<tr>
<td>4</td>
<td>foo</td>
<td>three</td>
<td>-0.862495</td>
<td>0.024580</td>
</tr>
<tr>
<td>5</td>
<td>foo</td>
<td>two</td>
<td>0.049851</td>
<td>1.185429</td>
</tr>
</tbody>
</table>

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the size method. It returns a Series whose index are the group names and whose values are the sizes of each group.

In [74]: grouped.size()

Out[74]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>bar</td>
<td>one</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>bar</td>
<td>three</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>bar</td>
<td>two</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>foo</td>
<td>one</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>foo</td>
<td>three</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>foo</td>
<td>two</td>
<td>2</td>
</tr>
</tbody>
</table>

In [75]: grouped.describe()

Out[75]:

<table>
<thead>
<tr>
<th></th>
<th>C</th>

</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>mean</td>
<td>std</td>
</tr>
<tr>
<td>---</td>
<td>-----</td>
<td>-----</td>
</tr>
<tr>
<td>mean</td>
<td>std</td>
<td>min</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0.254161</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0.215897</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>0.077118</td>
</tr>
</tbody>
</table>
| 3 | 1 | 0.211526 | NaN | 0.211526 | 0.211526 | 0.211526 | 0.211526 | 0.211526 | 1.0 |...
Another aggregation example is to compute the number of unique values of each group. This is similar to the `value_counts` function, except that it only counts unique values.

```
In [76]: ll = [['foo', 1], ['foo', 2], ['foo', 2], ['bar', 1], ['bar', 1]]

In [77]: df4 = pd.DataFrame(ll, columns=['A', 'B'])

In [78]: df4.groupby('A')['B'].nunique()
```

```
Out[78]:
A
bar 1
foo 2
Name: B, dtype: int64
```

**Note:** Aggregation functions will not return the groups that you are aggregating over if they are named `columns`, when `as_index=True`, the default. The grouped columns will be the indices of the returned object.

Passing `as_index=False` will return the groups that you are aggregating over, if they are named `columns`.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean()</td>
<td>Compute mean of groups</td>
</tr>
<tr>
<td>sum()</td>
<td>Compute sum of group values</td>
</tr>
<tr>
<td>size()</td>
<td>Compute group sizes</td>
</tr>
<tr>
<td>count()</td>
<td>Compute count of group</td>
</tr>
<tr>
<td>std()</td>
<td>Standard deviation of groups</td>
</tr>
<tr>
<td>var()</td>
<td>Compute variance of groups</td>
</tr>
<tr>
<td>sem()</td>
<td>Standard error of the mean of groups</td>
</tr>
<tr>
<td>describe()</td>
<td>Generates descriptive statistics</td>
</tr>
<tr>
<td>first()</td>
<td>Compute first of group values</td>
</tr>
<tr>
<td>last()</td>
<td>Compute last of group values</td>
</tr>
<tr>
<td>nth()</td>
<td>Take nth value, or a subset if n is a list</td>
</tr>
<tr>
<td>min()</td>
<td>Compute min of group values</td>
</tr>
<tr>
<td>max()</td>
<td>Compute max of group values</td>
</tr>
</tbody>
</table>

The aggregating functions above will exclude NA values. Any function which reduces a `Series` to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer or a filter, see [here](#).

### Applying multiple functions at once

With grouped `Series` you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [80]: grouped = df.groupby("A")

In [81]: grouped["C"].agg([np.sum, np.mean, np.std])
Out[81]:
    sum       mean       std
  A
  bar      0.392940   0.130980   0.181231
  foo     -1.796421  -0.359284   0.912265

On a grouped `DataFrame`, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [82]: grouped.agg([np.sum, np.mean, np.std])
Out[82]:
     C          D
    sum       mean       std     sum       mean       std
  A
  bar      0.392940   0.130980   0.181231   1.732707   0.577569   1.366330
  foo     -1.796421  -0.359284   0.912265   2.824590   0.564918   0.884785
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a `Series` like this:

```
In [83]:  (      
      .....:     grouped["C"]  
      .....:       .agg([np.sum, np.mean, np.std])  
      .....:         .rename(columns={"sum": "foo", "mean": "bar", "std": "baz"})  
      .....:     )  
      .....:
```
For a grouped DataFrame, you can rename in a similar manner:

```python
In [84]: (.....: grouped.agg([np.sum, np.mean, np.std]).rename(.....: columns={"sum": "foo", "mean": "bar", "std": "baz"}).....: ).....:
Out[84]:

<table>
<thead>
<tr>
<th></th>
<th>foo</th>
<th>bar</th>
<th>baz</th>
<th>foo</th>
<th>bar</th>
<th>baz</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A</td>
<td>A</td>
<td>A</td>
<td>A</td>
<td>A</td>
<td>A</td>
</tr>
<tr>
<td>bar</td>
<td>0.392940</td>
<td>0.130980</td>
<td>0.181231</td>
<td>1.732707</td>
<td>0.577569</td>
<td>1.366330</td>
</tr>
<tr>
<td>foo</td>
<td>-1.796421</td>
<td>-0.359284</td>
<td>0.912265</td>
<td>2.824590</td>
<td>0.564918</td>
<td>0.884785</td>
</tr>
</tbody>
</table>
```

Note: In general, the output column names should be unique. You can’t apply the same function (or two functions with the same name) to the same column.

```python
In [85]: grouped."C".agg(["sum", "sum"])  
Out[85]:

<table>
<thead>
<tr>
<th></th>
<th>sum</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A</td>
<td>A</td>
</tr>
<tr>
<td>bar</td>
<td>0.392940</td>
<td>0.392940</td>
</tr>
<tr>
<td>foo</td>
<td>-1.796421</td>
<td>-1.796421</td>
</tr>
</tbody>
</table>
```

`pandas` does allow you to provide multiple lambdas. In this case, `pandas` will mangle the name of the (nameless) lambda functions, appending <i>_<i> to each subsequent lambda.

```python
In [86]: grouped."C".agg([lambda x: x.max() - x.min(), lambda x: x.median() - x.mean()])  
Out[86]:

<table>
<thead>
<tr>
<th></th>
<th>lambda_0</th>
<th>lambda_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A</td>
<td>A</td>
</tr>
<tr>
<td>bar</td>
<td>0.331279</td>
<td>0.084917</td>
</tr>
<tr>
<td>foo</td>
<td>2.337259</td>
<td>-0.215962</td>
</tr>
</tbody>
</table>
```

2.18. Group by: split-apply-combine
Named aggregation

New in version 0.25.0.

To support column-specific aggregation with control over the output column names, pandas accepts the special syntax in `GroupBy.agg()`, known as “named aggregation”, where

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. pandas provides the `pandas.NamedAgg` namedtuple with the fields `['column', 'aggfunc']` to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

```python
In [87]: animals = pd.DataFrame(
    ...:     {
    ...:         "kind": ["cat", "dog", "cat", "dog"],
    ...:         "height": [9.1, 6.0, 9.5, 34.0],
    ...:         "weight": [7.9, 7.5, 9.9, 198.0],
    ...:     })

In [88]: animals
Out[88]:
    kind  height  weight
0    cat     9.1      7.9
1    dog     6.0      7.5
2    cat     9.5      9.9
3    dog    34.0    198.0

In [89]: animals.groupby("kind").agg(
    ...:     min_height=pd.NamedAgg(column="height", aggfunc="min"),
    ...:     max_height=pd.NamedAgg(column="height", aggfunc="max"),
    ...:     average_weight=pd.NamedAgg(column="weight", aggfunc=np.mean),
    ...: )

Out[89]:
    min_height  max_height  average_weight
kind
  cat     9.1          9.5  8.90
  dog     6.0         34.0 102.75
```

`pandas.NamedAgg` is just a namedtuple. Plain tuples are allowed as well.

```python
In [90]: animals.groupby("kind").agg(
    ...:     min_height=("height", "min"),
    ...:     max_height=("height", "max"),
    ...:     average_weight=("weight", np.mean),
    ...: )

Out[90]:
    min_height  max_height  average_weight
kind
  cat     9.1          9.5  8.90
  dog     6.0         34.0 102.75
```
If your desired output column names are not valid Python keywords, construct a dictionary and unpack the keyword arguments:

```python
In [91]: animals.groupby("kind").agg(
   ...:     **{
   ...:         "total weight": pd.NamedAgg(column="weight", aggfunc=sum)
   ...:     })
```

```sql
Out[91]:
```

<table>
<thead>
<tr>
<th>kind</th>
<th>total weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>17.8</td>
</tr>
<tr>
<td>dog</td>
<td>205.5</td>
</tr>
</tbody>
</table>

Additional keyword arguments are not passed through to the aggregation functions. Only pairs of (column, aggfunc) should be passed as **kwargs. If your aggregation functions requires additional arguments, partially apply them with `functools.partial()`.

**Note:** For Python 3.5 and earlier, the order of **kwargs in a functions was not preserved. This means that the output column ordering would not be consistent. To ensure consistent ordering, the keys (and so output columns) will always be sorted for Python 3.5.

Named aggregation is also valid for Series groupby aggregations. In this case there’s no column selection, so the values are just the functions:

```python
In [92]: animals.groupby("kind").height.agg(
   ...:     min_height="min",
   ...:     max_height="max",
   ...: )
```

```sql
Out[92]:
```

<table>
<thead>
<tr>
<th>kind</th>
<th>min_height</th>
<th>max_height</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>9.1</td>
<td>9.5</td>
</tr>
<tr>
<td>dog</td>
<td>6.0</td>
<td>34.0</td>
</tr>
</tbody>
</table>

**Applying different functions to DataFrame columns**

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```python
In [93]: grouped.agg({"C": np.sum, "D": lambda x: np.std(x, ddof=1)})
```

```sql
Out[93]:
```

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.392940</td>
<td>1.366330</td>
</tr>
<tr>
<td>foo</td>
<td>-1.796421</td>
<td>0.884785</td>
</tr>
</tbody>
</table>

The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via `dispatching`:  

---

2.18. Group by: split-apply-combine
Cython-optimized aggregation functions

Some common aggregations, currently only sum, mean, std, and sem, have optimized Cython implementations:

```python
In [95]: df.groupby("A").sum()
Out[95]:
   C    D
  A
bar  0.392940  1.732707
foo -1.796421  2.824590
```

```python
In [96]: df.groupby(["A", "B"]).mean()
Out[96]:
   C    D
  A B
  bar one  0.254161  1.511763
two  0.215897  0.990582
three -0.077118  1.211526
  foo one -0.491888  0.807291
two  0.024925  0.592714
three -0.862495  0.024580
```

Of course sum and mean are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

Aggregations with User-Defined Functions

Users can also provide their own functions for custom aggregations. When aggregating with a User-Defined Function (UDF), the UDF should not mutate the provided Series, see Mutating with User Defined Function (UDF) methods for more information.

```python
In [97]: animals.groupby("kind")[["height"]].agg(lambda x: set(x))
Out[97]:
   height
  kind
cat  {9.1, 9.5}
dog  {34.0, 6.0}
```

The resulting dtype will reflect that of the aggregating function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as DataFrame construction.

```python
In [98]: animals.groupby("kind")[["height"]].agg(lambda x: x.astype(int).sum())
Out[98]:
   height

(continues on next page)
2.18.5 Transformation

The transform method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the second chunk.

Similar to Aggregations with User-Defined Functions, the resulting dtype will reflect that of the transformation function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as `DataFrame` construction.

Suppose we wished to standardize the data within each group:

```python
In [99]: index = pd.date_range("10/1/1999", periods=1100)
In [100]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)
In [101]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()
In [102]: ts.head()
Out[102]:
2000-01-08  0.779333
2000-01-09  0.778852
2000-01-10  0.786476
2000-01-11  0.782797
2000-01-12  0.798110
Freq: D, dtype: float64
In [103]: ts.tail()
Out[103]:
2002-09-30  0.660294
2002-10-01  0.631095
2002-10-02  0.673601
2002-10-03  0.709213
2002-10-04  0.719369
Freq: D, dtype: float64
In [104]: transformed = ts.groupby(lambda x: x.year).transform(
    .....:     lambda x: (x - x.mean()) / x.std())
```

(continues on next page)
We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```python
# Original Data
In [105]: grouped = ts.groupby(lambda x: x.year)

In [106]: grouped.mean()
Out[106]:
2000    0.442441
2001    0.526246
2002    0.459365
dtype: float64

In [107]: grouped.std()
Out[107]:
2000    0.131752
2001    0.210945
2002    0.128753
dtype: float64

# Transformed Data
In [108]: grouped_trans = transformed.groupby(lambda x: x.year)

In [109]: grouped_trans.mean()
Out[109]:
2000    1.193722e-15
2001    1.945476e-15
2002    1.272949e-15
dtype: float64

In [110]: grouped_trans.std()
Out[110]:
2000    1.0
2001    1.0
2002    1.0
dtype: float64
```

We can also visually compare the original and transformed data sets.

```python
In [111]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})
In [112]: compare.plot()
Out[112]: <AxesSubplot:>
```
Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [113]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
Out[13]:
2000-01-08    0.623893
2000-01-09    0.623893
2000-01-10    0.623893
2000-01-11    0.623893
2000-01-12    0.623893
   ...    ...
2002-09-30    0.558275
2002-10-01    0.558275
2002-10-02    0.558275
2002-10-03    0.558275
2002-10-04    0.558275
Freq: D, Length: 1001, dtype: float64
```

Alternatively, the built-in methods could be used to produce the same outputs.

```
In [114]: max = ts.groupby(lambda x: x.year).transform("max")
In [115]: min = ts.groupby(lambda x: x.year).transform("min")
In [116]: max - min
```

(continues on next page)
Another common data transform is to replace missing data with the group mean.

```python
In [117]: data_df
Out[117]:
   A        B        C
0  1.539708 -1.166480  0.533026
1  1.302092 -0.505754  NaN
2 -0.371983  1.104803 -0.651520
3 -1.309622  1.118697 -1.161657
4 -1.924296  0.396437  0.812436
   ...       ...       ...
995 -0.093110  0.683847 -0.774753
996 -0.185043  1.438572  NaN
997 -0.394469 -0.642343  0.011374
998 -1.174126  1.857148  NaN
999  0.234564  0.517098  0.393534
```

We can verify that the group means have not changed in the transformed data and that the transformed data contains no NAs.

```python
In [122]: transformed = grouped.transform(lambda x: x.fillna(x.mean()))
```
In [123]: grouped_trans = transformed.groupby(key)

In [124]: grouped.mean()  # original group means
Out[124]:
    A     B     C
GR -0.098371 -0.015420  0.068053
JP  0.069025  0.023100 -0.077324
UK  0.034069 -0.052580 -0.116525
US  0.058664 -0.020399  0.028603

In [125]: grouped_trans.mean()  # transformation did not change group means
Out[125]:
    A     B     C
GR -0.098371 -0.015420  0.068053
JP  0.069025  0.023100 -0.077324
UK  0.034069 -0.052580 -0.116525
US  0.058664 -0.020399  0.028603

In [126]: grouped.count()  # original has some missing data points
Out[126]:
      A     B     C
GR  209  217   189
JP  240  255   217
UK  216  231   193
US  239  250   217

In [127]: grouped_trans.count()  # counts after transformation
Out[127]:
      A     B     C
GR  228  228   228
JP  267  267   267
UK  247  247   247
US  258  258   258

In [128]: grouped_trans.size()  # Verify non-NA count equals group size
Out[128]:
      GR   JP   UK   US
228  228  228  228

Note:  Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing as_index=False will not affect these transformation methods.

For example: fillna, ffill, bfill, shift..

In [129]: grouped.ffill()
Out[129]:
     A     B     C
0  1.539708 -1.166480  0.533026
1  1.302092  0.505754  0.533026
Window and resample operations

It is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
In [131]: df_re
Out[131]:
     A  B
0     1  0
1     1  1
2     1  2
3     1  3
4     1  4
...  ... ...
15    5 15
16    5 16
17    5 17
18    5 18
19    5 19
[20 rows x 2 columns]

In [132]: df_re.groupby("A").rolling(4).B.mean()
Out[132]:
     A  0  1  2  3
0   NaN NaN NaN NaN
1  NaN NaN  1.5 NaN
2  NaN  2.5 NaN NaN
3   3  3.5 NaN NaN
4   4  4.5 NaN NaN
... ...
15  15 15.5 NaN NaN
16  16 16.5 NaN NaN
17  16 17.5 NaN NaN
```

The `expanding()` method will accumulate a given operation (sum() in the example) for all the members of each particular group.

```
In [133]: df_re.groupby("A").expanding().sum()
Out[133]:
   B  
A   
  0  0
  1  1
  2  3
  3  6
  4 10
... ...
  5 15
  6 21
  7 28
  8 36
  9 45
[20 rows x 1 columns]
```

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

```
In [134]: df_re = pd.DataFrame(  
      .....:       {  
      .....:         "date": pd.date_range(start="2016-01-01", periods=4, freq="W"),  
      .....:         "group": [1, 1, 2, 2],  
      .....:         "val": [5, 6, 7, 8],  
      .....:     }  
      .....: ).set_index("date")
      .....: )
In [135]: df_re
Out[135]:

   group  val
date
2016-01-03  1  5
2016-01-10  1  6
2016-01-17  2  7
2016-01-24  2  8
```

```
In [136]: df_re.groupby("group").resample("1D").ffill()
Out[136]:

   group  val
date
1  2016-01-03  1  5
2016-01-04  1  5
```

(continues on next page)
2.18.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```python
In [137]: sf = pd.Series([1, 1, 2, 3, 3, 3])
In [138]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[138]:
3    3
4    3
5    3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```python
In [139]: dff = pd.DataFrame({"A": np.arange(8), "B": list("aabbbbcc")})
In [140]: dff.groupby("B").filter(lambda x: len(x) > 2)
Out[140]:
   A  B
2  2  b
3  3  b
4  4  b
5  5  b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```python
In [141]: dff.groupby("B").filter(lambda x: len(x) > 2, dropna=False)
Out[141]:
   A  B
0  NaN NaN
1  NaN NaN
2  2.0  NaN
3  3.0  b
4  4.0  b
5  5.0  b
```

(continues on next page)
For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```python
In [142]: dff["C"] = np.arange(8)
In [143]: dff.groupby("B").filter(lambda x: len(x["C"]) > 2)
```

```
A  B  C
2  2  b  2
3  3  b  3
4  4  b  4
5  5  b  5
```

Note: Some functions when applied to a groupby object will act as a filter on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

```python
In [144]: dff.groupby("B").head(2)
```

```
A  B  C
0  0  a  0
1  1  a  1
2  2  b  2
3  3  b  3
6  6  c  6
7  7  c  7
```

### 2.18.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```python
In [145]: grouped = df.groupby("A")
In [146]: grouped.agg(lambda x: x.std())
```

```
C   D
A
bar 0.181231 1.366330
foo 0.912265 0.884785
```

But, it’s rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:
What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed
arguments and invokes the function with any arguments on each group (in the above example, the std function). The
results are then combined together much in the style of agg and transform (it actually uses apply to infer the gluing,
documented next). This enables some operations to be carried out rather succinctly:

```python
In [148]: tsdf = pd.DataFrame(
    ....:     np.random.randn(1000, 3),
    ....:     index=pd.date_range("1/1/2000", periods=1000),
    ....:     columns=["A", "B", "C"],
    ....: )
    ....:
In [149]: tsdf.iloc[::2] = np.nan
In [150]: grouped = tsdf.groupby(lambda x: x.year)
In [151]: grouped.fillna(method="pad")
Out[151]:
         A      B      C
2000-01-01 NaN  NaN  NaN
2000-01-02 -0.353501 -0.080957 -0.876864
2000-01-03 -0.353501 -0.080957 -0.876864
2000-01-04 0.050976 0.044273 -0.559849
2000-01-05 0.050976 0.044273 -0.559849
... ... ... ...
2002-09-22 0.005011 0.053897 -1.026922
2002-09-23 0.005011 0.053897 -1.026922
2002-09-24 -0.456542 -1.849051 1.559856
2002-09-25 -0.456542 -1.849051 1.559856
2002-09-26 1.123162 0.354660 1.128135
[1000 rows x 3 columns]
```

In this example, we chopped the collection of time series into yearly chunks then independently called fillna on the
groups.

The nlargest and nsmallest methods work on Series style groupbys:

```python
In [152]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
In [153]: g = pd.Series(list("abababab"))
In [154]: gb = s.groupby(g)
In [155]: gb.nlargest(3)
Out[155]:
   a  b
0  4  9.0
1  0  9.0
```

(continues on next page)
2.18.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want GroupBy to infer how to combine the results. For these, use the apply function, which can be substituted for both aggregate and transform in many standard use cases. However, apply can handle some exceptional use cases, for example:

```python
In [157]: df
Out[157]:
     A  B    C     D
0  foo one -0.575  1.3461
1  bar one  0.254  1.5118
2  foo two -1.144  1.6271
3  bar three 0.215 -0.9905
4  foo two  1.193 -0.4416
5  bar two  0.077  1.2112
6  foo one  0.4085  0.2685
7  foo three -0.862  0.0246
```

```python
In [158]: grouped = df.groupby("A")
    # could also just call .describe()
In [159]: grouped["C"].apply(lambda x: x.describe())
Out[159]:
          A
bar count   3.000000
mean    0.130980
std     0.181231
min    -0.077118
25%     0.069390
... 
foo min   -1.143704
25%    -0.862495
50%    -0.575247
75%    -0.408530
```
max 1.193555
Name: C, Length: 16, dtype: float64

The dimension of the returned result can also change:

```python
In [160]: grouped = df.groupby('A')['C']

In [161]: def f(group):
    .....:     return pd.DataFrame({'original': group,
    .....:                              'demeaned': group - group.mean()})
    .....:

In [162]: grouped.apply(f)
Out[162]:
          original  demeaned
0 -0.575247 -0.215962
1  0.254161  0.123181
2 -1.143704 -0.784420
3  0.215897  0.084917
4  1.193555  1.552839
5 -0.077118 -0.208098
6 -0.408530 -0.049245
7 -0.862495 -0.503211

apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

```python
In [163]: def f(x):
    .....:     return pd.Series([x, x ** 2], index=['x', 'x^2'])
    .....:

In [164]: s = pd.Series(np.random.rand(5))

In [165]: s
Out[165]:
0   0.321438
1   0.493496
2   0.139505
3   0.910103
4   0.194158
dtype: float64

In [166]: s.apply(f)
Out[166]:
          x  x^2
0  0.321438  0.103323
1  0.493496  0.243538
2  0.139505  0.019462
3  0.910103  0.828287
4  0.194158  0.037697
```

Note: apply can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So
depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

Similar to Aggregations with User-Defined Functions, the resulting dtype will reflect that of the apply function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as DataFrame construction.

### 2.18.9 Numba Accelerated Routines

New in version 1.1.

If Numba is installed as an optional dependency, the transform and aggregate methods support engine='numba' and engine_kwargs arguments. See enhancing performance with Numba for general usage of the arguments and performance considerations.

The function signature must start with values, index exactly as the data belonging to each group will be passed into values, and the group index will be passed into index.

**Warning:** When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as NumPy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

### 2.18.10 Other useful features

#### Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```python
In [167]: df
Out[167]:
     A   B     C     D
0   foo   one  -0.575247  1.346061
1   bar   one   0.254161  1.511763
2   foo   two  -1.143704  1.627081
3   bar   three  0.215897  -0.990582
4   foo   two   1.193555  -0.441652
5   bar   two  -0.077118   1.211526
6   foo   one  -0.408530   0.268520
7   foo   three  -0.862495   0.024580
```

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```python
In [168]: df.groupby("A").std()
Out[168]:
     C    D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```
Note that `df.groupby('A').colname.std()` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered _before_ applying the aggregation function.

**Note:** Any object column, also if it contains numerical values such as `Decimal` objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in groupby.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```python
In [169]: from decimal import Decimal

In [170]: df_dec = pd.DataFrame({
    ...:     "id": [1, 2, 1, 2],
    ...:     "int_column": [1, 2, 3, 4],
    ...:     "dec_column": [
    ...:         Decimal("0.50"),
    ...:         Decimal("0.15"),
    ...:         Decimal("0.25"),
    ...:         Decimal("0.40"),
    ...:     ],
    ...: })

# Decimal columns can be sum'd explicitly by themselves...
In [171]: df_dec.groupby(["id"])[["dec_column"]].sum()
Out[171]:
     dec_column
id      
1 0.75
2 0.55

# ...but cannot be combined with standard data types or they will be excluded
In [172]: df_dec.groupby(["id"])[["int_column", "dec_column"]].sum()
Out[172]:
   int_column        
id      
1 4
2 6

# Use .agg function to aggregate over standard and "nuisance" data types
# at the same time
In [173]: df_dec.groupby(["id"]).agg({"int_column": "sum", "dec_column": "sum"})
Out[173]:
    int_column  dec_column
id      
1  4  0.75
2  6  0.55
```
Handling of (un)observed Categorical values

When using a Categorical grouper (as a single grouper, or as part of multiple groupers), the observed keyword controls whether to return a cartesian product of all possible groupers values (observed=False) or only those that are observed groupers (observed=True).

Show all values:

```
In [174]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=False).count()
Out[174]:
   a  3
   b  0
dtype: int64
```

Show only the observed values:

```
In [175]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=True).count()
Out[175]:
   a  3
dtype: int64
```

The returned dtype of the grouped will always include all of the categories that were grouped.

```
In [176]: s = (pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=False).count())
In [177]: s.index.dtype
Out[177]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```
**NA and NaT group handling**

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

**Grouping with ordered factors**

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [178]: data = pd.Series(np.random.randn(100))
In [179]: factor = pd.qcut(data, [0, 0.25, 0.5, 0.75, 1.0])
In [180]: data.groupby(factor).mean()
Out[180]:
  (-2.645, -0.523]  -1.362896
  (-0.523, 0.0296]  -0.260266
  (0.0296, 0.654]   0.361802
  (0.654, 2.21]    1.073801
dtype: float64
```

**Grouping with a grouper specification**

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [181]: import datetime
In [182]: df = pd.DataFrame(
    .....:
    "Branch": "A A A A A A A B".split(),
    "Buyer": "Carl Mark Carl Carl Joe Joe Joe Carl".split(),
    "Quantity": [1, 3, 5, 1, 8, 1, 9, 3],
    "Date": [datetime.datetime(2013, 1, 1, 13, 0),
              datetime.datetime(2013, 1, 1, 13, 5),
              datetime.datetime(2013, 10, 1, 20, 0),
              datetime.datetime(2013, 10, 2, 10, 0),
              datetime.datetime(2013, 10, 1, 20, 0),
              datetime.datetime(2013, 10, 2, 10, 0),
              datetime.datetime(2013, 12, 2, 12, 0),
              datetime.datetime(2013, 12, 2, 14, 0),
           ],
    )
In [183]: df
Out[183]:
```

(continues on next page)
Groupby a specific column with the desired frequency. This is like resampling.

```python
In [184]: df.groupby([pd.Grouper(freq="1M", key="Date"), "Buyer"]).sum()
Out[184]:
                      Quantity
Date  Buyer
2013-01-31  Carl  1
       Mark  3
2013-10-31  Carl  6
       Joe  9
2013-12-31  Carl  3
       Joe  9
```

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```python
In [185]: df = df.set_index("Date")
In [186]: df["Date"] = df.index + pd.offsets.MonthEnd(2)
In [187]: df.groupby([pd.Grouper(freq="6M", key="Date"), "Buyer"]).sum()
Out[187]:
                      Quantity
Date  Buyer
2013-02-28  Carl  1
       Mark  3
2014-02-28  Carl  9
       Joe 18
```

```python
In [188]: df.groupby([pd.Grouper(freq="6M", level="Date"), "Buyer"]).sum()
Out[188]:
                      Quantity
Date  Buyer
2013-01-31  Carl  1
       Mark  3
2014-01-31  Carl  9
       Joe 18
```
Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```python
In [189]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])

In [190]: df
Out[190]:
    A  B
0  1  2
1  1  4
2  5  6

In [191]: g = df.groupby('A')

In [192]: g.head(1)
Out[192]:
     A  B
0  1  2
2  5  6

In [193]: g.tail(1)
Out[193]:
     A  B
1  1  4
2  5  6
```

This shows the first or last n rows from each group.

Taking the nth row of each group

To select from a DataFrame or Series the nth item, use nth(). This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```python
In [194]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [195]: g = df.groupby('A')

In [196]: g.nth(0)
Out[196]:
    B
A
  1  NaN
  5  6.0

In [197]: g.nth(-1)
Out[197]:
    B
A
  1  4.0
  5  6.0

In [198]: g.nth(1)
```

(continues on next page)
If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to `dropna`:

```python
# nth(0) is the same as g.first()
In [199]: g.nth(0, dropna="any")
Out[199]:
   B
A  
 1  4.0
 5  6.0

In [200]: g.first()
Out[200]:
   B
A  
 1  4.0
 5  6.0

# nth(-1) is the same as g.last()
In [201]: g.nth(-1, dropna="any")  # NaNs denote group exhausted when using dropna
Out[201]:
   B
A  
 1  4.0
 5  6.0

In [202]: g.last()
Out[202]:
   B
A  
 1  4.0
 5  6.0

In [203]: g.B.nth(0, dropna="all")
Out[203]:
   B
A  
 1  4.0
 5  6.0
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```python
In [204]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=["A", "B"])
In [205]: g = df.groupby("A", as_index=False)
In [206]: g.nth(0)
(continues on next page)```
Out[206]:
    A  B
0  NaN
2  6.0

In [207]: g.nth(-1)
Out[207]:
    A  B
1  4.0
2  6.0

You can also select multiple rows from each group by specifying multiple nth values as a list of ints.

In [208]: business_dates = pd.date_range(start="4/1/2014", end="6/30/2014", freq="B")
In [209]: df = pd.DataFrame(1, index=business_dates, columns="a", "b")

# get the first, 4th, and last date index for each month
In [210]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[210]:
     a  b
2014 1 1
     4 1
     4 1
     5 1
     5 1
     5 1
     6 1
     6 1
     6 1

Enumerate group items

To see the order in which each row appears within its group, use the cumcount method:

In [211]: dfg = pd.DataFrame(list("aabba"), columns="A")
In [212]: dfg
Out[212]:
     A
0  a
1  a
2  a
3  b
4  b
5  a

In [213]: dfg.groupby("A").cumcount()
Out[213]:
   0
0  0
1  1
(continues on next page)
```
2    2
3    0
4    1
5    3
dtype: int64

In [214]: dfg.groupby("A").cumcount(ascending=False)
Out[214]:
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64
```

### Enumerate groups

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```
In [215]: dfg = pd.DataFrame(list("aabba"), columns=["A"])

In [216]: dfg
Out[216]:
   A
0  a
1  a
2  a
3  b
4  b
5  a

In [217]: dfg.groupby("A").ngroup()
Out[217]:
0    0
1    0
2    0
3    1
4    1
5    0
dtype: int64

In [218]: dfg.groupby("A").ngroup(ascending=False)
Out[218]:
0    1
1    1
2    1
```
Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```python
In [219]: np.random.seed(1234)
In [220]: df = pd.DataFrame(np.random.randn(50, 2))
In [221]: df["g"] = np.random.choice(["A", "B"], size=50)
In [222]: df.loc[df["g"] == "B", 1] += 3

We can easily visualize this with a boxplot:

```
The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the visualization documentation for more.

**Warning:** For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

### Piping function calls

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a DataFrame with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of prices (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```python
In [224]: n = 1000
In [225]: df = pd.DataFrame(
```
In [226]: df.head(2)
Out[226]:
<table>
<thead>
<tr>
<th>Store</th>
<th>Product</th>
<th>Revenue</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store_2</td>
<td>Product_1</td>
<td>26.12</td>
<td>1</td>
</tr>
<tr>
<td>Store_2</td>
<td>Product_1</td>
<td>28.86</td>
<td>1</td>
</tr>
</tbody>
</table>

Now, to find prices per store/product, we can simply do:

In [227]:
   (df.groupby(['Store', 'Product'])
    .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
    .unstack()
    .round(2))
Out[227]:

<table>
<thead>
<tr>
<th>Product</th>
<th>Product_1</th>
<th>Product_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Store_1</td>
<td>6.82</td>
<td>7.05</td>
</tr>
<tr>
<td>Store_2</td>
<td>6.30</td>
<td>6.64</td>
</tr>
</tbody>
</table>

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

In [228]:
def mean(groupby):
   ...
   return groupby.mean()

In [229]: df.groupby(['Store', 'Product']).pipe(mean)
Out[229]:

<table>
<thead>
<tr>
<th>Store</th>
<th>Product</th>
<th>Revenue</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store_1</td>
<td>Product_1</td>
<td>34.622727</td>
<td>5.075758</td>
</tr>
<tr>
<td></td>
<td>Product_2</td>
<td>35.482815</td>
<td>5.029630</td>
</tr>
<tr>
<td>Store_2</td>
<td>Product_1</td>
<td>32.972837</td>
<td>5.237589</td>
</tr>
<tr>
<td></td>
<td>Product_2</td>
<td>34.684360</td>
<td>5.224000</td>
</tr>
</tbody>
</table>

where mean takes a GroupBy object and finds the mean of the Revenue and Quantity columns respectively for each Store-Product combination. The mean function can be any function that takes in a GroupBy object; the .pipe will pass the GroupBy object as a parameter into the function you specify.
2.18.11 Examples

Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

```python
In [230]: df = pd.DataFrame({'a': [1, 0, 0], 'b': [0, 1, 0], 'c': [1, 0, 0], 'd': [2, 3, 4]})
In [231]: df
Out[231]:
   a  b  c  d
0  1  0  1  2
1  0  1  0  3
2  0  0  0  4
In [232]: df.groupby(df.sum(), axis=1).sum()
Out[232]:
   0  1
0  2  2
1  1  3
2  0  4
```

Multi-column factorization

By using `ngroup()`, we can extract information about the groups in a way similar to `factorize()` (as described further in the reshaping API) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the [Categorical introduction](https://pandas.pydata.org/pandas-docs/stable/user_guide/categorical.html) and the [API documentation](https.).)

```python
In [233]: dfg = pd.DataFrame({'A': [1, 1, 2, 3, 2], 'B': list('aaaba')})
In [234]: dfg
Out[234]:
   A  B
0  1  a
1  1  a
2  2  a
3  3  b
4  2  a
In [235]: dfg.groupby(['A', 'B']).ngroup()
Out[235]:
   0
0  0
1  0
2  1
3  2
4  1
dtype: int64
In [236]: dfg.groupby(['A', [0, 0, 0, 1, 1]]).ngroup()
```

(continues on next page)
Groupby by indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetimelike, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

Note: The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```python
In [237]: df = pd.DataFrame(np.random.randn(10, 2))
In [238]: df
Out[238]:
   0      1
0 -0.793893  0.321153
1  0.342250  1.618906
2 -0.975807  1.918201
3 -0.810847  1.918201
4 -1.977759 -1.405919
5  0.730057  1.316938
6 -0.751328 -1.316938
7 -0.257759 -1.081009
8  0.505895 -1.701948
9 -1.006349  0.020208
```

```python
In [239]: df.index // 5
Out[239]: Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1, 1], dtype='int64')
```

```python
In [240]: df.groupby(df.index // 5).std()
Out[240]:
   0      1
0  0.823647  1.312912
1  0.760109  0.942941
```
Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

```python
In [241]: df = pd.DataFrame(
   .....:   {
   .....:     "a": [0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2, 2],
   .....:     "b": [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],
   .....:     "c": [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
   .....:     "d": [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1],
   .....:   }
   .....:
)
```

```python
In [242]: def compute_metrics(x):
   .....:     result = {"b_sum": x["b"].sum(), "c_mean": x["c"].mean()}
   .....:     return pd.Series(result, name="metrics")
   .....:
```

```python
In [243]: result = df.groupby("a").apply(compute_metrics)
```

```
In [244]: result
Out[244]:
metrics  b_sum  c_mean
a  
0   2.0   0.5
1   2.0   0.5
2   2.0   0.5
```

```python
In [245]: result.stack()
Out[245]:
a metrics
0  b_sum   2.0
   c_mean  0.5
1  b_sum   2.0
   c_mean  0.5
2  b_sum   2.0
   c_mean  0.5
dtype: float64
```

2.19 Windowing Operations

pandas contains a compact set of APIs for performing windowing operations - an operation that performs an aggregation over a sliding partition of values. The API functions similarly to the `groupby` API in that `Series` and `DataFrame` calls the windowing method with necessary parameters and then subsequently call the aggregation function.

```python
In [1]: s = pd.Series(range(5))
```

```python
In [2]: s.rolling(window=2).sum()
```

(continues on next page)
The windows are comprised by looking back the length of the window from the current observation. The result above can be derived by taking the sum of the following windowed partitions of data:

```python
In [3]: for window in s.rolling(window=2):
    ...:     print(window)
    ...:
0 0
dtype: int64
0 0
1 1
dtype: int64
1 1
2 2
dtype: int64
2 2
3 3
dtype: int64
3 3
4 4
dtype: int64
```

### 2.19.1 Overview

pandas supports 4 types of windowing operations:

1. Rolling window: Generic fixed or variable sliding window over the values.
2. Weighted window: Weighted, non-rectangular window supplied by the `scipy.signal` library.
3. Expanding window: Accumulating window over the values.
4. Exponentially Weighted window: Accumulating and exponentially weighted window over the values.

<table>
<thead>
<tr>
<th>Concept</th>
<th>Method</th>
<th>Returned Object</th>
<th>Supports time-based windows</th>
<th>Supports chained groupby</th>
<th>Supports table method</th>
<th>Supports online operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rolling window</td>
<td>rolling</td>
<td>Rolling</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
<tr>
<td>Weighted window</td>
<td>rolling</td>
<td>Window</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Expanding window</td>
<td>expanding</td>
<td>Expanding</td>
<td>No</td>
<td>Yes</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
<tr>
<td>Exponentially Weighted</td>
<td>ewm</td>
<td>Exponential</td>
<td>Yes (as of version 1.2)</td>
<td>No</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
</tbody>
</table>
As noted above, some operations support specifying a window based on a time offset:

```python
In [4]: s = pd.Series(range(5), index=pd.date_range('2020-01-01', periods=5, freq='1D'))

In [5]: s.rolling(window='2D').sum()
Out[5]:
2020-01-01 0.0
2020-01-02 1.0
2020-01-03 3.0
2020-01-04 5.0
2020-01-05 7.0
Freq: D, dtype: float64
```

Additionally, some methods support chaining a `groupby` operation with a windowing operation which will first group the data by the specified keys and then perform a windowing operation per group.

```python
In [6]: df = pd.DataFrame({'A': ['a', 'b', 'a', 'b', 'a'], 'B': range(5)})

In [7]: df.groupby('A').expanding().sum()
Out[7]:
   B
A  
  a  0
  2  2.0
  4  6.0
  b  1
  3  4.0
```

**Note:** Windowing operations currently only support numeric data (integer and float) and will always return float64 values.

**Warning:** Some windowing aggregation, `mean`, `sum`, `var` and `std` methods may suffer from numerical imprecision due to the underlying windowing algorithms accumulating sums. When values differ with magnitude $1/\text{np.finfo(np.double).eps}$ this results in truncation. It must be noted, that large values may have an impact on windows, which do not include these values. Kahan summation is used to compute the rolling sums to preserve accuracy as much as possible.

New in version 1.3.0.

Some windowing operations also support the `method='table'` option in the constructor which performs the windowing operation over an entire `DataFrame` instead of a single column or row at a time. This can provide a useful performance benefit for a `DataFrame` with many columns or rows (with the corresponding `axis` argument) or the ability to utilize other columns during the windowing operation. The `method='table'` option can only be used if `engine='numba'` is specified in the corresponding method call.

For example, a `weighted mean` calculation can be calculated with `apply()` by specifying a separate column of weights.
New in version 1.3.

Some windowing operations also support an online method after constructing a windowing object which returns a new object that supports passing in new DataFrame or Series objects to continue the windowing calculation with the new values (i.e. online calculations). 

The methods on this new windowing objects must call the aggregation method first to “prime” the initial state of the online calculation. Then, new DataFrame or Series objects can be passed in the update argument to continue the windowing calculation.

All windowing operations support a min_periods argument that dictates the minimum amount of non-np.nan values a window must have; otherwise, the resulting value is np.nan. min_periods defaults to 1 for time-based windows and window for fixed windows.
Additionally, all windowing operations support the `aggregate` method for returning a result of multiple aggregations applied to a window.

```python
In [20]: df = pd.DataFrame({"A": range(5), "B": range(10, 15)})
In [21]: df.expanding().agg([np.sum, np.mean, np.std])
Out[21]:
   A         B
           sum  mean   std  sum  mean   std
0  0.0  0.0 NaN  10.0  10.0 NaN
1  3.0  1.0  1.000000  33.0  11.0  1.000000
2  6.0  1.5  1.290994  46.0  11.5  1.290994
3 10.0  2.0   1.581139  60.0  12.0   1.581139
```
2.19.2 Rolling window

Generic rolling windows support specifying windows as a fixed number of observations or variable number of observations based on an offset. If a time based offset is provided, the corresponding time based index must be monotonic.

```
In [22]: times = ['2020-01-01', '2020-01-03', '2020-01-04', '2020-01-05', '2020-01-29']

In [23]: s = pd.Series(range(5), index=pd.DatetimeIndex(times))

In [24]: s
Out[24]:
2020-01-01 0
2020-01-03 1
2020-01-04 2
2020-01-05 3
2020-01-29 4
dtype: int64

# Window with 2 observations
In [25]: s.rolling(window=2).sum()
Out[25]:
2020-01-01 NaN
2020-01-03 1.0
2020-01-04 3.0
2020-01-05 5.0
2020-01-29 7.0
dtype: float64

# Window with 2 days worth of observations
In [26]: s.rolling(window='2D').sum()
Out[26]:
2020-01-01 0.0
2020-01-03 1.0
2020-01-04 3.0
2020-01-05 5.0
2020-01-29 4.0
dtype: float64
```

For all supported aggregation functions, see *Rolling window functions*.

**Centering windows**

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

```
In [27]: s = pd.Series(range(10))

In [28]: s.rolling(window=5).mean()
Out[28]:
0   NaN
1   NaN
2   NaN
3   NaN
(continues on next page)
```
This can also be applied to datetime-like indices.

New in version 1.3.0.

```
In [30]: df = pd.DataFrame(
     ....:     {"A": [0, 1, 2, 3, 4]}, index=pd.date_range("2020", periods=5, freq="1D")
     ....: )
     ....:
In [31]: df
Out[31]:
      A
2020-01-01  0
2020-01-02  1
2020-01-03  2
2020-01-04  3
2020-01-05  4

In [32]: df.rolling("2D", center=False).mean()
Out[32]:
      A
2020-01-01  0.0
2020-01-02  0.5
2020-01-03  1.5
2020-01-04  2.5
2020-01-05  3.5

In [33]: df.rolling("2D", center=True).mean()
Out[33]:
      A
2020-01-01  0.5
```
Rolling window endpoints

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

<table>
<thead>
<tr>
<th>Value</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>'right'</td>
<td>close right endpoint</td>
</tr>
<tr>
<td>'left'</td>
<td>close left endpoint</td>
</tr>
<tr>
<td>'both'</td>
<td>close both endpoints</td>
</tr>
<tr>
<td>'neither'</td>
<td>open endpoints</td>
</tr>
</tbody>
</table>

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```
In [34]: df = pd.DataFrame(
    ....:     {"x": 1},
    ....:     index=[
    ....:         pd.Timestamp("20130101 09:00:01"),
    ....:         pd.Timestamp("20130101 09:00:02"),
    ....:         pd.Timestamp("20130101 09:00:03"),
    ....:         pd.Timestamp("20130101 09:00:04"),
    ....:         pd.Timestamp("20130101 09:00:06"),
    ....:     ],
    ....: )

In [35]: df["right"] = df.rolling("2s", closed="right").x.sum()  # default

In [36]: df["both"] = df.rolling("2s", closed="both").x.sum()

In [37]: df["left"] = df.rolling("2s", closed="left").x.sum()

In [38]: df["neither"] = df.rolling("2s", closed="neither").x.sum()

In [39]: df
Out[39]:
          x  right  both  left  neither
2013-01-01 09:00:01  1    1.0    1.0     NaN     NaN
2013-01-01 09:00:02  1    2.0    2.0     1.0     1.0
2013-01-01 09:00:03  1    2.0    3.0     2.0     1.0
2013-01-01 09:00:04  1    2.0    3.0     2.0     1.0
2013-01-01 09:00:06  1    1.0    2.0     1.0     NaN
```
Custom window rolling

New in version 1.0.

In addition to accepting an integer or offset as a window argument, rolling also accepts a BaseIndexer subclass that allows a user to define a custom method for calculating window bounds. The BaseIndexer subclass will need to define a get_window_bounds method that returns a tuple of two arrays, the first being the starting indices of the windows and second being the ending indices of the windows. Additionally, num_values, min_periods, center, closed and will automatically be passed to get_window_bounds and the defined method must always accept these arguments.

For example, if we have the following DataFrame

```
In [40]: use_expanding = [True, False, True, False, True]

In [41]: use_expanding
Out[41]: [True, False, True, False, True]

In [42]: df = pd.DataFrame({'values': range(5)})

In [43]: df
Out[43]:
   values
0      0
1      1
2      2
3      3
4      4
```

and we want to use an expanding window where use_expanding is True otherwise a window of size 1, we can create the following BaseIndexer subclass:

```
In [2]: from pandas.api.indexers import BaseIndexer

In [3]: class CustomIndexer(BaseIndexer):
   ...:     def get_window_bounds(self, num_values, min_periods, center, closed):
   ...:         start = np.empty(num_values, dtype=np.int64)
   ...:         end = np.empty(num_values, dtype=np.int64)
   ...:         for i in range(num_values):
   ...:             if self.use_expanding[i]:
   ...:                 start[i] = 0
   ...:                 end[i] = i + 1
   ...:             else:
   ...:                 start[i] = i
   ...:                 end[i] = i + self.window_size
   ...:         return start, end

In [4]: indexer = CustomIndexer(window_size=1, use_expanding=use_expanding)

In [5]: df.rolling(indexer).sum()
Out[5]:
   values
0      0.0
1      1.0
2      3.0
```

(continues on next page)
You can view other examples of `BaseIndexer` subclasses here.

New in version 1.1.

One subclass of note within those examples is the `VariableOffsetWindowIndexer` that allows rolling operations over a non-fixed offset like a `BusinessDay`.

```python
In [44]: from pandas.api.indexers import VariableOffsetWindowIndexer

In [45]: df = pd.DataFrame(range(10), index=pd.date_range("2020", periods=10))

In [46]: offset = pd.offsets.BDay(1)

In [47]: indexer = VariableOffsetWindowIndexer(index=df.index, offset=offset)

In [48]: df
Out[48]:
   0
2020-01-01  0
2020-01-02  1

```

For some problems knowledge of the future is available for analysis. For example, this occurs when each data point is a full time series read from an experiment, and the task is to extract underlying conditions. In these cases it can be useful to perform forward-looking rolling window computations. `FixedForwardWindowIndexer` class is available for this purpose. This `BaseIndexer` subclass implements a closed fixed-width forward-looking rolling window, and we can use it as follows:

```python
In [50]: from pandas.api.indexers import FixedForwardWindowIndexer
```
In [51]: indexer = FixedForwardWindowIndexer(window_size=2)

In [52]: df.rolling(indexer, min_periods=1).sum()
Out[52]:
   0
2020-01-01 1.0
2020-01-02 3.0
2020-01-03 5.0
2020-01-04 7.0
2020-01-05 9.0
2020-01-06 11.0
2020-01-07 13.0
2020-01-08 15.0
2020-01-09 17.0
2020-01-10 9.0

We can also achieve this by using slicing, applying rolling aggregation, and then flipping the result as shown in example below:

In [53]: df = pd.DataFrame(
        ....:     data=[
        ....:         [pd.Timestamp("2018-01-01 00:00:00"), 100],
        ....:         [pd.Timestamp("2018-01-01 00:00:01"), 101],
        ....:         [pd.Timestamp("2018-01-01 00:00:03"), 103],
        ....:         [pd.Timestamp("2018-01-01 00:00:04"), 111],
        ....:     ],
        ....:     columns=["time", "value"],
        ....: ).set_index("time")
        ....:

In [54]: df
Out[54]:
   value
time    
2018-01-01 00:00:00    100
2018-01-01 00:00:01    101
2018-01-01 00:00:03    103
2018-01-01 00:00:04    111

In [55]: reversed_df = df[::-1].rolling("2s").sum()[::-1]

In [56]: reversed_df
Out[56]:
   value
time    
2018-01-01 00:00:00    201.0
2018-01-01 00:00:01    101.0
2018-01-01 00:00:03    214.0
2018-01-01 00:00:04    111.0
Rolling apply

The apply() function takes an extra func argument and performs generic rolling computations. The func argument should be a single function that produces a single value from an ndarray input. raw specifies whether the windows are cast as Series objects (raw=False) or ndarray objects (raw=True).

```python
In [57]: def mad(x):
    ....:     return np.fabs(x - x.mean()).mean()
    ....:

In [58]: s = pd.Series(range(10))

In [59]: s.rolling(window=4).apply(mad, raw=True)
```

```
Out[59]:
0   NaN
1   NaN
2   NaN
3   1.0
4   1.0
5   1.0
6   1.0
7   1.0
8   1.0
9   1.0
dtype: float64
```

Numba engine

New in version 1.0.

Additionally, apply() can leverage Numba if installed as an optional dependency. The apply aggregation can be executed using Numba by specifying engine='numba' and engine_kwars arguments (raw must also be set to True). See enhancing performance with Numba for general usage of the arguments and performance considerations.

Numba will be applied in potentially two routines:

1. If func is a standard Python function, the engine will JIT the passed function. func can also be a JITed function in which case the engine will not JIT the function again.
2. The engine will JIT the for loop where the apply function is applied to each window.

The engine_kwars argument is a dictionary of keyword arguments that will be passed into the numba.jit decorator. These keyword arguments will be applied to both the passed function (if a standard Python function) and the apply for loop over each window.

New in version 1.3.0.

mean, median, max, min, and sum also support the engine and engine_kwars arguments.
Binary window functions

cov() and corr() can compute moving window statistics about two Series or any combination of DataFrame/Series or DataFrame/DataFrame. Here is the behavior in each case:

- two Series: compute the statistic for the pairing.
- DataFrame/Series: compute the statistics for each column of the DataFrame with the passed Series, thus returning a DataFrame.
- DataFrame/DataFrame: by default compute the statistic for matching column names, returning a DataFrame. If the keyword argument pairwise=True is passed then computes the statistic for each pair of columns, returning a DataFrame with a MultiIndex whose values are the dates in question (see the next section).

For example:

```python
In [60]: df = pd.DataFrame(
    ...:     np.random.randn(10, 4),
    ...:     index=pd.date_range("2020-01-01", periods=10),
    ...:     columns=["A", "B", "C", "D"],
    ...: )
    ...

In [61]: df = df.cumsum()

In [62]: df2 = df[:4]

In [63]: df2.rolling(window=2).corr(df2["B"])  
Out[63]:
       A     B     C     D
2020-01-01 NaN   NaN   NaN  NaN
2020-01-02 -1.0  1.0  -1.0  1.0
2020-01-03  1.0  1.0   1.0 -1.0
2020-01-04 -1.0  1.0   1.0 -1.0
```

Computing rolling pairwise covariances and correlations

In financial data analysis and other fields it’s common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the pairwise keyword argument, which in the case of DataFrame inputs will yield a MultiIndexed DataFrame whose index are the dates in question. In the case of a single DataFrame argument the pairwise argument can even be omitted:

```python
In [64]: covs = (  
    ...:     df["B", "C", "D"]
    ...:     .rolling(window=4)
    ...:     .cov(df[["A", "B", "C"]], pairwise=True)
    ...: )
    ...
```

Note: Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the covariance section for caveats associated with this method of calculating covariance and correlation matrices.
In [65]: covs
Out[65]:

2.19.3 Weighted window

The `win_type` argument in `.rolling` generates a weighted windows that are commonly used in filtering and spectral estimation. `win_type` must be string that corresponds to a `scipy.signal window function`. Scipy must be installed in order to use these windows, and supplementary arguments that the Scipy window methods take must be specified in the aggregation function.

In [66]: s = pd.Series(range(10))

In [67]: s.rolling(window=5).mean()
Out[67]:
0    NaN
1    NaN
2    NaN
3    NaN
4     2.0
5     3.0
6     4.0
7     5.0
8     6.0
9     7.0
dtype: float64

In [68]: s.rolling(window=5, win_type="triang").mean()
Out[68]:
0    NaN
1    NaN
2    NaN
3    NaN
4     2.0
5     3.0
6     4.0
7     5.0
8     6.0
Supplementary Scipy arguments passed in the aggregation function

```python
In [69]: s.rolling(window=5, win_type="gaussian").mean(std=0.1)
Out[69]:
0      NaN
1      NaN
2      NaN
3      NaN
4      2.0
5      3.0
6      4.0
7      5.0
8      6.0
9      7.0
dtype: float64
```

For all supported aggregation functions, see [Weighted window functions](#).

### 2.19.4 Expanding window

An expanding window yields the value of an aggregation statistic with all the data available up to that point in time. Since these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```python
In [70]: df = pd.DataFrame(range(5))
In [71]: df.rolling(window=len(df), min_periods=1).mean()
Out[71]:
   0
0  0.0
1  0.5
2  1.0
3  1.5
4  2.0
```

```python
In [72]: df.expanding(min_periods=1).mean()
Out[72]:
   0
0  0.0
1  0.5
2  1.0
3  1.5
4  2.0
```

For all supported aggregation functions, see [Expanding window functions](#).
2.19.5 Exponentially Weighted window

An exponentially weighted window is similar to an expanding window but with each prior point being exponentially weighted down relative to the current point.

In general, a weighted moving average is calculated as

$$y_t = \frac{\sum_{i=0}^{t} w_i x_{t-i}}{\sum_{i=0}^{t} w_i},$$

where $x_t$ is the input, $y_t$ is the result and the $w_i$ are the weights.

For all supported aggregation functions, see Exponentially-weighted window functions.

The EW functions support two variants of exponential weights. The default, adjust=True, uses the weights $w_i = (1 - \alpha)^i$ which gives

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots + (1 - \alpha)^t}$$

When adjust=False is specified, moving averages are calculated as

$$y_0 = x_0$$
$$y_t = (1 - \alpha)y_{t-1} + \alpha x_t,$$

which is equivalent to using weights

$$w_i = \begin{cases} \alpha(1 - \alpha)^i & \text{if } i < t \\ (1 - \alpha)^i & \text{if } i = t. \end{cases}$$

**Note:** These equations are sometimes written in terms of $\alpha' = 1 - \alpha$, e.g.

$$y_t = \alpha' y_{t-1} + (1 - \alpha') x_t.$$

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history, with adjust=True:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots}$$

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of $1 - \alpha$ we have

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots}{1 - (1 - \alpha)\alpha}$$

$$= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots}{1 - (1 - \alpha)\alpha}$$

$$= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots]$$

$$= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \ldots]$$

$$= \alpha x_t + (1 - \alpha)y_{t-1}$$

which is the same expression as adjust=False above and therefore shows the equivalence of the two variants for infinite series. When adjust=False, we have $y_0 = x_0$ and $y_t = \alpha x_t + (1 - \alpha)y_{t-1}$. Therefore, there is an assumption that $x_0$ is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.
One must have $0 < \alpha \leq 1$, and while it is possible to pass $\alpha$ directly, it’s often easier to think about either the **span**, **center of mass** (com) or **half-life** of an EW moment:

$$\alpha = \begin{cases} \frac{2}{s+1}, & \text{for span } s \geq 1 \\ \frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\ 1 - \exp \log \frac{0.5}{h}, & \text{for half-life } h > 0 \end{cases}$$

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: $c = (s - 1)/2$.
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

New in version 1.1.0.

You can also specify **halflife** in terms of a timedelta convertible unit to specify the amount of time it takes for an observation to decay to half its value when also specifying a sequence of **times**.

```python
In [73]: df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
In [74]: df
Out[74]:
   B
0  0.0
1  1.0
2  2.0
3 NaN
4  4.0
In [75]: times = ["2020-01-01", "2020-01-03", "2020-01-10", "2020-01-15", "2020-01-17"]
In [76]: df.ewm(halflife="4 days", times=pd.DatetimeIndex(times)).mean()
Out[76]:
   B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

The following formula is used to compute exponentially weighted mean with an input vector of times:

$$y_t = \frac{\sum_{i=0}^{t} 0.5^{\frac{t-i}{h}} x_{t-i}}{\sum_{i=0}^{t} 0.5^{\frac{t-i}{h}}}.$$ 

ExponentialMovingWindow also has an **ignore_na** argument, which determines how intermediate null values affect the calculation of the weights. When **ignore_na**=False (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When **ignore_na**=True, weights are calculated by ignoring intermediate null values. For example, assuming **adjust**=True, if **ignore_na**=False, the weighted average of 3, NaN, 5 would be calculated as

$$\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.$$
Whereas if ignore_na=True, the weighted average would be calculated as

\[
(1 - \alpha) \cdot 3 + 1 \cdot 5 \\
(1 - \alpha) + 1.
\]

The var(), std(), and cov() functions have a bias argument, specifying whether the result should contain biased or unbiased statistics. For example, if bias=True, ewmvar(x) is calculated as \(\text{ewmvar}(x) = \text{ewma}(x^{*2}) - \text{ewma}(x)^{*2}\); whereas if bias=False (the default), the biased variance statistics are scaled by debiasing factors

\[
\frac{(\sum_{i=0}^{t} w_i)^2}{(\sum_{i=0}^{t} w_i)^2 - \sum_{i=0}^{t} w_i^2}.
\]

(For \(w_i = 1\), this reduces to the usual \(N/(N-1)\) factor, with \(N = t+1\).) See Weighted Sample Variance on Wikipedia for further details.

### 2.20 Time series / date functionality

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy datetime64 and timedelta64 dtypes, pandas has consolidated a large number of features from other Python libraries like scikits.timeseries as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

#### Parsing time series information from various sources and formats

```python
In [1]: import datetime

In [2]: dti = pd.to_datetime(["1/1/2018", np.datetime64("2018-01-01"), datetime.datetime(2018, 1, 1)])

In [3]: dti
Out[3]: DatetimeIndex(['2018-01-01', '2018-01-01', '2018-01-01'], dtype='datetime64[ns]', freq=None)
```

Generate sequences of fixed-frequency dates and time spans

```python
In [4]: dti = pd.date_range("2018-01-01", periods=3, freq="H")

In [5]: dti
Out[5]: DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00', '2018-01-01 02:00:00'],
                    dtype='datetime64[ns]', freq='H')
```

Manipulating and converting date times with timezone information

```python
In [6]: dti = dti.tz_localize("UTC")

In [7]: dti
Out[7]:
```

(continues on next page)
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00', '2018-01-01 02:00:00+00:00'], dtype='datetime64[ns, UTC]', freq='H')

In [8]: dti.tz_convert("US/Pacific")
Out[8]:
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00', '2017-12-31 18:00:00-08:00'], dtype='datetime64[ns, US/Pacific]', freq='H')

Resampling or converting a time series to a particular frequency

In [9]: idx = pd.date_range("2018-01-01", periods=5, freq="H")
In [10]: ts = pd.Series(range(len(idx)), index=idx)
In [11]: ts
Out[11]:
2018-01-01 00:00:00 0
2018-01-01 01:00:00 1
2018-01-01 02:00:00 2
2018-01-01 03:00:00 3
2018-01-01 04:00:00 4
Freq: H, dtype: int64

In [12]: ts.resample("2H").mean()
Out[12]:
2018-01-01 00:00:00 0.5
2018-01-01 02:00:00 2.5
2018-01-01 04:00:00 4.0
Freq: 2H, dtype: float64

Performing date and time arithmetic with absolute or relative time increments

In [13]: friday = pd.Timestamp("2018-01-05")
In [14]: friday.day_name()
Out[14]: 'Friday'

# Add 1 day
In [15]: saturday = friday + pd.Timedelta("1 day")
In [16]: saturday.day_name()
Out[16]: 'Saturday'

# Add 1 business day (Friday --> Monday)
In [17]: monday = friday + pd.offsets.BDay()
In [18]: monday.day_name()
Out[18]: 'Monday'

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.
pandas captures 4 general time related concepts:

1. Date times: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. Time deltas: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. Time spans: A span of time defined by a point in time and its associated frequency.
4. Date offsets: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

<table>
<thead>
<tr>
<th>Concept</th>
<th>Scalar Class</th>
<th>Array Class</th>
<th>pandas Data Type</th>
<th>Primary Creation Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date times</td>
<td>Timestamp</td>
<td>DatetimeIndex</td>
<td>datetime64[ns] or datetime64[ns, tz]</td>
<td><code>to_datetime</code> or <code>date_range</code></td>
</tr>
<tr>
<td>Time deltas</td>
<td>Timedelta</td>
<td>TimedeltaIndex</td>
<td>timedelta64[ns]</td>
<td><code>to_timedelta</code> or <code>timedelta_range</code></td>
</tr>
<tr>
<td>Time spans</td>
<td>Period</td>
<td>PeriodIndex</td>
<td>period[freq]</td>
<td><code>Period</code> or <code>period_range</code></td>
</tr>
<tr>
<td>Date offsets</td>
<td>DateOffset</td>
<td>None</td>
<td>None</td>
<td><code>DateOffset</code></td>
</tr>
</tbody>
</table>

For time series data, it’s conventional to represent the time component in the index of a `Series` or `DataFrame` so manipulations can be performed with respect to the time element.

```
In [19]: pd.Series(range(3), index=pd.date_range("2000", freq="D", periods=3))
Out[19]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
Freq: D, dtype: int64
```

However, `Series` and `DataFrame` can directly also support the time component as data itself.

```
In [20]: pd.Series(pd.date_range("2000", freq="D", periods=3))
Out[20]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
dtype: datetime64[ns]
```

`Series` and `DataFrame` have extended data type support and functionality for `datetime`, `timedelta` and `Period` data when passed into those constructors. `DateOffset` data however will be stored as `object` data.

```
In [21]: pd.Series(pd.period_range("1/1/2011", freq="M", periods=3))
Out[21]:
0    2011-01
1    2011-02
2    2011-03
dtype: period[M]
```

```
In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
```

(continues on next page)
2.20.2 Timestamps vs. time spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```python
In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))
Out[28]: Timestamp('2012-05-01 00:00:00')

In [29]: pd.Timestamp("2012-05-01")
Out[29]: Timestamp('2012-05-01 00:00:00')

In [30]: pd.Timestamp(2012, 5, 1)
Out[30]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:

```python
In [31]: pd.Period("2011-01")
Out[31]: Period('2011-01', 'M')

In [32]: pd.Period("2012-05", freq="D")
Out[32]: Period('2012-05-01', 'D')
```
*Timestamp* and *Period* can serve as an index. Lists of *Timestamp* and *Period* are automatically coerced to *DatetimeIndex* and *PeriodIndex* respectively.

```python
In [33]: dates = [
    ....:     pd.Timestamp("2012-05-01"),
    ....:     pd.Timestamp("2012-05-02"),
    ....:     pd.Timestamp("2012-05-03"),
    ....:     ]

In [34]: ts = pd.Series(np.random.randn(3), dates)

In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex

In [36]: ts.index
Out[36]: DatetimeIndex(["2012-05-01", "2012-05-02", "2012-05-03"], dtype='datetime64[ns] →', freq=None)

In [37]: ts
Out[37]:
2012-05-01  0.469112
2012-05-02 -0.282863
2012-05-03 -1.509059
dtype: float64

In [38]: periods = [pd.Period("2012-01"), pd.Period("2012-02"), pd.Period("2012-03"))

In [39]: ts = pd.Series(np.random.randn(3), periods)

In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex

In [41]: ts.index
Out[41]: PeriodIndex(["2012-01", "2012-02", "2012-03"], dtype='period[M]'

In [42]: ts
Out[42]:
2012-01  -1.135632
2012-02   1.212112
2012-03  -0.173215
Freq: M, dtype: float64
```

Pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of *Timestamp* and sequences of timestamps using instances of *DatetimeIndex*. For regular time spans, pandas uses *Period* objects for scalar values and *PeriodIndex* for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.
2.20.3 Converting to timestamps

To convert a Series or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a Series, this returns a Series (with the same index), while a list-like is converted to a DatetimeIndex:

```
In [43]: pd.to_datetime(pd.Series(["Jul 31, 2009", "2010-01-10", None]))
Out[43]:
0    2009-07-31
1 2010-01-10
2    NaT
dtype: datetime64[ns]
```

```
In [44]: pd.to_datetime(["2005/11/23", "2010.12.31"])
Out[44]: DatetimeIndex(["2005-11-23", '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [45]: pd.to_datetime(["04-01-2012 10:00"], dayfirst=True)
Out[45]: DatetimeIndex(["2012-01-04 10:00:00"], dtype='datetime64[ns]', freq=None)
```

```
In [46]: pd.to_datetime(["14-01-2012", "01-14-2012"], dayfirst=True)
Out[46]: DatetimeIndex(["2012-01-14", '2012-14-01'], dtype='datetime64[ns]', freq=None)
```

**Warning:** You see in the above example that `dayfirst` isn’t strict, so if a date can’t be parsed with the day being first it will be parsed as if `dayfirst` were False.

If you pass a single string to `to_datetime`, it returns a single Timestamp. Timestamp can also accept string input, but it doesn’t accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [47]: pd.to_datetime("2010/11/12")
Out[47]: Timestamp('2010-11-12 00:00:00')
```

```
In [48]: pd.Timestamp("2010/11/12")
Out[48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the DatetimeIndex constructor directly:

```
In [49]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05"], freq=None)
Out[49]: DatetimeIndex(["2018-01-01", '2018-01-03', '2018-01-05'], dtype='datetime64[ns]', freq=None)
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [50]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05"], freq="infer")
Out[50]: DatetimeIndex(["2018-01-01", '2018-01-03', '2018-01-05'], dtype='datetime64[ns]', freq='2D')
```
Providing a format argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```python
In [51]: pd.to_datetime("2010/11/12", format="%Y/%m/%d")
Out[51]: Timestamp('2010-11-12 00:00:00')

In [52]: pd.to_datetime("12-11-2010 00:00", format="%d-%m-%Y %H:%M")
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the `format` option, see the Python `datetime` documentation.

Assembling datetime from multiple DataFrame columns

You can also pass a DataFrame of integer or string columns to assemble into a Series of Timestamps.

```python
In [53]: df = pd.DataFrame(
    .....:   {"year": [2015, 2016], "month": [2, 3], "day": [4, 5], "hour": [2, 3]}
    .....:   )
    .....:

In [54]: pd.to_datetime(df)
Out[54]:
0   2015-02-04 02:00:00
1   2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```python
In [55]: pd.to_datetime(df["year", "month", "day"])
Out[55]:
0   2015-02-04
1   2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- required: year, month, day
- optional: hour, minute, second, millisecond, microsecond, nanosecond

Invalid data

The default behavior, `errors='raise'`, is to raise when unparsable:

```python
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparsable:

```python
In [56]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```
Pass `errors='coerce'` to convert unparsable data to `NaT` (not a time):

```
In [57]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[57]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

**Epoch timestamps**

*pandas* supports converting integer or float epoch times to `Timestamp` and `DatetimeIndex`. The default unit is nanoseconds, since that is how `Timestamp` objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.

```
In [58]: pd.to_datetime([1349720105, 1349806505, 1349892905, 1349979305, 1350065705], unit='s')
Out[58]: DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05', '2012-10-10 18:15:05', '2012-10-11 18:15:05', '2012-10-12 18:15:05'], dtype='datetime64[ns]', freq=None)
```

```
In [59]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300, 1349720105400, 1349720105500], unit='ms')
Out[59]: DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000', '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000', '2012-10-08 18:15:05.500000'], dtype='datetime64[ns]', freq=None)
```

**Note:** The `unit` parameter does not use the same strings as the `format` parameter that was discussed above. The available units are listed on the documentation for `pandas.to_datetime()`.

Changed in version 1.0.0.

Constructing a `Timestamp` or `DatetimeIndex` with an epoch timestamp with the `tz` argument specified will raise a `ValueError`. If you have epochs in wall time in another timezone, you can read the epochs as timezone-naive timestamps and then localize to the appropriate timezone:

```
In [60]: pd.Timestamp(1262347200000000000).tz_localize("US/Pacific")
Out[60]: Timestamp('2010-01-01 12:00:00-0800', tz='US/Pacific')
```

```
In [61]: pd.DatetimeIndex([1262347200000000000]).tz_localize("US/Pacific")
Out[61]: DatetimeIndex(['2010-01-01 12:00:00-08:00'], dtype='datetime64[ns, US/Pacific]', freq=None)
```

**Note:** Epoch times will be rounded to the nearest nanosecond.
Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

```python
In [62]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit="s")
Out[62]: DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.433502913'], dtype='datetime64[ns]', freq=None)
```

```python
In [63]: pd.to_datetime(1490195805433502912, unit="ns")
Out[63]: Timestamp('2017-03-22 15:16:45.433502912')
```

See also:

Using the origin Parameter

From timestamps to epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

```python
In [64]: stamps = pd.date_range("2012-10-08 18:15:05", periods=4, freq="D")
In [65]: stamps
Out[65]: DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05', '2012-10-10 18:15:05', '2012-10-11 18:15:05'], dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```python
In [66]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta("1s")
Out[66]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

Using the origin Parameter

Using the origin parameter, one can specify an alternative starting point for creation of a DatetimeIndex. For example, to use 1960-01-01 as the starting date:

```python
In [67]: pd.to_datetime([1, 2, 3], unit="D", origin=pd.Timestamp("1960-01-01"))
Out[67]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq='D')
```

The default is set at origin='unix', which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```python
In [68]: pd.to_datetime([1, 2, 3], unit="D")
Out[68]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]', freq=None)
```
2.20.4 Generating ranges of timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```python
In [69]: dates = [
        ....:     datetime.datetime(2012, 5, 1),
        ....:     datetime.datetime(2012, 5, 2),
        ....:     datetime.datetime(2012, 5, 3),
        ....:     ]

# Note the frequency information
In [70]: index = pd.DatetimeIndex(dates)

In [71]: index
Out[71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

# Automatically converted to DatetimeIndex
In [72]: index = pd.Index(dates)

In [73]: index
Out[73]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a calendar day while the default for `bdate_range` is a business day:

```python
In [74]: start = datetime.datetime(2011, 1, 1)

In [75]: end = datetime.datetime(2012, 1, 1)

In [76]: index = pd.date_range(start, end)

In [77]: index
        dtype='datetime64[ns]', length=366, freq='D')

In [78]: index = pd.bdate_range(start, end)

In [79]: index
```

(continues on next page)
Convenience functions like `date_range` and `bdate_range` can utilize a variety of frequency aliases:

```python
In [80]: pd.date_range(start, periods=1000, freq="M")
Out[80]:
              '2011-09-30', '2011-10-31',
              ... '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
              '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
              '2094-03-31', '2094-04-30'],
dtype='datetime64[ns]', length=1000, freq='M')
```

```python
In [81]: pd.bdate_range(start, periods=250, freq="BQS")
Out[81]:
              '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
              '2013-01-01', '2013-04-01',
              ... '2071-01-01', '2071-07-01', '2071-10-01', '2071-10-03',
              '2072-01-01', '2072-07-01', '2072-10-01', '2072-10-03',
              '2073-01-01', '2073-04-03'],
dtype='datetime64[ns]', length=250, freq='BQS-JAN')
```

`date_range` and `bdate_range` make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```python
In [82]: pd.date_range(start, end, freq="BM")
Out[82]:
              '2011-09-30', '2011-10-31',
              ... '2070-01-31', '2070-02-28', '2070-03-31', '2070-04-29',
              '2070-05-31', '2070-06-30', '2070-07-31', '2070-08-31',
              '2070-09-30', '2070-10-31', '2070-11-30', '2070-12-30'],
dtype='datetime64[ns]', freq='BM')
```

```python
In [83]: pd.date_range(start, end, freq="W")
Out[83]:
dtype='datetime64[ns]', freq='W')
```
Specifying start, end, and periods will generate a range of evenly spaced dates from start to end inclusively, with periods number of elements in the resulting DatetimeIndex:

```
In [86]: pd.date_range("2018-01-01", "2018-01-05", periods=5)
Out[86]:
              '2018-01-05'], dtype='datetime64[ns]', freq='Y')
```

```
In [87]: pd.date_range("2018-01-01", "2018-01-05", periods=10)
Out[87]:
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',
               '2018-01-01 21:20:00', '2018-01-02 08:00:00',
               '2018-01-02 18:40:00', '2018-01-03 05:20:00',
               '2018-01-03 16:00:00', '2018-01-04 02:40:00',
               '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
dtype='datetime64[ns]', freq=None)
```
Custom frequency ranges

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```python
In [88]: weekmask = "Mon Wed Fri"

In [89]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]

In [90]: pd.bdate_range(start, end, freq="C", weekmask=weekmask, holidays=holidays)
Out[90]:
               '2011-01-24', '2011-01-26',
               '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
               '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
               '2011-12-28', '2011-12-30'],
dtype='datetime64[ns]', length=154, freq='C')
```

```python
In [91]: pd.bdate_range(start, end, freq="CBMS", weekmask=weekmask)
Out[91]:
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
               '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
dtype='datetime64[ns]', freq='CBMS')
```

- Custom business days

2.20.5 Timestamp limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```python
In [92]: pd.Timestamp.min
Out[92]: Timestamp('1677-09-21 00:12:43.145224193')

In [93]: pd.Timestamp.max
Out[93]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:

- Representing out-of-bounds spans
2.20.6 Indexing

One of the main uses for DatetimeIndex is as an index for pandas objects. The DatetimeIndex class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the shift method on pandas objects.
- Unioning of overlapping DatetimeIndex objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as year, month, etc.
- Regularization functions like snap and very fast asof logic.

DatetimeIndex objects have all the basic functionality of regular Index objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

See also:

Reindexing methods

Note: While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

DatetimeIndex can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```python
In [94]: rng = pd.date_range(start, end, freq="BM")
In [95]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [96]: ts.index
Out[96]:
       dtype='datetime64[ns]', freq='BM')
In [97]: ts[:5].index
Out[97]:
               '2011-05-31'],
       dtype='datetime64[ns]', freq='BM')
In [98]: ts[::2].index
Out[98]:
               '2011-09-30', '2011-11-30'],
       dtype='datetime64[ns]', freq='2BM')
```
Partial string indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [99]: ts["1/31/2011"]
Out[99]: 0.11920871129693428

In [100]: ts[datetime.datetime(2011, 12, 25):]
Out[100]:
2011-12-30  0.56702
Freq: BM, dtype: float64

In [101]: ts["10/31/2011":"12/31/2011"]
Out[101]:
2011-10-31 0.271860
2011-11-30 -0.424972
2011-12-30 0.567020
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [102]: ts["2011"]
Out[102]:
2011-01-31 0.119209
2011-02-28 -1.044236
2011-03-31 -0.861849
2011-04-29 -2.104569
2011-05-31 -0.494929
2011-06-30 1.071804
2011-07-29 0.721555
2011-08-31 -0.706771
2011-09-30 -1.039575
2011-10-31 0.271860
2011-11-30 -0.424972
2011-12-30 0.567020
Freq: BM, dtype: float64

In [103]: ts["2011-6"]
Out[103]:
2011-06-30 1.071804
Freq: BM, dtype: float64
```

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints will be included. This would include matching times on an included date:

```
Warning: Indexing DataFrame rows with a single string with getitem (e.g. frame[dtstring]) is deprecated starting with pandas 1.2.0 (given the ambiguity whether it is indexing the rows or selecting a column) and will be removed in a future version. The equivalent with .loc (e.g. frame.loc[dtstring]) is still supported.
```

```
In [104]: dft = pd.DataFrame(np.random.randn(100000, 1), columns=['A'])
(continues on next page)
```
......:  index = pd.date_range("20130101", periods=100000, freq=\"T\"),
......:)

2013-01-15 00:03:00  0.941451
2013-01-15 00:04:00  -0.984810
```

(continues on next page)
DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [111]: dft2 = pd.DataFrame(
       ....:     np.random.randn(20, 1),
       ....:     columns=\"A\",
       ....:     index=pd.MultiIndex.from_product(
       ....:         [pd.date_range(\"20130101\", periods=10, freq=\"12H\"), [\"a\", \"b\"]]
       ....:     ),
       ....: )

In [112]: dft2
Out[112]:
   A
2013-01-01 00:00:00 a -0.298694  
b  0.823553   
2013-01-01 12:00:00 a  0.943285   
b -1.479399  
2013-01-02 00:00:00 a -1.643342   
                    ...        
2013-01-04 12:00:00 b  0.069036   
2013-01-05 00:00:00 a  0.122297   
b  1.422060   
2013-01-05 12:00:00 a  0.370079   
b  1.016331   

[20 rows x 1 columns]
```

```
In [113]: dft2.loc[\"2013-01-05\"]
Out[113]:
   A
2013-01-05 00:00:00 a  0.122297   
b  1.422060  
2013-01-05 12:00:00 a  0.370079   
b  1.016331  
```

```
In [114]: idx = pd.IndexSlice

In [115]: dft2 = dft2.swaplevel(0, 1).sort_index()

In [116]: dft2.loc[idx[:, \"2013-01-05\"], :]
Out[116]:
   A
2013-01-05 00:00:00 a  0.122297   
b  1.422060  
2013-01-05 12:00:00 a  0.370079   
b  1.016331  
```

(continues on next page)
New in version 0.25.0.
Slicing with string indexing also honors UTC offset.

```
In [117]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific'))
In [118]: df
Out[118]:
     0
0 2019-01-01 00:00:00-08:00 0
```

**Slice vs. exact match**

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```
In [120]: series_minute = pd.Series([1, 2, 3],
   ....:     index=pd.DatetimeIndex(
   ....:         ['2011-12-31 23:59:00', '2012-01-01 00:00:00', '2012-01-01 00:02:00'],
   ....:     )
   ....:)
In [121]: series_minute.index.resolution
Out[121]: 'minute'
```

A timestamp string less accurate than a minute gives a `Series` object.

```
In [122]: series_minute['2011-12-31 23']
Out[122]:
2011-12-31 23:59:00    1
dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```
In [123]: series_minute['2011-12-31 23:59']
Out[123]: 1
```
If index resolution is second, then the minute-accurate timestamp gives a `Series`.

```python
In [125]: series_second = pd.Series(
    ...:     [1, 2, 3],
    ...:     pd.DatetimeIndex(
    ...:         ["2011-12-31 23:59:59", "2012-01-01 00:00:00", "2012-01-01 00:00:01"]
    ...:     ),
    ...: )
```

```python
In [126]: series_second.index.resolution
Out[126]: 'second'
```

```python
In [127]: series_second["2011-12-31 23:59"]
Out[127]:
```

If the timestamp string is treated as a slice, it can be used to index `DataFrame` with `.loc[]` as well.

```python
In [128]: dft_minute = pd.DataFrame(
    ...:     {"a": [1, 2, 3], "b": [4, 5, 6]}, index=series_minute.index
    ...: )
```

```python
In [129]: dft_minute.loc["2011-12-31 23"]
Out[129]:
```

**Warning:** However, if the string is treated as an exact match, the selection in DataFrame’s [] will be column-wise and not row-wise, see Indexing Basics. For example `dft_minute["2011-12-31 23:59"]` will raise `KeyError` as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use `.loc`.

```python
In [130]: dft_minute.loc["2011-12-31 23:59"]
Out[130]:
```

Note also that `DatetimeIndex` resolution cannot be less precise than day.

```python
In [131]: series_monthly = pd.Series(
    ...:     [1, 2, 3], pd.DatetimeIndex(["2011-12", "2012-01", "2012-02"])
    ...: )
```

(continues on next page)
Exact indexing

As discussed in previous section, indexing a DatetimeIndex with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with Timestamp or datetime objects is exact, because the objects have exact meaning. These also follow the semantics of 
including both endpoints.

These Timestamp and datetime objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

With no defaults.

(continues on next page)
Truncating & fancy indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```python
In [136]: rng2 = pd.date_range("2011-01-01", "2012-01-01", freq="W")

In [137]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)

In [138]: ts2.truncate(before="2011-11", after="2011-12")
Out[138]:
          2011-11-06  0.437823
           2011-11-13 -0.293083
           2011-11-20 -0.059881
           2011-11-27  1.252450
Freq: W-SUN, dtype: float64

In [139]: ts2["2011-11":"2011-12"]
Out[139]:
         2011-11-06  0.437823
         2011-11-13 -0.293083
         2011-11-20 -0.059881
         2011-11-27  1.252450
         2011-12-04  0.046611
         2011-12-11  0.059478
         2011-12-18 -0.286539
         2011-12-25  0.841669
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```python
In [140]: ts2[[0, 2, 6]].index
Out[140]: DatetimeIndex(["2011-01-02", "2011-01-16", "2011-02-13"], dtype='datetime64[ns]'
Freq=None)
```
2.20.7 Time/date components

There are several time/date properties that one can access from Timestamp or a collection of timestamps like a DatetimeIndex.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>The year of the datetime</td>
</tr>
<tr>
<td>month</td>
<td>The month of the datetime</td>
</tr>
<tr>
<td>day</td>
<td>The days of the datetime</td>
</tr>
<tr>
<td>hour</td>
<td>The hour of the datetime</td>
</tr>
<tr>
<td>minute</td>
<td>The minutes of the datetime</td>
</tr>
<tr>
<td>second</td>
<td>The seconds of the datetime</td>
</tr>
<tr>
<td>microsecond</td>
<td>The microseconds of the datetime</td>
</tr>
<tr>
<td>nanosecond</td>
<td>The nanoseconds of the datetime</td>
</tr>
<tr>
<td>date</td>
<td>Returns datetime.date (does not contain timezone information)</td>
</tr>
<tr>
<td>time</td>
<td>Returns datetime.time (does not contain timezone information)</td>
</tr>
<tr>
<td>timetz</td>
<td>Returns datetime.time as local time with timezone information</td>
</tr>
<tr>
<td>dayofyear</td>
<td>The ordinal day of year</td>
</tr>
<tr>
<td>day_of_year</td>
<td>The ordinal day of year</td>
</tr>
<tr>
<td>weekofyear</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>week</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>dayofweek</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>day_of_week</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>weekday</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>quarter</td>
<td>Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.</td>
</tr>
<tr>
<td>days_in_month</td>
<td>The number of days in the month of the datetime</td>
</tr>
<tr>
<td>is_month_start</td>
<td>Logical indicating if first day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_month_end</td>
<td>Logical indicating if last day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_start</td>
<td>Logical indicating if first day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_end</td>
<td>Logical indicating if last day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_year_start</td>
<td>Logical indicating if first day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_year_end</td>
<td>Logical indicating if last day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_leap_year</td>
<td>Logical indicating if the date belongs to a leap year</td>
</tr>
</tbody>
</table>

Furthermore, if you have a Series with datetimelike values, then you can access these properties via the .dt accessor, as detailed in the section on .dt accessors.

New in version 1.1.0.

You may obtain the year, week and day components of the ISO year from the ISO 8601 standard:

```python
In [141]: idx = pd.date_range(start="2019-12-29", freq="D", periods=4)

In [142]: idx.isocalendar()
Out[142]:
   year  week  day
2019  52     7
2020  1      1
2019  53     1
2020  1      2
2020  1      3
```

```python
In [143]: idx.to_series().dt.isocalendar()
Out[143]:
(continues on next page)
```
2.20.8 DateOffset objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in `DatetimeIndex` were spaced when using `date_range()`
- the frequency of a `Period` or `PeriodIndex`

These frequency strings map to a `DateOffset` object and its subclasses. A `DateOffset` is similar to a `Timedelta` that represents a duration of time but follows specific calendar duration rules. For example, a `Timedelta` day will always increment datetimes by 24 hours, while a `DateOffset` day will increment datetimes to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all `DateOffset` subclasses that are an hour or smaller (Hour, Minute, Second, Milli, Micro, Nano) behave like `Timedelta` and respect absolute time.

The basic `DateOffset` acts similar to `dateutil.relativedelta` (relativedelta documentation) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) or the apply method can be used to perform the shift.

```python
# This particular day contains a day light savings time transition
In [144]: ts = pd.Timestamp("2016-10-30 00:00:00", tz="Europe/Helsinki")

# Respects absolute time
In [145]: ts + pd.Timedelta(days=1)
Out[145]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

# Respects calendar time
In [146]: ts + pd.DateOffset(days=1)
Out[146]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [147]: friday = pd.Timestamp("2018-01-05")

In [148]: friday.day_name()
Out[148]: 'Friday'

# Add 2 business days (Friday --> Tuesday)
In [149]: two_business_days = 2 * pd.offsets.BDay()

In [150]: two_business_days.apply(friday)
Out[150]: Timestamp('2018-01-09 00:00:00')

In [151]: friday + two_business_days
Out[151]: Timestamp('2018-01-09 00:00:00')

In [152]: (friday + two_business_days).day_name()
Out[152]: 'Tuesday'
```

Most `DateOffsets` have associated frequencies strings, or offset aliases, that can be passed into `freq` keyword arguments. The available date offsets and associated frequency strings can be found below:

2.20. Time series / date functionality
### Date Offset

</tbody>
</table>

**DateOffsets** additionally have `rollforward()` and `rollback()` methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```python
In [153]: ts = pd.Timestamp("2018-01-06 00:00:00")
(continues on next page)
```
In [154]: ts.day_name()
Out[154]: 'Saturday'

# BusinessHour's valid offset dates are Monday through Friday
In [155]: offset = pd.offsets.BusinessHour(start="09:00")

# Bring the date to the closest offset date (Monday)
In [156]: offset.rollforward(ts)
Out[156]: Timestamp('2018-01-08 09:00:00')

# Date is brought to the closest offset date first and then the hour is added
In [157]: ts + offset
Out[157]: Timestamp('2018-01-08 10:00:00')

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use normalize() before or after applying the operation (depending on whether you want the time information included in the operation).

In [158]: ts = pd.Timestamp("2014-01-01 09:00")
In [159]: day = pd.offsets.Day()

In [160]: day.apply(ts)
Out[160]: Timestamp('2014-01-02 09:00:00')

In [161]: day.apply(ts).normalize()
Out[161]: Timestamp('2014-01-02 00:00:00')

In [162]: ts = pd.Timestamp("2014-01-01 22:00")
In [163]: hour = pd.offsets.Hour()

In [164]: hour.apply(ts)
Out[164]: Timestamp('2014-01-01 23:00:00')

In [165]: hour.apply(ts).normalize()
Out[165]: Timestamp('2014-01-01 00:00:00')

In [166]: hour.apply(pd.Timestamp("2014-01-01 23:30")).normalize()
Out[166]: Timestamp('2014-01-02 00:00:00')

**Parametric offsets**

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the Week offset for generating weekly data accepts a weekday parameter which results in the generated dates always lying on a particular day of the week:

In [167]: d = datetime.datetime(2008, 8, 18, 9, 0)
In [168]: d
Out[168]: datetime.datetime(2008, 8, 18, 9, 0)

(continues on next page)
In [169]: d + pd.offsets.Week()
Out[169]: Timestamp('2008-08-25 09:00:00')

In [170]: d + pd.offsets.Week(weekday=4)
Out[170]: Timestamp('2008-08-22 09:00:00')

In [171]: (d + pd.offsets.Week(weekday=4)).weekday()
Out[171]: 4

In [172]: d - pd.offsets.Week()
Out[172]: Timestamp('2008-08-11 09:00:00')

The normalize option will be effective for addition and subtraction.

In [173]: d + pd.offsets.Week(normalize=True)
Out[173]: Timestamp('2008-08-25 00:00:00')

In [174]: d - pd.offsets.Week(normalize=True)
Out[174]: Timestamp('2008-08-11 00:00:00')

Another example is parameterizing YearEnd with the specific ending month:

In [175]: d + pd.offsets.YearEnd()
Out[175]: Timestamp('2008-12-31 09:00:00')

In [176]: d + pd.offsets.YearEnd(month=6)
Out[176]: Timestamp('2009-06-30 09:00:00')

Using offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

In [177]: rng = pd.date_range("2012-01-01", "2012-01-03")

In [178]: s = pd.Series(rng)

In [179]: rng
Out[179]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')

In [180]: rng + pd.DateOffset(months=2)
Out[180]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq=None)

In [181]: s + pd.DateOffset(months=2)
Out[181]:
0  2012-03-01
1  2012-03-02
2  2012-03-03
dtype: datetime64[ns]
If the offset class maps directly to a Timedelta (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a Timedelta - see the Timedelta section for more examples.

```
In [183]: s - pd.offsets.Day(2)
Out[183]:
0  2011-12-30
1  2011-12-31
2  2012-01-01
dtype: datetime64[ns]
```

```
In [184]: td = s - pd.Series(pd.date_range("2011-12-29", "2011-12-31"))
```

```
In [185]: td + pd.offsets.Minute(15)
Out[185]:
0  3 days 00:15:00
1  3 days 00:15:00
2  3 days 00:15:00
dtype: timedelta64[ns]
```

Note that some offsets (such as BQuarterEnd) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a PerformanceWarning

```
In [187]: rng + pd.offsets.BQuarterEnd()
Out[187]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype='datetime64[ns]
˓→', freq=None)
```

### Custom business days

The CDay or CustomBusinessDay class provides a parametric BusinessDay class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```
In [188]: weekmask_egypt = "Sun Mon Tue Wed Thu"
```

# They also observe International Workers' Day so let's
# add that for a couple of years

(continues on next page)
In [189]: holidays = [
   ....:   "2012-05-01",
   ....:   datetime.datetime(2013, 5, 1),
   ....:   np.datetime64("2014-05-01"),
   ....:   ]
   ....:

In [190]: bday_egypt = pd.offsets.CustomBusinessDay(
   ....:   holidays=holidays,
   ....:   weekmask=weekmask_egypt,
   ....:   )
   ....:

In [191]: dt = datetime.datetime(2013, 4, 30)

In [192]: dt + 2 * bday_egypt
Out[192]: Timestamp('2013-05-05 00:00:00')

Let's map to the weekday names:

In [193]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [194]: pd.Series(dts.weekday, dts).map(pd.Series("Mon Tue Wed Thu Fri Sat Sun".split()))
Out[194]:
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object

Holiday calendars can be used to provide the list of holidays. See the holiday calendar section for more information.

In [195]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [196]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [197]: dt = datetime.datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [198]: dt + bday_us
Out[198]: Timestamp('2014-01-21 00:00:00')

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

In [199]: bmth_us = pd.offsets.
   ....: CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())

# Skip new years
In [200]: dt = datetime.datetime(2013, 12, 17)

(continues on next page)
In [201]: dt + bmth_us
Out[201]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [202]: pd.date_range(start="20100101", end="20120101", freq=bmth_us)
Out[202]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
              '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
              '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
              '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
dtype='datetime64[ns]', freq='CBMS')

Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to
note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is
not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used
consistently within the user’s application.

Business hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and
end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp
by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it.
If the result exceeds the business hours end, the remaining hours are added to the next business day.

In [203]: bh = pd.offsets.BusinessHour()
In [204]: bh
Out[204]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [205]: pd.Timestamp("2014-08-01 10:00").weekday()
Out[205]: 4

In [206]: pd.Timestamp("2014-08-01 10:00") + bh
Out[206]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [207]: pd.Timestamp("2014-08-01 08:00") + bh
Out[207]: Timestamp('2014-08-01 09:00:00')

# If the results is on the end time, move to the next business day
In [208]: pd.Timestamp("2014-08-01 16:00") + bh
Out[208]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [209]: pd.Timestamp("2014-08-01 16:30") + bh

(continues on next page)
Out[209]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [210]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(2)
Out[210]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
In [211]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(-3)
Out[211]: Timestamp('2014-07-31 15:00:00')

You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

In [212]: bh = pd.offsets.BusinessHour(start="11:00", end=datetime.time(20, 0))
In [213]: bh
Out[213]: <BusinessHour: BH=11:00-20:00>
In [214]: pd.Timestamp("2014-08-01 13:00") + bh
Out[214]: Timestamp('2014-08-01 14:00:00')
In [215]: pd.Timestamp("2014-08-01 09:00") + bh
Out[215]: Timestamp('2014-08-01 12:00:00')
In [216]: pd.Timestamp("2014-08-01 18:00") + bh
Out[216]: Timestamp('2014-08-01 19:00:00')

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid BusinessDay.

In [217]: bh = pd.offsets.BusinessHour(start="17:00", end="09:00")
In [218]: bh
Out[218]: <BusinessHour: BH=17:00-09:00>
In [219]: pd.Timestamp("2014-08-01 17:00") + bh
Out[219]: Timestamp('2014-08-01 18:00:00')
In [220]: pd.Timestamp("2014-08-01 23:00") + bh
Out[220]: Timestamp('2014-08-02 00:00:00')

# Although 2014-08-02 is Saturday,
# it is valid because it starts from 08-01 (Friday).
In [221]: pd.Timestamp("2014-08-02 04:00") + bh
Out[221]: Timestamp('2014-08-02 05:00:00')

# Although 2014-08-04 is Monday,
# it is out of business hours because it starts from 08-03 (Sunday).
In [222]: pd.Timestamp("2014-08-04 04:00") + bh
Out[222]: Timestamp('2014-08-04 18:00:00')

Applying BusinessHour.rollforward and rollback to out of business hours results in the next business hour start
or previous day’s end. Different from other offsets, `BusinessHour.rollforward` may output different results from `apply` by definition.

This is because one day’s business hour end is equal to next day’s business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

```python
# This adjusts a Timestamp to business hour edge
In [223]: pd.offsets.BusinessHour().rollback(pd.Timestamp('2014-08-02 15:00'))
Out[223]: Timestamp('2014-08-01 17:00:00')

In [224]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
Out[224]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')).
# And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
In [225]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
Out[225]: Timestamp('2014-08-04 10:00:00')

# BusinessDay results (for reference)
In [226]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02'))
Out[226]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessDay().apply(pd.Timestamp('2014-08-01'))
# The result is the same as rollworward because BusinessDay never overlap.
In [227]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02'))
Out[227]: Timestamp('2014-08-04 10:00:00')
```

`BusinessHour` regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use `CustomBusinessHour` offset, as explained in the following subsection.

**Custom business hour**

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. `CustomBusinessHour` works as the same as `BusinessHour` except that it skips specified custom holidays.

```python
In [228]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [229]: bhour_us = pd.offsets.CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [230]: dt = datetime.datetime(2014, 1, 17, 15)

In [231]: dt + bhour_us
Out[231]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [232]: dt + bhour_us * 2
Out[232]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either `BusinessHour` and `CustomBusinessDay`.

2.20. Time series / date functionality
In [233]: bhour_mon = pd.offsets.CustomBusinessHour(start="10:00", weekmask="Tue Wed Thu Fri")

# Monday is skipped because it's a holiday, business hour starts from 10:00
In [234]: dt + bhour_mon * 2
Out[234]: Timestamp('2014-01-21 10:00:00')

**Offset aliases**

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as *offset aliases*.

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>business day frequency</td>
</tr>
<tr>
<td>C</td>
<td>custom business day frequency</td>
</tr>
<tr>
<td>D</td>
<td>calendar day frequency</td>
</tr>
<tr>
<td>W</td>
<td>weekly frequency</td>
</tr>
<tr>
<td>M</td>
<td>month end frequency</td>
</tr>
<tr>
<td>SM</td>
<td>semi-month end frequency (15th and end of month)</td>
</tr>
<tr>
<td>BM</td>
<td>business month end frequency</td>
</tr>
<tr>
<td>CBM</td>
<td>custom business month end frequency</td>
</tr>
<tr>
<td>MS</td>
<td>month start frequency</td>
</tr>
<tr>
<td>SMS</td>
<td>semi-month start frequency (1st and 15th)</td>
</tr>
<tr>
<td>BMS</td>
<td>business month start frequency</td>
</tr>
<tr>
<td>CBMS</td>
<td>custom business month start frequency</td>
</tr>
<tr>
<td>Q</td>
<td>quarter end frequency</td>
</tr>
<tr>
<td>BQ</td>
<td>business quarter end frequency</td>
</tr>
<tr>
<td>QS</td>
<td>quarter start frequency</td>
</tr>
<tr>
<td>BQS</td>
<td>business quarter start frequency</td>
</tr>
<tr>
<td>A, Y</td>
<td>year end frequency</td>
</tr>
<tr>
<td>BA, BY</td>
<td>business year end frequency</td>
</tr>
<tr>
<td>AS, YS</td>
<td>year start frequency</td>
</tr>
<tr>
<td>BAS, BYS</td>
<td>business year start frequency</td>
</tr>
<tr>
<td>BH</td>
<td>business hour frequency</td>
</tr>
<tr>
<td>H</td>
<td>hourly frequency</td>
</tr>
<tr>
<td>T, min</td>
<td>minutely frequency</td>
</tr>
<tr>
<td>S</td>
<td>secondly frequency</td>
</tr>
<tr>
<td>L, ms</td>
<td>milliseconds</td>
</tr>
<tr>
<td>U, us</td>
<td>microseconds</td>
</tr>
<tr>
<td>N</td>
<td>nanoseconds</td>
</tr>
</tbody>
</table>
Combining aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

In [235]: pd.date_range(start, periods=5, freq="B")
Out[235]:
dtype='datetime64[ns]', freq='B')

In [236]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
Out[236]:
dtype='datetime64[ns]', freq='B')

You can combine together day and intraday offsets:

In [237]: pd.date_range(start, periods=10, freq="2h20min")
Out[237]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00', '2011-01-01 04:40:00', '2011-01-01 07:00:00', '2011-01-01 09:20:00', '2011-01-01 11:40:00', '2011-01-01 14:00:00', '2011-01-01 16:20:00', '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
dtype='datetime64[ns]', freq='140T')

In [238]: pd.date_range(start, periods=10, freq="1D10U")
Out[238]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-02 00:00:00.000010', '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030', '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050', '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070', '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
dtype='datetime64[ns]', freq='86400000010U')

Anchored offsets

For some frequencies you can specify an anchoring suffix:

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W-SUN</td>
<td>weekly frequency (Sundays). Same as ‘W’</td>
</tr>
<tr>
<td>W-MON</td>
<td>weekly frequency (Mondays)</td>
</tr>
<tr>
<td>W-TUE</td>
<td>weekly frequency (Tuesdays)</td>
</tr>
<tr>
<td>W-WED</td>
<td>weekly frequency (Wednesdays)</td>
</tr>
<tr>
<td>W-THU</td>
<td>weekly frequency (Thursdays)</td>
</tr>
<tr>
<td>W-FRI</td>
<td>weekly frequency (Fridays)</td>
</tr>
<tr>
<td>W-SAT</td>
<td>weekly frequency (Saturdays)</td>
</tr>
<tr>
<td>(B)Q(S)-DEC</td>
<td>quarterly frequency, year ends in December. Same as ‘Q’</td>
</tr>
<tr>
<td>(B)Q(S)-JAN</td>
<td>quarterly frequency, year ends in January</td>
</tr>
<tr>
<td>Alias</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>(B)Q(S)-FEB</td>
<td>quarterly frequency, year ends in February</td>
</tr>
<tr>
<td>(B)Q(S)-MAR</td>
<td>quarterly frequency, year ends in March</td>
</tr>
<tr>
<td>(B)Q(S)-APR</td>
<td>quarterly frequency, year ends in April</td>
</tr>
<tr>
<td>(B)Q(S)-MAY</td>
<td>quarterly frequency, year ends in May</td>
</tr>
<tr>
<td>(B)Q(S)-JUN</td>
<td>quarterly frequency, year ends in June</td>
</tr>
<tr>
<td>(B)Q(S)-JUL</td>
<td>quarterly frequency, year ends in July</td>
</tr>
<tr>
<td>(B)Q(S)-AUG</td>
<td>quarterly frequency, year ends in August</td>
</tr>
<tr>
<td>(B)Q(S)-SEP</td>
<td>quarterly frequency, year ends in September</td>
</tr>
<tr>
<td>(B)Q(S)-OCT</td>
<td>quarterly frequency, year ends in October</td>
</tr>
<tr>
<td>(B)Q(S)-NOV</td>
<td>quarterly frequency, year ends in November</td>
</tr>
<tr>
<td>(B)A(S)-DEC</td>
<td>annual frequency, anchored end of December. Same as ‘A’</td>
</tr>
<tr>
<td>(B)A(S)-JAN</td>
<td>annual frequency, anchored end of January</td>
</tr>
<tr>
<td>(B)A(S)-FEB</td>
<td>annual frequency, anchored end of February</td>
</tr>
<tr>
<td>(B)A(S)-MAR</td>
<td>annual frequency, anchored end of March</td>
</tr>
<tr>
<td>(B)A(S)-APR</td>
<td>annual frequency, anchored end of April</td>
</tr>
<tr>
<td>(B)A(S)-MAY</td>
<td>annual frequency, anchored end of May</td>
</tr>
<tr>
<td>(B)A(S)-JUN</td>
<td>annual frequency, anchored end of June</td>
</tr>
<tr>
<td>(B)A(S)-JUL</td>
<td>annual frequency, anchored end of July</td>
</tr>
<tr>
<td>(B)A(S)-AUG</td>
<td>annual frequency, anchored end of August</td>
</tr>
<tr>
<td>(B)A(S)-SEP</td>
<td>annual frequency, anchored end of September</td>
</tr>
<tr>
<td>(B)A(S)-OCT</td>
<td>annual frequency, anchored end of October</td>
</tr>
<tr>
<td>(B)A(S)-NOV</td>
<td>annual frequency, anchored end of November</td>
</tr>
</tbody>
</table>

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.
Anchored offset semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When \( n \neq 0 \), if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved \( |n|-1 \) additional steps forwards or backwards.

```python
In [239]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=1)
Out[239]: Timestamp('2014-02-01 00:00:00')

In [240]: pd.Timestamp("2014-01-02") + pd.offsets.MonthEnd(n=1)
Out[240]: Timestamp('2014-01-31 00:00:00')

In [241]: pd.Timestamp("2014-01-02") - pd.offsets.MonthBegin(n=1)
Out[241]: Timestamp('2014-01-01 00:00:00')

In [242]: pd.Timestamp("2014-01-02") - pd.offsets.MonthEnd(n=1)
Out[242]: Timestamp('2013-12-31 00:00:00')

In [243]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=4)
Out[243]: Timestamp('2014-05-01 00:00:00')

In [244]: pd.Timestamp("2014-01-02") - pd.offsets.MonthBegin(n=4)
Out[244]: Timestamp('2013-10-01 00:00:00')
```

If the given date is on an anchor point, it is moved \( |n| \) points forwards or backwards.

```python
In [245]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=1)
Out[245]: Timestamp('2014-02-01 00:00:00')

In [246]: pd.Timestamp("2014-01-31") + pd.offsets.MonthEnd(n=1)
Out[246]: Timestamp('2014-02-28 00:00:00')

In [247]: pd.Timestamp("2014-01-01") - pd.offsets.MonthBegin(n=1)
Out[247]: Timestamp('2013-12-01 00:00:00')

In [248]: pd.Timestamp("2014-01-31") - pd.offsets.MonthEnd(n=1)
Out[248]: Timestamp('2013-12-31 00:00:00')

In [249]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=4)
Out[249]: Timestamp('2014-05-01 00:00:00')

In [250]: pd.Timestamp("2014-01-31") - pd.offsets.MonthBegin(n=4)
Out[250]: Timestamp('2013-10-01 00:00:00')
```

For the case when \( n=0 \), the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

```python
In [251]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=0)
Out[251]: Timestamp('2014-02-01 00:00:00')

In [252]: pd.Timestamp("2014-01-02") + pd.offsets.MonthEnd(n=0)
Out[252]: Timestamp('2014-01-31 00:00:00')
```

(continues on next page)
In [253]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=0)
Out[253]: Timestamp('2014-01-01 00:00:00')

In [254]: pd.Timestamp("2014-01-31") + pd.offsets.MonthEnd(n=0)
Out[254]: Timestamp('2014-01-31 00:00:00')

Holidays / holiday calendars

Holidays and calendars provide a simple way to define holiday rules to be used with CustomBusinessDay or in other analysis that requires a predefined set of holidays. The AbstractHolidayCalendar class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the start_date and end_date class attributes determine over what date range holidays are generated. These should be overwritten on the AbstractHolidayCalendar class to have the range apply to all calendar subclasses. USFederalHolidayCalendar is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearest_workday</td>
<td>move Saturday to Friday and Sunday to Monday</td>
</tr>
<tr>
<td>sunday_to_monday</td>
<td>move Sunday to following Monday</td>
</tr>
<tr>
<td>next_monday_or_tuesday</td>
<td>Saturday to Monday and Sunday/Monday to Tuesday</td>
</tr>
<tr>
<td>previous_friday</td>
<td>move Saturday and Sunday to previous Friday</td>
</tr>
<tr>
<td>next_monday</td>
<td>move Saturday and Sunday to following Monday</td>
</tr>
</tbody>
</table>

An example of how holidays and holiday calendars are defined:

In [255]: from pandas.tseries.holiday import (...
       Holiday,
       USMemorialDay,
       AbstractHolidayCalendar,
       nearest_workday,
       MO,
       )

In [256]: class ExampleCalendar(AbstractHolidayCalendar): ...
       rules = [
       USMemorialDay,
       Holiday("July 4th", month=7, day=4, observance=nearest_workday),
       Holiday("Columbus Day",
                   month=10,
                   day=1,
                   offset=pd.DateOffset(weekday=MO(2))),
       ]

(continues on next page)
In [257]: cal = ExampleCalendar()

In [258]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
Out[258]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)

hint weekday=MO(2) is same as 2 * Week(weekday=2)

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the ExampleCalendar. Like any other offset, it can be used to create a DatetimeIndex or added to datetime or Timestamp objects.

In [259]: pd.date_range(......: start="7/1/2012", end="7/10/2012", freq=pd.offsets.CDay(calendar=cal)......: ).to_pydatetime()
......:
Out[259]: array([datetime.datetime(2012, 7, 2, 0, 0),
            datetime.datetime(2012, 7, 3, 0, 0),
            datetime.datetime(2012, 7, 5, 0, 0),
            datetime.datetime(2012, 7, 6, 0, 0),
            datetime.datetime(2012, 7, 9, 0, 0),
            datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)

In [260]: offset = pd.offsets.CustomBusinessDay(calendar=cal)

In [261]: datetime.datetime(2012, 5, 25) + offset
Out[261]: Timestamp('2012-05-29 00:00:00')

In [262]: datetime.datetime(2012, 7, 3) + offset
Out[262]: Timestamp('2012-07-05 00:00:00')

In [263]: datetime.datetime(2012, 7, 3) + 2 * offset
Out[263]: Timestamp('2012-07-06 00:00:00')

In [264]: datetime.datetime(2012, 7, 6) + offset
Out[264]: Timestamp('2012-07-09 00:00:00')

Ranges are defined by the start_date and end_date class attributes of AbstractHolidayCalendar. The defaults are shown below.

In [265]: AbstractHolidayCalendar.start_date
Out[265]: Timestamp('1970-01-01 00:00:00')

In [266]: AbstractHolidayCalendar.end_date
Out[266]: Timestamp('2200-12-31 00:00:00')

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.
Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```python
In [270]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory, USLaborDay
In [271]: cal = get_calendar("ExampleCalendar")
In [272]: cal.rules
Out[272]: [Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x7f434d7b8670>),
Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
In [273]: new_cal = HolidayCalendarFactory("NewExampleCalendar", cal, USLaborDay)
In [274]: new_cal.rules
Out[274]: [Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x7f434d7b8670>),
Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
```

### 2.20.9 Time series-related instance methods

#### Shifting / lagging

One may want to shift or lag the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the `pandas` objects.

```python
In [275]: ts = pd.Series(range(len(rng)), index=rng)
In [276]: ts = ts[:5]
In [277]: ts.shift(1)
Out[277]: 2012-01-01 NaN
       2012-01-02 0.0
       2012-01-03 1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an `offset alias`.
When `freq` is specified, `shift` method changes all the dates in the index rather than changing the alignment of the data and the index:

```
In [278]: ts.shift(5, freq="D")
Out[278]:
2012-01-06   0
2012-01-07   1
2012-01-08   2
Freq: D, dtype: int64
```

```
In [279]: ts.shift(5, freq=pd.offsets.BDay())
Out[279]:
2012-01-06   0
2012-01-09   1
2012-01-10   2
dtype: int64
```

```
In [280]: ts.shift(5, freq="BM")
Out[280]:
2012-05-31   0
2012-05-31   1
2012-05-31   2
dtype: int64
```

Note that with when `freq` is specified, the leading entry is no longer NaN because the data is not being realigned.

**Frequency conversion**

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [281]: dr = pd.date_range("1/1/2010", periods=3, freq=3 * pd.offsets.BDay())
In [282]: ts = pd.Series(np.random.randn(3), index=dr)
In [283]: ts
Out[283]:
2010-01-01  1.494522
2010-01-06 -0.778425
2010-01-11 -0.253355
Freq: 3B, dtype: float64
```

```
In [284]: ts.asfreq(pd.offsets.BDay())
Out[284]:
2010-01-01  1.494522
2010-01-04  NaN
2010-01-05  NaN
2010-01-06 -0.778425
2010-01-07  NaN
2010-01-08  NaN
2010-01-11 -0.253355
Freq: B, dtype: float64
```
asfreq provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```py
In [285]: ts.asfreq(pd.offsets.BDay(), method="pad")
Out[285]:
2010-01-01  1.494522
2010-01-04  1.494522
2010-01-05  1.494522
2010-01-06  -0.778425
2010-01-07  -0.778425
2010-01-08  -0.778425
2010-01-11  -0.253355
Freq: B, dtype: float64
```

**Filling forward / backward**

Related to asfreq and reindex is `fillna()`, which is documented in the missing data section.

**Converting to Python datetimes**

DatetimeIndex can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

### 2.20.10 Resampling

pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some cookbook examples for some advanced strategies.

The `resample()` method can be used directly from DataFrameGroupBy objects, see the groupby docs.

**Basics**

```py
In [286]: rng = pd.date_range("1/1/2012", periods=100, freq="S")

In [287]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)

In [288]: ts.resample("5Min").sum()
Out[288]:
2012-01-01  25103
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via dispatching is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:
In [289]: ts.resample("5Min").mean()
Out[289]:
2012-01-01 251.03
Freq: 5T, dtype: float64

In [290]: ts.resample("5Min").ohlc()
Out[290]:
<table>
<thead>
<tr>
<th>open</th>
<th>high</th>
<th>low</th>
<th>close</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01</td>
<td>308</td>
<td>460</td>
<td>9</td>
</tr>
</tbody>
</table>

In [291]: ts.resample("5Min").max()
Out[291]:
2012-01-01 460
Freq: 5T, dtype: int64

For downsampling, closed can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:

In [292]: ts.resample("5Min", closed="right").mean()
Out[292]:
2011-12-31 23:55:00 308.000000
2012-01-01 00:00:00 250.454545
Freq: 5T, dtype: float64

In [293]: ts.resample("5Min", closed="left").mean()
Out[293]:
2012-01-01 251.03
Freq: 5T, dtype: float64

Parameters like label are used to manipulate the resulting labels. label specifies whether the result is labeled with the beginning or the end of the interval.

In [294]: ts.resample("5Min").mean()  # by default label='left'
Out[294]:
2012-01-01 251.03
Freq: 5T, dtype: float64

In [295]: ts.resample("5Min", label="left").mean()
Out[295]:
2012-01-01 251.03
Freq: 5T, dtype: float64

Warning: The default values for label and closed is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

This might unintendely lead to looking ahead, where the value for a later time is pulled back to a previous time as in the following example with the BusinessDay frequency:

In [296]: s = pd.date_range("2000-01-01", "2000-01-05").to_series()

In [297]: s.iloc[2] = pd.NaT

In [298]: s.dt.day_name()
Out[298]:

2.20. Time series / date functionality 875
2000-01-01 Saturday
2000-01-02 Sunday
2000-01-03 NaN
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: D, dtype: object

# default: label='left', closed='left'
In [299]: s.resample("B").last().dt.day_name()

Out[299]:
1999-12-31 Sunday
2000-01-03 NaN
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: B, dtype: object

Notice how the value for Sunday got pulled back to the previous Friday. To get the behavior where the value for
Sunday is pushed to Monday, use instead

In [300]: s.resample("B", label="right", closed="right").last().dt.day_name()

Out[300]:
2000-01-03 Sunday
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: B, dtype: object

The axis parameter can be set to 0 or 1 and allows you to resample the specified axis for a DataFrame.

kind can be set to ‘timestamp’ or ‘period’ to convert the resulting index to/from timestamp and time span representa-
tions. By default resample retains the input representation.

convention can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency
periods are converted to higher frequency periods.

Upsampling

For upsampling, you can specify a way to upsample and the limit parameter to interpolate over the gaps that are
created:

# from secondly to every 250 milliseconds
In [301]: ts[:2].resample("250L").asfreq()

Out[301]:
2012-01-01 00:00:00.000 308.0
2012-01-01 00:00:00.250 NaN
2012-01-01 00:00:00.500 NaN
2012-01-01 00:00:00.750 NaN
2012-01-01 00:00:01.000 204.0
Freq: 250L, dtype: float64

In [302]: ts[:2].resample("250L").ffill()

Out[302]:
2012-01-01 00:00:00.000 308
2012-01-01 00:00:00.250 308
(continues on next page)
Sparse resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don't want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

If we want to resample to the full range of the series:

```python
In [306]: ts.resample("3T").sum()
Out[306]:
2014-01-01 00:00:00    0
2014-01-01 00:03:00    0
2014-01-01 00:06:00    0
2014-01-01 00:09:00    0
2014-01-01 00:12:00    0
          ..
2014-04-09 23:48:00    0
2014-04-09 23:51:00    0
2014-04-09 23:54:00    0
2014-04-09 23:57:00    0
2014-04-10 00:00:00    99
Freq: 3T, Length: 47521, dtype: int64
```

We can instead only resample those groups where we have points as follows:

```python
In [307]: from functools import partial

In [308]: from pandas.tseries.frequencies import to_offset

In [309]: def round(t, freq):
    ....:     freq = to_offset(freq)
(continues on next page)
......: return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)
......:

In [310]: ts.groupby(partial(round, freq="3T")).sum()
Out[310]:
2014-01-01  0
2014-01-02  1
2014-01-03  2
2014-01-04  3
2014-01-05  4
   ...  
2014-04-06  95
2014-04-07  96
2014-04-08  97
2014-04-09  98
2014-04-10  99
Length: 100, dtype: int64

Aggregation

Similar to the aggregating API, groupby API, and the window API, a Resampler can be selectively resampled. Resampling a DataFrame, the default will be to act on all columns with the same function.

In [311]: df = pd.DataFrame(
      ....:     np.random.randn(1000, 3),
      ....:     index=pd.date_range("1/1/2012", freq="S", periods=1000),
      ....:     columns=["A", "B", "C"],
      ....:   )
      ....: 
In [312]: r = df.resample("3T")

In [313]: r.mean()
Out[313]:
         A        B        C
2012-01-01 00:00:00 -0.033823 -0.121514 -0.081447
2012-01-01 00:03:00  0.056909  0.146731 -0.024320
2012-01-01 00:06:00 -0.058837  0.047046 -0.052021
2012-01-01 00:09:00  0.063123 -0.026158 -0.066533
2012-01-01 00:12:00  0.186340 -0.003144  0.074752
2012-01-01 00:15:00 -0.085954 -0.016287 -0.050046

We can select a specific column or columns using standard getitem.

In [314]: r["A"].mean()
Out[314]:
2012-01-01 00:00:00  -0.033823
2012-01-01 00:03:00  0.056909
2012-01-01 00:06:00  -0.058837
2012-01-01 00:09:00  0.063123
2012-01-01 00:12:00  0.186340

(continues on next page)
You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
in [316]: r["A"].agg([np.sum, np.mean, np.std])
```

```
Out[316]:

<table>
<thead>
<tr>
<th></th>
<th>sum</th>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.088060</td>
<td>-0.033823</td>
<td>1.043263</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>10.243678</td>
<td>0.056999</td>
<td>1.058534</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>-10.590584</td>
<td>-0.058837</td>
<td>0.949264</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>11.362228</td>
<td>0.063123</td>
<td>1.028096</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>33.541257</td>
<td>0.186340</td>
<td>0.884586</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>-8.595393</td>
<td>-0.085954</td>
<td>1.035476</td>
</tr>
</tbody>
</table>
```

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
in [317]: r.agg([np.sum, np.mean])
```

```
Out[317]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>sum</td>
<td>mean</td>
<td>sum</td>
</tr>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.088060</td>
<td>-0.033823</td>
<td>-21.872530</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>10.243678</td>
<td>0.056999</td>
<td>26.411633</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>-10.590584</td>
<td>-0.058837</td>
<td>8.468289</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>11.362228</td>
<td>0.063123</td>
<td>-4.708526</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>33.541257</td>
<td>0.186340</td>
<td>-0.565895</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>-8.595393</td>
<td>-0.085954</td>
<td>-1.628689</td>
</tr>
</tbody>
</table>
```

By passing a dict to `agg` you can apply a different aggregation to the columns of a DataFrame:

```
in [318]: r.agg({"A": np.sum, "B": lambda x: np.std(x, ddof=1)})
```

```
Out[318]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>sum</td>
<td>mean</td>
</tr>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.088060</td>
<td>1.001294</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>10.243678</td>
<td>1.074597</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>-10.590584</td>
<td>0.987309</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>11.362228</td>
<td>0.944953</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>33.541257</td>
<td>1.095025</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>-8.595393</td>
<td>1.035312</td>
</tr>
</tbody>
</table>
```

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:
Furthermore, you can also specify multiple aggregation functions for each column separately.

```python
In [320]: r.agg({"A": ["sum", "std"], "B": ["mean", "std"]})
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th></th>
<th>B</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.088060</td>
<td>1.043263</td>
<td>-0.121514</td>
<td>1.001294</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>10.243678</td>
<td>1.058534</td>
<td>0.146731</td>
<td>1.074597</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>-10.590584</td>
<td>0.949264</td>
<td>0.047046</td>
<td>0.987309</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>11.362228</td>
<td>1.028096</td>
<td>-0.026158</td>
<td>0.944953</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>33.541257</td>
<td>0.884586</td>
<td>-0.003144</td>
<td>1.095025</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>-8.595393</td>
<td>1.035476</td>
<td>-0.016287</td>
<td>1.035312</td>
<td></td>
</tr>
</tbody>
</table>
```

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can passed to the on keyword.

```python
In [321]: df = pd.DataFrame(......:
.....: {"date": pd.date_range("2015-01-01", freq="W", periods=5), "a": np.
.....: arange(5)},
.....: index=pd.MultiIndex.from_arrays(......:
.....: [[1, 2, 3, 4, 5], pd.date_range("2015-01-01", freq="W", periods=5)],
.....: names=["v", "d"],
.....: )
.....: )
```

```python
In [322]: df.resample("M", on="date").sum()
```

<table>
<thead>
<tr>
<th>date</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015-01-04     2015-01-04</td>
<td>0</td>
</tr>
<tr>
<td>2015-01-11     2015-01-11</td>
<td>1</td>
</tr>
<tr>
<td>2015-01-18     2015-01-18</td>
<td>2</td>
</tr>
<tr>
<td>2015-01-25     2015-01-25</td>
<td>3</td>
</tr>
<tr>
<td>2015-02-01     2015-02-01</td>
<td>4</td>
</tr>
</tbody>
</table>

Similarly, if you instead want to resample by a datetimelike level of MultiIndex, its name or location can be passed.
to the level keyword.

```python
In [324]: df.resample("M", level="d").sum()
Out[324]:
   a
d 2015-01-31   6
     2015-02-28   4
```

**Iterating through groups**

With the `Resampler` object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```python
In [325]: small = pd.Series(
    ...:     range(6),
    ...:     index=pd.to_datetime(
    ...:         ["2017-01-01T00:00:00",
    ...:          "2017-01-01T00:30:00",
    ...:          "2017-01-01T00:31:00",
    ...:          "2017-01-01T01:00:00",
    ...:          "2017-01-01T03:00:00",
    ...:          "2017-01-01T03:05:00"],
    ...:     )
    ...: )
    ...

In [326]: resampled = small.resample("H")

In [327]: for name, group in resampled:
    ...:     print("Group: ", name)
    ...:     print("-
```

(continues on next page)
See *Iterating through groups* or `Resampler.__iter__` for more.

### Use origin or offset to adjust the start of the bins

New in version 1.1.0.

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like `30D`) or that divide a day evenly (like `90s` or `1min`). This can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can specify a fixed Timestamp with the argument `origin`.

For example:

```python
In [328]: start, end = "2000-10-01 23:30:00", "2000-10-02 00:30:00"
In [329]: middle = "2000-10-02 00:00:00"
In [330]: rng = pd.date_range(start, end, freq="7min")
In [331]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
In [332]: ts
Out[332]:
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64
```

Here we can see that, when using `origin` with its default value (`'start_day'`), the result after `'2000-10-02 00:00:00'` are not identical depending on the start of time series:

```python
In [333]: ts.resample("17min", origin="start_day").sum()
Out[333]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64
```

```python
In [334]: ts[middle:end].resample("17min", origin="start_day").sum()
```

(continues on next page)
Here we can see that, when setting origin to 'epoch', the result after '2000-10-02 00:00:00' are identical depending on the start of time series:

```python
In [355]: ts.resample("17min", origin="epoch").sum()
Out[355]:
2000-10-01 23:18:00 0
2000-10-01 23:35:00 18
2000-10-01 23:52:00 27
2000-10-02 00:09:00 39
2000-10-02 00:26:00 24
Freq: 17T, dtype: int64
```

```python
In [356]: ts[middle:end].resample("17min", origin="epoch").sum()
Out[356]:
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

If needed you can use a custom timestamp for origin:

```python
In [357]: ts.resample("17min", origin="2001-01-01").sum()
Out[357]:
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

```python
In [358]: ts[middle:end].resample("17min", origin=pd.Timestamp("2001-01-01")).sum()
Out[358]:
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

If needed you can just adjust the bins with an offset Timedelta that would be added to the default origin. Those two examples are equivalent for this time series:

```python
In [359]: ts.resample("17min", origin="start").sum()
Out[359]:
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

```python
In [360]: ts.resample("17min", offset="23h30min").sum()
Out[360]:
(continues on next page)
```
Note the use of 'start' for origin on the last example. In that case, origin will be set to the first value of the timeseries.

**Backward resample**

New in version 1.3.0.

Instead of adjusting the beginning of bins, sometimes we need to fix the end of the bins to make a backward resample with a given freq. The backward resample sets closed to 'right' by default since the last value should be considered as the edge point for the last bin.

We can set origin to 'end'. The value for a specific Timestamp index stands for the resample result from the current Timestamp minus freq to the current Timestamp with a right close.

```
In [341]: ts.resample('17min', origin='end').sum()
Out[341]:
2000-10-01 23:35:00    0
2000-10-01 23:52:00    18
2000-10-02 00:09:00    27
2000-10-02 00:26:00    63
Freq: 17T, dtype: int64
```

Besides, in contrast with the 'start_day' option, end_day is supported. This will set the origin as the ceiling midnight of the largest Timestamp.

```
In [342]: ts.resample('17min', origin='end_day').sum()
Out[342]:
2000-10-01 23:38:00    3
2000-10-01 23:55:00    15
2000-10-02 00:12:00    45
2000-10-02 00:29:00    45
Freq: 17T, dtype: int64
```

The above result uses 2000-10-02 00:29:00 as the last bin's right edge since the following computation.

```
In [343]: ceil_mid = rng.max().ceil('D')
In [344]: freq = pd.offsets.Minute(17)
In [345]: bin_res = ceil_mid - freq * ((ceil_mid - rng.max()) // freq)
In [346]: bin_res
Out[346]: Timestamp('2000-10-02 00:29:00')
```
2.20.11 Time span representation

Regular intervals of time are represented by Period objects in pandas while sequences of Period objects are collected in a PeriodIndex, which can be created with the convenience function `period_range`.

**Period**

A Period represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via freq keyword using a frequency alias like below. Because freq represents a span of Period, it cannot be negative like “-3D”.

```python
In [347]: pd.Period("2012", freq="A-DEC")
Out[347]: Period('2012', 'A-DEC')
```

```python
In [348]: pd.Period("2012-1-1", freq="D")
Out[348]: Period('2012-01-01', 'D')
```

```python
In [349]: pd.Period("2012-1-1 19:00", freq="H")
Out[349]: Period('2012-01-01 19:00', 'H')
```

```python
In [350]: pd.Period("2012-1-1 19:00", freq="5H")
Out[350]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between Period with different freq (span).

```python
In [351]: p = pd.Period("2012", freq="A-DEC")
In [352]: p + 1
Out[352]: Period('2013', 'A-DEC')
```

```python
In [353]: p - 3
Out[353]: Period('2009', 'A-DEC')
```

```python
In [354]: p = pd.Period("2012-01", freq="2M")
In [355]: p + 2
Out[355]: Period('2012-05', '2M')
```

```python
In [356]: p - 1
Out[356]: Period('2011-11', '2M')
```

```python
In [357]: p == pd.Period("2012-01", freq="3M")
Out[357]: False
```

If Period freq is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, ValueError will be raised.

```python
In [358]: p = pd.Period("2014-07-01 09:00", freq="H")
In [359]: p + pd.offsets.Hour(2)
Out[359]: Period('2014-07-01 11:00', 'H')
```

```python
In [360]: p + datetime.timedelta(minutes=120)
```

(continues on next page)
Out[360]: Period('2014-07-01 11:00', 'H')

In[361]: p + np.timedelta64(7200, "s")
Out[361]: Period('2014-07-01 11:00', 'H')

In[1]: p + pd.offsets.Minute(5)
Traceback...
ValueError: Input has different freq from Period(freq=H)

If Period has other frequencies, only the same offsets can be added. Otherwise, ValueError will be raised.

In[362]: p = pd.Period("2014-07", freq="M")

In[363]: p + pd.offsets.MonthEnd(3)
Out[363]: Period('2014-10', 'M')

In[1]: p + pd.offsets.MonthBegin(3)
Traceback...
ValueError: Input has different freq from Period(freq=M)

Taking the difference of Period instances with the same frequency will return the number of frequency units between them:

Out[364]: <10 * YearEnds: month=12>

PeriodIndex and period_range

Regular sequences of Period objects can be collected in a PeriodIndex, which can be constructed using the period_range convenience function:

In[365]: prng = pd.period_range("1/1/2011", "1/1/2012", freq="M")

In[366]: prng
                     '2012-01'],
                     dtype='period[M]')

The PeriodIndex constructor can also be used directly:

In[367]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq="M")
Out[367]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]')

Passing multiplied frequency outputs a sequence of Period which has multiplied span.

In[368]: pd.period_range(start="2014-01", freq="3M", periods=4)
If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

```python
In [369]: pd.period_range(
       ....:     start=pd.Period("2017Q1", freq="Q"), end=pd.Period("2017Q2", freq="Q"),
       ....:     freq="M"
       ....: )
Out[369]: PeriodIndex(["2017-03", '2017-04', '2017-05', '2017-06'], dtype='period[M]')
```

Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```python
In [370]: ps = pd.Series(np.random.randn(len(prng)), prng)
In [371]: ps
Out[371]: 2011-01 -2.916901
2011-02 0.514474
2011-03 1.346470
2011-04 0.816397
2011-05 2.258648
2011-06 0.494789
2011-07 0.301239
2011-08 0.464776
2011-09 -1.393581
2011-10 0.056780
2011-11 0.197035
2011-12 2.261385
2012-01 -0.329583
Freq: M, dtype: float64
```

`PeriodIndex` supports addition and subtraction with the same rule as `Period`.

```python
In [372]: idx = pd.period_range("2014-07-01 09:00", periods=5, freq="H")
In [373]: idx
Out[373]: PeriodIndex(["2014-07-01 09:00", '2014-07-01 10:00', '2014-07-01 11:00',
                      '2014-07-01 12:00', '2014-07-01 13:00'],
                      dtype='period[H]')
In [374]: idx + pd.offsets.Hour(2)
Out[374]: PeriodIndex(["2014-07-01 11:00", '2014-07-01 12:00', '2014-07-01 13:00',
                      '2014-07-01 14:00', '2014-07-01 15:00'],
                      dtype='period[H]')
In [375]: idx = pd.period_range("2014-07", periods=5, freq="M")
In [376]: idx
                      dtype='period[M]')
In [377]: idx + pd.offsets.MonthEnd(3)
(continues on next page)
```
PeriodIndex has its own dtype named period. refer to Period Dtypes.

**Period dtypes**

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the timezone aware dtype (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using frequency strings.

```python
In [378]: pi = pd.period_range("2016-01-01", periods=3, freq="M")
In [379]: pi
Out[379]: PeriodIndex(["2016-01", "2016-02", "2016-03"], dtype='period[M]')
In [380]: pi.dtype
Out[380]: period[M]
```

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like to_period():

```python
# change monthly freq to daily freq
In [381]: pi.astype("period[D"])
Out[381]: PeriodIndex(["2016-01-31", "2016-02-29", "2016-03-31"], dtype='period[D']')

# convert to DatetimeIndex
In [382]: pi.astype("datetime64[ns"]
Out[382]: DatetimeIndex(["2016-01-01", "2016-02-01", "2016-03-01"], dtype='datetime64[ns]
˓→', freq='M')

# convert to PeriodIndex
In [383]: dti = pd.date_range("2011-01-01", freq="M", periods=3)
In [384]: dti
Out[384]: DatetimeIndex(["2011-01-31", "2011-02-28", "2011-03-31"], dtype='datetime64[ns]
˓→', freq='M')

In [385]: dti.astype("period[M"]
Out[385]: PeriodIndex(["2011-01", "2011-02", "2011-03"], dtype='period[M]')
```
PeriodIndex partial string indexing

PeriodIndex now supports partial string slicing with non-monotonic indexes.

New in version 1.1.0.

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to DatetimeIndex Partial String Indexing.

```python
In [386]: ps["2011-01"]
Out[386]: -2.9169013294054507

In [387]: ps[datetime.datetime(2011, 12, 25):]
Out[387]:
2011-12  2.261385
2012-01  -0.329583
Freq: M, dtype: float64

In [388]: ps["10/31/2011":"12/31/2011"]
Out[388]:
2011-10  0.056780
2011-11  0.197035
2011-12  2.261385
Freq: M, dtype: float64

Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.

In [389]: ps["2011"]
Out[389]:
2011-01  -2.916901
2011-02   0.514474
2011-03   1.346470
2011-04   0.816397
2011-05   2.258648
2011-06   0.494789
2011-07   0.301239
2011-08   0.464776
2011-09  -1.393581
2011-10   0.056780
2011-11   0.197035
2011-12   2.261385
Freq: M, dtype: float64

In [390]: dfp = pd.DataFrame(
   .....:     np.random.randn(600, 1),
   .....:     columns=["A"],
   .....:     index=pd.period_range("2013-01-01 9:00", periods=600, freq="T"),
   .....:     )
   .....:

In [391]: dfp
Out[391]:
          A
2013-01-01 09:00  0.538468
2013-01-01 09:01 -1.365819
```

[120 rows x 1 columns]
**Frequency conversion and resampling with PeriodIndex**

The frequency of Period and PeriodIndex can be converted via the asfreq method. Let’s start with the fiscal year 2011, ending in December:

```python
In [394]: p = pd.Period("2011", freq="A-DEC")
In [395]: p
Out[395]: Period('2011', 'A-DEC')
```

We can convert it to a monthly frequency. Using the how parameter, we can specify whether to return the starting or ending month:

```python
In [396]: p.asfreq("M", how="start")
Out[396]: Period('2011-01', 'M')

In [397]: p.asfreq("M", how="end")
Out[397]: Period('2011-12', 'M')
```

The shorthands 's' and 'e' are provided for convenience:

```python
In [398]: p.asfreq("M", "s")
Out[398]: Period('2011-01', 'M')

In [399]: p.asfreq("M", "e")
Out[399]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```python
In [400]: p = pd.Period("2011-12", freq="M")
In [401]: p.asfreq("A-NOV")
Out[401]: Period('2012', 'A-NOV')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC defines regular calendar quarters:

```python
In [402]: p = pd.Period("2012Q1", freq="Q-DEC")
In [403]: p.asfreq("D", "s")
Out[403]: Period('2012-01-01', 'D')

In [404]: p.asfreq("D", "e")
Out[404]: Period('2012-03-31', 'D')
```

Q-MAR defines fiscal year end in March:
In [405]: p = pd.Period("2011Q4", freq="Q-MAR")

In [406]: p.asfreq("D", "s")
Out[406]: Period('2011-01-01', 'D')

In [407]: p.asfreq("D", "e")
Out[407]: Period('2011-03-31', 'D')

2.20.12 Converting between representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

In [408]: rng = pd.date_range("1/1/2012", periods=5, freq="M")

In [409]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [410]: ts
Out[410]:
2012-01-31  1.931253
2012-02-29 -0.184594
2012-03-31  0.249656
2012-04-30 -0.978151
2012-05-31 -0.873389
Freq: M, dtype: float64

In [411]: ps = ts.to_period()

In [412]: ps
Out[412]:
2012-01  1.931253
2012-02 -0.184594
2012-03  0.249656
2012-04 -0.978151
2012-05 -0.873389
Freq: M, dtype: float64

In [413]: ps.to_timestamp()
Out[413]:
2012-01-01  1.931253
2012-02-01 -0.184594
2012-03-01  0.249656
2012-04-01 -0.978151
2012-05-01 -0.873389
Freq: M, dtype: float64

Remember that 's' and 'e' can be used to return the timestamps at the start or end of the period:

In [414]: ps.to_timestamp("D", how="s")
Out[414]:
2012-01-01  1.931253
2012-02-01 -0.184594
2012-03-01  0.249656
Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```python
In [415]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")
In [416]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [417]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9
In [418]: ts.head()
Out[418]:
1990-03-01 09:00  -0.109291
1990-06-01 09:00   0.209694
1990-09-01 09:00   1.637235
1990-12-01 09:00   0.173592
1991-03-01 09:00   1.039926
Freq: H, dtype: float64
```

### 2.20.13 Representing out-of-bounds spans

If you have data that is outside of the Timestamp bounds, see Timestamp limitations, then you can use a PeriodIndex and/or Series of Periods to do computations.

```python
In [419]: span = pd.period_range("1215-01-01", "1381-01-01", freq="D")
In [420]: span
Out[420]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
            '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
            '1215-01-09', '1215-01-10',
            ...
            '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
            '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
            '1380-12-31', '1381-01-01'],
dtype='period[D]', length=60632)
```

To convert from an int64 based YYYYMMDD representation.

```python
In [421]: s = pd.Series([20121231, 20141130, 99991231])
In [422]: s
Out[422]:
0   20121231
1   20141130
2   99991231
dtype: int64
```

(continues on next page)
In [423]: def conv(x):
    .....:     return pd.Period(year=x // 10000, month=x // 100 % 100, day=x % 100, freq="D")
    .....:
In [424]: s.apply(conv)
Out[424]:
0   2012-12-31
1   2014-11-30
2   9999-12-31
dtype: period[D]
In [425]: s.apply(conv)[2]
Out[425]: Period('9999-12-31', 'D')

These can easily be converted to a PeriodIndex:

In [426]: span = pd.PeriodIndex(s.apply(conv))
In [427]: span
Out[427]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'], dtype='period[D'])

2.20.14 Time zone handling

pandas provides rich support for working with timestamps in different time zones using the pytz and dateutil libraries or datetime.timezone objects from the standard library.

Working with time zones

By default, pandas objects are time zone unaware:

In [428]: rng = pd.date_range("3/6/2012 00:00", periods=15, freq="D")
In [429]: rng.tz is None
Out[429]: True

To localize these dates to a time zone (assign a particular time zone to a naive date), you can use the tz_localize method or the tz keyword argument in date_range(), Timestamp, or DatetimeIndex. You can either pass pytz or dateutil time zone objects or Olson time zone database strings. Olson time zone strings will return pytz time zone objects by default. To return dateutil time zone objects, append dateutil/ before the string.

- In pytz you can find a list of common (and less common) time zones using from pytz import common_timezones, all_timezones.
- dateutil uses the OS time zones so there isn’t a fixed list available. For common zones, the names are the same as pytz.

In [430]: import dateutil

# pytz
In [431]: rng_pytz = pd.date_range("3/6/2012 00:00", periods=3, freq="D", tz="Europe/London")

In [432]: rng_pytz.tz
Out[432]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [433]: rng_dateutil = pd.date_range("3/6/2012 00:00", periods=3, freq="D")
In [434]: rng_dateutil = rng_dateutil.tz_localize("dateutil/Europe/London")
In [435]: rng_dateutil.tz
Out[435]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [436]: rng_utc = pd.date_range("3/6/2012 00:00", periods=3, freq="D",
                         tz=dateutil.tz.tzutc(),
                         )

In [437]: rng_utc.tz
Out[437]: tzutc()

New in version 0.25.0.

# datetime.timezone
In [438]: rng_utc = pd.date_range("3/6/2012 00:00", periods=3, freq="D",
                         tz=datetime.timezone.utc,
                         )

In [439]: rng_utc.tz
Out[439]: datetime.timezone.utc

Note that the UTC time zone is a special case in dateutil and should be constructed explicitly as an instance of
dateutil.tz.tzutc. You can also construct other time zones objects explicitly first.

In [440]: import pytz

# pytz
In [441]: tz_pytz = pytz.timezone("Europe/London")
In [442]: rng_pytz = pd.date_range("3/6/2012 00:00", periods=3, freq="D")
In [443]: rng_pytz = rng_pytz.tz_localize(tz_pytz)
In [444]: rng_pytz.tz == tz_pytz
Out[444]: True

# dateutil
In [445]: tz_dateutil = dateutil.tz.gettz("Europe/London")
In [446]: rng_dateutil = pd.date_range("3/6/2012 00:00", periods=3, freq="D", tz=tz_dateutil)
In [447]: rng_dateutil.tz == tz_dateutil
Out[447]: True

To convert a time zone aware pandas object from one time zone to another, you can use the tz_convert method.

In [448]: rng_pytz.tz_convert("US/Eastern")
Out[448]:
DatetimeIndex(['2012-03-05 19:00:00-05:00', '2012-03-06 19:00:00-05:00',
              '2012-03-07 19:00:00-05:00'],
             dtype='datetime64[ns, US/Eastern]', freq=None)

Note: When using pytz time zones, DatetimeIndex will construct a different time zone object than a Timestamp for the same time zone input. A DatetimeIndex can hold a collection of Timestamp objects that may have different UTC offsets and cannot be succinctly represented by one pytz time zone instance while one Timestamp represents one point in time with a specific UTC offset.

In [449]: dti = pd.date_range("2019-01-01", periods=3, freq="D", tz="US/Pacific")
In [450]: dti.tz
Out[450]: <DstTzInfo 'US/Pacific' LMT-1 day, 16:07:00 STD>
In [451]: ts = pd.Timestamp("2019-01-01", tz="US/Pacific")
In [452]: ts.tz
Out[452]: <DstTzInfo 'US/Pacific' PST-1 day, 16:00:00 STD>

Warning: Be wary of conversions between libraries. For some time zones, pytz and dateutil have different definitions of the zone. This is more of a problem for unusual time zones than for 'standard' zones like US/Eastern.

Warning: Be aware that a time zone definition across versions of time zone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See here for how to handle such a situation.

Warning: For pytz time zones, it is incorrect to pass a time zone object directly into the datetime.datetime constructor (e.g., datetime.datetime(2011, 1, 1, tz=pytz.timezone('US/Eastern'))). Instead, the datetime needs to be localized using the localize method on the pytz time zone object.
**Warning:** Be aware that for times in the future, correct conversion between time zones (and UTC) cannot be guaranteed by any time zone library because a timezone’s offset from UTC may be changed by the respective government.

**Warning:** If you are using dates beyond 2038-01-18, due to current deficiencies in the underlying libraries caused by the year 2038 problem, daylight saving time (DST) adjustments to timezone aware dates will not be applied. If and when the underlying libraries are fixed, the DST transitions will be applied.

For example, for two dates that are in British Summer Time (and so would normally be GMT+1), both the following asserts evaluate as true:

```
In [453]: d_2037 = "2037-03-31T010101"
In [454]: d_2038 = "2038-03-31T010101"
In [455]: DST = "Europe/London"
In [456]: assert pd.Timestamp(d_2037, tz=DST) != pd.Timestamp(d_2037, tz="GMT")
In [457]: assert pd.Timestamp(d_2038, tz=DST) == pd.Timestamp(d_2038, tz="GMT")
```

Under the hood, all timestamps are stored in UTC. Values from a time zone aware `DatetimeIndex` or `Timestamp` will have their fields (day, hour, minute, etc.) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```
In [458]: rng_eastern = rng_utc.tz_convert("US/Eastern")
In [459]: rng_berlin = rng_utc.tz_convert("Europe/Berlin")
In [460]: rng_eastern[2]
Out[460]: Timestamp('2012-03-07 19:00:00-0500', tz='US/Eastern', freq='D')
In [461]: rng_berlin[2]
Out[461]: Timestamp('2012-03-08 01:00:00+0100', tz='Europe/Berlin', freq='D')
Out[462]: True
```

Operations between `Series` in different time zones will yield UTC `Series`, aligning the data on the UTC timestamps:

```
In [463]: ts_utc = pd.Series(range(3), pd.date_range("20130101", periods=3, tz="UTC"))
In [464]: eastern = ts_utc.tz_convert("US/Eastern")
In [465]: berlin = ts_utc.tz_convert("Europe/Berlin")
In [466]: result = eastern + berlin
In [467]: result
Out[467]:
2013-01-01 00:00:00+00:00  0
(continues on next page)
To remove time zone information, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove the time zone yielding the local time representation. `tz_convert(None)` will remove the time zone after converting to UTC time.

```python
In [469]: didx = pd.date_range(start="2014-08-01 09:00", freq="H", periods=3, tz="US/Eastern")

In [470]: didx
Out[470]:
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
               '2014-08-01 11:00:00-04:00'],
dtype='datetime64[ns, US/Eastern]'
)

In [471]: didx.tz_localize(None)
Out[471]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
               '2014-08-01 11:00:00'],
dtype='datetime64[ns]'
)

In [472]: didx.tz_convert(None)
Out[472]:
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
dtype='datetime64[ns]'
)

# tz_convert(None) is identical to tz_convert('UTC').tz_localize(None)
In [473]: didx.tz_convert("UTC").tz_localize(None)
Out[473]:
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
dtype='datetime64[ns]'
)
Fold

New in version 1.1.0.

For ambiguous times, pandas supports explicitly specifying the keyword-only fold argument. Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time. Fold is supported only for constructing from naive `datetime.datetime` (see `datetime` documentation for details) or from `Timestamp` or for constructing from components (see below). Only `dateutil` timezones are supported (see `dateutil` documentation for details on how `pytz` deals with ambiguous datetimes) as `pytz` timezones do not support fold (see `pytz` documentation for details on how `pytz` deals with ambiguous datetimes). To localize an ambiguous datetime with `pytz`, please use `Timestamp.tz_localize()`. In general, we recommend to rely on `Timestamp.tz_localize()` when localizing ambiguous datetimes if you need direct control over how they are handled.

```python
In [474]: pd.Timestamp(
   ....:     year=2019,
   ....:     month=10,
   ....:     day=27,
   ....:     hour=1,
   ....:     minute=30,
   ....:     tz="dateutil/Europe/London",
   ....:     fold=0,
   ....: )
Out[474]: Timestamp('2019-10-27 01:30:00+0100', tz='dateutil/Europe/London')

In [475]: pd.Timestamp(
   ....:     year=2019,
   ....:     month=10,
   ....:     day=27,
   ....:     hour=1,
   ....:     minute=30,
   ....:     tz="dateutil/Europe/London",
   ....:     fold=1,
   ....: )
Out[475]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil/Europe/London')
```

Ambiguous times when localizing

tz.localize may not be able to determine the UTC offset of a timestamp because daylight savings time (DST) in a local time zone causes some times to occur twice within one day (“clocks fall back”). The following options are available:

- 'raise': Raises a `pytz.AmbiguousTimeError` (the default behavior)
- 'infer': Attempt to determine the correct offset base on the monotonicity of the timestamps
- 'NaT': Replaces ambiguous times with NaT
- bool: True represents a DST time, False represents non-DST time. An array-like of bool values is supported for a sequence of times.

```python
In [476]: rng_hourly = pd.DatetimeIndex(
   ....:     ["11/06/2011 00:00", "11/06/2011 01:00", "11/06/2011 01:00", "11/06/2011...
   ....:     02:00"])
```

(continues on next page)
This will fail as there are ambiguous times ('11/06/2011 01:00')

```
In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try using the 'ambiguous' argument
```

Handle these ambiguous times by specifying the following.

```
In [477]: rng_hourly.tz_localize("US/Eastern", ambiguous="infer")
Out[477]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
              '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
           dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
In [478]: rng_hourly.tz_localize("US/Eastern", ambiguous="NaT")
Out[478]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', 'NaT', 'NaT',
              '2011-11-06 02:00:00-05:00'],
           dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
In [479]: rng_hourly.tz_localize("US/Eastern",ambiguous=[True, True, False, False])
Out[479]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
              '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
           dtype='datetime64[ns, US/Eastern]', freq=None)
```

### Nonexistent times when localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times (“clocks spring forward”). The behavior of localizing a timeseries with nonexistent times can be controlled by the `nonexistent` argument. The following options are available:

- 'raise': Raises a `pytz.NonExistentTimeError` (the default behavior)
- 'NaT': Replaces nonexistent times with NaT
- 'shift_forward': Shifts nonexistent times forward to the closest real time
- 'shift_backward': Shifts nonexistent times backward to the closest real time
- `timedelta` object: Shifts nonexistent times by the `timedelta` duration

```
In [480]: dti = pd.date_range(start="2015-03-29 02:30:00", periods=3, freq="H")
# 2:30 is a nonexistent time
```

Localization of nonexistent times will raise an error by default.

```
In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00
```

Transform nonexistent times to NaT or shift the times.
In [481]: dti
Out[481]:
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00',
              '2015-03-29 04:30:00'],
            dtype='datetime64[ns]', freq='H')

In [482]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_forward")
Out[482]:
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
            dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [483]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_backward")
Out[483]:
DatetimeIndex(['2015-03-29 01:59:59.999999999+01:00',
              '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
            dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [484]: dti.tz_localize("Europe/Warsaw", nonexistent=pd.Timedelta(1, unit="H"))
Out[484]:
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
            dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [485]: dti.tz_localize("Europe/Warsaw", nonexistent="NaT")
Out[485]:
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
            dtype='datetime64[ns, Europe/Warsaw]', freq=None)

### Time zone series operations

A *Series* with time zone naive values is represented with a dtype of `datetime64[ns]`.

In [486]: s_naive = pd.Series(pd.date_range("20130101", periods=3))

In [487]: s_naive
Out[487]:
0   2013-01-01
1   2013-01-02
2   2013-01-03
dtype: datetime64[ns]

A *Series* with a time zone aware values is represented with a dtype of `datetime64[ns, tz]` where `tz` is the time zone.

In [488]: s_aware = pd.Series(pd.date_range("20130101", periods=3, tz="US/Eastern"))

In [489]: s_aware
Out[489]:
0   2013-01-01 00:00:00-05:00
(continues on next page)
Both of these `Series` time zone information can be manipulated via the `.dt` accessor, see the `dt accessor section`.

For example, to localize and convert a naive stamp to time zone aware.

```
In [490]: s_naive.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")
Out[490]:
0 2012-12-31 19:00:00-05:00
1 2013-01-01 19:00:00-05:00
2 2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Time zone information can also be manipulated using the `astype` method. This method can convert between different timezone-aware dtypes.

```
# convert to a new time zone
In [491]: s_aware.astype("datetime64[ns, CET]")
Out[491]:
0 2013-01-01 06:00:00+01:00
1 2013-01-02 06:00:00+01:00
2 2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

**Note:** Using `Series.to_numpy()` on a `Series`, returns a NumPy array of the data. NumPy does not currently support time zones (even though it is `printing` in the local time zone!), therefore an object array of Timestamps is returned for time zone aware data:

```
In [492]: s_naive.to_numpy()
Out[492]:
array(['2013-01-01T00:00:00.000000000',
      '2013-01-02T00:00:00.000000000',
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
In [493]: s_aware.to_numpy()
Out[493]:
array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern'),
       Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern'),
       Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern')],
      dtype=object)
```

By converting to an object array of Timestamps, it preserves the time zone information. For example, when converting back to a `Series`:

```
In [494]: pd.Series(s_aware.to_numpy())
Out[494]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

However, if you want an actual NumPy `datetime64[ns]` array (with the values converted to UTC) instead of an array
of objects, you can specify the `dtype` argument:

```python
In [495]: s_aware.to_numpy(dtype="datetime64[ns]")
Out[495]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

## 2.21 Time deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

Timedelta is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

### 2.21.1 Parsing

You can construct a `Timedelta` scalar through various arguments, including ISO 8601 Duration strings.

```python
In [1]: import datetime

# strings
In [2]: pd.Timedelta("1 days")
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta("1 days 00:00:00")
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta("1 days 2 hours")
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta("-1 days 2 min 3us")
Out[5]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit="d")
Out[7]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')

In [9]: pd.Timedelta(np.timedelta64(1, "ms"))
Out[9]: Timedelta('0 days 00:00:00.001000')
```

(continues on next page)
# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta("-1us")
Out[10]: Timedelta('1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta("nan")
Out[11]: NaT

In [12]: pd.Timedelta("nat")
Out[12]: NaT

# ISO 8601 Duration strings
In [13]: pd.Timedelta("P0DT0H1M0S")
Out[13]: Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta("P0DT0H0M0.000000123S")
Out[14]: Timedelta('0 days 00:00:00.000000123')

DateOffsets (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

In [15]: pd.Timedelta(pd.offsets.Second(2))
Out[15]: Timedelta('0 days 00:00:02')

Further, operations among the scalars yield another scalar Timedelta.

   ....: -Timedelta(
   ....:     "00:00:00.000123"
   ....: )
   ....:
Out[16]: Timedelta('2 days 00:00:02.000123')

to_timedelta

Using the top-level pd.to_timedelta, you can convert a scalar, array, list, or Series from a recognized timedelta format / value into a Timedelta type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a TimedeltaIndex.

You can parse a single string to a Timedelta:

In [17]: pd.to_timedelta("1 days 06:05:01.00003")
Out[17]: Timedelta('1 days 06:05:01.00003')

In [18]: pd.to_timedelta("15.5us")
Out[18]: Timedelta('0 days 00:00:00.000015500')

or a list/array of strings:

In [19]: pd.to_timedelta(['"1 days 06:05:01.00003", "15.5us", "nan"'])
Out[19]: TimedeltaIndex(['1 days 06:05:01.00003', '15.5us', 'nan'], dtype='timedelta64[ns]', freq=None)
The unit keyword argument specifies the unit of the Timedelta:

```python
In [20]: pd.to_timedelta(np.arange(5), unit="s")
Out[20]:
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
               '0 days 00:00:03', '0 days 00:00:04'],
               dtype='timedelta64[ns]', freq=None)
```

```python
In [21]: pd.to_timedelta(np.arange(5), unit="d")
Out[21]:
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

### Timedelta limitations

pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

```python
In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224193')
```

```python
In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days 23:47:16.854775807')
```

### 2.21.2 Operations

You can operate on Series/DataFrames and construct timedelta64[ns] Series through subtraction operations on datetime64[ns] Series, or Timestamps.

```python
In [24]: s = pd.Series(pd.date_range("2012-1-1", periods=3, freq="D"))
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
In [26]: df = pd.DataFrame({"A": s, "B": td})
In [27]: df
Out[27]:
   A                  B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days
In [28]: df["C"] = df["A"] + df["B"]
In [29]: df
Out[29]:
   A                  B                  C
0 2012-01-01 0 days 2012-01-01 0 days
1 2012-01-02 1 days 2012-01-02 1 days
2 2012-01-03 2 days 2012-01-03 2 days
In [30]: df.dtypes
```

(continues on next page)
Out[30]:
A   datetime64[ns]
B   timedelta64[ns]
C   datetime64[ns]
dtype: object

In [31]: s - s.max()
Out[31]:
0   -2 days
1   -1 days
2    0 days
dtype: timedelta64[ns]

In [32]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[32]:
0  364 days 20:55:00
1  365 days 20:55:00
2  366 days 20:55:00
dtype: timedelta64[ns]

In [33]: s + datetime.timedelta(minutes=5)
Out[33]:
0  2012-01-01 00:05:00
1  2012-01-02 00:05:00
2  2012-01-03 00:05:00
dtype: datetime64[ns]

In [34]: s + pd.offsets.Minute(5)
Out[34]:
0  2012-01-01 00:05:00
1  2012-01-02 00:05:00
2  2012-01-03 00:05:00
dtype: datetime64[ns]

In [35]: s + pd.offsets.Minute(5) + pd.offsets.Milli(5)
Out[35]:
0  2012-01-01 00:05:00.005
1  2012-01-02 00:05:00.005
2  2012-01-03 00:05:00.005
dtype: datetime64[ns]

Operations with scalars from a timedelta64[ns] series:

In [36]: y = s - s[0]
In [37]: y
Out[37]:
0    0 days
1    1 days
2    2 days
dtype: timedelta64[ns]

Series of timedeltas with NaT values are supported:
In [38]: y = s - s.shift()

In [39]: y
Out[39]:
0   NaT
1   1 days
2   1 days
dtype: timedelta64[ns]

Elements can be set to NaT using np.nan analogously to datetimes:

In [40]: y[1] = np.nan

In [41]: y
Out[41]:
0   NaT
1   NaT
2   1 days
dtype: timedelta64[ns]

Operands can also appear in a reversed order (a singular object operated with a Series):

In [42]: s.max() - s
Out[42]:
0   2 days
1   1 days
2   0 days
dtype: timedelta64[ns]

In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[43]:
0   -365 days +03:05:00
1   -366 days +03:05:00
2   -367 days +03:05:00
dtype: timedelta64[ns]

In [44]: datetime.timedelta(minutes=5) + s
Out[44]:
0   2012-01-01 00:05:00
1   2012-01-02 00:05:00
2   2012-01-03 00:05:00
dtype: datetime64[ns]

min, max and the corresponding idxmin, idxmax operations are supported on frames:

In [45]: A = s - pd.Timestamp("20120101") - pd.Timedelta("00:05:05")

In [46]: B = s - pd.Series(pd.date_range("2012-1-2", periods=3, freq="D"))

In [47]: df = pd.DataFrame({"A": A, "B": B})

In [48]: df
Out[48]:
(continues on next page)
min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

```python
In [53]: df.min().max()
Out[53]: Timedelta('-1 days +23:54:55')

In [54]: df.min(axis=1).min()
Out[54]: Timedelta('-1 days +00:00:00')

In [55]: df.min().idxmax()
Out[55]: 'A'

In [56]: df.min(axis=1).idxmin()
Out[56]: 0
```

You can fillna on timedeltas, passing a timedelta to get a particular value.

```python
In [57]: y.fillna(pd.Timedelta(0))
Out[57]:
0  0 days
1  0 days
2  1 days
dtype: timedelta64[ns]
```
In [58]: y.fillna(pd.Timedelta(10, unit="s"))
Out[58]:
0  0 days 00:00:10
1  0 days 00:00:10
2  1 days 00:00:00
dtype: timedelta64[ns]

In [59]: y.fillna(pd.Timedelta("-1 days, 00:00:05"))
Out[59]:
0 -1 days +00:00:05
1 -1 days +00:00:05
2  1 days 00:00:00
dtype: timedelta64[ns]

You can also negate, multiply and use abs on Timedeltas:

In [60]: td1 = pd.Timedelta("-1 days 2 hours 3 seconds")
In [61]: td1
Out[61]: Timedelta('1 days 02:00:03')
In [62]: -1 * td1
Out[62]: Timedelta('1 days 02:00:03')
In [63]: -td1
Out[63]: Timedelta('1 days 02:00:03')
In [64]: abs(td1)
Out[64]: Timedelta('1 days 02:00:03')

2.21.3 Reductions

Numeric reduction operation for timedelta64[ns] will return Timedelta objects. As usual NaT are skipped during evaluation.

In [65]: y2 = pd.Series(
   ...:     pd.to_timedelta(["-1 days +00:00:05", "nat", "-1 days +00:00:05", "1 days"])
   ...: )
   ...:
In [66]: y2
Out[66]:
0  -1 days +00:00:05
1   NaT
2  -1 days +00:00:05
3  1 days 00:00:00
dtype: timedelta64[ns]

In [67]: y2.mean()
Out[67]: Timedelta("-1 days +16:00:03.333333334")

(continues on next page)
2.21.4 Frequency conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```python
In [71]: december = pd.Series(pd.date_range("20121201", periods=4))

In [72]: january = pd.Series(pd.date_range("20130101", periods=4))

In [73]: td = january - december

In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)

In [75]: td[3] = np.nan

In [76]: td
Out[76]:
0   31 days 00:00:00
1   31 days 00:00:00
2   31 days 00:05:03
3    NaT
dtype: timedelta64[ns]

In [77]: td / np.timedelta64(1, "D")
Out[77]:
0   31.000000
1   31.000000
2   31.003507
3    NaN
dtype: float64

In [78]: td.astype("timedelta64[D"])
Out[78]:
0   31.0
1   31.0
2   31.0
3    NaN
dtype: float64
```
# to seconds
In [79]: td / np.timedelta64(1, "s")
Out[79]:
   0  2678400.0
   1  2678400.0
   2  2678703.0
   3    NaN
 dtype: float64

In [80]: td.astype("timedelta64[s]")
Out[80]:
   0  2678400.0
   1  2678400.0
   2  2678703.0
   3    NaN
 dtype: float64

# to months (these are constant months)
In [81]: td / np.timedelta64(1, "M")
Out[81]:
   0  1.018501
   1  1.018501
   2  1.018617
   3    NaN
 dtype: float64

Dividing or multiplying a \texttt{timedelta64[ns]} Series by an integer or integer Series yields another \texttt{timedelta64[ns]} dtypes Series.

In [82]: td * -1
Out[82]:
   0  -31 days +00:00:00
   1  -31 days +00:00:00
   2  -32 days +23:54:57
   3      NaN
 dtype:timedelta64[ns]

In [83]: td * pd.Series([1, 2, 3, 4])
Out[83]:
   0  31 days 00:00:00
   1  62 days 00:00:00
   2  93 days 00:15:09
   3      NaN
 dtype:timedelta64[ns]

Rounded division (floor-division) of a \texttt{timedelta64[ns]} Series by a scalar \texttt{Timedelta} gives a series of integers.

In [84]: td // pd.Timedelta(days=3, hours=4)
Out[84]:
   0  9.0
   1  9.0
   2  9.0
3 NaN
dtype: float64

In [85]: pd.Timedelta(days=3, hours=4) // td
Out[85]:
0  0.0
1  0.0
2  0.0
3  NaN
dtype: float64

The mod (%) and divmod operations are defined for Timedelta when operating with another timedelta-like or with a numeric argument.

In [86]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[86]: Timedelta('0 days 01:00:00')

# divmod against a timedelta-like returns a pair (int, Timedelta)
In [87]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[87]: (10, Timedelta('0 days 00:10:00'))

# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [88]: divmod(pd.Timedelta(hours=25), 86400000000000)
Out[88]: (Timedelta('0 days 00:00:00.000000001'), Timedelta('0 days 01:00:00'))

2.21.5 Attributes

You can access various components of the Timedelta or TimedeltaIndex directly using the attributes days, seconds, microseconds, nanoseconds. These are identical to the values returned by datetime.timedelta, in that, for example, the .seconds attribute represents the number of seconds >= 0 and < 1 day. These are signed according to whether the Timedelta is signed.

These operations can also be directly accessed via the .dt property of the Series as well.

**Note:** Note that the attributes are NOT the displayed values of the Timedelta. Use .components to retrieve the displayed values.

For a Series:

In [89]: td.dt.days
Out[89]:
0  31.0
1  31.0
2  31.0
3  NaN
dtype: float64

In [90]: td.dt.seconds
Out[90]:
0  0.0
(continues on next page)
You can access the value of the fields for a scalar `Timedelta` directly.

```python
In [91]: tds = pd.Timedelta("31 days 5 min 3 sec")
In [92]: tds.days
Out[92]: 31
In [93]: tds.seconds
Out[93]: 303
In [94]: (-tds).seconds
Out[94]: 86097
```

You can use the `.components` property to access a reduced form of the timedelta. This returns a `DataFrame` indexed similarly to the `Series`. These are the displayed values of the `Timedelta`.

```python
In [95]: td.dt.components
Out[95]:
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0    31.0    0.0      0.0      0.0         0.0           0.0          0.0
1    31.0    0.0      0.0      0.0         0.0           0.0          0.0
2    31.0    0.0      5.0      3.0         0.0           0.0          0.0
3     NaN    NaN      NaN      NaN          NaN           NaN          NaN
In [96]: td.dt.components.seconds
Out[96]:
   0   0.0
1   0.0
2   3.0
3  NaN
Name: seconds, dtype: float64
```

You can convert a `Timedelta` to an ISO 8601 Duration string with the `.isoformat` method.

```python
In [97]: pd.Timedelta(
      ....:     days=6, minutes=50, seconds=3, milliseconds=10, microseconds=10, ...
      ....:     nanoseconds=12
      ....: ).isoformat()
Out[97]: 'P6DT0H50M3.010010012S'
```
2.21.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor.

Using `TimedeltaIndex` you can pass string-like, Timedelta, timedelta, or `np.timedelta64` objects. Passing `np.nan/pd.NaT/nat` will represent missing values.

```
In [98]: pd.TimedeltaIndex(
    ....:     ["1 days", "1 days 00:00:05", np.timedelta64(2, "D"),
    ....:      datetime.timedelta(days=2, seconds=2),
    ....:     ]
    ....: )
Out[98]: TimedeltaIndex(["1 days 00:00:00", '1 days 00:00:05', '2 days 00:00:00',
    '2 days 00:00:02'], dtype='timedelta64[ns]', freq=None)
```

The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [99]: pd.TimedeltaIndex(["0 days", "10 days", "20 days"], freq="infer")
Out[99]: TimedeltaIndex(["0 days", '10 days', '20 days'], dtype='timedelta64[ns]', freq='10D')
```

Generating ranges of time deltas

Similar to `date_range()`, you can construct regular ranges of a TimedeltaIndex using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [100]: pd.timedelta_range(start="1 days", periods=5)
Out[100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
    dtype='timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [101]: pd.timedelta_range(start="1 days", end="5 days")
Out[101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
    dtype='timedelta64[ns]', freq='D')
```

```
In [102]: pd.timedelta_range(end="10 days", periods=4)
Out[102]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'],
    dtype='timedelta64[ns]', freq='D')
```

```
In [103]: pd.timedelta_range(start="1 days", end="2 days", freq="30T")
Out[103]: TimedeltaIndex(["1 days 00:00:00", '1 days 00:30:00', '1 days 01:00:00',
    '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
    '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
    '1 days 04:30:00'], dtype='timedelta64[ns]', freq='30T')
```

(continues on next page)
1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00', '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00', '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00', '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00', '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00', '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00', '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00', '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00', '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00', '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00', '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00', '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00', '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00', '2 days 00:00:00'],

dtype='timedelta64[ns]', freq='30T')

In [104]: pd.timedelta_range(start="1 days", periods=5, freq="2D5H")
Out[104]:
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
 '7 days 15:00:00', '9 days 20:00:00'],
dtype='timedelta64[ns]', freq='53H')

In [105]: pd.timedelta_range("0 days", "4 days", periods=5)
Out[105]:
TimedeltaIndex(["0 days", '1 days', '2 days', '3 days', '4 days'],
dtype='timedelta64[ns]', freq=None)

In [106]: pd.timedelta_range("0 days", "4 days", periods=10)
Out[106]:
TimedeltaIndex(["0 days 00:00:00", '0 days 10:40:00', '0 days 21:20:00',
 '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
 '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
 '4 days 00:00:00'],
dtype='timedelta64[ns]', freq=None)

Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

In [107]: s = pd.Series(
    ....:     np.arange(100),
    ....:     index=pd.timedelta_range("1 days", periods=100, freq="h"),
    ....: )

In [108]: s
Out[108]:
1 days 00:00:00    0

(continues on next page)
Selections work similarly, with coercion on string-likes and slices:

```
In [109]: s["1 day":"2 day"]
Out[109]:
1 days 00:00:00 0
1 days 01:00:00 1
1 days 02:00:00 2
1 days 03:00:00 3
1 days 04:00:00 4
.. 2 days 19:00:00 43
2 days 20:00:00 44
2 days 21:00:00 45
2 days 22:00:00 46
2 days 23:00:00 47
Freq: H, Length: 48, dtype: int64
```

```
In [110]: s["1 day 01:00:00"]
Out[110]: 1
```

```
In [111]: s[pd.Timedelta("1 day 1h")]  
Out[111]: 1
```

Furthermore you can use partial string selection and the range will be inferred:

```
In [112]: s["1 day":"1 day 5 hours"]
Out[112]:
1 days 00:00:00 0
1 days 01:00:00 1
1 days 02:00:00 2
1 days 03:00:00 3
1 days 04:00:00 4
1 days 05:00:00 5
Freq: H, dtype: int64
```
Operations

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```python
In [113]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])
In [114]: tdi.to_list()
Out[114]: [Timedelta('1 days'), NaT, Timedelta('2 days')]
In [115]: dti = pd.date_range('20130101', periods=3)
In [116]: dti.to_list()
Out[116]: [Timestamp('2013-01-01 00:00:00'), Timestamp('2013-01-02 00:00:00'), Timestamp('2013-01-03 00:00:00')]
In [117]: (dti + tdi).to_list()
Out[117]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]
In [118]: (dti - tdi).to_list()
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

Conversions

Similarly to frequency conversion on a `Series` above, you can convert these indices to yield another `Index`.

```python
In [119]: tdi / np.timedelta64(1, 's')
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
In [120]: tdi.astype('timedelta64[s]')
Out[120]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

Scalars type ops work as well. These can potentially return a different type of index.

```python
# adding or timedelta and date -> datelike
In [121]: tdi + pd.Timestamp('20130101')
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]', freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [122]: (pd.Timestamp('20130101') - tdi).to_list()
Out[122]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [123]: tdi + pd.Timedelta('10 days')
Out[123]: TimedeltaIndex(['10 days'], freq=None)

# division can result in a Timedelta if the divisor is an integer
In [124]: tdi / 2
Out[124]: TimedeltaIndex(['0 days 12:00:00', 'NaT', '1 days 00:00:00'], freq=None)
```

(continues on next page)
# or a Float64Index if the divisor is a Timedelta

```python
In [125]: tdi / tdi[0]
Out[125]: Float64Index([1.0, nan, 2.0], dtype='float64')
```

## 2.21.7 Resampling

Similar to timeseries resampling, we can resample with a TimedeltaIndex.

```python
In [126]: s.resample("D").mean()
Out[126]:
1 days 11.5
2 days 35.5
3 days 59.5
4 days 83.5
5 days 97.5
Freq: D, dtype: float64
```

## 2.22 Options and settings

### 2.22.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```python
In [1]: import pandas as pd

In [2]: pd.options.display.max_rows
Out[2]: 15

In [3]: pd.options.display.max_rows = 999

In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the pandas namespace:

- `get_option() / set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

**Note**: Developers can check out `pandas/core/config_init.py` for more information.

All of the functions above accept a regexp pattern (`re.search` style) as an argument, and so passing in a substring will work - as long as it is unambiguous:
The following will not work because it matches multiple option names, e.g. display.max_colwidth, display.max_rows, display.max_columns:

```python
In [10]: try:
    ....:     pd.get_option("column")
    ....:     except KeyError as e:
    ....:         print(e)
    ....:
'Pattern matched multiple keys'
```

Note: Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with describe_option. When called with no argument describe_option will print out the descriptions for all available options.

### 2.22.2 Getting and setting options

As described above, get_option() and set_option() are available from the pandas namespace. To change an option, call set_option('option_regex', new_value).

```python
In [11]: pd.get_option("mode.sim_interactive")
Out[11]: False

In [12]: pd.set_option("mode.sim_interactive", True)

In [13]: pd.get_option("mode.sim_interactive")
Out[13]: True
```

Note: The option ‘mode.sim_interactive’ is mostly used for debugging purposes.

All options also have a default value, and you can use reset_option to do just that:

```python
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999
```
It’s also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

`option_context` context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the `with` block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
    ....:   print(pd.get_option("display.max_rows"))
    ....:   print(pd.get_option("display.max_columns"))
    ....:
    10
    5
In [21]: print(pd.get_option("display.max_rows"))
    60
In [22]: print(pd.get_option("display.max_columns"))
    0
```

### 2.22.3 Setting startup options in Python/IPython environment

Using startup scripts for the Python/IPython environment to import pandas and set options makes working with pandas more efficient. To do this, create a `.py` or `.ipy` script in the startup directory of the desired profile. An example where the startup folder is in a default IPython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the IPython documentation. An example startup script for pandas is displayed below:

```
import pandas as pd

pd.set_option("display.max_rows", 999)
pd.set_option("precision", 5)
```

### 2.22.4 Frequently used options

The following is a walk-through of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7, 2))
In [24]: pd.set_option("max_rows", 7)
```
In [25]: df
Out[25]:
    0       1
0  0.469112 -0.282863
1 -1.509069 -1.135632
2  1.212112 -0.173215
3  0.119209 -0.732155
4 -0.861849 -2.104569
5  0.494929  1.071804
6  0.721555 -0.706771

In [26]: pd.set_option("max_rows", 5)

In [27]: df
Out[27]:
    0       1
0  0.469112 -0.282863
1 -1.509069 -1.135632
2  1.212112 -0.173215
3  0.119209 -0.732155
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771

[7 rows x 2 columns]

In [28]: pd.reset_option("max_rows")

Once the `display.max_rows` is exceeded, the `display.min_rows` options determines how many rows are shown in the truncated repr.

In [29]: pd.set_option("max_rows", 8)

In [30]: pd.set_option("min_rows", 4)

# below max_rows -> all rows shown
In [31]: df = pd.DataFrame(np.random.randn(7, 2))

In [32]: df
Out[32]:
    0       1
0 -1.039575  0.271860
1 -0.424972  0.567020
2  0.276232 -1.087401
3 -0.673690  0.113648
4 -1.478427  0.524988
5  0.404705  0.577046
6 -1.715002 -1.039268

# above max_rows -> only min_rows (4) rows shown
In [33]: df = pd.DataFrame(np.random.randn(9, 2))

In [34]: df

(continues on next page)
display.expand_frame_repr allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

In [37]: df = pd.DataFrame(np.random.randn(5, 10))
In [38]: pd.set_option("expand_frame_repr", True)
In [39]: df
Out[39]: 0 1 2 3 4 5 6 7 8 9

In [62]: pd.reset_option("max_info_columns")

display.max_info_rows: df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions then specified. Note that you can specify the option df.info(null_counts=True) to override on showing a particular frame.

In [63]: df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))

### 2.22.5 Available options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>display.chop_threshold</td>
<td>None</td>
<td>If set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends.</td>
</tr>
<tr>
<td>display.colheader_justify</td>
<td>right</td>
<td>Controls the justification of column headers. used by DataFrameFormatter.</td>
</tr>
<tr>
<td>display.column_space</td>
<td>12</td>
<td>No description available.</td>
</tr>
<tr>
<td>display.date_dayfirst</td>
<td>False</td>
<td>When True, prints and parses dates with the day first, eg 20/01/2005</td>
</tr>
<tr>
<td>display.date_yearfirst</td>
<td>False</td>
<td>When True, prints and parses dates with the year first, eg 2005/01/20</td>
</tr>
<tr>
<td>display.encoding</td>
<td>UTF-8</td>
<td>Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console.</td>
</tr>
<tr>
<td>display.expand_frame_repr</td>
<td>True</td>
<td>Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width.</td>
</tr>
</tbody>
</table>
Table 5 – continued from previous page

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>display.float_format</td>
<td>None</td>
<td>The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See core.format.EngFormatter for an example.</td>
</tr>
<tr>
<td>display.large_repr</td>
<td>truncate</td>
<td>For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default), or switch to the view from df.info() (the behaviour in earlier versions of pandas). allowable settings, ['truncate', 'info']</td>
</tr>
<tr>
<td>display.latex.repr</td>
<td>False</td>
<td>Whether to produce a latex DataFrame representation for Jupyter frontends that support it.</td>
</tr>
<tr>
<td>display.latex.escape</td>
<td>True</td>
<td>Escapes special characters in DataFrames, when using the to_latex method.</td>
</tr>
<tr>
<td>display.latex.longtable</td>
<td>False</td>
<td>Specifies if the to_latex method of a DataFrame uses the longtable format.</td>
</tr>
<tr>
<td>display.latex.multicolumn</td>
<td>True</td>
<td>Combines columns when using a MultiIndex</td>
</tr>
<tr>
<td>display.latex.multicolumn_format</td>
<td>‘l’</td>
<td>Alignment of multicolumn labels</td>

### Table 5 – continued from previous page

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>display.max_colwidth</td>
<td>50</td>
<td>The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. ‘None’ value means unlimited.</td>
</tr>
<tr>
<td>display.max_info_columns</td>
<td>100</td>
<td>max_info_columns is used in DataFrame.info method to decide if per column information will be printed.</td>
</tr>
<tr>
<td>display.max_info_rows</td>
<td>1690785</td>
<td>df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions then specified.</td>
</tr>
<tr>
<td>display.max_rows</td>
<td>60</td>
<td>This sets the maximum number of rows pandas should output when printing out various output. For example, this value determines whether the repr() for a dataframe prints out fully or just a truncated or summary repr. ‘None’ value means unlimited.</td>
</tr>
<tr>
<td>display.min_rows</td>
<td>10</td>
<td>The numbers of rows to show in a truncated repr (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows.</td>
</tr>
<tr>
<td>display.max_seq_items</td>
<td>100</td>
<td>when pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string. If set to None, the number of items to be printed is unlimited.</td>
</tr>
<tr>
<td>display.memory_usage</td>
<td>True</td>
<td>This specifies if the memory usage of a DataFrame should be displayed when the df.info() method is invoked.</td>
</tr>
<tr>
<td>display.multi_sparse</td>
<td>True</td>
<td>“Sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups)</td>
</tr>
<tr>
<td>display.notebook_repr_html</td>
<td>True</td>
<td>When True, IPython notebook will use html representation for pandas objects (if it is available).</td>
</tr>
<tr>
<td>display.pprint_nest_depth</td>
<td>3</td>
<td>Controls the number of nested levels to process when pretty-printing</td>
</tr>
</tbody>
</table>
Table 5 – continued from previous page

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>display.precision</td>
<td>6</td>
<td>Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to numpy’s precision print option</td>
</tr>
<tr>
<td>display.show_dimensions</td>
<td>truncate</td>
<td>Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns)</td>
</tr>
<tr>
<td>display.width</td>
<td>80</td>
<td>Width of the display in characters. In case Python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width.</td>

2.22.6 Number formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the set_options API.

Use the set_eng_float_format function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```python
In [87]: import numpy as np

In [88]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [89]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [90]: s / 1.0e3
Out[90]:
     a  303.638u
     b -721.084u
     c -622.696u
     d  648.250u
     e  -1.945m
dtype: float64

In [91]: s / 1.0e6
Out[91]:
     a  303.638n
     b -721.084n
     c -622.696n
     d  648.250n
     e  -1.945u
dtype: float64
```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

2.22.7 Unicode formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.
Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to True. However, this will result in longer render times than the standard `len` function.

```
In [94]: pd.set_option("display.unicode.east_asian_width", True)
In [95]: df
Out[95]:
0   UK  Alice
1
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```
In [96]: df = pd.DataFrame({"a": ["xxx", "¡¡"], "b": ["yyy", "¡¡"]})
In [97]: df
Out[97]:
a  b
0  xxx  yyy
1   ¡¡  ¡¡
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```
In [98]: pd.set_option("display.unicode.ambiguous_as_wide", True)
In [99]: df
```

(continues on next page)
2.22.8 Table schema display

DataFrame and Series will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [100]: pd.set_option("display.html.table_schema", True)
```

Only 'display.max_rows' are serialized and published.

2.23 Enhancing performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas DataFrame using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the DataFrame. Using `pandas.eval()` we will speed up a sum by an order of ~2.

Note: In addition to following the steps in this tutorial, users interested in enhancing performance are highly encouraged to install the recommended dependencies for pandas. These dependencies are often not installed by default, but will offer speed improvements if present.

2.23.1 Cython (writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to cython.

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It's always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an example from the Cython documentation but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.
Pure Python

We have a DataFrame to which we want to apply a function row-wise.

```python
In [1]: df = pd.DataFrame(
    ...:     {
    ...:         "a": np.random.randn(1000),
    ...:         "b": np.random.randn(1000),
    ...:         "N": np.random.randint(100, 1000, (1000)),
    ...:         "x": "x",
    ...:     }
    ...
)
...

In [2]: df
Out[2]:
     a       b       N  x
0  0.469112 -0.218470 585  x
1 -0.282863 -0.061645 841  x
2 -1.509059 -0.723780 251  x
3 -1.135632  0.551225 972  x
4  1.212112 -0.497767 181  x
...
995 -1.512743  0.874737 374  x
996  0.933753  1.120790 246  x
997 -0.308013  0.198768 157  x
998 -0.079915  1.757555 977  x
999 -0.101589 -1.115680 770  x
[1000 rows x 4 columns]
```

Here's the function in pure Python:

```python
In [3]: def f(x):
    ...:     return x * (x - 1)
    ...

In [4]: def integrate_f(a, b, N):
    ...:     s = 0
    ...:     dx = (b - a) / N
    ...:     for i in range(N):
    ...:         s += f(a + i * dx)
    ...:     return s * dx
    ...
```

We achieve our result by using `apply` (row-wise):

```python
In [7]: %timeit df.apply(lambda x: integrate_f(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 174 ms per loop
```

But clearly this isn’t fast enough for us. Let’s take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` ipython magic function:
By far the majority of time is spend inside either \texttt{integrate\_f} or \texttt{f}, hence we’ll concentrate our efforts cythonizing these two functions.

**Plain Cython**

First we’re going to need to import the Cython magic function to IPython:

```
In [6]: %load_ext Cython
```

Now, let’s simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```
In [7]: %%cython
    ...: def fPlain(x):
    ...:     return x * (x - 1)
    ...: def integrate_fPlain(a, b, N):
    ...:     s = 0
    ...:     dx = (b - a) / N
    ...:     for i in range(N):
    ...:         s += fPlain(a + i * dx)
    ...:     return s * dx
    ...
```

**Note**: If you’re having trouble pasting the above into your ipython, you may need to be using bleeding edge IPython for paste to play well with cell magics.

```
In [4]: %timeit df.apply(lambda x: integrate_fPlain(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 85.5 ms per loop
```

Already this has shaved a third off, not too bad for a simple copy and paste.
Adding type

We get another huge improvement simply by providing type information:

```
In [8]: %%cython
    ...: cdef double f_typed(double x) except? -2:
    ...:     return x * (x - 1)
    ...:
    ...:
    ...: cpdef double integrate_f_typed(double a, double b, int N):
    ...:     cdef int i
    ...:     cdef double s, dx
    ...:     s = 0
    ...:     dx = (b - a) / N
    ...:     for i in range(N):
    ...:         s += f_typed(a + i * dx)
    ...:     return s * dx
```

```
In [9]: %timeit df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 20.3 ms per loop
```

Now, we’re talking! It’s now over ten times faster than the original Python implementation, and we haven’t really modified the code. Let’s have another look at what’s eating up time:

```
In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
73919 function calls (73901 primitive calls) in 0.026 seconds
```

```
Ordered by: internal time
List reduced from 198 to 4 due to restriction <4>
```

```
ncalls  tottime  percall  cumtime  percall filename:lineno(function)
3000  0.003    0.000   0.016    0.000  series.py:928(__getitem__)
3000  0.002    0.000   0.011    0.000  series.py:1034(_get_value)
3000  0.001    0.000   0.005    0.000  base.py:3317(get_loc)
3000  0.001    0.000   0.004    0.000  base.py:5174(_get_values_for_loc)
```

Using ndarray

It’s calling series... a lot! It’s creating a Series from each row, and get-ting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

**Note:** We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```
In [10]: %%cython
    ....: cimport numpy as np
    ....: import numpy as np
    ....: cdef double f_typed(double x) except? -2:
    ....:     return x * (x - 1)
    ....:
    ....: cpdef double integrate_f_typed(double a, double b, int N):
    ....:     cdef int i
    ....:     cdef double s, dx
```

(continues on next page)
The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the zeros array.

**Warning:** You can not pass a `Series` directly as a `ndarray` typed parameter to a Cython function. Instead pass the actual `ndarray` using the `Series.to_numpy()`. The reason is that the Cython definition is specific to an `ndarray` and not the passed `Series`.

So, do not do this:

```python
apply_integrate_f(df["a"], df["b"], df["N"])
```

But rather, use `Series.to_numpy()` to get the underlying `ndarray`:

```python
apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
```

**Note:** Loops like this would be extremely slow in Python, but in Cython looping over NumPy arrays is fast.

We’ve gotten another big improvement. Let’s check again where the time is spent:

```bash
In [11]: %prun -l 4 apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
260 function calls in 0.001 seconds

Ordered by: internal time
List reduced from 63 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
1    0.001    0.001    0.001    0.001 {built-in method _cython_magic__fa09264b1a45e5e135d9cf3d137f1551.apply_integrate_f}
As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

**More advanced techniques**

There is still hope for improvement. Here’s an example of using some more advanced Cython techniques:

```cython
In [12]: %cython
cimport cython
cimport numpy as np
cimport numpy as np
cdef double f_typed(double x) except? -2:
   return x * (x - 1)
cpdef double integrate_f_typed(double a, double b, int N):
   cdef int i
   cdef double s, dx
   s = 0
   dx = (b - a) / N
   for i in range(N):
      s += f_typed(a + i * dx)
   return s * dx
@cython.boundscheck(False)
@cython.wraparound(False)
cdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
   np.ndarray[double] col_b,
   np.ndarray[int] col_N):
   cdef int i, n = len(col_N)
   assert len(col_a) == len(col_b) == n
   cdef np.ndarray[double] res = np.empty(n)
   for i in range(n):
      res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
   return res
```

```python
In [4]: %timeit apply_integrate_f_wrap(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].
to_numpy())
1000 loops, best of 3: 987 us per loop
```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn’t checked. For more about `boundscheck` and `wraparound`, see the Cython docs on compiler directives.
2.23.2 Numba (JIT compilation)

An alternative to statically compiling Cython code is to use a dynamic just-in-time (JIT) compiler with Numba.

Numba allows you to write a pure Python function which can be JIT compiled to native machine instructions, similar in performance to C, C++ and Fortran, by decorating your function with @jit.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycce tool). Numba supports compilation of Python to run on either CPU or GPU hardware and is designed to integrate with the Python scientific software stack.

**Note:** The @jit compilation will add overhead to the runtime of the function, so performance benefits may not be realized especially when using small data sets. Consider caching your function to avoid compilation overhead each time your function is run.

Numba can be used in 2 ways with pandas:

1. Specify the **engine="numba"** keyword in select pandas methods
2. Define your own Python function decorated with @jit and pass the underlying NumPy array of Series or DataFrame (using to_numpy()) into the function

**pandas Numba Engine**

If Numba is installed, one can specify **engine="numba"** in select pandas methods to execute the method using Numba. Methods that support **engine="numba"** will also have an **engine_kwargs** keyword that accepts a dictionary that allows one to specify "nogil", "nopython" and "parallel" keys with boolean values to pass into the @jit decorator. If **engine_kwargs** is not specified, it defaults to {"nogil": False, "nopython": True, "parallel": False} unless otherwise specified.

In terms of performance, the **first time a function is run using the Numba engine will be slow** as Numba will have some function compilation overhead. However, the JIT compiled functions are cached, and subsequent calls will be fast. In general, the Numba engine is performant with a larger amount of data points (e.g. 1+ million).

```python
In [1]: data = pd.Series(range(1_000_000))  # noqa: E225
In [2]: roll = data.rolling(10)
In [3]: def f(x):
   ...:     return np.sum(x) + 5
   
# Run the first time, compilation time will affect performance
In [4]: %timeit -r 1 -n 1 roll.apply(f, engine='numba', raw=True)
1.23 s ± 0 ns per loop (mean ± std. dev. of 1 run, 1 loop each)
# Function is cached and performance will improve
In [5]: %timeit roll.apply(f, engine='numba', raw=True)
188 ms ± 1.93 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)
In [6]: %timeit roll.apply(f, engine='cython', raw=True)
3.92 s ± 59 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```
Custom Function Examples

A custom Python function decorated with `@jit` can be used with pandas objects by passing their NumPy array representations with `to_numpy()`.

```python
import numba

@numba.jit
def f_plain(x):
    return x ** (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype="float64")
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(
        df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy()
    )
    return pd.Series(result, index=df.index, name="result")
```

In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop

In this example, using Numba was faster than Cython.

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following example of doubling each observation:

```python
import numba

def double_every_value_nonumba(x):
    return x * 2
```
@numba.vectorize
def double_every_value_withnumba(x):  # noqa E501
    return x * 2

# Custom function without numba
In [5]: %timeit df["col1_doubled"] = df["a"].apply(double_every_value_nonumba)  # noqa,
˓→E501
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df["col1_doubled"] = df["a"] * 2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit df["col1_doubled"] = double_every_value_withnumba(df["a"].to_numpy())
1000 loops, best of 3: 145 us per loop

Caveats

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. If you try to @jit a function that contains unsupported Python or NumPy code, compilation will revert object mode which will mostly likely not speed up your function. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument nopython=True (e.g. @jit(nopython=True)). For more on troubleshooting Numba modes, see the Numba troubleshooting page.

Using parallel=True (e.g. @jit(parallel=True)) may result in a SIGABRT if the threading layer leads to unsafe behavior. You can first specify a safe threading layer before running a JIT function with parallel=True.

Generally if the you encounter a segfault (SIGSEGV) while using Numba, please report the issue to the Numba issue tracker.

2.23.3 Expression evaluation via eval()

The top-level function pandas.eval() implements expression evaluation of Series and DataFrame objects.

Note: To benefit from using eval() you need to install numexpr. See the recommended dependencies section for more details.

The point of using eval() for expression evaluation rather than plain Python is two-fold: 1) large DataFrame objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default numexpr is used for evaluation).

Note: You should not use eval() for simple expressions or for expressions involving small DataFrames. In fact, eval() is many orders of magnitude slower for smaller expressions/objects than plain ol’ Python. A good rule of thumb is to only use eval() when you have a DataFrame with more than 10,000 rows.

eval() supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.
Note: The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

**Supported syntax**

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (<<) and right shift (>>) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4 or not df_bool`
- List and tuple literals, e.g., `[1, 2]` or `(1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval("df")` (this is not very useful)
- Math functions: `sin`, `cos`, `exp`, `expm1`, `log`, `sqrt`, `sinh`, `cosh`, `tanh`, `arcsin`, `arccos`, `arctan`, `arccosh`, `arcsinh`, `arctanh`, `abs`, `arctan2` and `log10`.

This Python syntax is **not** allowed:

- Expressions
  - Function calls other than math functions.
  - `is`/`is not` operations
  - `if` expressions
  - `lambda` expressions
  - List/set/dict comprehensions
  - Literal dict and set expressions
  - `yield` expressions
  - Generator expressions
  - Boolean expressions consisting of only scalar values

- Statements
  - Neither simple nor compound statements are allowed. This includes things like `for`, `while`, and `if`.

**eval() examples**

`pandas.eval()` works well with expressions containing large arrays.

First let’s create a few decent-sized arrays to play with:

```python
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in range(4)]
```

Now let’s compare adding them together using plain ol’ Python versus `eval()`:
In [15]: %timeit df1 + df2 + df3 + df4
5.93 ms +- 519 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [16]: %timeit pd.eval("df1 + df2 + df3 + df4")
4.65 ms +- 607 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

Now let’s do the same thing but with comparisons:

In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
5.83 ms +- 1.19 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [18]: %timeit pd.eval("(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)")
4.31 ms +- 74.3 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

eval() also works with unaligned pandas objects:

In [19]: s = pd.Series(np.random.randn(50))

In [20]: %timeit df1 + df2 + df3 + df4 + s
18.7 ms +- 123 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [21]: %timeit pd.eval("df1 + df2 + df3 + df4 + s")
5.24 ms +- 732 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

**Note:** Operations such as

```
1 and 2  # would parse to 1 & 2, but should evaluate to 2
3 or 4   # would parse to 3 | 4, but should evaluate to 3
~1       # this is okay, but slower when using eval
```

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type bool or np.bool_. Again, you should perform these kinds of operations in plain Python.

**The DataFrame.eval method**

In addition to the top level pandas.eval() function you can also evaluate an expression in the “context” of a DataFrame.

In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=["a", "b"])

In [23]: df.eval("a + b")
Out[23]:
   a       b
0  0.24  -0.25
1  0.86  -0.80
2  0.26   0.12
3  1.34  -1.34
4 -0.32   0.32

dtype: float64
Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don’t have to prefix the name of the `DataFrame` to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for formulaic evaluation. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

The `inplace` keyword determines whether this assignment will performed on the original DataFrame or return a copy with the new column.

```
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [25]: df.eval("c = a + b", inplace=True)

In [26]: df.eval("d = a + b + c", inplace=True)

In [27]: df.eval("a = 1", inplace=True)

In [28]: df
Out[28]:
   a  b  c  d
0  0  5  5 10
1  1  6  7 14
2  2  7  9 18
3  3  8 11 22
4  4  9 13 26
```

When `inplace` is set to `False`, the default, a copy of the DataFrame with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
Out[29]:
   a  b  c  d
0  0  5  5 10
1  1  6  7 14
2  2  7  9 18
3  3  8 11 22
4  4  9 13 26

In [30]: df.eval("e = a - c", inplace=False)
Out[30]:
   a  b  c  d  e
0  0  5  5 10  -4
1  1  6  7 14  -6
2  2  7  9 18  -8
3  3  8 11 22 -10
4  4  9 13 26 -12

In [31]: df
Out[31]:
   a  b  c  d
0  0  5  5 10
1  1  6  7 14
2  2  7  9 18
3  3  8 11 22
4  4  9 13 26
```
As a convenience, multiple assignments can be performed by using a multi-line string.

```python
In [32]: df.eval(
       ....:     
       ....:     c = a + b
       ....:     d = a + b + c
       ....:     a = 1
     ....:     inplace=False,
       ....:     )

Out[32]:
    a  b  c  d
0  1  5  6 12
1  1  6  7 14
2  1  7  8 16
3  1  8  9 18
4  1  9 10 20
```

The equivalent in standard Python would be

```python
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [34]: df["c"] = df["a"] + df["b"]
In [35]: df["d"] = df["a"] + df["b"] + df["c"]
In [36]: df["a"] = 1

In [37]: df

Out[37]:
    a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8  8 18
4  1  9 10 14
```

The query method has a `inplace` keyword which determines whether the query modifies the original frame.

```python
In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [39]: df.query("a > 2")
Out[39]:
    a  b
0  3  8
4  4  9

In [40]: df.query("a > 2", inplace=True)
In [41]: df
Out[41]:
    a  b
0  3  8
4  4  9
```

2.23. Enhancing performance
Local variables

You must *explicitly reference* any local variable that you want to use in an expression by placing the `@` character in front of the name. For example,

```
In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list("ab"))
In [43]: newcol = np.random.randn(len(df))
In [44]: df.eval("b + @newcol")
Out[44]:
   0   1   2
-- -- --
  0  2.493083
  1  0.173926
  2  2.493083
  3  0.173926
  4  2.493083

In [45]: df.query("b < @newcol")
Out[45]:
a  b
-- --
 0  0.863987 -0.115998
 2 -2.621419 -1.297879
```

If you don’t prefix the local variable with `@`, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```
In [46]: a = np.random.randn()
In [47]: df.query("@a < a")
Out[47]:
a  b
-- --
 0  0.863987 -0.115998
```

With `pandas.eval()` you cannot use the `@` prefix at all, because it isn’t defined in that context. Pandas will let you know this if you try to use `@` in a top-level call to `pandas.eval()`. For example,

```
In [49]: a, b = 1, 2
In [50]: pd.eval("@a + b")
Traceback (most recent call last):
  File "/opt/conda/envs/pandas/lib/python3.8/site-packages/IPython/core/interactiveshell.py", line 3444, in run_code
    exec(code_obj, self.user_global_ns, self.user_ns)
  File "<ipython-input-50-f23f43311349>", line 1, in <module>
```
pd.eval("@a + b")

File "/pandas/pandas/core/computation/eval.py", line 337, in eval
    _check_for_locals(expr, level, parser)

File "/pandas/pandas/core/computation/eval.py", line 161, in _check_for_locals
    raise SyntaxError(msg)

File "<string>", line unknown
SyntaxError: The '@' prefix is not allowed in top-level eval calls. please refer to your variables by name without the '@' prefix.

In this case, you should simply refer to the variables like you would in standard Python.

In [51]: pd.eval("a + b")
Out[51]: 3

pandas.eval() parsers

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

In [52]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"

In [53]: x = pd.eval(expr, parser="python")

In [54]: expr_no_parens = "df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0"

In [55]: y = pd.eval(expr_no_parens, parser="pandas")

In [56]: np.all(x == y)
Out[56]: True

The same expression can be “anded” together with the word and as well:

In [57]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"

In [58]: x = pd.eval(expr, parser="python")

In [59]: expr_with_ands = "df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0"

In [60]: y = pd.eval(expr_with_ands, parser="pandas")

In [61]: np.all(x == y)
Out[61]: True

The and and or operators here have the same precedence that they would in vanilla Python.
There's also the option to make `eval()` operate identical to plain ol' Python.

**Note:** Using the 'python' engine is generally *not* useful, except for testing other evaluation engines against it. You will achieve **no** performance benefits using `eval()` with `engine='python'` and in fact may incur a performance hit.

You can see this by using `pandas.eval()` with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python:

```
In [62]: %timeit df1 + df2 + df3 + df4
8.07 ms +- 619 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [63]: %timeit pd.eval("df1 + df2 + df3 + df4", engine="python")
8.53 ms +- 1.37 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

---

**pandas.eval() performance**

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame/Series` objects should see a significant performance benefit. Here is a plot showing the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

![Dataframe eval performance chart](chart.png)

**Note:** Operations with smallish objects (around 15k-20k rows) are faster using plain Python:
This plot was created using a DataFrame with 3 columns each containing floating point values generated using numpy.random.randn().

Technical minutia regarding expression evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to ndarray.astype(str) will truncate any strings that are more than 60 characters in length. Second, we can’t pass object arrays to numexpr thus string comparisons must be evaluated in Python space.

The upshot is that this only applies to object-dtype expressions. So, if you have an expression—for example

```
In [64]: df = pd.DataFrame(
.....:   {"strings": np.repeat(list("cba"), 3), "nums": np.repeat(range(3), 3)}
.....: )
.....:

In [65]: df
Out[65]:
strings   nums
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>c   0</td>
</tr>
<tr>
<td>1</td>
<td>c   0</td>
</tr>
<tr>
<td>2</td>
<td>c   0</td>
</tr>
<tr>
<td>3</td>
<td>b   1</td>
</tr>
<tr>
<td>4</td>
<td>b   1</td>
</tr>
<tr>
<td>5</td>
<td>b   1</td>
</tr>
<tr>
<td>6</td>
<td>a   2</td>
</tr>
<tr>
<td>7</td>
<td>a   2</td>
</tr>
<tr>
<td>8</td>
<td>a   2</td>
</tr>
</tbody>
</table>

In [66]: df.query("strings == 'a' and nums == 1")
Out[66]:
```

(continues on next page)
the numeric part of the comparison (nums == 1) will be evaluated by numexpr.

In general, DataFrame.query() / pandas.eval() will evaluate the subexpressions that can be evaluated by numexpr and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.

### 2.24 Scaling to large datasets

pandas provides data structures for in-memory analytics, which makes using pandas to analyze datasets that are larger than memory datasets somewhat tricky. Even datasets that are a sizable fraction of memory become unwieldy, as some pandas operations need to make intermediate copies.

This document provides a few recommendations for scaling your analysis to larger datasets. It’s a complement to Enhancing performance, which focuses on speeding up analysis for datasets that fit in memory.

But first, it’s worth considering not using pandas. pandas isn’t the right tool for all situations. If you’re working with very large datasets and a tool like PostgreSQL fits your needs, then you should probably be using that. Assuming you want or need the expressiveness and power of pandas, let’s carry on.

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

#### 2.24.1 Load less data

Suppose our raw dataset on disk has many columns:

```
  id_0  name_0   x_0   y_0  id_1  name_1   x_1   y_1
--     --       --   -- --     --       --   --
timestamp
2000-01-01 00:00:00 1015  Michael  -0.399453  0.095427 994  Frank  -0.176842 ...
  Dan  -0.315310  0.713892 1025  Victor  -0.135779  0.346801
2000-01-01 00:01:00 969  Patricia  0.650773  -0.874275 1003  Laura  0.459153 ...
  Ursula  0.913244  -0.630308 1047  Wendy  -0.886285  0.035852
2000-01-01 00:02:00 1016  Victor  -0.721465  -0.584710 1046  Michael  0.524994 ...
  Ray  -0.656593  0.692568 1064  Yvonne  0.070426  0.432047
2000-01-01 00:03:00 939  Alice  -0.746004  -0.908008 996  Ingrid  -0.414523 ...
  Jerry  -0.956894  0.608210 978  Wendy  0.855949  -0.648988
2000-01-01 00:04:00 1017  Dan  0.919451  -0.803504 1048  Jerry  -0.569235 ...
  Frank  -0.577022  -0.409088 994  Bob  -0.270132  0.335176
  ...  ...    ...    ...    ...    ...    ...
2000-12-30 23:56:00 999  Tim  0.162578  0.512817 973  Kevin  -0.403352 ...
  Tim  -0.380415  0.068097 1041  Charlie  0.191477  -0.599519
2000-12-30 23:57:00 970  Laura  -0.433586  -0.600289 958  Oliver  -0.966577 ...
  Zelda  0.971274  0.402032 1038  Ursula  0.574016  -0.930992
2000-12-30 23:58:00 1065  Edith  0.232211  -0.454540 971  Tim  0.158484 ...
  Alice  0.222079  0.919274 1022  Dan  0.031345  0.657755
```

(continues on next page)
To load the columns we want, we have two options. Option 1 loads in all the data and then filters to what we need.

```
In [3]: columns = ['id_0', 'name_0', 'x_0', 'y_0']

In [4]: pd.read_parquet("timeseries_wide.parquet")[columns]
```

```
Out[4]:

<table>
<thead>
<tr>
<th>timestamp</th>
<th>id_0</th>
<th>name_0</th>
<th>x_0</th>
<th>y_0</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 00:00:00</td>
<td>1015</td>
<td>Michael</td>
<td>-0.399453</td>
<td>0.095427</td>
</tr>
<tr>
<td>2000-01-01 00:01:00</td>
<td>969</td>
<td>Patricia</td>
<td>0.650773</td>
<td>-0.874275</td>
</tr>

<td>Ursula</td>
<td>-0.906523</td>
<td>0.943178</td>
</tr>
</tbody>
</table>
```

```
[525601 rows x 4 columns]
```

If we were to measure the memory usage of the two calls, we'd see that specifying columns uses about 1/10th the memory in this case.

With `pandas.read_csv()`, you can specify `usecols` to limit the columns read into memory. Not all file formats that can be read by pandas provide an option to read a subset of columns.

### 2.24. Scaling to large datasets
2.24.2 Use efficient datatypes

The default pandas data types are not the most memory efficient. This is especially true for text data columns with relatively few unique values (commonly referred to as “low-cardinality” data). By using more efficient data types, you can store larger datasets in memory.

```python
In [6]: ts = pd.read_parquet("timeseries.parquet")

In [7]: ts
Out[7]:
   id  name      x      y
  timestamp
2000-01-01 00:00:00  1029  Michael  0.278837  0.247932
2000-01-01 00:00:30  1010  Patricia  0.077144  0.490260
2000-01-01 00:01:00  1001    Victor  0.214525  0.258635
2000-01-01 00:01:30  1018    Alice -0.646866  0.822104
2000-01-01 00:02:00    991     Dan  0.902389  0.466665
2000-12-30 23:58:00  992    Sarah  0.721155  0.944118
2000-12-30 23:58:30  1007   Ursula  0.409277  0.133227
2000-12-30 23:59:00  1009  Hannah -0.452802  0.184318
2000-12-30 23:59:30  978    Kevin -0.904728 -0.179146
2000-12-31 00:00:00  973  Ingrid -0.370763 -0.794667
[1051201 rows x 4 columns]
```

Now, let’s inspect the data types and memory usage to see where we should focus our attention.

```python
In [8]: ts.dtypes
Out[8]:
   id    name     x     y
dtype: object
```

```python
In [9]: ts.memory_usage(deep=True)  # memory usage in bytes
Out[9]:
   Index     id     name      x      y
Index  8409608  65537768  8409608  8409608
id  8409608
name 8409608
x  8409608
y  8409608
dtype: int64
```

The `name` column is taking up much more memory than any other. It has just a few unique values, so it’s a good candidate for converting to a `Categorical`. With a Categorical, we store each unique name once and use space-efficient integers to know which specific name is used in each row.

```python
In [10]: ts2 = ts.copy()

In [11]: ts2["name"] = ts2["name"].astype("category")
```

(continues on next page)
In [12]: ts2.memory_usage(deep=True)
Out[12]:
| Index | 8409608 |
| id    | 8409608 |
| name  | 1053894 |
| x     | 8409608 |
| y     | 8409608 |
| dtype : int64 |

We can go a bit further and downcast the numeric columns to their smallest types using `pandas.to_numeric()`.

In [13]: ts2["id"] = pd.to_numeric(ts2["id"], downcast="unsigned")
In [14]: ts2["x", "y"] = ts2["x", "y"].apply(pd.to_numeric, downcast="float")
In [15]: ts2.dtypes
Out[15]:
| id      | uint16    |
| name    | category  |
| x       | float32   |
| y       | float32   |
| dtype   | object    |

In [16]: ts2.memory_usage(deep=True)
Out[16]:
| Index | 8409608 |
| id    | 2102402 |
| name  | 1053894 |
| x     | 4204804 |
| y     | 4204804 |
| dtype : int64 |

In [17]: reduction = ts2.memory_usage(deep=True).sum() / ts.memory_usage(deep=True).sum()
In [18]: print(f"{reduction:0.2f}")
0.20

In all, we’ve reduced the in-memory footprint of this dataset to 1/5 of its original size.

See `Categorical data` for more on `Categorical` and `dtypes` for an overview of all of pandas’ `dtypes`.

### 2.24.3 Use chunking

Some workloads can be achieved with chunking: splitting a large problem like “convert this directory of CSVs to parquet” into a bunch of small problems (“convert this individual CSV file into a Parquet file. Now repeat that for each file in this directory.”). As long as each chunk fits in memory, you can work with datasets that are much larger than memory.

**Note:** Chunking works well when the operation you’re performing requires zero or minimal coordination between chunks. For more complicated workflows, you’re better off using another library.

2.24. Scaling to large datasets
Suppose we have an even larger “logical dataset” on disk that’s a directory of parquet files. Each file in the directory represents a different year of the entire dataset.

```
data/
|-- timeseries
    |-- ts-00.parquet
    |-- ts-01.parquet
    |-- ts-02.parquet
    |-- ts-03.parquet
    |-- ts-04.parquet
    |-- ts-05.parquet
    |-- ts-06.parquet
    |-- ts-07.parquet
    |-- ts-08.parquet
    |-- ts-09.parquet
    |-- ts-10.parquet
    |-- ts-11.parquet
```

Now we’ll implement an out-of-core `value_counts`. The peak memory usage of this workflow is the single largest chunk, plus a small series storing the unique value counts up to this point. As long as each individual file fits in memory, this will work for arbitrary-sized datasets.

```
In [19]: %time
   ....: files = pathlib.Path("data/timeseries/").glob("ts*.parquet")
   ....: counts = pd.Series(dtype=int)
   ....: for path in files:
   ....:     df = pd.read_parquet(path)
   ....:     counts = counts.add(df["name"].value_counts(), fill_value=0)
   ....: counts.astype(int)
   ....:
CPU times: user 614 ms, sys: 17.9 ms, total: 632 ms
Wall time: 445 ms
Out[19]:
Alice    229802
Bob     229211
Charlie  229303
Dan     230621
Edith   230349
   ...
Victor  230502
Wendy   230038
Xavier  229553
Yvonne  228766
Zelda   229909
Length: 26, dtype: int64
```

Some readers, like `pandas.read_csv()`, offer parameters to control the `chunksize` when reading a single file.

Manually chunking is an OK option for workflows that don’t require too sophisticated of operations. Some operations, like `groupby`, are much harder to do chunkwise. In these cases, you may be better switching to a different library that implements these out-of-core algorithms for you.
2.24.4 Use other libraries

pandas is just one library offering a DataFrame API. Because of its popularity, pandas’ API has become something of a standard that other libraries implement. The pandas documentation maintains a list of libraries implementing a DataFrame API in our ecosystem page.

For example, Dask, a parallel computing library, has dask.dataframe, a pandas-like API for working with larger than memory datasets in parallel. Dask can use multiple threads or processes on a single machine, or a cluster of machines to process data in parallel.

We’ll import dask.dataframe and notice that the API feels similar to pandas. We can use Dask’s `read_parquet` function, but provide a globstring of files to read in.

```python
In [20]: import dask.dataframe as dd

In [21]: ddf = dd.read_parquet("data/timeseries/ts*.parquet", engine="pyarrow")

In [22]: ddf
Out[22]:
Dask DataFrame Structure:
    id  name  x  y
npartitions=12
    int64  object  float64  float64
    ...  ...  ...  ...
Dask Name: read-parquet, 12 tasks
```

Inspecting the ddf object, we see a few things

- There are familiar attributes like `.columns` and `.dtypes`
- There are familiar methods like `.groupby`, `.sum`, etc.
- There are new attributes like `.npartitions` and `.divisions`

The partitions and divisions are how Dask parallelizes computation. A Dask DataFrame is made up of many pandas DataFrames. A single method call on a Dask DataFrame ends up making many pandas method calls, and Dask knows how to coordinate everything to get the result.

```python
In [23]: ddf.columns
Out[23]: Index(['id', 'name', 'x', 'y'], dtype='object')

In [24]: ddf.dtypes
Out[24]:
id  int64
name  object
x  float64
y  float64
dtype: object

In [25]: ddf.npartitions
Out[25]: 12
```

One major difference: the dask.dataframe API is lazy. If you look at the repr above, you’ll notice that the values aren’t actually printed out; just the column names and dtypes. That’s because Dask hasn’t actually read the data yet.

2.24. Scaling to large datasets
Rather than executing immediately, doing operations build up a task graph.

```python
In [26]: ddf
Out[26]:
Dask DataFrame Structure:
     id    name     x     y
npartitions=12
   int64  object  float64  float64
   ...   ...     ...     ...
   ...   ...     ...     ...
   ...   ...     ...     ...
   ...   ...     ...     ...

Dask Name: read-parquet, 12 tasks

In [27]: ddf["name"]
Out[27]:
Dask Series Structure:
npartitions=12
  object
  ...
  ...
  ...
  ...

Name: name, dtype: object
Dask Name: getitem, 24 tasks

In [28]: ddf["name"].value_counts()
Out[28]:
Dask Series Structure:
npartitions=1
  int64
  ...

Name: name, dtype: int64
Dask Name: value-counts-agg, 39 tasks
```

Each of these calls is instant because the result isn’t being computed yet. We’re just building up a list of computation to do when someone needs the result. Dask knows that the return type of a pandas.Series.value_counts is a pandas Series with a certain dtype and a certain name. So the Dask version returns a Dask Series with the same dtype and the same name.

To get the actual result you can call .compute().

```python
In [29]: %time ddf["name"].value_counts().compute()
CPU times: user 748 ms, sys: 202 ms, total: 950 ms
Wall time: 455 ms
Out[29]:
Laura    230906
Ingrid   230838
Kevin    230698
Dan      230621
Frank    230595
      ...
Ray      229603
Xavier   229553

(continues on next page)
```
At that point, you get back the same thing you’d get with pandas, in this case a concrete pandas Series with the count of each name.

Calling `.compute` causes the full task graph to be executed. This includes reading the data, selecting the columns, and doing the `value_counts`. The execution is done in parallel where possible, and Dask tries to keep the overall memory footprint small. You can work with datasets that are much larger than memory, as long as each partition (a regular pandas DataFrame) fits in memory.

By default, `dask.dataframe` operations use a threadpool to do operations in parallel. We can also connect to a cluster to distribute the work on many machines. In this case we’ll connect to a local “cluster” made up of several processes on this single machine.

```python
>>> from dask.distributed import Client, LocalCluster

>>> cluster = LocalCluster()

>>> client = Client(cluster)

>>> client
<Client: 'tcp://127.0.0.1:53349' processes=4 threads=8, memory=17.18 GB>
```

Once this client is created, all of Dask’s computation will take place on the cluster (which is just processes in this case).

Dask implements the most used parts of the pandas API. For example, we can do a familiar groupby aggregation.

```python
In [30]: %time ddf.groupby("name")[["x", "y"]].mean().compute().head()
CPU times: user 1.54 s, sys: 384 ms, total: 1.93 s
Wall time: 803 ms

Out[30]:
   x     y
name
Alice 0.000086 0.001170
Bob  -0.000843 -0.000799
Charlie 0.000564 0.000038
Dan    0.000584 0.000818
Edith -0.000116 -0.000044
```

The grouping and aggregation is done out-of-core and in parallel.

When Dask knows the divisions of a dataset, certain optimizations are possible. When reading parquet datasets written by dask, the divisions will be known automatically. In this case, since we created the parquet files manually, we need to supply the divisions manually.

```python
In [31]: N = 12

In [32]: starts = [f'20{i:02d}-01-01' for i in range(N)]

In [33]: ends = [f'20{i:02d}-12-13' for i in range(N)]

In [34]: divisions = tuple(pd.to_datetime(starts)) + (pd.Timestamp(ends[-1]),)
```

(continues on next page)
In [35]: ddf.divisions = divisions

In [36]: ddf
Out[36]:
Dask DataFrame Structure:
  id name x y
npartitions=12
2000-01-01 int64 object float64 float64
2001-01-01 ... ... ... ... ...
... ... ... ... ... ...
2011-01-01 ... ... ... ... ...
2011-12-13 ... ... ... ... ...

Dask Name: read-parquet, 12 tasks

Now we can do things like fast random access with .loc.

In [37]: ddf.loc["2002-01-01 12:01":"2002-01-01 12:05"].compute()
Out[37]:
  id name          x       y
timestamp
2002-01-01 12:01:00 983 Laura 0.243985 -0.079392
2002-01-01 12:02:00 1001 Laura -0.523119 -0.226026
2002-01-01 12:03:00 1059 Oliver 0.612886 0.405680
2002-01-01 12:04:00 993 Kevin 0.451977 0.332947
2002-01-01 12:05:00 1014 Yvonne -0.948681 0.361748

Dask knows to just look in the 3rd partition for selecting values in 2002. It doesn’t need to look at any other data.

Many workflows involve a large amount of data and processing it in a way that reduces the size to something that fits in memory. In this case, we’ll resample to daily frequency and take the mean. Once we’ve taken the mean, we know the results will fit in memory, so we can safely call compute without running out of memory. At that point it’s just a regular pandas object.

In [38]: ddf[["x", "y"]].resample("1D").mean().cumsum().compute().plot()
Out[38]: <AxesSubplot:xlabel='timestamp'>
These Dask examples have all been done using multiple processes on a single machine. Dask can be deployed on a cluster to scale up to even larger datasets.

You see more Dask examples at https://examples.dask.org.

## 2.25 Sparse data structures

pandas provides data structures for efficiently storing sparse data. These are not necessarily sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (NaN / missing value, though any value can be chosen, including 0) is omitted. The compressed values are not actually stored in the array.

```python
In [1]: arr = np.random.randn(10)
In [2]: arr[2:-2] = np.nan
In [3]: ts = pd.Series(pd.arrays.SparseArray(arr))
In [4]: ts
Out[4]:
0  0.469112
1 -0.282863
```

(continues on next page)
Notice the dtype, Sparse[float64, nan]. The nan means that elements in the array that are nan aren’t actually stored, only the non-nan elements are. Those non-nan elements have a float64 dtype.

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```
In [5]: df = pd.DataFrame(np.random.randn(10000, 4))
In [6]: df.iloc[:9998] = np.nan
In [7]: sdf = df.astype(pd.SparseDtype("float", np.nan))
In [8]: sdf.head()
Out[8]:
   0  1  2  3
0  NaN NaN NaN NaN
1  NaN NaN NaN NaN
2  NaN NaN NaN NaN
3  NaN NaN NaN NaN
4  NaN NaN NaN NaN
In [9]: sdf.dtypes
Out[9]:
0  Sparse[float64, nan]
1  Sparse[float64, nan]
2  Sparse[float64, nan]
3  Sparse[float64, nan]
dtype: object
In [10]: sdf.sparse.density
Out[10]: 0.0002
```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter.

```
In [11]: 'dense : {:.2f} bytes'.format(df.memory_usage().sum() / 1e3)
Out[11]: 'dense : 320.13 bytes'
In [12]: 'sparse: {:.2f} bytes'.format(sdf.memory_usage().sum() / 1e3)
Out[12]: 'sparse: 0.22 bytes'
```

Functionally, their behavior should be nearly identical to their dense counterparts.
2.25.1 SparseArray

`arrays.SparseArray` is a `ExtensionArray` for storing an array of sparse values (see `dtypes` for more on extension arrays). It is a 1-dimensional ndarray-like object storing only values distinct from the `fill_value`:

```python
In [13]: arr = np.random.randn(10)
In [14]: arr[2:5] = np.nan
In [15]: arr[7:8] = np.nan
In [16]: sparr = pd.arrays.SparseArray(arr)
In [17]: sparr
Out[17]:
[-1.9556635297215477, -1.6588664275960427, nan, nan, nan, 1.1589328886422277, 0.
   -14529711373305043, nan, 0.6060271905134522, 1.3342113401317768]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

A sparse array can be converted to a regular (dense) ndarray with `numpy.asarray()`

```python
In [18]: np.asarray(sparr)
Out[18]:
array([-1.9557, -1.6589, nan, nan, nan, 1.1589, 0.1453,
       nan, 0.606 , 1.3342])
```

2.25.2 SparseDtype

The `SparseArray.dtype` property stores two pieces of information

1. The dtype of the non-sparse values
2. The scalar fill value

```python
In [19]: sparr.dtype
Out[19]: Sparse[Float64, nan]
```

A `SparseDtype` may be constructed by passing only a dtype

```python
In [20]: pd.SparseDtype(np.dtype('datetime64[ns]'))
Out[20]: Sparse[datetime64[ns], numpy.datetime64('NaT')]
```

in which case a default fill value will be used (for NumPy dtypes this is often the “missing” value for that dtype). To override this default an explicit fill value may be passed instead

```python
In [21]: pd.SparseDtype(np.dtype('datetime64[ns]'),
   fill_value=pd.Timestamp('2017-01-01'))
Out[21]: Sparse[datetime64[ns], Timestamp('2017-01-01 00:00:00')]
```

Finally, the string alias `Sparse[dtype]` may be used to specify a sparse dtype in many places
2.25.3 Sparse accessor

pandas provides a .sparse accessor, similar to .str for string data, .cat for categorical data, and .dt for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

In [23]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int"]")

In [24]: s.sparse.density
Out[24]: 0.5

In [25]: s.sparse.fill_value
Out[25]: 0

This accessor is available only on data with SparseDtype, and on the Series class itself for creating a Series with sparse data from a scipy COO matrix with.

New in version 0.25.0.

A .sparse accessor has been added for DataFrame as well. See Sparse accessor for more.

2.25.4 Sparse calculation

You can apply NumPy ufuncs to SparseArray and get a SparseArray as a result.

In [26]: arr = pd.arrays.SparseArray([1., np.nan, np.nan, -2., np.nan])

In [27]: np.abs(arr)
Out[27]: [1.0, nan, nan, 2.0, nan]

Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)

The ufunc is also applied to fill_value. This is needed to get the correct dense result.

In [28]: arr = pd.arrays.SparseArray([1., -1, -1, -2., -1], fill_value=-1)

In [29]: np.abs(arr)
Out[29]: [1.0, 1, 1, 2.0, 1]

Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)
In [30]: np.abs(arr).to_dense()
Out[30]: array([1., 1., 1., 2., 1.])

2.25.5 Migrating

Note: SparseSeries and SparseDataFrame were removed in pandas 1.0.0. This migration guide is present to aid in migrating from previous versions.

In older versions of pandas, the SparseSeries and SparseDataFrame classes (documented below) were the preferred way to work with sparse data. With the advent of extension arrays, these subclasses are no longer needed. Their purpose is better served by using a regular Series or DataFrame with sparse values instead.

Note: There's no performance or memory penalty to using a Series or DataFrame with sparse values, rather than a SparseSeries or SparseDataFrame.

This section provides some guidance on migrating your code to the new style. As a reminder, you can use the Python warnings module to control warnings. But we recommend modifying your code, rather than ignoring the warning.

Construction

From an array-like, use the regular `Series` or `DataFrame` constructors with `SparseArray` values.

# Previous way
```python
>>> pd.SparseDataFrame("
A": [0, 1])
```

# New way
```
In [31]: pd.DataFrame("
A": pd.arrays.SparseArray([0, 1]))
Out[31]:
     A
0  0
1  1
```

From a SciPy sparse matrix, use `DataFrame.sparse.from_spmatrix()`.

# Previous way
```python
>>> from scipy import sparse
>>> mat = sparse.eye(3)
>>> df = pd.SparseDataFrame(mat, columns=['A', 'B', 'C'])
```

# New way
```
In [32]: from scipy import sparse

In [33]: mat = sparse.eye(3)

In [34]: df = pd.DataFrame.sparse.from_spmatrix(mat, columns=['A', 'B', 'C'])

In [35]: df.dtypes
Out[35]:
A     Sparse[float64, 0]
(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.4

(continued from previous page)

B
Sparse[float64, 0]
C
Sparse[float64, 0]
dtype: object
Conversion
From sparse to dense, use the .sparse accessors
In [36]: df.sparse.to_dense()
Out[36]:
A
B
C
0 1.0 0.0 0.0
1 0.0 1.0 0.0
2 0.0 0.0 1.0
In [37]: df.sparse.to_coo()
Out[37]:
<3x3 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>
From dense to sparse, use DataFrame.astype() with a SparseDtype.
In [38]: dense = pd.DataFrame({"A": [1, 0, 0, 1]})
In [39]: dtype = pd.SparseDtype(int, fill_value=0)
In [40]: dense.astype(dtype)
Out[40]:
A
0 1
1 0
2 0
3 1
Sparse Properties
Sparse-specific properties, like density, are available on the .sparse accessor.
In [41]: df.sparse.density
Out[41]: 0.3333333333333333
General differences
In a SparseDataFrame, all columns were sparse. A DataFrame can have a mixture of sparse and dense columns. As
a consequence, assigning new columns to a DataFrame with sparse values will not automatically convert the input to
be sparse.
# Previous Way
>>> df = pd.SparseDataFrame({"A": [0, 1]})
>>> df['B'] = [0, 0] # implicitly becomes Sparse
>>> df['B'].dtype
Sparse[int64, nan]
Instead, you’ll need to ensure that the values being assigned are sparse

966

Chapter 2. User Guide


In [42]: df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1])})

In [43]: df['B'] = [0, 0]  # remains dense

In [44]: df['B'].dtype
Out[44]: dtype('int64')

In [45]: df['B'] = pd.arrays.SparseArray([0, 0])

In [46]: df['B'].dtype
Out[46]: Sparse[int64, 0]

The SparseDataFrame.default_kind and SparseDataFrame.default_fill_value attributes have no replacement.

### 2.25.6 Interaction with scipy.sparse

Use `DataFrame.sparse.from_spmatrix()` to create a DataFrame with sparse values from a sparse matrix.

New in version 0.25.0.

In [47]: from scipy.sparse import csr_matrix

In [48]: arr = np.random.random(size=(1000, 5))

In [49]: arr[arr < .9] = 0

In [50]: sp_arr = csr_matrix(arr)

In [51]: sp_arr
Out[51]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
    with 517 stored elements in Compressed Sparse Row format>

In [52]: sdf = pd.DataFrame.sparse.from_spmatrix(sp_arr)

In [53]: sdf.head()
Out[53]:
     0  1  2  3  4
0 0.956380 0.0 0.0 0.000000 0.0
1 0.000000 0.0 0.0 0.000000 0.0
2 0.000000 0.0 0.0 0.000000 0.0
3 0.000000 0.0 0.0 0.000000 0.0
4 0.999552 0.0 0.0 0.956153 0.0

In [54]: sdf.dtypes
Out[54]:
0  Sparse[float64, 0]
1  Sparse[float64, 0]
2  Sparse[float64, 0]
3  Sparse[float64, 0]
4  Sparse[float64, 0]
dtype: object
All sparse formats are supported, but matrices that are not in COOrdinate format will be converted, copying data as needed. To convert back to sparse SciPy matrix in COO format, you can use the `DataFrame.sparse.to_coo()` method:

```python
In [55]: sdf.sparse.to_coo()
Out[55]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
   with 517 stored elements in COOrdinate format>
```

The method requires a `MultiIndex` with two or more levels.

```python
In [56]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
In [57]: s.index = pd.MultiIndex.from_tuples(
    ....:   [(1, 2, "a", 0),
    ....:    (1, 2, "a", 1),
    ....:    (1, 1, "b", 0),
    ....:    (1, 1, "b", 1),
    ....:    (2, 1, "b", 0),
    ....:    (2, 1, "b", 1),
    ....:   ],
    ....:   names=["A", "B", "C", "D"],
    ....:   )
In [58]: ss = s.astype('Sparse')
In [59]: ss
Out[59]:
A  B  C  D
1 2  a  0  3.0
   1  NaN
1  b  0  1.0
   1  3.0
2 1  b  0  NaN
   1  NaN
dtype: Sparse[float64, nan]
```

In the example below, we transform the `Series` to a sparse representation of a 2-d array by specifying that the first and second `MultiIndex` levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

```python
In [60]: A, rows, columns = ss.sparse.to_coo(
    ....:   row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
    ....:   )
In [61]: A
Out[61]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'>
```
with 3 stored elements in COOrdinate format

In [62]: A.todense()
Out[62]:
matrix([[0., 0., 1., 3.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

In [63]: rows
Out[63]: [(1, 1), (1, 2), (2, 1)]

In [64]: columns
Out[64]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

In [65]: A, rows, columns = ss.sparse.to_coo(
   ....: row_levels=['A', 'B', 'C'], column_levels=['D'], sort_labels=False)
   ....: )
   ....:

In [66]: A
Out[66]:
<3x2 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [67]: A.todense()
Out[67]:
matrix([[3., 0.],
        [1., 3.],
        [0., 0.]])

In [68]: rows
Out[68]: [(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]}

In [69]: columns
Out[69]: [0, 1]

A convenience method Series.sparse.from_coo() is implemented for creating a Series with sparse values from a scipy.sparse.coo_matrix.

In [70]: from scipy import sparse

In [71]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4))

In [72]: A
Out[72]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [73]: A.todense()
Out[73]:

(continues on next page)
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

The default behaviour (with dense_index=False) simply returns a Series containing only the non-null entries.

```
In [74]: ss = pd.Series.sparse.from_coo(A)
In [75]: ss
Out[75]:
0    2    1.0
3    2.0
1    0    3.0
dtype: Sparse[float64, nan]
```

Specifying dense_index=True will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to dense_index=False) if the sparse matrix is large (and sparse) enough.

```
In [76]: ss_dense = pd.Series.sparse.from_coo(A, dense_index=True)
In [77]: ss_dense
Out[77]:
0    0    NaN
1    NaN
2    1.0
3    2.0
1    0    3.0
1    NaN
2    NaN
3    NaN
2    0    NaN
1    NaN
2    NaN
3    NaN
dtype: Sparse[float64, nan]
```

### 2.26 Frequently Asked Questions (FAQ)

#### 2.26.1 DataFrame memory usage

The memory usage of a DataFrame (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see the list of options), specifies if the DataFrame’s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the DataFrame below is shown when calling `info()`:

```
In [1]: dtypes = [
    ...:   "int64",
    ...:   "float64",
    ...:   "datetime64[ns]",
```
...:  "timedelta64[ns]",
...:  "complex128",
...:  "object",
...:  "bool",
...:  ]
...

In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)

In [5]: df["categorical"] = df["object"].astype("category")

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
# Column  Non-Null Count  Dtype
---  ------  --------------  -----  
0 int64   5000 non-null  int64
1 float64 5000 non-null  float64
2 datetime64[ns] 5000 non-null  datetime64[ns]
3 timedelta64[ns] 5000 non-null  timedelta64[ns]
4 complex128 5000 non-null  complex128
5 object   5000 non-null  object
6 bool     5000 non-null  bool
7 categorical 5000 non-null  category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
        object(1), timedelta64[ns](1)
memory usage: 288.2+ KB

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with dtype=object.

Passing memory_usage='deep' will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

In [7]: df.info(memory_usage="deep")
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
# Column  Non-Null Count  Dtype
---  ------  --------------  -----  
0 int64   5000 non-null  int64
1 float64 5000 non-null  float64
2 datetime64[ns] 5000 non-null  datetime64[ns]
3 timedelta64[ns] 5000 non-null  timedelta64[ns]
4 complex128 5000 non-null  complex128
5 object   5000 non-null  object
6 bool     5000 non-null  bool
7 categorical 5000 non-null  category

(continues on next page)
By default the display option is set to True but can be explicitly overridden by passing the memory_usage argument when invoking df.info().

The memory usage of each column can be found by calling the memory_usage() method. This returns a Series with an index represented by column names and memory usage of each column shown in bytes. For the DataFrame above, the memory usage of each column and the total memory usage can be found with the memory_usage method:

```
In [8]: df.memory_usage()
Out[8]:
Index     128
int64   40000
float64  40000
datetime64[ns]  40000
timedelta64[ns]  40000
complex128  80000
object    40000
bool      5000
categorical 9968
dtype: int64

# total memory usage of dataframe
In [9]: df.memory_usage().sum()
Out[9]: 295096
```

By default the memory usage of the DataFrame’s index is shown in the returned Series, the memory usage of the index can be suppressed by passing the index=False argument:

```
In [10]: df.memory_usage(index=False)
Out[10]:
int64   40000
float64  40000
datetime64[ns]  40000
timedelta64[ns]  40000
complex128  80000
object    40000
bool      5000
categorical 9968
dtype: int64
```

The memory usage displayed by the info() method utilizes the memory_usage() method to determine the memory usage of a DataFrame while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also Categorical Memory Usage.
2.26.2 Using if/truth statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a bool. This happens in an if-statement or when using the boolean operations: and, or, and not. It is not clear what the result of the following code should be:

```python
>>> if pd.Series([False, True, False]):
    ...
    pass
```

Should it be True because it’s not zero-length, or False because there are False values? It is unclear, so instead, pandas raises a ValueError:

```python
>>> if pd.Series([False, True, False]):
...    print("I was true")
Traceback
...    ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the DataFrame, e.g. use any(), all() or empty(). Alternatively, you might want to compare if the pandas object is None:

```python
>>> if pd.Series([False, True, False]) is not None:
...    print("I was not None")
I was not None
```

Below is how to check if any of the values are True:

```python
>>> if pd.Series([False, True, False]).any():
...    print("I am any")
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method bool():

```python
In [11]: pd.Series([True]).bool()
Out[11]: True

In [12]: pd.Series([False]).bool()
Out[12]: False

In [13]: pd.DataFrame([[True]]).bool()
Out[13]: True

In [14]: pd.DataFrame([[False]]).bool()
Out[14]: False
```
Bitwise boolean

Bitwise boolean operators like == and != return a boolean Series, which is almost always what you want anyways.

```python
>>> s = pd.Series(range(5))
>>> s == 4
0   False
1   False
2   False
3   False
4    True
dtype: bool
```

See boolean comparisons for more examples.

Using the in operator

Using the Python in operator on a Series tests for membership in the index, not membership among the values.

```python
In [15]: s = pd.Series(range(5), index=list("abcde"))
In [16]: 2 in s
0 Out[16]: False
In [17]: 'b' in s
0 Out[17]: True
```

If this behavior is surprising, keep in mind that using in on a Python dictionary tests keys, not values, and Series are dict-like. To test for membership in the values, use the method `isin()`:

```python
In [18]: s.isin([2])
0 Out[18]:
a   False
b   False
c   True
d   False
e   False
dtype: bool
In [19]: s.isin([2]).any()
0 Out[19]: True
```

For DataFrames, likewise, in applies to the column axis, testing for membership in the list of column names.
2.26.3 Mutating with User Defined Function (UDF) methods

This section applies to pandas methods that take a UDF. In particular, the methods `.apply`, `.aggregate`, `.transform`, and `.filter`.

It is a general rule in programming that one should not mutate a container while it is being iterated over. Mutation will invalidate the iterator, causing unexpected behavior. Consider the example:

```python
In [20]: values = [0, 1, 2, 3, 4, 5]
In [21]: n_removed = 0
In [22]: for k, value in enumerate(values):
   ....:     idx = k - n_removed
   ....:     if value % 2 == 1:
   ....:         del values[idx]
   ....:         n_removed += 1
   ....:     else:
   ....:         values[idx] = value + 1

In [23]: values
Out[23]: [1, 4, 5]
```

One probably would have expected that the result would be `[1, 3, 5]`. When using a pandas method that takes a UDF, internally pandas is often iterating over the DataFrame or other pandas object. Therefore, if the UDF mutates (changes) the DataFrame, unexpected behavior can arise.

Here is a similar example with `DataFrame.apply()`:

```python
In [24]: def f(s):
   ....:     s.pop("a")
   ....:     return s
   ....:
In [25]: df = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6]})
In [26]: try:
   ....:     df.apply(f, axis="columns")
   ....:     except Exception as err:
   ....:         print(repr(err))
   ....:
KeyError('a')
```

To resolve this issue, one can make a copy so that the mutation does not apply to the container being iterated over.

```python
In [27]: values = [0, 1, 2, 3, 4, 5]
In [28]: n_removed = 0
In [29]: for k, value in enumerate(values.copy()):
   ....:     idx = k - n_removed
   ....:     if value % 2 == 1:
   ....:         del values[idx]
   ....:         n_removed += 1
   ....:     else:
   ....:         values[idx] = value + 1
```

(continues on next page)
In [33]: df.apply(f, axis="columns")
Out[33]:
    b
0  4  
1  5
2  6

2.26.4 NaN, Integer NA values and NA type promotions

Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A masked array solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value NaN (Not-A-Number) is used everywhere as the NA value, and there are API functions isna and notna which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

In [34]: s = pd.Series([1, 2, 3, 4, 5], index=list("abcde"))

In [35]: s
Out[35]:
a  1
b  2
In [36]: s.dtype
Out[36]: dtype('int64')

In [37]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])

In [38]: s2
Out[38]:
   a   1.0
   b   2.0
   c   3.0
   f   NaN
   u   NaN
   dtype: float64

In [39]: s2.dtype
Out[39]: dtype('float64')

This trade-off is made largely for memory and performance reasons, and also so that the resulting Series continues to be “numeric”.

If you need to represent integers with possibly missing values, use one of the nullable-integer extension dtypes provided by pandas:

- Int8Dtype
- Int16Dtype
- Int32Dtype
- Int64Dtype

In [40]: s_int = pd.Series([1, 2, 3, 4, 5], index=list('abcde'), dtype=pd.Int64Dtype())

In [41]: s_int
Out[41]:
   a   1
   b   2
   c   3
   d   4
   e   5
   dtype: Int64

In [42]: s_int.dtype
Out[42]: Int64Dtype()

In [43]: s2_int = s_int.reindex(['a', 'b', 'c', 'f', 'u'])

In [44]: s2_int
Out[44]:
   a   1
   b   2
   c   3
   f   NaN
   u   NaN
   dtype: float64

(continues on next page)
See *Nullable integer data type* for more.

### NA type promotions

When introducing NAs into an existing `Series` or `DataFrame` via `reindex()` or some other means, boolean and integer types will be promoted to a different `dtype` in order to store the NAs. The promotions are summarized in this table:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Promotion dtype for storing NAs</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating</td>
<td>no change</td>
</tr>
<tr>
<td>object</td>
<td>no change</td>
</tr>
<tr>
<td>integer</td>
<td>cast to float64</td>
</tr>
<tr>
<td>boolean</td>
<td>cast to object</td>
</tr>
</tbody>
</table>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than $2^{**}53$. Some explanation for the motivation is in the next section.

### Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy.floating</td>
<td>float16, float32, float64, float128</td>
</tr>
<tr>
<td>numpy.integer</td>
<td>int8, int16, int32, int64</td>
</tr>
<tr>
<td>numpy.unsignedinteger</td>
<td>uint8, uint16, uint32, uint64</td>
</tr>
<tr>
<td>numpy.object_</td>
<td>object_</td>
</tr>
<tr>
<td>numpy.bool_</td>
<td>bool_</td>
</tr>
<tr>
<td>numpy.character</td>
<td>string_, unicode_</td>
</tr>
</tbody>
</table>

The R language, by contrast, only has a handful of built-in data types: `integer`, `numeric` (floating-point), `character`, and `boolean`. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean `mask` denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using NaN. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.
2.26.5 Differences with NumPy

For Series and DataFrame objects, var() normalizes by N-1 to produce unbiased estimates of the sample variance, while NumPy’s var normalizes by N, which measures the variance of the sample. Note that cov() normalizes by N-1 in both pandas and NumPy.

2.26.6 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the copy() method. If you are doing a lot of copying of DataFrame objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See this link for more information.

2.26.7 Byte-ordering issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like:

```
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order before passing it to Series or DataFrame constructors using something similar to the following:

```
In [46]: x = np.array(list(range(10)), ">i4")  # big endian
In [47]: newx = x.byteswap().newbyteorder()  # force native byteorder
In [48]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details.

2.27 Cookbook

This is a repository for short and sweet examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great First Pull Request.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the Stack-Overflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

pandas (pd) and NumPy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.
2.27.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame(
   ...:      {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
   ...:     )
   ...:

In [2]: df
Out[2]:
   AAA  BBB  CCC
  0  4   10  100
  1  5  -1  50
  2  6  -30 -30
  3  7  -50 -50
```

**if-then...**

An if-then on one column

```
In [3]: df.loc[df.AAA >= 5, "BBB"] = -1

In [4]: df
Out[4]:
   AAA  BBB  CCC
  0  4   10  100
  1  5  -1  50
  2  6  -1 -30
  3  7  -1 -50
```

An if-then with assignment to 2 columns:

```
In [5]: df.loc[df.AAA >= 5, ["BBB", "CCC"] = 555

In [6]: df
Out[6]:
   AAA  BBB  CCC
  0  4   10  100
  1  5   555 555
  2  6   555 555
  3  7   555 555
```

Add another line with different logic, to do the -else

```
In [7]: df.loc[df.AAA < 5, ["BBB", "CCC"] = 2000

In [8]: df
Out[8]:
   AAA  BBB  CCC
  0  4  2000 2000
```

(continues on next page)
Or use pandas where after you’ve set up a mask

```
In [9]: df_mask = pd.DataFrame(
    ...:     {"AAA": [True] * 4, "BBB": [False] * 4, "CCC": [True, False] * 2}
    ...: )
    ...

In [10]: df.where(df_mask, -1000)
Out[10]:
   AAA  BBB  CCC
0  4   -1000  2000
1  5   -1000  -1000
2  6   -1000   555
3  7   -1000  -1000
```

if-then-else using NumPy’s where()

```
In [11]: df = pd.DataFrame(
    ...:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    ...: )
    ...

In [12]: df
Out[12]:
   AAA  BBB  CCC
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50

In [13]: df["logic"] = np.where(df["AAA"] > 5, "high", "low")

In [14]: df
Out[14]:
   AAA  BBB  CCC  logic
0   4   10  100  low
1   5   20   50  low
2   6   30  -30  high
3   7   40  -50  high
Splitting

Split a frame with a boolean criterion

```python
In [15]: df = pd.DataFrame(
        ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
        ....: )
        ....:

In [16]: df
Out[16]:
        AAA  BBB  CCC
    0  4     10   100
    1  5     20    50
    2  6     30   -30
    3  7     40   -50

In [17]: df[df.AAA <= 5]
Out[17]:
        AAA  BBB  CCC
    0  4     10   100
    1  5     20    50

In [18]: df[df.AAA > 5]
Out[18]:
        AAA  BBB  CCC
    2  6     30   -30
    3  7     40   -50
```

Building criteria

Select with multi-column criteria

```python
In [19]: df = pd.DataFrame(
        ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
        ....: )
        ....:

In [20]: df
Out[20]:
        AAA  BBB  CCC
    0  4     10   100
    1  5     20    50
    2  6     30   -30
    3  7     40   -50

... and (without assignment returns a Series)

In [21]: df.loc[(df["BBB"] < 25) & (df["CCC"] >= -40), "AAA"]
Out[21]:
    0  4
    1  5
Name: AAA, dtype: int64
```
...or (without assignment returns a Series)

```python
In [22]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= -40), "AAA"]
Out[22]:
0  4
1  5
2  6
3  7
Name: AAA, dtype: int64
```

...or (with assignment modifies the DataFrame.)

```python
In [23]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= 75), "AAA"] = 0.1
In [24]: df
Out[24]:
   AAA  BBB  CCC
0  0.1  10  100
1  5.0  20   50
2  0.1  30  -30
3  0.1  40  -50
```

Select rows with data closest to certain value using argsort

```python
In [25]: df = pd.DataFrame(
   ..........:
   .......:   {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
   ..........: )
   ..........:
In [26]: df
Out[26]:
   AAA  BBB  CCC
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
In [27]: aValue = 43.0
In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out[28]:
   AAA  BBB  CCC
1   5   20   50
0   4   10  100
2   6   30  -30
3   7   40  -50
```

Dynamically reduce a list of criteria using a binary operators

```python
In [29]: df = pd.DataFrame(
   ..........:
   .......:   {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
   ..........: )
   ..........:
```
In [30]: df
Out[30]:
     AAA  BBB  CCC
0   4.0  10.0  100
1   5.0  20.0   50
2   6.0  30.0 - 30
3   7.0  40.0 - 50

In [31]: Crit1 = df.AAA <= 5.5
In [32]: Crit2 = df.BBB == 10.0
In [33]: Crit3 = df.CCC > -40.0

One could hard code:

In [34]: AllCrit = Crit1 & Crit2 & Crit3

... Or it can be done with a list of dynamically built criteria

In [35]: import functools
In [36]: CritList = [Crit1, Crit2, Crit3]
In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)
In [38]: df[AllCrit]
Out[38]:
     AAA  BBB  CCC
0   4.0  10.0  100

2.27.2 Selection

Dataframes

The indexing docs.

Using both row labels and value conditionals

In [39]: df = pd.DataFrame(
     ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
     ....: )
In [40]: df
Out[40]:
     AAA  BBB  CCC
0   4.0  10.0  100
1   5.0  20.0   50
2   6.0  30.0 - 30
3   7.0  40.0 - 50
In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]

Out[41]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>30</td>
</tr>
<tr>
<td></td>
<td>100</td>
<td>-30</td>
</tr>
</tbody>
</table>

Use loc for label-oriented slicing and iloc positional slicing

In [42]: df = pd.DataFrame(

   ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]},
   ....:     index=['foo', 'bar', 'boo', 'kar'],
   ....: )

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style: exclusive of end)
2. Label-oriented (Non-Python slicing style: inclusive of end)
3. General (Either slicing style: depends on if the slice contains labels or positions)

In [43]: df.loc["bar":"kar"]  # Label

Out[43]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>30</td>
</tr>
<tr>
<td>kar</td>
<td>7</td>
<td>40</td>
</tr>
</tbody>
</table>

# Generic

In [44]: df[0:3]

Out[44]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>4</td>
<td>10</td>
</tr>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>30</td>
</tr>
</tbody>
</table>

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

In [46]: data = {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}

In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4])  # Note index starts at 1.

In [48]: df2.iloc[1:3]  # Position-oriented

Out[48]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>4</td>
<td>10</td>
</tr>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>30</td>
</tr>
</tbody>
</table>

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.
In [49]: df2.loc[1:3]  # Label-oriented
Out[49]:

AAA    BBB    CCC
1  4      10     100
2  5      20      50
3  6      30     -30

Using inverse operator (~) to take the complement of a mask

In [50]: df = pd.DataFrame(
   .....:   {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
   .....: )
   .....:

In [51]: df
Out[51]:

AAA    BBB    CCC
0   4      10     100
1   5      20      50
2   6      30     -30
3   7      40     -50

In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]
Out[52]:

AAA    BBB    CCC
1   5      20      50
3   7      40     -50

New columns

Efficiently and dynamically creating new columns using applymap

In [53]: df = pd.DataFrame({"AAA": [1, 2, 1, 3], "BBB": [1, 1, 2, 2], "CCC": [2, 1, 3, 1]})

In [54]: df
Out[54]:

AAA    BBB    CCC
0   1      1      2
1   2      1      1
2   1      2      3
3   3      2      1

In [55]: source_cols = df.columns  # Or some subset would work too

In [56]: new_cols = [str(x) + "_cat" for x in source_cols]
In [57]: categories = {1: "Alpha", 2: "Beta", 3: "Charlie"}

In [58]: df[new_cols] = df[source_cols].applymap(categories.get)

In [59]: df

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
<th>AAA_cat</th>
<th>BBB_cat</th>
<th>CCC_cat</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
<td>Alpha</td>
<td>Alpha</td>
<td>Beta</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>Beta</td>
<td>Alpha</td>
<td>Alpha</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
<td>Alpha</td>
<td>Beta</td>
<td>Charlie</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>2</td>
<td>Charlie</td>
<td>Beta</td>
<td>Alpha</td>
</tr>
</tbody>
</table>

Keep other columns when using min() with groupby

In [60]: df = pd.DataFrame(
   ....:     {"AAA": [1, 1, 1, 2, 2, 2, 3, 3], "BBB": [2, 1, 3, 4, 5, 1, 2, 3]}
   ....: )
   ....:

In [61]: df

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
</tr>
</tbody>
</table>

Method 1: idxmin() to get the index of the minimums

In [62]: df.loc[df.groupby("AAA")["BBB"].idxmin()]

Out[62]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
</tr>
</tbody>
</table>

Method 2: sort then take first of each

In [63]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()

Out[63]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Notice the same results, with the exception of the index.
2.27.3 Multiindexing

The *multindexing* docs.

Creating a MultiIndex from a labeled frame

```python
In [64]: df = pd.DataFrame(
            
            })

In [65]: df
Out[65]:
   row  One_X  One_Y  Two_X  Two_Y
0    0     1.1   1.2   1.11  1.22
1    1     1.1   1.2   1.11  1.22
2    2     1.1   1.2   1.11  1.22

# As Labelled Index
In [66]: df = df.set_index("row")

In [67]: df
Out[67]:
   One_X  One_Y  Two_X  Two_Y
row
0     1.1   1.2   1.11  1.22
1     1.1   1.2   1.11  1.22
2     1.1   1.2   1.11  1.22

# With Hierarchical Columns
In [68]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split("_")) for c in df.columns])

In [69]: df
Out[69]:
   One  Two
   X   Y
row
0   1.1  1.2  1.11  1.22
1   1.1  1.2  1.11  1.22
2   1.1  1.2  1.11  1.22

# Now stack & Reset
In [70]: df = df.stack(0).reset_index(1)

In [71]: df
Out[71]:
   level_1  X   Y
```

(continues on next page)
row
0  One 1.10 1.20
0  Two 1.11 1.22
1  One 1.10 1.20
1  Two 1.11 1.22
2  One 1.10 1.20
2  Two 1.11 1.22

# And fix the labels (Notice the label 'level_1' got added automatically)
In [72]: df.columns = ["Sample", "All_X", "All_Y"]

In [73]: df
Out[73]:

<table>
<thead>
<tr>
<th>row</th>
<th>Sample</th>
<th>All_X</th>
<th>All_Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>0</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>1</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>1</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>2</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>2</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
</tbody>
</table>

Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

In [74]: cols = pd.MultiIndex.from_tuples(
               
               [(x, y) for x in ["A", "B", "C"] for y in ["O", "I"]]
               
               )

In [75]: df = pd.DataFrame(np.random.randn(2, 6), index=["n", "m"], columns=cols)

In [76]: df
Out[76]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td></td>
<td></td>
</tr>
<tr>
<td>m</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In [77]: df = df.div(df["C"], level=1)

In [78]: df
Out[78]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td></td>
<td></td>
</tr>
<tr>
<td>m</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Slicing

Slicing a MultiIndex with `xs`

```
In [79]: coords = ["AA", "one"], ["AA", "six"], ["BB", "one"], ["BB", "two"], ["BB", "six"]

In [80]: index = pd.MultiIndex.from_tuples(coords)

In [81]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ["MyData"])

In [82]: df
```

```
Out[82]:
MyData
AA one 11
 six 22
BB one 33
 two 44
 six 55

To take the cross section of the 1st level and 1st axis the index:

```
# Note : level and axis are optional, and default to zero
In [83]: df.xs("BB", level=0, axis=0)
```

```
Out[83]:
MyData
 one 33
 two 44
 six 55
```

...and now the 2nd level of the 1st axis.

```
In [84]: df.xs("six", level=1, axis=0)
```

```
Out[84]:
MyData
 AA 22
 BB 55
```

Slicing a MultiIndex with `xs`, method #2

```
In [85]: import itertools

In [86]: index = list(itertools.product(["Ada", "Quinn", "Violet"], ["Comp", "Math", "Sci"]))

In [87]: headr = list(itertools.product(["Exams", "Labs"], ["I", "II"]))

In [88]: indx = pd.MultiIndex.from_tuples(index, names=["Student", "Course"])

In [89]: cols = pd.MultiIndex.from_tuples(headr)  # Notice these are un-named

In [90]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]

In [91]: df = pd.DataFrame(data, indx, cols)
```

(continues on next page)
In [92]: df
Out[92]:

<table>
<thead>
<tr>
<th>Student</th>
<th>Course</th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ada</td>
<td>Comp</td>
<td>70 71</td>
<td>72 73</td>
</tr>
<tr>
<td>Ada</td>
<td>Math</td>
<td>71 73</td>
<td>75 74</td>
</tr>
<tr>
<td>Ada</td>
<td>Sci</td>
<td>72 75</td>
<td>75 75</td>
</tr>
<tr>
<td>Quinn</td>
<td>Comp</td>
<td>73 74</td>
<td>75 76</td>
</tr>
<tr>
<td>Quinn</td>
<td>Math</td>
<td>74 76</td>
<td>78 77</td>
</tr>
<tr>
<td>Quinn</td>
<td>Sci</td>
<td>75 78</td>
<td>78 78</td>
</tr>
<tr>
<td>Violet</td>
<td>Comp</td>
<td>76 77</td>
<td>78 79</td>
</tr>
<tr>
<td>Violet</td>
<td>Math</td>
<td>77 79</td>
<td>81 80</td>
</tr>
<tr>
<td>Violet</td>
<td>Sci</td>
<td>78 81</td>
<td>81 81</td>
</tr>
</tbody>
</table>

In [93]: All = slice(None)

In [94]: df.loc["Violet"]
Out[94]:

<table>
<thead>
<tr>
<th>Student</th>
<th>Course</th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ada</td>
<td>Math</td>
<td>71 73</td>

<td>71 73</td>
<td></td>
</tr>
</tbody>
</table>
In [98]: df.loc[(All, "Math"), (All, "II")]
Out[98]:
<table>
<thead>
<tr>
<th>Student</th>
<th>Course</th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ada</td>
<td>Math</td>
<td>73</td>
<td>74</td>
</tr>
<tr>
<td>Quinn</td>
<td>Math</td>
<td>76</td>
<td>77</td>
</tr>
<tr>
<td>Violet</td>
<td>Math</td>
<td>79</td>
<td>80</td>
</tr>
</tbody>
</table>

Setting portions of a MultiIndex with xs

### Sorting

Sort by specific column or an ordered list of columns, with a MultiIndex

In [99]: df.sort_values(by=("Labs", "II"), ascending=False)
Out[99]:
<table>
<thead>
<tr>
<th>Student</th>
<th>Course</th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Violet</td>
<td>Sci</td>
<td>78</td>
<td>81</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>77</td>
<td>81</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>76</td>
<td>79</td>
</tr>
<tr>
<td>Quinn</td>
<td>Sci</td>
<td>75</td>
<td>78</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>74</td>
<td>78</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>73</td>
<td>76</td>
</tr>
<tr>
<td>Ada</td>
<td>Sci</td>
<td>72</td>
<td>75</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>71</td>
<td>74</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>70</td>
<td>73</td>
</tr>
</tbody>
</table>

Partial selection, the need for sortedness;

### Levels

Prepending a level to a multiindex

Flatten Hierarchical columns

### 2.27.4 Missing data

The missing data docs.

Fill forward a reversed timeseries

In [100]: df = pd.DataFrame(
        ....:     np.random.randn(6, 1),
        ....:     index=pd.date_range("2013-08-01", periods=6, freq="B"),
        ....:     columns=list("A"),
        ....: )
        ....:
(continues on next page)
In [101]: df.loc[df.index[3], "A"] = np.nan

In [102]: df
Out[102]:
         A
2013-08-01  0.721555
2013-08-02 -0.706771
2013-08-05 -1.039575
2013-08-06  NaN
2013-08-07 -0.424972
2013-08-08  0.567020

In [103]: df.reindex(df.index[::-1]).ffill()
Out[103]:
         A
2013-08-08  0.567020
2013-08-07 -0.424972
2013-08-06 -0.424972
2013-08-05 -1.039575
2013-08-02 -0.706771
2013-08-01  0.721555

cumsum reset at NaN values

Replace

Using replace with backrefs

2.27.5 Grouping

The grouping docs.

Basic grouping with apply

Unlike agg, apply’s callable is passed a sub-DataFrame which gives you access to all the columns

In [104]: df = pd.DataFrame({
                    "animal": "cat dog cat fish dog cat cat".split(),
                    "size": list("SSMMMLL"),
                    "weight": [8, 10, 11, 1, 20, 12, 12],
                    "adult": [False] * 5 + [True] * 2,
                    })

In [105]: df
Out[105]:
animal size  weight  adult
0  cat     S       8  False
1  dog     S      10  False
2  cat     M      11  False
# List the size of the animals with the highest weight.

```python
In [106]: df.groupby("animal").apply(lambda subf: subf["size"][subf["weight"].idxmax()])
Out[106]:
animal
  cat L
  dog M
  fish M
dtype: object
```

Using `get_group`

```python
In [107]: gb = df.groupby(["animal"])  
In [108]: gb.get_group("cat")
Out[108]:
animal  size  weight  adult
   0   cat   S     8  False
   2   cat   M    11  False
   5   cat   L    12   True
   6   cat   L    12   True
```

Apply to different items in a group

```python
In [109]: def GrowUp(x):
    ....:     avg_weight = sum(x[x["size"] == "S"]["weight"] * 1.5)  
    ....:     avg_weight += sum(x[x["size"] == "M"]["weight"] * 1.25)  
    ....:     avg_weight += sum(x[x["size"] == "L"]["weight"])
    ....:     avg_weight /= len(x)
    ....:     return pd.Series(["L", avg_weight, True], index=["size", "weight", "adult"])

CSV

The CSV docs
read_csv in action
appending to a csv
Reading a csv chunk-by-chunk
Reading only certain rows of a csv chunk-by-chunk
Reading the first few lines of a frame
Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which read_csv understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here
Inferring dtypes from a file
Dealing with bad lines
Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```
In [189]: for i in range(3):
    ....:     data = pd.DataFrame(np.random.randn(10, 4))
    ....:     data.to_csv("file{}.csv".format(i))
    ....:
In [190]: files = ["file_0.csv", "file_1.csv", "file_2.csv"]
In [191]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```
In [192]: import glob
In [193]: import os
In [194]: files = glob.glob("file_*.csv")
In [195]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*(...)` functions described in the `io docs`.

Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format:

```
In [196]: i = pd.date_range("20000101", periods=10000)
In [197]: df = pd.DataFrame({"year": i.year, "month": i.month, "day": i.day})
In [198]: df.head()
Out[198]:
 year  month  day
   0  2000    1   1
   1  2000    1   2
   2  2000    1   3
   3  2000    1   4
   4  2000    1   5
In [199]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format=%Y%m%d)
```

```
.....: ds = df.apply(lambda x: "%04d%02d%02d" % (x["year"], x["month"], x["day"]), axis=1)
```

(continues on next page)
Skip row between header and data

Option 1: pass rows explicitly to skip rows

```python
In [200]: from io import StringIO

In [201]: pd.read_csv(StringIO(data),
   ...:     sep=";",
   ...:     skiprows=[11, 12],
   ...:     index_col=0,
   ...:     parse_dates=True,
   ...:     header=10,
   ...: )

Out[202]:
   date   Param1  Param2  Param4  Param5
01-01-1990 00:00:00 1 1 2 3
01-01-1990 01:00:00 5 3 4 5
01-01-1990 02:00:00 9 5 6 7
01-01-1990 03:00:00 13 7 8 9
01-01-1990 04:00:00 17 9 10 11
01-01-1990 05:00:00 21 11 12 13
```

(continues on next page)
Option 2: read column names and then data

```python
In [203]: pd.read_csv(StringIO(data), sep=";", header=10, nrows=10).columns
Out[203]: Index(['date', 'Param1', 'Param2', 'Param4', 'Param5'], dtype='object')

In [204]: columns = pd.read_csv(StringIO(data), sep=";", header=10, nrows=10).columns

In [205]: pd.read_csv(StringIO(data), sep=";", index_col=0, header=12, parse_dates=True, names=columns)

Out[205]:
         Param1  Param2  Param4  Param5
date
1990-01-01 00:00:00    1      1      2      3
1990-01-01 01:00:00    5      3      4      5
1990-01-01 02:00:00    9      5      6      7
1990-01-01 03:00:00    9      7      8      9
1990-01-01 04:00:00    17     10     11     12
1990-01-01 05:00:00    21     11     12     13
```

### SQL

The [SQL docs](#) for [Reading from databases with SQL](#).

### Excel

The [Excel docs](#) for [Reading from a filelike handle](#) and [Modifying formatting in XlsxWriter output](#).
HTML

Reading HTML tables from a server that cannot handle the default request header

**HDFStore**

The *HDFStores* docs

Simple queries with a Timestamp Index
Managing heterogeneous data using a linked multiple table hierarchy
Merging on-disk tables with millions of rows
Avoiding inconsistencies when writing to a store from multiple processes/threads

De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. See here

Creating a store chunk-by-chunk from a csv file
Appending to a store, while creating a unique index

Large Data work flows

Reading in a sequence of files, then providing a global unique index to a store while appending
Groupby on a HDFStore with low group density
Groupby on a HDFStore with high group density
Hierarchical queries on a HDFStore
Counting with a HDFStore
Troubleshoot HDFStore exceptions
Setting min_itemsize with strings
Using ptrepack to create a completely-sorted-index on a store

Storing Attributes to a group node

```
In [206]: df = pd.DataFrame(np.random.rand(8, 3))

In [207]: store = pd.HDFStore("test.h5")

In [208]: store.put("df", df)

# you can store an arbitrary Python object via pickle
In [209]: store.get_storer("df").attrs.my_attribute = {"A": 10}

In [210]: store.get_storer("df").attrs.my_attribute
Out[210]: {'A': 10}
```

You can create or load a HDFStore in-memory by passing the *driver* parameter to PyTables. Changes are only written to disk when the HDFStore is closed.

```
In [211]: store = pd.HDFStore("test.h5", "w", driver="H5FD_CORE")

In [212]: df = pd.DataFrame(np.random.rand(8, 3))
```

(continues on next page)
In [213]: store["test"] = df

# only after closing the store, data is written to disk:
In [214]: store.close()

Binary files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called main.c compiled with gcc main.c -std=gnu99 on a 64-bit machine,

```c
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }

    FILE *file = fopen("binary.dat", "wb");
    fwrite(&d, sizeof(Data), n, file);
    fclose(file);

    return 0;
}
```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```python
names = "count", "avg", "scale"

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = "i4", "f8", "f4"
dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats}, align=True)
df = pd.DataFrame(np.fromfile("binary.dat", dt))
```
2.27.10 Computation

Numerical integration (sample-based) of a time series

Correlation

Often it’s useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from `DataFrame.corr()`. This can be achieved by passing a boolean mask to `where` as follows:

```python
In [215]: df = pd.DataFrame(np.random.random(size=(100, 5)))
In [216]: corr_mat = df.corr()
In [217]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool_), k=-1)
In [218]: corr_mat.where(mask)
```

Out[218]:
```
     0    1    2    3    4
0  NaN  NaN  NaN  NaN  NaN
1 -0.079861  NaN  NaN  NaN  NaN
2 -0.236573  0.183801  NaN  NaN  NaN
3 -0.013795 -0.051975  0.037235  NaN  NaN
4 -0.031974  0.118342 -0.073499 -0.02063  NaN
```

The method argument within `DataFrame.corr` can accept a callable in addition to the named correlation types. Here we compute the distance correlation matrix for a `DataFrame` object.

```python
In [219]: def distcorr(x, y):
    ...:     n = len(x)
    ...:     a = np.zeros(shape=(n, n))
    ...:     b = np.zeros(shape=(n, n))
    ...:     for i in range(n):
    ...:         for j in range(i + 1, n):
    ...:             a[i, j] = abs(x[i] - x[j])
    ...:             b[i, j] = abs(y[i] - y[j])
    ...:     a += a.T
    ...:     b += b.T
    ...:     a_bar = np.vstack([np.nanmean(a, axis=0)] * n)
    ...:     b_bar = np.vstack([np.nanmean(b, axis=0)] * n)
    ...:     A = a - a_bar - a_bar.T + np.full(shape=(n, n), fill_value=a_bar.mean())
    ...:     B = b - b_bar - b_bar.T + np.full(shape=(n, n), fill_value=b_bar.mean())
    ...:     cov_ab = np.sqrt(np.nansum(A * B)) / n
    ...:     std_a = np.sqrt(np.sqrt(np.nansum(A ** 2)) / n)
    ...:     std_b = np.sqrt(np.sqrt(np.nansum(B ** 2)) / n)
    ...:     return cov_ab / std_a / std_b
```

(continues on next page)
In [220]: df = pd.DataFrame(np.random.normal(size=(100, 3)))

In [221]: df.corr(method=distcorr)
Out[221]:
     0       1       2
0  1.000000  0.197613  0.216328
1  0.197613  1.000000  0.208749
2  0.216328  0.208749  1.000000

2.27.11 Timedeltas

The Timedeltas docs.

Using timedeltas

In [222]: import datetime

dtype: datetime64[ns]

In [228]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[228]:
0 -365 days +03:05:00
Adding and subtracting deltas and dates

In [230]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])

In [231]: df = pd.DataFrame({'A': s, 'B': deltas})

In [232]: df
Out[232]:
   A             B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

In [233]: df['New Dates'] = df['A'] + df['B']

In [234]: df['Delta'] = df['A'] - df['New Dates']

In [235]: df
Out[235]:
   A     B   New Dates  Delta
0 2012-01-01 0 days 2012-01-01 0 days
1 2012-01-02 1 days 2012-01-03 -1 days
2 2012-01-03 2 days 2012-01-05 -2 days

In [236]: df.dtypes
Out[236]:
A          datetime64[ns]
B          timedelta64[ns]
New Dates  datetime64[ns]
Delta      timedelta64[ns]
dtype: object

Another example

Values can be set to NaT using np.nan, similar to datetime

In [237]: y = s - s.shift()

In [238]: y
Out[238]:
0  NaT
1  1 days

(continues on next page)
In [239]: y[1] = np.nan

In [240]: y
Out[240]:
0   NaT
1   NaT
2   1 days
dtype: timedelta64[ns]

2.27.12 Creating example data

To create a dataframe from every combination of some given values, like R’s `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

In [241]: def expand_grid(data_dict):
      ....:     rows = itertools.product(*data_dict.values())
      ....:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
      ....:

In [242]: df = expand_grid(
      ....:     {"height": [60, 70], "weight": [100, 140, 180], "sex": ["Male", "Female"]}
      ....: )
      ....:

In [243]: df
Out[243]:
    height  weight  sex
0     60      100  Male
1     60      100  Female
2     60      140  Male
3     60      140  Female
4     60      180  Male
5     60      180  Female
6     70      100  Male
7     70      100  Female
8     70      140  Male
9     70      140  Female
10    70      180  Male
11    70      180  Female
This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in pandas.* namespace are public.

Some subpackages are public which include pandas.errors, pandas.plotting, and pandas.testing. Public functions in pandas.io and pandas.tseries submodules are mentioned in the documentation. pandas.api.types subpackage holds some public functions related to data types in pandas.

**Warning:** The pandas.core, pandas.compat, and pandas.util top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

### 3.1 Input/output

#### 3.1.1 Pickling

- `read_pickle(filepath_or_buffer[, ...])` Load pickled pandas object (or any object) from file.
- `DataFrame.to_pickle(path[, compression, ...])` Pickle (serialize) object to file.

**pandas.read_pickle**

`pandas.read_pickle(filepath_or_buffer, compression='infer', storage_options=None)`

Load pickled pandas object (or any object) from file.

**Warning:** Loading pickled data received from untrusted sources can be unsafe. See [here](#).

**Parameters**

- `filepath_or_buffer` [str, path object or file-like object] File path, URL, or buffer where the pickled object will be loaded from.

  Changed in version 1.0.0: Accept URL. URL is not limited to S3 and GCS.

- `compression` [['infer', 'gzip', 'bz2', 'zip', 'xz', None], default 'infer'] If ‘infer’ and ‘path_or_url’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression) If ‘infer’ and ‘path_or_url’ is not path-like, then use None (= no decompression).
storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

unpickled [same type as object stored in file]

See also:

DataFrame.to_pickle  Pickle (serialize) DataFrame object to file.

Series.to_pickle  Pickle (serialize) Series object to file.

read_hdf  Read HDF5 file into a DataFrame.

read_sql  Read SQL query or database table into a DataFrame.

read_parquet  Load a parquet object, returning a DataFrame.

Notes

read_pickle is only guaranteed to be backwards compatible to pandas 0.20.3.

Examples

```python
def example():
    original_df = pd.DataFrame( {
        "foo": range(5),
        "bar": range(5, 10)
    } )

    unpickled_df = pd.read_pickle("./dummy.pkl")

    import os
    os.remove("./dummy.pkl")
```

```python
def example():
    original_df = pd.DataFrame( {
        "foo": range(5),
        "bar": range(5, 10)
    } )

    unpickled_df = pd.read_pickle("./dummy.pkl")

    import os
    os.remove("./dummy.pkl")
```
pandas.DataFrame.to_pickle

DataFrame.to_pickle(path, compression='infer', protocol=5, storage_options=None)

Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and path_or_buf is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’: (otherwise no compression). If dict given and mode is ‘zip’ or inferred as ‘zip’, other entries passed as additional compression options.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

read_pickle Load pickled pandas object (or any object) from file.

Dataframe.to_hdf Write DataFrame to an HDF5 file.

Dataframe.to_sql Write DataFrame to a SQL database.

Dataframe.to_parquet Write a DataFrame to the binary parquet format.

Examples

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})

>>> original_df
   foo  bar
0  0    5
1  1    6
2  2    7
3  3    8
4  4    9

>>> original_df.to_pickle('./dummy.pkl')

>>> unpickled_df = pd.read_pickle('./dummy.pkl')

>>> unpickled_df
   foo  bar
0  0    5
1  1    6
(continues on next page)
```
>>> import os
>>> os.remove("./dummy.pkl")

3.1.2 Flat file

<table>
<thead>
<tr>
<th>pandas.read_table</th>
<th>Read general delimited file into DataFrame.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas.read_csv</td>
<td>Read a comma-separated values (csv) file into DataFrame.</td>
</tr>
<tr>
<td>DataFrame.to_csv</td>
<td>Write object to a comma-separated values (csv) file.</td>
</tr>
<tr>
<td>pandas.read_fwf</td>
<td>Read a table of fixed-width formatted lines into DataFrame.</td>
</tr>
</tbody>
</table>

Read general delimited file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

Parameters

- filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

If you want to pass in a path object, pandas accepts any os.PathLike.

By file-like object, we refer to objects with a read() method, such as a file handle (e.g. via builtin open function) or StringIO.

- sep [str, default \t (tab-stop)] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniff tool, csv.Sniffer. In addition, separators longer than 1 character and different from ‘\s+’ will be interpreted as
regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `\r\t`.

delimiter [str, default None] Alias for sep.

header [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=none. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass header=0 to override the column names. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so usecols=[[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=\['foo', 'bar']])[[\'foo', \'bar'] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for \['bar', \'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, ‘X.2’, …’X.N’, rather than ‘X’…’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32, 'c': 'Int64'} Use str or object together with suitable na_values settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine [{‘c’, ‘python’}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.
false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be lambda x: x in [0, 2].

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: '', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', '<NaN>', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

• If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.

• If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.

• If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.

• If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] If True, parse an index or column with a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use pd.to_datetime after pd.read_csv. To parse an index or column with a mixture of timezones, specify date_parser
to be a partially-applied `pandas.to_datetime()` with `utc=True`. See Parsing a CSV with mixed timezones for more.

Note: A fast-path exists for iso8601-formatted dates.

`infer_datetime_format` [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

`keep_date_col` [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

`date_parser` [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

`dayfirst` [bool, default False] DD/MM format dates, international and European format.

`cache_dates` [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

`iterator` [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

Changed in version 1.2: TextFileReader is a context manager.

`chunksize` [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on `iterator` and `chunksize`.

Changed in version 1.2: TextFileReader is a context manager.

`compression` [‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None], default ‘infer’. For on-the-fly decompression of on-disk data. If ‘infer’ and `filepath_or_buffer` is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

`thousands` [str, optional] Thousands separator.

`decimal` [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

`lineterminator` [str (length 1), optional] Character to break file into lines. Only valid with C parser.

`quotechar` [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

`quoting` [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

`doublequote` [bool, default True] When `quotechar` is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive `quotechar` elements INSIDE a field as a single `quotechar` element.
escapechar  [str (length 1), optional] One-character string used to escape other characters.

comment  [str, optional] Indicates remainder of line should not be parsed. If found at the be-
inginning of a line, the line will be ignored altogether. This parameter must be a single char-
acter. Like empty lines (as long as skip_blank_lines=True), fully commented lines are
ignored by the parameter header but not by skiprows. For example, if comment='#', parsing
#empty
a,b,c
1,2,3
with header=0 will result in ‘a,b,c’ being treated as the header.

encoding  [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of
Python standard encodings.

Changed in version 1.2: When encoding is None, errors="replace" is passed to open().
Otherwise, errors="strict" is passed to open(). This behavior was previously only the
case for engine="python".

Changed in version 1.3.0: encoding_errors is a new argument. encoding has no longer
an influence on how encoding errors are handled.

dialect  [str or csv.Dialect, optional] If provided, this parameter will override values (default
or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace,
quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued.
See csv.Dialect documentation for more details.

error_bad_lines  [bool, default None] Lines with too many fields (e.g. a csv line with too many
commas) will by default cause an exception to be raised, and no DataFrame will be returned.
If False, then these “bad lines” will be dropped from the DataFrame that is returned.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to
specify behavior upon encountering a bad line instead.

warn_bad_lines  [bool, default None] If error_bad_lines is False, and warn_bad_lines is True,
a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to
specify behavior upon encountering a bad line instead.

on_bad_lines  [{'error', 'warn', 'skip'}, default 'error'] Specifies what to do upon encountering
a bad line (a line with too many fields). Allowed values are :

• ‘error’, raise an Exception when a bad line is encountered.
• ‘warn’, raise a warning when a bad line is encountered and skip that line.
• ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0.

delim_whitespace  [bool, default False] Specifies whether or not whitespace (e.g. ‘’ or
’’) will be used as the sep. Equivalent to setting sep=\s+. If this option is set to True,
nothing should be passed in for the delimiter parameter.

low_memory  [bool, default True] Internally process the file in chunks, resulting in lower mem-
ory use while parsing, but possibly mixed type inference. To ensure no mixed types either
set False, or specify the type with the dtype parameter. Note that the entire file is read into
a single DataFrame regardless, use the chunksize or iterator parameter to return the data in
chunks. (Only valid with C parser).
**memory_map**  [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float_precision**  [str, optional] Specifies which converter the C engine should use for floating-point values. The options are None or ‘high’ for the ordinary converter, ‘legacy’ for the original lower precision pandas converter, and ‘round_trip’ for the round-trip converter.

Changed in version 1.2.

**storage_options**  [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.

**Returns**

- **DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

**See also:**

- **DataFrame.to_csv** Write DataFrame to a comma-separated values (csv) file.
- **read_csv** Read a comma-separated values (csv) file into DataFrame.
- **read_fwf** Read a table of fixed-width formatted lines into DataFrame.

**Examples**

```python
>>> pd.read_table('data.csv')
```

**pandas.read_csv**

**pandas.read_csv**(`filepath_or_buffer`, **sep=NoDefault.no_default**, **delimiter=**None**, header=’infer’**, **names=NoDefault.no_default**, **index_col=**None**, **usecols=**None**, **squeeze=**False**, **prefix=NoDefault.no_default**, **mangle_dupe_cols=**True**, **dtype=**None**, **engine=**None**, **converters=**None**, **true_values=**None**, **false_values=**None**, **skipinitialspace=**False**, **skiprows=**None**, **skipfooter=**0**, **nrows=**None**, **na_values=**None**, **keep_default_na=**True**, **na_filter=**True**, **verbose=**False**, **skip_blank_lines=**True**, **parse_dates=**False**, **infer_datetime_format=**False**, **keep_date_col=**False**, **dayfirst=**False**, **cache_dates=**True**, **iterator=**False**, **chunksize=**None**, **compression=’infer’**, **thousands=**None**, **decimal=’.‘**, **lineterminator=**None**, **quotechar=’‘**, **quoting=0**, **doublequote=**True**, **escapechar=**None**, **comment=**None**, **encoding=**None**, **encoding_errors=’strict’**, **dialect=**None**, **error_bad_lines=**None**, **warn_bad_lines=**None**, **on_bad_lines=**None**, **delim_whitespace=**False**, **low_memory=**True**, **memory_map=**False**, **float_precision=**None**, **storage_options=**None**)

Read a comma-separated values (csv) file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**
filepath_or_buffer  [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

If you want to pass in a path object, pandas accepts any os.PathLike.

By file-like object, we refer to objects with a read() method, such as a file handle (e.g. via builtin open function) or StringIO.

sep  [str, default ‘ ‘] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from ‘\s+’ will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: ‘\r\t’.

delimiter  [str, default None] Alias for sep.

header  [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names  [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass header=0 to override the column names. Duplicates in this list are not allowed.

index_col  [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols  [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze  [bool, default False] If the parsed data only contains one column then return a Series.

prefix  [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1,…

mangle_dupe_cols  [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, …‘X.N’, rather than ‘X’…”X’. Passing in False will cause data to be overwritten if there
are duplicate names in the columns.

**dtype** [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{ 'a': np.float64, 'b': np.int32, 'c': 'Int64' } Use *str or object* together with suitable *na_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [{‘c’, ‘python’}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, optional] Values to consider as True.

**false_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skip spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.
- If *keep_default_na* is True, and *na_values* are not specified, only the default NaN values are used for parsing.
- If *keep_default_na* is False, and *na_values* are specified, only the NaN values specified *na_values* are used for parsing.
- If *keep_default_na* is False, and *na_values* are not specified, no strings will be parsed as NaN.

Note that if *na_filter* is passed in as False, the *keep_default_na* and *na_values* parameters will be ignored.

**na_filter** [bool, default True] Detect missing value markers (empty strings and the value of *na_values*). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip_blank_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.
**parse_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1], [3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an un-parsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See Parsing a CSV with mixed timezones for more.

Note: A fast-path exists for iso8601-formatted dates.

**infer_datetime_format** [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep_date_col** [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**date_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [bool, default False] DD/MM format dates, international and European format.

**cache_dates** [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

**iterator** [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

Changed in version 1.2: `TextFileReader` is a context manager.

**chunksize** [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on `iterator` and `chunksize`.

Changed in version 1.2: `TextFileReader` is a context manager.

**compression** [‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None], default ‘infer’) For on-the-fly decompression of on-disk data. If ‘infer’ and `filepath_or_buffer` is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

**thousands** [str, optional] Thousands separator.
decimal  [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).
lineterminator  [str (length 1), optional] Character to break file into lines. Only valid with C parser.
quotechar  [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.
quoting  [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).
doublequote  [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.
escapechar  [str (length 1), optional] One-character string used to escape other characters.
comment  [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='#', parsing #empty\nna,b,c'\n\n1,2,3 with header=0 will result in ‘a,b,c’ being treated as the header.
encoding  [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings.
  Changed in version 1.2: When encoding is None, errors="replace" is passed to open(). Otherwise, errors="strict" is passed to open(). This behavior was previously only the case for engine="python".
  Changed in version 1.3.0: encoding_errors is a new argument. encoding has no longer an influence on how encoding errors are handled.
encoding_errors  [str, optional, default “strict”] How encoding errors are treated. List of possible values.
  New in version 1.3.0.
dialect  [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.
error_bad_lines  [bool, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.
  Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.
warn_bad_lines  [bool, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.
  Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.
on_bad_lines  [['error', 'warn', 'skip'], default 'error'] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are:
  • ‘error’, raise an Exception when a bad line is encountered.
  • ‘warn’, raise a warning when a bad line is encountered and skip that line.
- `skip`, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0.

**`delim_whitespace`** [bool, default False] Specifies whether or not whitespace (e.g. `' '` or `'') will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to True, nothing should be passed in for the delimiter parameter.

**`low_memory`** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single DataFrame regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

**`memory_map`** [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**`float_precision`** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are `None` or `high` for the ordinary converter, `legacy` for the original lower precision pandas converter, and `round_trip` for the round-trip converter.

Changed in version 1.2.

**`storage_options`** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.

**Returns**

- `DataFrame` or `TextParser` A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

- `DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.
- `read_csv` Read a comma-separated values (csv) file into DataFrame.
- `read_fwf` Read a table of fixed-width formatted lines into DataFrame.

**Examples**

```python
>>> pd.read_csv('data.csv')
```
Write object to a comma-separated values (csv) file.

**Parameters**

- `path_or_buf` [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a non-binary file object is passed, it should be opened with `newline='
'`, disabling universal newlines. If a binary file object is passed, `mode` might need to contain a `b`.

Changed in version 1.2.0: Support for binary file objects was introduced.

- `sep` [str, default ','] String of length 1. Field delimiter for the output file.

- `na_rep` [str, default ''] Missing data representation.

- `float_format` [str, default None] Format string for floating point numbers.

- `columns` [str, default None] Columns to write.

- `header` [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

- `index` [bool, default True] Write row names (index).

- `index_label` [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and `header` and `index` are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use `index_label=False` for easier importing in R.

- `mode` [str] Python write mode, default 'w'.

- `encoding` [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'. `encoding` is not supported if `path_or_buf` is a non-binary file object.

- `compression` [str or dict, default 'infer'] If str, represents compression mode. If dict, value at 'method' is the compression mode. Compression mode may be any of the following possible values: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is 'infer' and `path_or_buf` is path-like, then detect compression mode from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression). If dict given and mode is one of {'zip', 'gzzip', 'bz2'}, inferred as one of the above, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key 'method' as compression mode and other entries as additional compression options if compression mode is 'zip'.

Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes 'gzip' and 'bz2' as well as 'zip'.

Changed in version 1.2.0: Compression is supported for binary file objects.

Changed in version 1.2.0: Previous versions forwarded dict entries for 'gzip' to `gzip.open` instead of `gzip.GzipFile` which prevented setting `mtime`.

- `quoting` [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a `float_format` then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.
quotechar  [str, default ‘”’] String of length 1. Character used to quote fields.

line_terminator  [str, optional] The newline character or character sequence to use in the output file. Defaults to os.linesep, which depends on the OS in which this method is called (‘\n’ for linux, ‘\n\r’ for Windows, i.e.).

chunksize  [int or None] Rows to write at a time.

date_format  [str, default None] Format string for datetime objects.

doublequote  [bool, default True] Control quoting of quotechar inside a field.

escapechar  [str, default None] String of length 1. Character used to escape sep and quotechar when appropriate.

decimal  [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.

errors  [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

storage_options  [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

None or str  If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv  Load a CSV file into a DataFrame.

to_excel  Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})

>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'

Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
...                           archive_name='out.csv')

```python
>>> df.to_csv('out.zip', index=False,
...            compression=compression_opts)
```

1034 Chapter 3. API reference
pandas.read_fwf

**pandas.read_fwf(filepath_or_buffer, colspecs='infer', widths=None, infer_nrows=100, **kwds)**

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

- **filepath_or_buffer** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via built-in `open` function) or `StringIO`.

- **colspecs** [list of tuple(int, int) or 'infer'. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via skiprows (default='infer').

- **widths** [list of int, optional] A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

- **infer_nrows** [int, default 100] The number of rows to consider when letting the parser determine the colspecs.

- **kwds** [optional] Optional keyword arguments can be passed to `TextFileReader`.

**Returns**

- **DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

- **DataFrame.to_csv** Write DataFrame to a comma-separated values (csv) file.
- **read_csv** Read a comma-separated values (csv) file into DataFrame.

**Examples**

```python
>>> pd.read_fwf('data.csv')
```

### 3.1.3 Clipboard

- **read_clipboard([sep])** Read text from clipboard and pass to `read_csv`.
- **DataFrame.to_clipboard([excel, sep])** Copy object to the system clipboard.
**pandas.read_clipboard**

pandas.read_clipboard(sep=r'\s+', **kwargs)

Read text from clipboard and pass to read_csv.

**Parameters**

- **sep** [str, default 's+'] A string or regex delimiter. The default of 's+' denotes one or more whitespace characters.

- **kwargs** See read_csv for the full argument list.

**Returns**

- **DataFrame** A parsed DataFrame object.

**pandas.DataFrame.to_clipboard**

DataFrame.to_clipboard(excel=True, sep=None, **kwargs)

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
  - False, write a string representation of the object to the clipboard.

- **sep** [str, default '	'] Field delimiter.

- **kwargs** These parameters will be passed to DataFrame.to_csv.

**See also:**

- **DataFrame.to_csv** Write a DataFrame to a comma-separated values (csv) file.
- **read_clipboard** Read text from clipboard and pass to read_table.

**Notes**

Requirements for your platform.

- Linux : xclip, or xsel (with PyQt4 modules)
- Windows : none
- OS X : none
Examples

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```python
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',' , index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

3.1.4 Excel

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_excel</code></td>
<td>Read an Excel file into a pandas DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.to_excel</code></td>
<td>Write object to an Excel sheet.</td>
</tr>
<tr>
<td><code>ExcelFile.parse</code></td>
<td>Parse specified sheet(s) into a DataFrame.</td>
</tr>
</tbody>
</table>

pandas.read_excel

```python
pandas.read_excel(io=local_file, sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=True, mangle_dupe_cols=True, storage_options=None)
```

Read an Excel file into a pandas DataFrame.

Supports `xls`, `xlsx`, `xlsm`, `xlsb`, `odf`, `ods` and `odt` file extensions read from a local filesystem or URL. Supports an option to read a single sheet or a list of sheets.

Parameters

- `io` [str, bytes, ExcelFile, xld.Book, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.xlsx`.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.

  By file-like object, we refer to objects with a read() method, such as a file handle (e.g. via built-in open function) or `StringIO`.

- `sheet_name` [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets. Specify None to get all sheets.
Available cases:

- Defaults to 0: 1st sheet as a DataFrame
- 1: 2nd sheet as a DataFrame
- "Sheet1": Load sheet with name “Sheet1”
- [0, 1, "Sheet5"]: Load first, second and sheet named “Sheet5” as a dict of DataFrame
- None: All sheets.

**header** [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a MultiIndex. Use None if there is no header.

**names** [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None.

**index_col** [int, list of int, default None] Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a MultiIndex. If a subset of data is selected with usecols, index_col is based on the subset.

**usecols** [int, str, list-like, or callable default None]

- If None, then parse all columns.
- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. “A:E” or “A,C,E:F”). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.
- If callable, then evaluate each column name against it and parse the column if the callable returns True.

Returns a subset of the columns according to behavior above.

**squeeze** [bool, default False] If the parsed data only contains one column then return a Series.

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use object to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [str, default None] If io is not a buffer or path, this must be set to identify io. Supported engines: “xlrd”, “openpyxl”, “odf”, “pyxlsb”. Engine compatibility:

- “xlrd” supports old-style Excel files (.xls).
- “openpyxl” supports newer Excel file formats.
- “odf” supports OpenDocument file formats (.ods, .odt).
- “pyxlsb” supports Binary Excel files.

Changed in version 1.2.0: The engine xlrd now only supports old-style .xls files. When engine=None, the following logic will be used to determine the engine:

- If path_or_buffer is an OpenDocument format (.odf, .ods, .odt), then odf will be used.
- Otherwise if path_or_buffer is an xls format, xlrd will be used.
- Otherwise if path_or_buffer is in xlsb format, pyxlsb will be used.

New in version 1.3.0.
• Otherwise openpyxl will be used.

Changed in version 1.3.0.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

**true_values** [list, default None] Values to consider as True.

**false_values** [list, default None] Values to consider as False.

**skiprows** [list-like, int, or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file. If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**nrows** [int, default None] Number of rows to parse.

**na_values** [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A #N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA', ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

• If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.

• If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.

• If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.

• If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

**na_filter** [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**parse_dates** [bool, list-like, or dict, default False] The behavior is as follows:

• bool. If True -> try parsing the index.

• list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.

• list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.

• dict, e.g. `{‘foo’ : [1, 3]}` -> parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. If you don’t want to parse some cells as date just change their type in Excel to “Text”. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_excel`.

Note: A fast-path exists for iso8601-formatted dates.
date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses dateutil.parser.parser to do the conversion. Pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

thousands [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

comment [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

skipfooter [int, default 0] Rows at the end to skip (0-indexed).

convert_float [bool, default True] Convert integral floats to int (i.e., 1.0 -> 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally. Depreciated since version 1.3.0: convert_float will be removed in a future version.

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, ‘X.2’, ..., ‘X.N’, rather than ‘X’...’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a local path or a file-like buffer. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file. See notes in sheet_name argument for more information on when a dict of DataFrames is returned.

See also:

DataFrame.to_excel Write DataFrame to an Excel file.
DataFrame.to_csv Write DataFrame to a comma-separated values (csv) file.
read_csv Read a comma-separated values (csv) file into DataFrame.
read_fwf Read a table of fixed-width formatted lines into DataFrame.

Examples

The file can be read using the file name as string or an open file object:

```python
>>> pd.read_excel('tmp.xlsx', index_col=0)
   Name  Value
0  string1  1
1  string2  2
2  #Comment  3
```
Index and header can be specified via the `index_col` and `header` arguments

```python
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None)
    0 1 2
 0 NaN Name Value
 1 0.0 string1 1
 2 1.0 string2 2
 3 2.0 #Comment 3
```

Column types are inferred but can be explicitly specified

```python
>>> pd.read_excel('tmp.xlsx', index_col=0,
    ... dtype={'Name': str, 'Value': float})
     Name  Value
0  string1  1.0
1  string2  2.0
2     #Comment  3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```python
>>> pd.read_excel('tmp.xlsx', index_col=0,
    ... na_values=['string1', 'string2'])
     Name  Value
0      NaN   1
1      NaN   2
2    #Comment  3
```

Comment lines in the excel input file can be skipped using the `comment` kwarg

```python
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#')
     Name  Value
0  string1  1.0
1  string2  2.0
2  None     NaN
```

### pandas.DataFrame.to_excel

`DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None, storage_options=None)`

Write object to an Excel sheet.

To write a single object to an Excel.xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an `ExcelWriter` object with a target file name, and specify a sheet in the file to write to.
Multiple sheets may be written to by specifying unique `sheet_name`. With all data written to the file it is necessary to save the changes. Note that creating an `ExcelWriter` object with a file name that already exists will result in the contents of the existing file being erased.

**Parameters**

- `excel_writer` [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- `sheet_name` [str, default `Sheet1`] Name of sheet which will contain DataFrame.
- `float_format` [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- `columns` [sequence or list of str, optional] Columns to write.
- `header` [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- `index` [bool, default True] Write row names (index).
- `index_label` [str or sequence, optional] Column label for index column(s) if desired. If not specified, and `header` and `index` are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- `startrow` [int, default 0] Upper left cell row to dump data frame.
- `startcol` [int, default 0] Upper left cell column to dump data frame.

  Deprecated since version 1.2.0: As the `xlwt` package is no longer maintained, the `xlwt` engine will be removed in a future version of pandas.

- `merge_cells` [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- `encoding` [str, optional] Encoding of the resulting excel file. Only necessary for `xlwt`, other writers support unicode natively.
- `inf_rep` [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).
- `verbose` [bool, default True] Display more information in the error logs.
- `freeze_panes` [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.
- `storage_options` [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

  New in version 1.2.0.

**See also:**

- `to_csv` Write DataFrame to a comma-separated values (csv) file.
- `ExcelWriter` Class for writing DataFrame objects into excel sheets.
- `read_excel` Read an Excel file into a pandas DataFrame.
read_csv  Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.
Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([["a", "b"], ["c", "d"]],
...                     index=["row 1", "row 2"],
...                     columns=["col 1", "col 2"])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
...               sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx',
...                      mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the engine keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.ExcelFile.parse

ExcelFile.parse( sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False,
                 converters=None, true_values=None, false_values=None, skiprows=None, nrows=None,
                 na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None,
                 skipfooter=0, convert_float=None, mangle_dupe_cols=True, **kwds)

Parse specified sheet(s) into a DataFrame.

Equivalent to read_excel(ExcelFile, ...) See the read_excel docstring for more info on accepted parameters.

Returns

DataFrame or dict of DataFrames  DataFrame from the passed in Excel file.
Write Styler to an Excel sheet.

To write a single Styler to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

**Parameters**

- **excel_writer** [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- **sheet_name** [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- **na_rep** [str, default ‘’] Missing data representation.
- **float_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- **columns** [sequence or list of str, optional] Columns to write.
- **header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow** [int, default 0] Upper left cell row to dump data frame.
- **startcol** [int, default 0] Upper left cell column to dump data frame.
- **engine** [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.
  
  Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.
- **merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- **encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- **inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).
- **verbose** [bool, default True] Display more information in the error logs.
- **freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.
**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

**to_csv** Write DataFrame to a comma-separated values (csv) file.

**ExcelWriter** Class for writing DataFrame objects into excel sheets.

**read_excel** Read an Excel file into a pandas DataFrame.

**read_csv** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with `to_csv()`, `to_excel` serializes lists and dictionaries to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

**Examples**

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([["a", "b"], ["c", "d"]],
...                     index=["row 1", "row 2"],
...                     columns=["col 1", "col 2"])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
...               sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter("output.xlsx") as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter("output.xlsx",
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel("output1.xlsx", engine='xlsxwriter')
```
ExcelWriter(path[, engine, date_format, ...])  Class for writing DataFrame objects into excel sheets.

pandas.ExcelWriter

class pandas.ExcelWriter(path, engine=None, date_format=None, datetime_format=None, mode='w', storage_options=None, if_sheet_exists='error', engine_kwargs=None, **kwargs)

Class for writing DataFrame objects into excel sheets.

Default is to use xlwt for xls, openpyxl for xlsx, odf for ods. See DataFrame.to_excel for typical usage.

The writer should be used as a context manager. Otherwise, call close() to save and close any opened file handles.

Parameters

path [str or typing.BinaryIO] Path to xls or xlsx or ods file.

engine [str (optional)] Engine to use for writing. If None, defaults to io.excel.<extension>. writer. NOTE: can only be passed as a keyword argument.

Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.

date_format [str, default None] Format string for dates written into Excel files (e.g. ‘YYYY-MM-DD’).

datetime_format [str, default None] Format string for datetime objects written into Excel files. (e.g. ‘YYYY-MM-DD HH:MM:SS’).

mode [{‘w’, ‘a’}, default ‘w’] File mode to use (write or append). Append does not work with fsspec URLs.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”.

New in version 1.2.0.

if_sheet_exists [{‘error’, ‘new’, ‘replace’}, default ‘error’] How to behave when trying to write to a sheet that already exists (append mode only).

• error: raise a ValueError.

• new: Create a new sheet, with a name determined by the engine.

• replace: Delete the contents of the sheet before writing to it.

New in version 1.3.0.

engine_kwargs [dict, optional] Keyword arguments to be passed into the engine.

New in version 1.3.0.

**kwargs [dict, optional] Keyword arguments to be passed into the engine.

Deprecated since version 1.3.0: Use engine_kwargs instead.
Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

Examples

Default usage:

```python
>>> df = pd.DataFrame(["ABC", "XYZ"], columns=["Foo", "Bar"])
>>> with ExcelWriter("path_to_file.xlsx") as writer:
...     df.to_excel(writer)
```

To write to separate sheets in a single file:

```python
>>> df1 = pd.DataFrame(["AAA", "BBB"], columns=["Spam", "Egg"])
>>> df2 = pd.DataFrame(["ABC", "XYZ"], columns=["Foo", "Bar"])
>>> with ExcelWriter("path_to_file.xlsx") as writer:
...     df1.to_excel(writer, sheet_name="Sheet1")
...     df2.to_excel(writer, sheet_name="Sheet2")
```

You can set the date format or datetime format:

```python
>>> from datetime import date, datetime
... >>> df = pd.DataFrame(
...     ...     [[date(2014, 1, 31), date(1999, 9, 24)],
...     ...     [datetime(1998, 5, 26, 23, 33, 4), datetime(2014, 2, 28, 13, 5, 13)],
...     ...     ],
...     ...     index=["Date", "Datetime"],
...     ...     columns=["X", "Y"],
...     ... )
>>> with ExcelWriter(
...     ...     "path_to_file.xlsx",
...     ...     date_format="YYYY-MM-DD",
...     ...     datetime_format="YYYY-MM-DD HH:MM:SS"
...     ... ) as writer:
...     df.to_excel(writer)
```

You can also append to an existing Excel file:

```python
>>> with ExcelWriter("path_to_file.xlsx", mode="a", engine="openpyxl") as writer:
...     df.to_excel(writer, sheet_name="Sheet3")
```

You can store Excel file in RAM:

```python
>>> import io
>>> df = pd.DataFrame(["ABC", "XYZ"], columns=["Foo", "Bar"])
>>> buffer = io.BytesIO()
>>> with pd.ExcelWriter(buffer) as writer:
...     df.to_excel(writer)
```

You can pack Excel file into zip archive:
```python
>>> import zipfile
>>> df = pd.DataFrame([['ABC', 'XYZ']], columns=['Foo', 'Bar'])
>>> with zipfile.ZipFile("path_to_file.zip", "w") as zf:
...     with zf.open("filename.xlsx", "w") as buffer:
...         with pd.ExcelWriter(buffer) as writer:
...             df.to_excel(writer)
```
• 'columns': dict like {column -> {index -> value}}
• 'values': just the values array

The allowed and default values depend on the value of the typ parameter.

• when typ == 'series',
  – allowed orients are {'split', 'records', 'index'}
  – default is 'index'
  – The Series index must be unique for orient 'index'.

• when typ == 'frame',
  – allowed orients are {'split', 'records', 'index', 'columns', 'values', 'table'}
  – default is 'columns'
  – The DataFrame index must be unique for orients 'index' and 'columns'.
  – The DataFrame columns must be unique for orients 'index', 'columns', and 'records'.

typ [{‘frame’, ‘series’}, default ‘frame’] The type of object to recover.
dtype [bool or dict, default None] If True, infer dtypes; if a dict of column to dtype, then use those; if False, then don't infer dtypes at all, applies only to the data.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_axes [bool, default None] Try to convert the axes to the proper dtypes.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_dates [bool or list of str, default True] If True then default datelike columns may be converted (depending on keep_default_dates). If False, no dates will be converted. If a list of column names, then those columns will be converted and default datelike columns may also be converted (depending on keep_default_dates).

keep_default_dates [bool, default True] If parsing dates (convert_dates is not False), then try to parse the default datelike columns. A column label is datelike if
  • it ends with '_at',
  • it ends with '_time',
  • it begins with 'timestamp',
  • it is 'modified', or
  • it is 'date'.

numpy [bool, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

Deprecated since version 1.0.0.

precise_float [bool, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality.
date_unit [str, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

encoding [str, default is ‘utf-8’] The encoding to use to decode py3 bytes.

encoding_errors [str, optional, default “strict”] How encoding errors are treated. List of possible values.

New in version 1.3.0.

lines [bool, default False] Read the file as a json object per line.

chunksize [int, optional] Return JsonReader object for iteration. See the line-delimited json docs for more information on chunksize. This can only be passed if lines=True. If this is None, the file will be read into memory all at once.

Changed in version 1.2: JsonReader is a context manager.

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buf is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

nrows [int, optional] The number of lines from the line-delimited json file that has to be read. This can only be passed if lines=True. If this is None, all the rows will be returned.

New in version 1.1.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

Series or DataFrame The type returned depends on the value of typ.

See also:

DataFrame.to_json Convert a DataFrame to a JSON string.

Series.to_json Convert a Series to a JSON string.

Notes

Specific to orient=’table’, if a DataFrame with a literal Index name of index gets written with to_json(), the subsequent read operation will incorrectly set the Index name to None. This is because index is also used by DataFrame.to_json() to denote a missing Index name, and the subsequent read_json() operation cannot distinguish between the two. The same limitation is encountered with a MultiIndex and any names beginning with 'level_'.

1050 Chapter 3. API reference
**Examples**

```python
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
                    index=['row 1', 'row 2'],
                    columns=['col 1', 'col 2'])
```

Encoding/decoding a Dataframe using 'split' formatted JSON:

```python
>>> df.to_json(orient='split')
'{"columns": ["col 1", "col 2"], "index": ["row 1", "row 2"], "data": [["a", "b"], ["c", "d"]]}'
>>> pd.read_json(_, orient='split')
  col 1  col 2  
row 1   a     b     
row 2   c     d     
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> df.to_json(orient='index')
'{"row 1": {"col 1": "a", "col 2": "b"}, "row 2": {"col 1": "c", "col 2": "d"}}'
>>> pd.read_json(_, orient='index')
  col 1  col 2  
row 1   a     b     
row 2   c     d     
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> df.to_json(orient='records')
'[{"col 1": "a", "col 2": "b"}, {"col 1": "c", "col 2": "d"}]'
>>> pd.read_json(_, orient='records')
  col 1  col 2  
  0    a     b     
  1    c     d     
```

Encoding with Table Schema

```python
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"}, {"name": "col 1", "type": "string"}, {"name": "col 2", "type": "string"}], "primaryKey": ["index"], "pandas_version": "0.20.0"}, "data": [{"index": "row 1", "col 1": "a", "col 2": "b"}, {"index": "row 2", "col 1": "c", "col 2": "d"}]}
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

pandas.io.json.to_json

pandas.io.json.to_json(path_or_buf, obj, orient=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, compression='infer', index=True, indent=0, storage_options=None)

build_table_schema(data[, index, ...]) Create a Table schema from data.

pandas.io.json.build_table_schema

pandas.io.json.build_table_schema(data, index=True, primary_key=None, version=True)
Create a Table schema from data.

Parameters

- **data** [Series, DataFrame]
- **index** [bool, default True] Whether to include data.index in the schema.
- **primary_key** [bool or None, default True] Column names to designate as the primary key. The default None will set 'primaryKey' to the index level or levels if the index is unique.
- **version** [bool, default True] Whether to include a field pandas_version with the version of pandas that generated the schema.

Returns

- **schema** [dict]

Notes

See Table Schema for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the any dtype, and use the enum field constraint to list the allowed values. The ordered attribute is included in an ordered field.

Examples

```python
>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...     }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'}, {'name': 'A', 'type': 'integer'}, {'name': 'B', 'type': 'string'}, {'name': 'C', 'type': 'datetime'}], 'primaryKey': ['idx'], 'pandas_version': '0.20.0'}
```
3.1.6 HTML

**read_html**

```
read_html(io[, match, flavor, header, ...])
```

Read HTML tables into a list of DataFrame objects.

**DataFrame.to_html**

```
DataFrame.to_html([buf, columns, col_space, ...])
```

Render a DataFrame as an HTML table.

**pandas.read_html**

```
pandas.read_html(io, match=’.+’, flavor=None, header=None, index_col=None, skiprows=None, attrs=None, parse_dates=False, thousands=’,’, encoding=None, decimal=’.’, converters=None, na_values=None, keep_default_na=True, displayed_only=True)
```

Read HTML tables into a list of DataFrame objects.

**Parameters**

- **io** [str, path object or file-like object] A URL, a file-like object, or a raw string containing HTML. Note that lxml only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.

- **match** [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to ‘.+’ (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between Beautiful Soup and lxml.

- **flavor** [str, optional] The parsing engine to use. ‘bs4’ and ‘html5lib’ are synonymous with each other, they are both there for backwards compatibility. The default of None tries to use lxml to parse and if that fails it falls back on bs4 + html5lib.

- **header** [int or list-like, optional] The row (or list of rows for a MultiIndex) to use to make the columns headers.

- **index_col** [int or list-like, optional] The column (or list of columns) to use to create the index.

- **skiprows** [int, list-like or slice, optional] Number of rows to skip after parsing the column integer. 0-based. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.

- **attrs** [dict, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or Beautiful Soup. However, these attributes must be valid HTML table attributes to work correctly. For example,

  ```python
  attrs = {'id': 'table'}
  ```

  is a valid attribute dictionary because the ‘id’ HTML tag attribute is a valid HTML attribute for any HTML tag as per this document.

  ```python
  attrs = {'asdf': 'table'}
  ```

  is not a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found here. A working draft of the HTML 5 spec can be found here. It contains the latest information on table attributes for the modern web.

- **parse_dates** [bool, optional] See **read_csv()** for more details.
thousands [str, optional] Separator to use to parse thousands. Defaults to ','.

encoding [str, optional] The encoding used to decode the web page. Defaults to `None`. `None` preserves the previous encoding behavior, which depends on the underlying parser library (e.g., the parser library will try to use the encoding provided by the document).

decimal [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

na_values [iterable, default None] Custom NA values.

keep_default_na [bool, default True] If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they're appended to.

displayed_only [bool, default True] Whether elements with “display: none” should be parsed.

Returns

dfs A list of DataFrames.

See also:

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

Before using this function you should read the gotchas about the HTML parsing libraries.

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the header=0 argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for <table> elements and only for <tr> and <th> rows and <td> elements within each <tr> or <th> element in the table. <td> stands for “table data”. This function attempts to properly handle colspan and rowspan attributes. If the function has a <thead> argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only <th> elements into the header).

Similar to read_csv the header argument is applied after skiprows is applied.

This function will always return a list of DataFrame or it will fail, e.g., it will not return an empty list.

Examples

See the read_html documentation in the IO section of the docs for some examples of reading in HTML tables.
pandas.DataFrame.to_html

DataFrame.to_html(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, max_cols=None, show_dimensions=False, decimal='.', bold_rows=True, classes=None, escape=True, notebook=False, border=None, table_id=None, render_links=False, encoding=None)

Render a DataFrame as an HTML table.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

col_space [str or int, list or dict of int or str, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.

header [bool, optional] Whether to print column labels, default True.

index [bool, optional, default True] Whether to print index (row) labels.

na_rep [str, optional, default ‘NaN’] String representation of NaN to use.

formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by na_rep.

Changed in version 1.2.0.

sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names [bool, optional, default True] Prints the names of the indexes.

justify [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial

3.1. Input/output
unset.

**max_rows**  [int, optional] Maximum number of rows to display in the console.

**min_rows**  [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above **max_rows**).

**max_cols**  [int, optional] Maximum number of columns to display in the console.

**show_dimensions**  [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal**  [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

**bold_rows**  [bool, default True] Make the row labels bold in the output.

**classes**  [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

**escape**  [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

**notebook**  [[True, False], default False] Whether the generated HTML is for IPython Notebook.

**border**  [int] A border=border attribute is included in the opening <table> tag. Default pd.options.display.html.border.

**encoding**  [str, default “utf-8”] Set character encoding.

New in version 1.0.

**table_id**  [str, optional] A css id is included in the opening <table> tag if specified.

**render_links**  [bool, default False] Convert URLs to HTML links.

**Returns**

str or None  If buf is None, returns the result as a string. Otherwise returns None.

See also:

to_string  Convert DataFrame to a string.

Styler.to_html(buf=None, *table_attributes=..., encoding=..., doctype_html=..., exclude_styles=..., table_id=..., render_links=..., html=True)

Write Styler to a file, buffer or string in HTML-CSS format.

New in version 1.3.0.

**Parameters**

buf  [str, Path, or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

(table_id=..., encoding=..., doctype_html=..., exclude_styles=..., html=True)

Write Styler to a file, buffer or string in HTML-CSS format.

New in version 1.3.0.

**Parameters**

buf  [str, Path, or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

**table_uuid**  [str, optional] Id attribute assigned to the <table> HTML element in the format:

<table id="T_<table_uuid>" .>

If not given uses Styler’s initially assigned value.
table_attributes  [str, optional] Attributes to assign within the `<table>` HTML element in the format:

```html
<table .. <table_attributes> >
```

If not given defaults to Styler’s preexisting value.

encoding  [str, optional] Character encoding setting for file output, and HTML meta tags, defaults to “utf-8” if None.

doctype_html  [bool, default False] Whether to output a fully structured HTML file including all HTML elements, or just the core `<style>` and `<table>` elements.

exclude_styles  [bool, default False] Whether to include the `<style>` element and all associated element class and id identifiers, or solely the `<table>` element without styling identifiers.

Returns

str or None  If `buf` is None, returns the result as a string. Otherwise returns `None`.

See also:

DataFrame.to_html  Write a DataFrame to a file, buffer or string in HTML format.

### 3.1.7 XML

| pandas.read_xml(path_or_buffer[, xpath, ...]) | Read XML document into a DataFrame object. |
| DataFrame.to_xml([path_or_buffer, index, ...]) | Render a DataFrame to an XML document. |

pandas.read_xml

```python
def pandas.read_xml(path_or_buffer, xpath='/*', namespaces=None, elems_only=False, attrs_only=False, names=None, encoding='utf-8', parser='lxml', stylesheet=None, compression='infer', storage_options=None):
    Read XML document into a DataFrame object.
```

New in version 1.3.0.

Parameters

path_or_buffer  [str, path object, or file-like object] Any valid XML string or path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file.

xpath  [str, optional, default ‘/*’] The XPath to parse required set of nodes for migration to DataFrame. XPath should return a collection of elements and not a single element. Note: The etree parser supports limited XPath expressions. For more complex XPath, use lxml which requires installation.

namespaces  [dict, optional] The namespaces defined in XML document as dicts with key being namespace prefix and value the URI. There is no need to include all namespaces in XML, only the ones used in xpath expression. Note: if XML document uses default namespace denoted as `xmlns`='<URI>' without a prefix, you must assign any temporary namespace prefix such as ‘doc’ to the URI in order to parse underlying nodes and/or attributes. For example,

```python
namespaces = {"doc": "https://example.com"}"
```
**`read_xml`**

Parse XML data into a DataFrame.

**Parameters**

- `xpath` : str, optional, default `None`
  - Specify the XPath pattern to target data.

- `elem_only` : [bool, optional, default False] Parse only the child elements at the specified xpath. By default, all child elements and non-empty text nodes are returned.

- `attrs_only` : [bool, optional, default False] Parse only the attributes at the specified xpath. By default, all attributes are returned.

- `names` : [list-like, optional] Column names for DataFrame of parsed XML data. Use this parameter to rename original element names and distinguish same named elements.

- `encoding` : [str, optional, default ‘utf-8’] Encoding of XML document.

- `parser` : [{'lxml','etree'}, default ‘lxml’] Parser module to use for retrieval of data. Only ‘lxml’ and ‘etree’ are supported. With ‘lxml’ more complex XPath searches and ability to use XSLT stylesheet are supported.

- `stylesheet` : [str, path object or file-like object] A URL, file-like object, or a raw string containing an XSLT script. This stylesheet should flatten complex, deeply nested XML documents for easier parsing. To use this feature you must have lxml module installed and specify ‘lxml’ as parser. The xpath must reference nodes of transformed XML document generated after XSLT transformation and not the original XML document. Only XSLT 1.0 scripts and not later versions is currently supported.

- `compression` : [{'infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buffer is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

- `storage_options` : [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

**Returns**

- df : A DataFrame.

**See also:**

- `read_json` : Convert a JSON string to pandas object.

- `read_html` : Read HTML tables into a list of DataFrame objects.

**Notes**

This method is best designed to import shallow XML documents in following format which is the ideal fit for the two-dimensions of a DataFrame (row by column).

```xml
<root>
  <row>
    <column1>data</column1>
    <column2>data</column2>
    <column3>data</column3>
    ...
  </row>
  ...
</root>
```

(continues on next page)
As a file format, XML documents can be designed any way including layout of elements and attributes as long as it conforms to W3C specifications. Therefore, this method is a convenience handler for a specific flatter design and not all possible XML structures.

However, for more complex XML documents, stylesheet allows you to temporarily redesign original document with XSLT (a special purpose language) for a flatter version for migration to a DataFrame.

This function will always return a single DataFrame or raise exceptions due to issues with XML document, xpath, or other parameters.

**Examples**

```python
>>> xml = '''<?xml version='1.0' encoding='utf-8'?><data xmlns="http://example.com">
... <row>
...     <shape>square</shape>
...     <degrees>360</degrees>
...     <sides>4.0</sides>
... </row>
... <row>
...     <shape>circle</shape>
...     <degrees>360</degrees>
...     <sides/>
... </row>
... <row>
...     <shape>triangle</shape>
...     <degrees>180</degrees>
...     <sides>3.0</sides>
... </row>
... </data>'''

>>> df = pd.read_xml(xml)

>>> df
shape  degrees  sides
0     square   360   4.0
1      circle  360    NaN
2   triangle  180   3.0
```

```python
>>> xml = '''<?xml version='1.0' encoding='utf-8'?><data>
... <row shape="square" degrees="360" sides="4.0"/>
... <row shape="circle" degrees="360"/>
... <row shape="triangle" degrees="180" sides="3.0"/>
... </data>'''

>>> df = pd.read_xml(xml, xpath=".//row")

>>> df
shape  degrees  sides
0     square   360   4.0
1      circle  360    NaN
2   triangle  180   3.0
```
shape  degrees  sides
0  square     360  4.0
1    circle   360       NaN
2  triangle   180  3.0

```python
>>> xml = '''<?xml version='1.0' encoding='utf-8'>
... <doc:data xmlns:doc='https://example.com'>
...  <doc:row>
...    <doc:shape>square</doc:shape>
...    <doc:degrees>360</doc:degrees>
...    <doc:sides>4.0</doc:sides>
...  </doc:row>
...  <doc:row>
...    <doc:shape>circle</doc:shape>
...    <doc:degrees>360</doc:degrees>
...    <doc:sides/>
...  </doc:row>
...  <doc:row>
...    <doc:shape>triangle</doc:shape>
...    <doc:degrees>180</doc:degrees>
...    <doc:sides>3.0</doc:sides>
...  </doc:row>
... </doc:data>'''

>>> df = pd.read_xml(xml, 
...                   xpath='//doc:row', 
...                   namespaces={'doc': 'https://example.com'})

>>> df
shape    degrees  sides
0   square     360  4.0
1     circle   360       NaN
2  triangle   180  3.0
```

**pandas.DataFrame.to_xml**

DataFrame.to_xml(path_or_buffer=None, index=True, root_name='data', row_name='row', na_rep=None, attr_cols=None, elem_cols=None, namespaces=None, prefix=None, encoding='utf-8', xml_declaration=True, pretty_print=True, parser='lxml', stylesheet=None, compression='infer', storage_options=None)

Render a DataFrame to an XML document.

New in version 1.3.0.

Parameters

- **path_or_buffer** [str, path object or file-like object, optional] File to write output to. If None, the output is returned as a string.
- **index** [bool, default True] Whether to include index in XML document.
- **root_name** [str, default ‘data’] The name of root element in XML document.
- **row_name** [str, default ‘row’] The name of row element in XML document.

**attr_cols** [list-like, optional] List of columns to write as attributes in row element. Hierarchical columns will be flattened with underscore delimiting the different levels.

**elem_cols** [list-like, optional] List of columns to write as children in row element. By default, all columns output as children of row element. Hierarchical columns will be flattened with underscore delimiting the different levels.

**namespaces** [dict, optional] All namespaces to be defined in root element. Keys of dict should be prefix names and values of dict corresponding URIs. Default namespaces should be given empty string key. For example,

```python
namespaces = {"": "https://example.com"}
```

**prefix** [str, optional] Namespace prefix to be used for every element and/or attribute in document. This should be one of the keys in **namespaces** dict.

**encoding** [str, default 'utf-8'] Encoding of the resulting document.

**xml_declaration** [bool, default True] Whether to include the XML declaration at start of document.

**pretty_print** [bool, default True] Whether output should be pretty printed with indentation and line breaks.

**parser** [{‘lxml’,’etree’}, default ‘lxml’] Parser module to use for building of tree. Only ‘lxml’ and ‘etree’ are supported. With ‘lxml’, the ability to use XSLT stylesheet is supported.

**stylesheet** [str, path object or file-like object, optional] A URL, file-like object, or a raw string containing an XSLT script used to transform the raw XML output. Script should use layout of elements and attributes from original output. This argument requires 1xml to be installed. Only XSLT 1.0 scripts and not later versions is currently supported.

**compression** [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buffer is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

**Returns**

None or str If io is None, returns the resulting XML format as a string. Otherwise returns None.

**See also:**

- **to_json** Convert the pandas object to a JSON string.
- **to_html** Convert DataFrame to a HTML.
Examples

```python
>>> df = pd.DataFrame({'shape': ['square', 'circle', 'triangle'],
...                    'degrees': [360, 360, 180],
...                    'sides': [4, np.nan, 3]})

```
3.1.8 Latex

DataFrame.to_latex([buf, columns, ...])  
Render object to a LaTeX tabular, longtable, or nested table/tabular.

pandas.DataFrame.to_latex

DataFrame.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None)  
Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires \usepackage{booktabs}. The output can be copy/pasted into a main LaTeX document or read from an external file with \input{table.tex}.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

Parameters

buf  [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns  [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space  [int, optional] The minimum width of each column.

header  [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index  [bool, default True] Write row names (index).

na_rep  [str, default ‘NaN’] Missing data representation.

formatters  [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format  [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example float_format="%.2f" and float_format="{:0.2f}".format will both result in 0.1234 being formatted as 0.12.
sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in LaTe\m table format e.g. ‘rcl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a \usepackage{longtable} to your LaTe\m preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to column_format The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a \usepackage{multirow} to your LaTe\m preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str or tuple, optional] Tuple (full_caption, short_caption), which results in \caption[short_caption]{full_caption}; if a single string is passed, no short caption will be set.

label [str, optional] The LaTe\m label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

position [str, optional] The LaTe\m positional argument for tables, to be placed after \begin{} in the output.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

DataFrames.to_string Render a DataFrame to a console-friendly tabular output.

DataFrames.to_html Render a DataFrame as an HTML table.
Examples

```python
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
...                     mask=['red', 'purple'],
...                     weapon=['sai', 'bo staff']))
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

```
Styler.to_latex(buf, column_format, ...) Write Styler to a file, buffer or string in LaTeX format.
```

```
pandas.io.formats.style.Styler.to_latex

Styler.to_latex(buf=None, *, column_format=None, position=None, position_float=None, hrules=False, label=None, caption=None, sparse_index=None, sparse_columns=None, multirow_align='c', multicol_align='r', siunitx=False, encoding=None, convert_css=False)

Write Styler to a file, buffer or string in LaTeX format.

New in version 1.3.0.

Parameters

- **buf** [str, Path, or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

- **column_format** [str, optional] The LaTeX column specification placed in location:
  ```latex
  \begin{tabular}{\{column_format\}}
  \end{tabular}
  ```
  Defaults to ‘l’ for index and non-numeric data columns, and, for numeric data columns, to ‘r’ by default, or ‘S’ if siunitx is True.

- **position** [str, optional] The LaTeX positional argument (e.g. ‘h!’) for tables, placed in location:
  ```latex
  \begin{table}[\{position\}]
  \end{table}
  ```

- **position_float** [[‘centering’, ‘raggedleft’, ‘raggedright’], optional] The LaTeX float command placed in location:
  ```latex
  \begin{table}[\{position\}]
  \end{table}
  ```

- **hrules** [bool, default False] Set to True to add \toprule, \midrule and \bottomrule from the \{booktabs\} LaTeX package.

- **label** [str, optional] The LaTeX label included as: \label{<label>}. This is used with \ref{<label>} in the main .tex file.

- **caption** [str, tuple, optional] If string, the LaTeX table caption included as: \caption{<caption>}. If tuple, i.e (“full caption”, “short caption”), the caption included as: \caption{<caption[1]>}{<caption[0]>}.  

3.1. Input/output 1065
sparse_index [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to pandas.options.styler.sparse.index value.

sparse_columns [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to pandas.options.styler.sparse.columns value.

multirow_align ["c", "t", "b"] If sparsifying hierarchical MultiIndexes whether to align text centrally, at the top or bottom.

multicol_align ["r", "c", "l"] If sparsifying hierarchical MultiIndex columns whether to align text at the left, centrally, or at the right.

siunitx [bool, default False] Set to True to structure LaTeX compatible with the \{siunitx\} package.

encoding [str, default “utf-8”] Character encoding setting.

convert_css [bool, default False] Convert simple cell-styles from CSS to LaTeX format. Any CSS not found in conversion table is dropped. A style can be forced by adding option –latex. See notes.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

Styler.format Format the text display value of cells.

Notes

Latex Packages
For the following features we recommend the following LaTeX inclusions:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Inclusion</th>
</tr>

</tr>
</tbody>
</table>

Cell Styles
LaTeX styling can only be rendered if the accompanying styling functions have been constructed with appropriate LaTeX commands. All styling functionality is built around the concept of a CSS (attribute, value) pair (see Table Visualization), and this should be replaced by a LaTeX (command, options) approach. Each cell will be styled individually using nested LaTeX commands with their accompanied options.

For example, the following code will highlight and bold a cell in HTML-CSS:

```python
>> df = pd.DataFrame([[1, 2], [3, 4]])
>>> s = df.style.highlight_max(axis=None, ... props='background-color:red; font-weight:bold;')
>>> s.render()
```

The equivalent using LaTeX only commands is the following:

```python
>>> s = df.style.highlight_max(axis=None, ... props='cellcolor:red; fbseries:;')
>>> s.to_latex()
```

Internally these structured LaTeX (command, options) pairs are translated to the display_value with the default structure: \texttt{(command, options) <display_value>.} Where there are multiple commands the latter is nested recursively, so that the above example highlighted cell is rendered as \texttt{cellcolor{red} \bfseries 4}.

Occasionally this format does not suit the applied command, or combination of LaTeX packages that is in use, so additional flags can be added to the options, within the tuple, to result in different positions of required braces (the default being the same as --nowrap):

<table>
<thead>
<tr>
<th>Tuple Format</th>
<th>Output Structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>(command, options)</td>
<td>command &lt;options&gt; &lt;display_value&gt;</td>
</tr>
<tr>
<td>(command, options --nowrap)</td>
<td>command &lt;options&gt; &lt;display_value&gt;</td>
</tr>
<tr>
<td>(command, options --rwrap)</td>
<td>command &lt;options&gt;[display_value]</td>
</tr>
<tr>
<td>(command, options --wrap)</td>
<td>command &lt;options&gt;{display_value}</td>
</tr>
<tr>
<td>(command, options --lwrap)</td>
<td>command {options} &lt;display_value&gt;</td>
</tr>
<tr>
<td>(command, options --dwrap)</td>
<td>command {options} {display_value}</td>
</tr>
</tbody>
</table>

For example the textbf command for font-weight should always be used with --rwrap so (textbf, --rwrap) will render a working cell, wrapped with braces, as \textbf{<display_value>}

A more comprehensive example is as follows:

```python
>> df = pd.DataFrame([[1, 2.2, "dogs"], [3, 4.4, "cats"], [2, 6.6, "cows"]], ... index=["ix1", "ix2", "ix3"], ... columns=["Integers", "Floats", "Strings"])
>>> s = df.style.highlight_max( ... props='cellcolor:[HTML]{FFFF00}; color:red;' 'textit:--rwrap; textbf:--rwrap;' ... )
>>> s.to_latex()
```

<table>
<thead>
<tr>
<th>Integers</th>
<th>Floats</th>
<th>Strings</th>
</tr>
</thead>
<tbody>
<tr>
<td>ix1</td>
<td>1</td>
<td>2.200000 dogs</td>
</tr>
<tr>
<td>ix2</td>
<td>3</td>
<td>4.400000 cats</td>
</tr>
<tr>
<td>ix3</td>
<td>2</td>
<td>6.600000 cows</td>
</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.3.4

Table Styles
Internally Styler uses its table_styles object to parse the column_format, position, position_float,
and label input arguments. These arguments are added to table styles in the format:
set_table_styles([
{"selector": "column_format", "props": f":{column_format};"},
{"selector": "position", "props": f":{position};"},
{"selector": "position_float", "props": f":{position_float};"},
{"selector": "label", "props": f":{{{label.replace(':','§')}}};"}
], overwrite=False)
Exception is made for the hrules argument which, in fact, controls all three commands: toprule, bottomrule
and midrule simultaneously. Instead of setting hrules to True, it is also possible to set each individual rule
definition, by manually setting the table_styles, for example below we set a regular toprule, set an hline
for bottomrule and exclude the midrule:
set_table_styles([
{'selector': 'toprule', 'props': ':toprule;'},
{'selector': 'bottomrule', 'props': ':hline;'},
], overwrite=False)
If other commands are added to table styles they will be detected, and positioned immediately above the ‘\begin{tabular}’ command. For example to add odd and even row coloring, from the {colortbl} package, in format
\rowcolors{1}{pink}{red}, use:
set_table_styles([
{'selector': 'rowcolors', 'props': ':{1}{pink}{red};'}
], overwrite=False)
A more comprehensive example using these arguments is as follows:
>>>
...
...
...
...
>>>
...
...
>>>
...
...
>>>
...
...
...
...

df.columns = pd.MultiIndex.from_tuples([
("Numeric", "Integers"),
("Numeric", "Floats"),
("Non-Numeric", "Strings")
])
df.index = pd.MultiIndex.from_tuples([
("L0", "ix1"), ("L0", "ix2"), ("L1", "ix3")
])
s = df.style.highlight_max(
props='cellcolor:[HTML]{FFFF00}; color:{red}; itshape:; bfseries:;'
)
s.to_latex(
column_format="rrrrr", position="h", position_float="centering",
hrules=True, label="table:5", caption="Styled LaTeX Table",
multirow_align="t", multicol_align="r"
)

Formatting
To format values Styler.format() should be used prior to calling Styler.to_latex, as well as other methods
such as Styler.hide_index() or Styler.hide_columns(), for example:

3.1.9 HDFStore: PyTables (HDF5)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_hdf</code></td>
<td>Read from the store, close it if we opened it.</td>
</tr>
<tr>
<td><code>HDFStore.put</code></td>
<td>Store object in HDFStore.</td>

<td>Return a list of all the top-level nodes.</td>
</tr>
<tr>
<td><code>HDFStore.walk</code></td>
<td>Walk the pytables group hierarchy for pandas objects.</td>
</tr>
</tbody>
</table>

**pandas.read_hdf**

```python
pandas.read_hdf(path_or_buf, key=None, mode='r', errors='strict', where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, **kwargs)
```

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria.

**Warning:** Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html for more.

**Parameters**

- **path_or_buf** [str, path object, pandas.HDFStore] Any valid string path is acceptable. Only supports the local file system, remote URLs and file-like objects are not supported.
  - If you want to pass in a path object, pandas accepts any `os.PathLike`.
  - Alternatively, pandas accepts an open `pandas.HDFStore` object.
- **key** [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.
- **mode** [‘r’, ‘r+’, ‘a’], default ‘r’] Mode to use when opening the file. Ignored if path_or_buf is a pandas.HDFStore. Default is ‘r’.
- **errors** [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.
- **where** [list, optional] A list of Term (or convertible) objects.
- **start** [int, optional] Row number to start selection.
- **stop** [int, optional] Row number to stop selection.
- **columns** [list, optional] A list of columns names to return.
- **iterator** [bool, optional] Return an iterator object.
- **chunksize** [int, optional] Number of rows to include in an iteration when using an iterator.
**kwargs Additional keyword arguments passed to HDFStore.

**Returns**

- **item** [object] The selected object. Return type depends on the object stored.

**See also:**

- **DataFrame.to_hdf** Write a HDF file from a DataFrame.
- **HDFStore** Low-level access to HDF files.

**Examples**

```python
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

**pandas.HDFStore.put**

HDFStore.put(key, value, format=None, index=True, append=False, complib=None, complevel=None, min_itemsize=None, nan_rep=None, data_columns=None, encoding=None, errors='strict', track_times=True, dropna=False)

Store object in HDFStore.

**Parameters**

- **key** [str]
- **value** [[Series, DataFrame]]
- **format** ['fixed(f)|table(t)', default is 'fixed'] Format to use when storing object in HDFStore. Value can be one of:
  - 'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- **append** [bool, default False] This will force Table format, append the input data to the existing.
- **data_columns** [list, default None] List of columns to create as data columns, or True to use all columns. See here.
- **encoding** [str, default None] Provide an encoding for strings.
- **track_times** [bool, default True] Parameter is propagated to ‘create_table’ method of ‘PyTables’. If set to False it enables to have the same h5 files (same hashes) independent on creation time. New in version 1.1.0.
**pandas.HDFStore.append**

HDFStore.append(key, value, format=None, axes=None, index=True, append=True, complib=None, complevel=None, columns=None, min_itemsize=None, nan_rep=None, chunksize=None, expectedrows=None, dropna=None, data_columns=None, encoding=None, errors='strict')

Append to Table in file. Node must already exist and be Table format.

**Parameters**

- **key** [str]
- **value** [{Series, DataFrame}]
- **format** ['table' is the default] Format to use when storing object in HDFStore. Value can be one of:
  - 'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- **append** [bool, default True] Append the input data to the existing.
- **data_columns** [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See here.
- **min_itemsize** [dict of columns that specify minimum str sizes]
- **nan_rep** [str to use as str nan representation]
- **chunksize** [size to chunk the writing]
- **expectedrows** [expected TOTAL row size of this table]
- **encoding** [default None, provide an encoding for str]
- **dropna** [bool, default False] Do not write an ALL nan row to the store settable by the option 'io.hdf.dropna_table'.

**Notes**

Does not check if data being appended overlaps with existing data in the table, so be careful

**pandas.HDFStore.get**

HDFStore.get(key)

Retrieve pandas object stored in file.

**Parameters**

- **key** [str]

**Returns**

- **object** Same type as object stored in file.
**pandas.HDFStore.select**

HDFStore.select(key, where=None, start=None, stop=None, columns=None, iterator=False, auto_close=False)

Retrieve pandas object stored in file, optionally based on where criteria.

**Warning:** Pandas uses PyTables for reading and writing HDF files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.

See: [https://docs.python.org/3/library/pickle.html](https://docs.python.org/3/library/pickle.html) for more.

**Parameters**

- **key** [str] Object being retrieved from file.
- **where** [list or None] List of Term (or convertible) objects, optional.
- **start** [int or None] Row number to start selection.
- **stop** [int, default None] Row number to stop selection.
- **columns** [list or None] A list of columns that if not None, will limit the return columns.
- **iterator** [bool or False] Returns an iterator.
- **chunksize** [int or None] Number or rows to include in iteration, return an iterator.
- **auto_close** [bool or False] Should automatically close the store when finished.

**Returns**

- **object** Retrieved object from file.

**pandas.HDFStore.info**

HDFStore.info()

Print detailed information on the store.

**Returns**

- **str**

**pandas.HDFStore.keys**

HDFStore.keys(include='pandas')

Return a list of keys corresponding to objects stored in HDFStore.

**Parameters**

- **include** [str, default ‘pandas’] When kind equals ‘pandas’ return pandas objects. When kind equals ‘native’ return native HDF5 Table objects.

  New in version 1.1.0.

**Returns**

- **list** List of ABSOLUTE path-names (e.g. have the leading ‘/’).

**Raises**
raises ValueError if kind has an illegal value

**pandas.HDFStore.groups**

HDFStore.groups()

Return a list of all the top-level nodes.

Each node returned is not a pandas storage object.

**Returns**

- list List of objects.

**pandas.HDFStore.walk**

HDFStore.walk(where=’/’)  

Walk the pytables group hierarchy for pandas objects.

This generator will yield the group path, subgroups and pandas object names for each group.

Any non-pandas PyTables objects that are not a group will be ignored.

The where group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.

**Parameters**

- where [str, default ‘/’] Group where to start walking.

**Yields**

- path [str] Full path to a group (without trailing ‘/’).
- groups [list] Names (strings) of the groups contained in path.
- leaves [list] Names (strings) of the pandas objects contained in path.

**Warning:** One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

### 3.1.10 Feather

**read_feather**(path[, columns, use_threads, ...])  

Load a feather-format object from the file path.

**DataFrame.to_feather**(path, **kwargs)  

Write a DataFrame to the binary Feather format.
**pandas: powerful Python data analysis toolkit, Release 1.3.4**

**pandas.read_feather**

`pandas.read_feather(path, columns=None, use_threads=True, storage_options=None)`  
Load a feather-format object from the file path.

- **Parameters**
  - `path` [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.feather`.
  - If you want to pass in a path object, pandas accepts any `os.PathLike`.
  - `columns` [sequence, default None] If not provided, all columns are read.
  - `use_threads` [bool, default True] Whether to parallelize reading using multiple threads.
  - `storage_options` [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

- **Returns**
  - type of object stored in file

**pandas.DataFrame.to_feather**

`DataFrame.to_feather(path, **kwargs)`  
Write a DataFrame to the binary Feather format.

- **Parameters**
  - `path` [str or file-like object] If a string, it will be used as Root Directory path.
  - `**kwargs` : Additional keywords passed to `pyarrow.feather.write_feather()`. Starting with pyarrow 0.17, this includes the `compression`, `compression_level`, `chunksize` and `version` keywords.

  - New in version 1.1.0.

3.11 Parquet

<table>
<thead>
<tr>
<th><code>read_parquet(path, engine, columns, ...)</code>)</th>
<th>Load a parquet object from the file path, returning a DataFrame.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.to_parquet(path, engine, ...)</code>)</td>
<td>Write a DataFrame to the binary parquet format.</td>
</tr>
</tbody>
</table>
pandas.read_parquet

pandas.read_parquet(path='auto', columns=None, storage_options=None, use_nullable_dtypes=False, **kwargs)

Load a parquet object from the file path, returning a DataFrame.

Parameters

- **path** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file:///localhost/path/to/table.parquet. A file URL can also be a path to a directory that contains multiple partitioned parquet files. Both pyarrow and fastparquet support paths to directories as well as file URLs. A directory path could be: file:///localhost/path/to/tables or s3://bucket/partition_dir

- **engine** [{'auto', 'pyarrow', 'fastparquet'}, default 'auto'] Parquet library to use. If 'auto', then the option io.parquet.engine is used. The default io.parquet.engine behavior is to try 'pyarrow', falling back to 'fastparquet' if 'pyarrow' is unavailable.

- **columns** [list, default=None] If not None, only these columns will be read from the file.

- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.3.0.

- **use_nullable_dtypes** [bool, default False] If True, use dtypes that use pd.NA as missing value indicator for the resulting DataFrame. (only applicable for the pyarrow engine) As new dtypes are added that support pd.NA in the future, the output with this option will change to use those dtypes. Note: this is an experimental option, and behaviour (e.g. additional support dtypes) may change without notice.

New in version 1.2.0.

- **kwargs** Any additional kwargs are passed to the engine.

Returns

DataFrame

pandas.DataFrame.to_parquet

DataFrame.to_parquet(path=None, engine='auto', compression='snappy', index=None, partition_cols=None, storage_options=None, **kwargs)

Write a DataFrame to the binary parquet format.

This function writes the dataframe as a parquet file. You can choose different parquet backends, and have the option of compression. See the user guide for more details.

Parameters

- **path** [str or file-like object, default None] If a string, it will be used as Root Directory path when writing a partitioned dataset. By file-like object, we refer to objects with a write() method,
such as a file handle (e.g. via builtin open function) or io.BytesIO. The engine fastparquet does not accept file-like objects. If path is None, a bytes object is returned. Changed in version 1.2.0.

Previously this was “fname”

**engine** [{‘auto’, ‘pyarrow’, ‘fastparquet’}, default ‘auto’] Parquet library to use. If ‘auto’, then the option io.parquet.engine is used. The default io.parquet.engine behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

**compression** [{‘snappy’, ‘gzip’, ‘brotli’, None}, default ‘snappy’] Name of the compression to use. Use None for no compression.

**index** [bool, default None] If True, include the dataframe’s index(es) in the file output. If False, they will not be written to the file. If None, similar to True the dataframe’s index(es) will be saved. However, instead of being saved as values, the RangeIndex will be stored as a range in the metadata so it doesn’t require much space and is faster. Other indexes will be included as columns in the file output.

**partition_cols** [list, optional, default None] Column names by which to partition the dataset. Columns are partitioned in the order they are given. Must be None if path is not a string.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**kwargs** Additional arguments passed to the parquet library. See pandas io for more details.

**Returns**

bytes if no path argument is provided else None

See also:

- read_parquet Read a parquet file.
- DataFrame.to_csv Write a csv file.
- DataFrame.to_sql Write to a sql table.
- DataFrame.to_hdf Write to hdf.

**Notes**

This function requires either the fastparquet or pyarrow library.
Examples

```python
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gz',
...    compression='gzip')
>>> pd.read_parquet('df.parquet.gz')
   col1  col2
0    1    3
1    2    4
```

If you want to get a buffer to the parquet content you can use a io.BytesIO object, as long as you don’t use partition_cols, which creates multiple files.

```python
>>> import io

>>> f = io.BytesIO()
>>> df.to_parquet(f)
>>> f.seek(0)
>>> content = f.read()
```

### 3.1.12 ORC

<table>
<thead>
<tr>
<th>read_orc(path[, columns])</th>
<th>Load an ORC object from the file path, returning a DataFrame.</th>
</tr>
</thead>
</table>

**pandas.read_orc**

`pandas.read_orc(path, columns=None, **kwargs)`

Load an ORC object from the file path, returning a DataFrame.

New in version 1.0.0.

**Parameters**

- `path` [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.orc`.

  - If you want to pass in a path object, pandas accepts any `os.PathLike`.

  - By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via `builtin open function`) or `StringIO`.

- `columns` [list, default None] If not None, only these columns will be read from the file.

- `**kwargs` Any additional kwargs are passed to pyarrow.

**Returns**

- `DataFrame`
Notes
Before using this function you should read the user guide about ORC and install optional dependencies.

3.1.13 SAS

| pandas.read_sas(filepath_or_buffer[, format=\n, index=\n, encoding=\n, chunksize=\n, iterator=False]) | Read SAS files stored as either XPORT or SAS7BDAT format files. |

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.sas.

If you want to pass in a path object, pandas accepts any os.PathLike.

By file-like object, we refer to objects with a read() method, such as a file handle (e.g. via builtin open function) or StringIO.

format [str {'xport', 'sas7bdat'} or None] If None, file format is inferred from file extension. If ‘xport’ or ‘sas7bdat’, uses the corresponding format.

index [identifier of index column, defaults to None] Identifier of column that should be used as index of the DataFrame.

encoding [str, default is None] Encoding for text data. If None, text data are stored as raw bytes.

chunksize [int] Read file chunksize lines at a time, returns iterator.

Changed in version 1.2: TextFileReader is a context manager.

iterator [bool, defaults to False] If True, returns an iterator for reading the file incrementally.

Changed in version 1.2: TextFileReader is a context manager.

Returns

 DataFrame if iterator=False and chunksize=None, else SAS7BDATReader or XportReader
3.1.14 SPSS

`read_spss(path[, usecols, convert_categoricals])` Load an SPSS file from the file path, returning a DataFrame.

New in version 0.25.0.

**Parameters**

- **path** [str or Path] File path.
- **usecols** [list-like, optional] Return a subset of the columns. If None, return all columns.
- **convert_categoricals** [bool, default is True] Convert categorical columns into pd.Categorical.

**Returns**

DataFrame

3.1.15 SQL

`read_sql_table(table_name, con[, schema, ...])` Read SQL database table into a DataFrame.

`read_sql_query(sql, con[, index_col, ...])` Read SQL query into a DataFrame.

`read_sql(sql, con[, index_col, ...])` Read SQL query or database table into a DataFrame.

`DataFrame.to_sql(name, con[, schema, ...])` Write records stored in a DataFrame to a SQL database.

**pandas.read_sql_table**

`pandas.read_sql_table(table_name, con[, schema=None, index_col=None, coerce_float=True, parse_dates=None, columns=None, chunksize=None])` Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

**Parameters**

- **table_name** [str] Name of SQL table in database.
- **con** [SQLAlchemy connectable or str] A database URI could be provided as str. SQLite DBAPI connection mode not supported.
- **schema** [str, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).
- **index_col** [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
- **coerce_float** [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.
- **parse_dates** [list or dict, default None]
• List of column names to parse as dates.
• Dict of \{column_name: format string\} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
• Dict of \{column_name: arg dict\}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default None] List of column names to select from SQL table.
chunksize [int, default None] If specified, returns an iterator where chunksize is the number of rows to include in each chunk.

Returns
DataFrame or Iterator[DataFrame] A SQL table is returned as two-dimensional data structure with labeled axes.

See also:
read_sql_query  Read SQL query into a DataFrame.
read_sql  Read SQL query or database table into a DataFrame.

Notes
Any datetime values with time zone information will be converted to UTC.

Examples

```python
>>> pd.read_sql_table('table_name', 'postgres:///db_name')
```

pandas.read_sql_query

pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None, dtype=None)

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an index_col parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

sql [str SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.
con [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.
index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.
params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name': 'value'}. 
parse_dates [list or dict, default: None]
  • List of column names to parse as dates.
  • Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  • Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

chunksize [int, default None] If specified, return an iterator where chunksize is the number of rows to include in each chunk.

dtype [Type name or dict of columns] Data type for data or columns. E.g. np.float64 or {‘a’: np.float64, ‘b’: np.int32, ‘c’: ‘Int64’}

Returns
   DataFrame or Iterator[DataFrame]

See also:
   read_sql_table Read SQL database table into a DataFrame.
   read_sql Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information parsed via the parse_dates parameter will be converted to UTC.

pandas.read_sql

pandas.read_sql(sql, con=None, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around read_sql_table and read_sql_query (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to read_sql_query, while a database table name will be routed to read_sql_table. Note that the delegated function might have more specific notes about their functionality not listed here.

Parameters

sql [str or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.

con [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable; str connections are closed automatically. See here.

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
**params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method.

The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s paramstyle, is supported. Eg. for psycopg2, uses %\{name\} so use params={‘name’ : ‘value’}.

**parse_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

**columns** [list, default: None] List of column names to select from SQL table (only used when reading a table).

**chunksize** [int, default None] If specified, return an iterator where chunksize is the number of rows to include in each chunk.

**Returns**

DataFrame or Iterator[DataFrame]

**See also:**

*read_sql_table* Read SQL database table into a DataFrame.

*read_sql_query* Read SQL query into a DataFrame.

**Examples**

Read data from SQL via either a SQL query or a SQL tablename. When using a SQLite database only SQL queries are accepted, providing only the SQL tablename will result in an error.

```python
>>> from sqlite3 import connect
>>> conn = connect(':memory:')
>>> df = pd.DataFrame(data=[[0, '10/11/12'], [1, '12/11/10']],
... columns=['int_column', 'date_column'])
>>> df.to_sql('test_data', conn)
```

```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data', conn)
     int_column    date_column
0       0     10/11/12
1       1     12/11/10
```

```python
>>> pd.read_sql('test_data', 'postgres:///db_name')
```

Apply date parsing to columns through the parse_dates argument

```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
... conn,
... parse_dates=['date_column'])
     int_column    date_column
0       0     10/11/12
1       1     12/11/10
```

(continues on next page)
The parse_dates argument calls `pd.to_datetime` on the provided columns. Custom argument values for applying `pd.to_datetime` on a column are specified via a dictionary format:

1. Ignore errors while parsing the values of “date_column”

   ```
   >>> pd.read_sql('SELECT int_column, date_column FROM test_data',
                  ...               conn,
                  ...               parse_dates={"date_column": {"errors": "ignore"}})
   ```

2. Apply a dayfirst date parsing order on the values of “date_column”

   ```
   >>> pd.read_sql('SELECT int_column, date_column FROM test_data',
                  ...               conn,
                  ...               parse_dates={"date_column": {"dayfirst": True}})
   ```

3. Apply custom formatting when date parsing the values of “date_column”

   ```
   >>> pd.read_sql('SELECT int_column, date_column FROM test_data',
                  ...               conn,
                  ...               parse_dates={"date_column": {"format": "%d/%m/%y"}})
   ```

---

**pandas.DataFrame.to_sql**

DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

**Parameters**

- **name** [str] Name of SQL table.
- **con** [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See here.
- **schema** [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
if_exists  [{‘fail’, ‘replace’, ‘append’}, default ‘fail’] How to behave if the table already exists.
  • fail: Raise a ValueError.
  • replace: Drop the table before inserting new values.
  • append: Insert new values to the existing table.

index  [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.

index_label  [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize  [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

dtype  [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

method  [{None, ‘multi’, callable}, optional] Controls the SQL insertion clause used:
  • None : Uses standard SQL INSERT clause (one per row).
  • ‘multi’: Pass multiple values in a single INSERT clause.
  • callable with signature (pd_table, conn, keys, data_iter).

Raises

ValueError  When the table already exists and if_exists is ‘fail’ (the default).

See also:

read_sql  Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as Timestamp with timezone type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

References

[1], [2]
Examples

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine

>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({
        'name': ['User 1', 'User 2', 'User 3']
    })

>>> df
   name
0  User 1
1  User 2
2  User 3

>>> df.to_sql('users', con=engine)

>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An sqlalchemy.engine.Connection can also be passed to con:

```python
>>> with engine.begin() as connection:
...     df1 = pd.DataFrame({
...         'name': ['User 4', 'User 5']
...     })
...     df1.to_sql('users', con=connection, if_exists='append')
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```python
>>> df2 = pd.DataFrame({
        'name': ['User 6', 'User 7']
    })

>>> df2.to_sql('users', con=engine, if_exists='append')

>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'), (0, 'User 4'), (1, 'User 5'), (0, 'User 6'), (1, 'User 7')]
```

Overwrite the table with just df2.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace', index_label='id')

>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({'A': [1, None, 2]})

>>> df
   A
0  1.0
1  NaN
2  2.0
```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...          dtype={'A': Integer()})

>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]

3.1.16 Google BigQuery

read_gbq(query[, project_id, index_col, ...]) Load data from Google BigQuery.

pandas.read_gbq

pandas.read_gbq(query, project_id=None, index_col=None, col_order=None, reauth=False,
auth_local_webserver=False, dialect=None, location=None, configuration=None,
credentials=None, use_bqstorage_api=None, max_results=None, progress_bar_type=None)

Load data from Google BigQuery.

This function requires the pandas-gbq package.

See the How to authenticate with Google BigQuery guide for authentication instructions.

Parameters

query [str] SQL-Like Query to return data values.

project_id [str, optional] Google BigQuery Account project ID. Optional when available from
the environment.

index_col [str, optional] Name of result column to use for index in results DataFrame.

col_order [list(str), optional] List of BigQuery column names in the desired order for results
DataFrame.

reauth [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful
if multiple accounts are used.

auth_local_webserver [bool, default False] Use the local webserver flow instead of the console
flow when getting user credentials.

New in version 0.2.0 of pandas-gbq.

dialect [str, default ‘legacy’] Note: The default value is changing to ‘standard’ in a future ver-
version.

SQL syntax dialect to use. Value can be one of:

'legacy’ Use BigQuery’s legacy SQL dialect. For more information see BigQuery Legacy
SQL Reference.

'standard' Use BigQuery’s standard SQL, which is compliant with the SQL 2011 stan-
dard. For more information see BigQuery Standard SQL Reference.

location [str, optional] Location where the query job should run. See the BigQuery locations
documentation for a list of available locations. The location must match that of any datasets
used in the query.

New in version 0.5.0 of pandas-gbq.
**configuration** [dict, optional] Query config parameters for job processing. For example:

```python
configuration = {'query': {'useQueryCache': False}}
```

For more information see BigQuery REST API Reference.

**credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.

*New in version 0.8.0 of pandas-gbq.*

**use_bqstorage_api** [bool, default False] Use the BigQuery Storage API to download query results quickly, but at an increased cost. To use this API, first enable it in the Cloud Console. You must also have the bigquery.readsessions.create permission on the project you are billing queries to.

This feature requires version 0.10.0 or later of the pandas-gbq package. It also requires the google-cloud-bigquery-storage and fastavro packages.

*New in version 0.25.0.*

**max_results** [int, optional] If set, limit the maximum number of rows to fetch from the query results.

*New in version 0.12.0 of pandas-gbq.*

*New in version 1.1.0.*

**progress_bar_type** [Optional, str] If set, use the tqdm library to display a progress bar while the data downloads. Install the tqdm package to use this feature.

Possible values of `progress_bar_type` include:

- `None` No progress bar.
- `'tqdm'` Use the `tqdm.tqdm()` function to print a progress bar to `sys.stderr`.
- `'tqdm_notebook'` Use the `tqdm.tqdm_notebook()` function to display a progress bar as a Jupyter notebook widget.
- `'tqdm_gui'` Use the `tqdm.tqdm_gui()` function to display a progress bar as a graphical dialog box.

Note that this feature requires version 0.12.0 or later of the pandas-gbq package. And it requires the `tqdm` package. Slightly different than pandas-gbq, here the default is `None`.

*New in version 1.0.0.*

**Returns**

- `df` : `DataFrame` DataFrame representing results of query.

See also:

- `pandas_gbq.read_gbq` This function in the pandas-gbq library.
- `DataFrame.to_gbq` Write a DataFrame to Google BigQuery.
3.1.17 STATA

**pandas.read_stata**

```python
pandas.read_stata(filepath_or_buffer[, convert_dates=True, convert_categoricals=True, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False, compression=None, storage_options=None])
```

Read Stata file into DataFrame.

**Parameters**

- `filepath_or_buffer` [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.dta`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via the built-in `open` function) or `StringIO`.

- `convert_dates` [bool, default True] Convert date variables to DataFrame time values.

- `convert_categoricals` [bool, default True] Read value labels and convert columns to Categorical/Factor variables.

- `index_col` [str, optional] Column to set as index.

- `convert_missing` [bool, default False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

- `preserve_dtypes` [bool, default True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

- `columns` [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

- `order_categoricals` [bool, default True] Flag indicating whether converted categorical data are ordered.

- `chunksize` [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

- `iterator` [bool, default False] Return StataReader object.

- `compression` [str or dict, default None] If string, specifies compression mode. If dict, value at key ‘method’ specifies compression mode. Compression mode must be one of {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is ‘infer’ and `filepath_or_buffer` is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression). If dict and compression mode is one of {'zip', 'gzip', 'bz2'}, or inferred as one of the above, other entries passed as additional compression options.

- `storage_options` [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”), and
“gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

**Returns**

*DataFrame or StataReader*

**See also:**

*io.stata.StataReader* Low-level reader for Stata data files.

*DataFrame.to_stata* Export Stata data files.

**Notes**

Categorical variables read through an iterator may not have the same categories and dtype. This occurs when a variable stored in a DTA file is associated to an incomplete set of value labels that only label a strict subset of the values.

**Examples**

Read a Stata dta file:

```python
>>> df = pd.read_stata('filename.dta')
```

Read a Stata dta file in 10,000 line chunks:

```python
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...      do_something(chunk)
```

**pandas.DataFrame.to_stata**

*DataFrame.to_stata*(path, convert_dates=None, write_index=True, byteorder=None, time_stamp=None, data_label=None, variable_labels=None, version=114, convert_strl=None, compression=None, storage_options=None)

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

**Parameters**

- **path** [str, buffer or path object] String, path object (pathlib.Path or py._path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.
  
  Changed in version 1.0.0.

- **convert_dates** [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises NotImplementedError if a datetime column has timezone information.

- **write_index** [bool] Write the index to Stata dataset.
byteorder  [str] Can be “>”, “<”, “little”, or “big”. default is sys.byteorder.

time_stamp  [datetime] A datetime to use as file creation date. Default is the current time.

data_label  [str, optional] A label for the data set. Must be 80 characters or smaller.

variable_labels  [dict] Dictionary containing columns as keys and variable labels as values. Each
     label must be 80 characters or smaller.

version  [(114, 117, 118, 119, None), default 114] Version to use in the output dta file. Set to
     None to let pandas decide between 118 or 119 formats depending on the number of columns
     in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata
     13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata
     15 and later. Version 114 limits string variables to 244 characters or fewer while versions
     117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119
     support Unicode characters, and version 119 supports more than 32,767 variables.

     Version 119 should usually only be used when the number of variables exceeds the capacity
     of dta format 118. Exporting smaller datasets in format 119 may have unintended conse-
     quences, and, as of November 2020, Stata SE cannot read version 119 files.

     Changed in version 1.0.0: Added support for formats 118 and 119.

customize  [list, optional] List of column names to convert to string columns to Stata StrL
     format. Only available if version is 117. Storing strings in the StrL format can produce
     smaller dta files if strings have more than 8 characters and values are repeated.

compression  [str or dict, default ‘infer’] For on-the-fly compression of the output dta. If string,
     specifies compression mode. If dict, value at key ‘method’ specifies compression mode.
     Compression mode must be one of {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression
     mode is ‘infer’ and fnname is path-like, then detect compression from the following exten-
     sions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression). If dict and compression
     mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of the above, other entries passed as
     additional compression options.

     New in version 1.1.0.

storage_options  [dict, optional] Extra options that make sense for a particular storage connec-
     tion, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are
     forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and
     “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for
     more details.

     New in version 1.2.0.

Raises

NotImplementedError
     • If datetimes contain timezone information
     • Column dtype is not representable in Stata

ValueError
     • Columns listed in convert_dates are neither datetime64[ns] or datetime.datetime
     • Column listed in convert_dates is not in DataFrame
     • Categorical label contains more than 32,000 characters

See also:

read_stata  Import Stata data files.
**io.stata.StataWriter** Low-level writer for Stata data files.

**io.stata.StataWriter117** Low-level writer for version 117 files.

### Examples

```python
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon', 'parrot'],
                     'speed': [350, 18, 361, 15]})
>>> df.to_stata('animals.dta')
```

---

**pandas.io.stata.StataReader.data_label**

**property** StataReader.data_label

- Return data label of Stata file.

**pandas.io.stata.StataReader.value_labels**

- **StataReader.value_labels()**
  - Return a dict, associating each variable name a dict, associating each value its corresponding label.
  - **Returns**
    - dict

**pandas.io.stata.StataReader.variable_labels**

- **StataReader.variable_labels()**
  - Return variable labels as a dict, associating each variable name with corresponding label.
  - **Returns**
    - dict

pandas.melt

pandas.melt(frame, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

- **id_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.
- **value_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.
- **var_name** [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.
- **value_name** [scalar, default ‘value’] Name to use for the ‘value’ column.
col_level  [int or str, optional] If columns are a MultiIndex then use this level to melt.

ignore_index  [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

   DataFrame  Unpivoted DataFrame.

See also:

   DataFrame.melt  Identical method.

   pivot_table  Create a spreadsheet-style pivot table as a DataFrame.

   DataFrame.pivot  Return reshaped DataFrame organized by given index / column values.

   DataFrame.explode  Explode a DataFrame from list-like columns to long format.

Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
                      'B': {0: 1, 1: 3, 2: 5},
                      'C': {0: 2, 1: 4, 2: 6}})
```

```
A B C
0 a 1 2
1 b 3 4
2 c 5 6
```

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A variable value
0   a     B   1
1   b     B   3
2   c     B   5
```

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A variable value
0   a     B   1
1   b     B   3
2   c     B   5
3   a     C   2
4   b     C   4
5   c     C   6
```

The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B'],
                   var_name='myVarname', value_name='myValname')
   A myVarname   myValname
0   a     B       1
1   b     B       3
2   c     B       5
```

Original index values can be kept around:

3.2. General functions  1095
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
   A  variable  value
0  a       B     1
1  b       B     3
2  c       B     5
0  a       C     2
1  b       C     4
2  c       C     6
```

If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C  D  E  F
0  a  1  2
1  b  3  4
2  c  5  6
```

```python
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A  variable  value
0  a       B     1
1  b       B     3
2  c       B     5
```

```python
>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D) variable_0 variable_1 value
0  a       B       E     1
1  b       B       E     3
2  c       B       E     5
```

**pandas.pivot**

`pandas.pivot(data, index=None, columns=None, values=None)`

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified `index` / `columns` to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

**Parameters**

- **data** [DataFrame]
- **index** [str or object or a list of str, optional] Column to use to make new frame’s index. If None, uses existing index.
- **columns** [str or object or a list of str] Column to use to make new frame’s columns.
- **values** [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.
Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any index, columns combinations with multiple values.
DataFrame.pivot_table when you need to aggregate.

See also:

DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.
DataFrame.unstack Pivot based on the index values instead of a column.
wide_to_long Wide panel to long format. Less flexible but more user-friendly than melt.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Examples

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
... 'two'],
... 'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
... 'baz': [1, 2, 3, 4, 5, 6],
... 'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one  A   1   x
1  one  B   2   y
2  one  C   3   z
3  two  A   4   q
4  two  B   5   w
5  two  C   6   t
```

```python
>>> df.pivot(index='foo', columns='bar', values='baz')
     bar
foo
one  1  2  3
two  4  5  6
```

```python
>>> df.pivot(index='foo', columns='bar')[['baz']]
     bar
foo
one  1  2  3
two  4  5  6
```

```python
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
     baz  zoo
bar
foo
one  1  2  3
two  4  5  6
```

(continues on next page)
You could also assign a list of column names or a list of index names.

```python
>>> df = pd.DataFrame(
    ...     {
    ...         "lev1": [1, 1, 2, 2],
    ...         "lev2": [1, 1, 2, 2],
    ...         "lev3": [1, 2, 1, 2],
    ...         "lev4": [1, 2, 3, 4],
    ...         "values": [0, 1, 2, 3]
    ...     })
>>> df
   lev1 lev2 lev3 lev4  values
0    1    1    1    1      0
1    1    1    2    2      1
2    1    2    1    3      2
3    2    1    2    4      3
4    1    1    1    5      4
5    2    2    2    6      5
```

```python
>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")
   lev2  lev3
lev1
0    1.0  2.0
1    1.0  NaN
```

```python
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"], values="values")
   lev3  lev1
lev2
   1.0  1.0
   2.0  NaN
  lev1
   1.0  3.0
   NaN  5.0
```

A ValueError is raised if there are any duplicates.

```python
>>> df = pd.DataFrame({
    ...     "foo": ['one', 'one', 'two', 'two'],
    ...     "bar": ['A', 'A', 'B', 'C'],
    ...     "baz": [1, 2, 3, 4]
    ... })
>>> df
   foo  bar  baz
0  one   A    1
1  one   A    2
2  two   B    3
3  two   C    4
```

Notice that the first two rows are the same for our `index` and `columns` arguments.

```python
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape

pandas.pivot_table

`pandas.pivot_table(data=None, values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False, sort=True)`

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

**Parameters**

- `data` [DataFrame]:
- `values` [column to aggregate, optional]:
- `index` [column, Grouper, array, or list of the previous]: If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- `columns` [column, Grouper, array, or list of the previous]: If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- `aggfunc` [function, list of functions, dict, default numpy.mean]: If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.
- `fill_value` [scalar, default None]: Value to replace missing values with (in the resulting pivot table, after aggregation).
- `margins` [bool, default False]: Add all row / columns (e.g. for subtotal / grand totals).
- `dropna` [bool, default True]: Do not include columns whose entries are all NaN.
- `margins_name` [str, default ‘All’]: Name of the row / column that will contain the totals when margins is True.
- `observed` [bool, default False]: This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.
  - Changed in version 0.25.0.
- `sort` [bool, default True]: Specifies if the result should be sorted.
  - New in version 1.3.0.

**Returns**

- `DataFrame` An Excel style pivot table.

**See also:**

- `DataFrame.pivot` Pivot without aggregation that can handle non-numeric data.
- `DataFrame.melt` Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
**wide_to_long** Wide panel to long format. Less flexible but more user-friendly than melt.

**Examples**

```python
>>> df = pd.DataFrame({
    "A": ["foo", "foo", "foo", "foo", "foo",
          "bar", "bar", "bar", "bar"],
    "B": ["one", "one", "one", "two", "two",
          "one", "one", "two", "two"],
    "C": ["small", "large", "large", "small",
          "small", "large", "small", "small"],
    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]
})
```

This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values="D", index=['A', 'B'],
                         columns=['C'], aggfunc=np.sum)
```

We can also fill missing values using the `fill_value` parameter.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                         columns=['B'], aggfunc=np.sum, fill_value=0)
```

The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                         aggfunc={'D': np.mean,
```

(continues on next page)
We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                        aggfunc={'D': np.mean, 'E': [min, max, np.mean]})
```

<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>mean</td>
<td>max</td>
</tr>
<tr>
<td>bar</td>
<td>5.50000</td>
<td>9.0000</td>
</tr>
<tr>
<td></td>
<td>large</td>
<td></td>
</tr>
<tr>
<td></td>
<td>small</td>
<td>5.50000</td>
</tr>
<tr>
<td>foo</td>
<td>2.00000</td>
<td>5.0000</td>
</tr>
<tr>
<td></td>
<td>large</td>
<td></td>
</tr>
<tr>
<td></td>
<td>small</td>
<td>2.33333</td>
</tr>
</tbody>
</table>

**pandas.crosstab**

Computes a simple cross-tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

Parameters

- **index** [array-like, Series, or list of arrays/Series] Values to group by in the rows.
- **columns** [array-like, Series, or list of arrays/Series] Values to group by in the columns.
- **values** [array-like, optional] Array of values to aggregate according to the factors. Requires `aggfunc` to be specified.
- **rownames** [sequence, default None] If passed, must match number of row arrays passed.
- **colnames** [sequence, default None] If passed, must match number of column arrays passed.
- **aggfunc** [function, optional] If specified, requires `values` to be specified as well.
- **margins** [bool, default False] Add row/column margins (subtotals).
- **margins_name** [str, default ‘All’] Name of the row/column that will contain the totals when margins is True.
- **dropna** [bool, default True] Do not include columns whose entries are all NaN.
- **normalize** [bool, {'all', 'index', 'columns'}, or {0,1}, default False] Normalize by dividing all values by the sum of values.
  - If passed ‘all’ or `True`, will normalize over all values.
  - If passed ‘index’ will normalize over each row.
If passed ‘columns’ will normalize over each column.

If margins is True, will also normalize margin values.

Returns

DataFrame Cross tabulation of the data.

See also:

DataFrame.pivot Reshape data based on column values.
pivot_table Create a pivot table as a DataFrame.

Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have all of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren’t overlapping indexes an empty DataFrame will be returned.

Examples

```python
>>> a = np.array(["foo", "foo", "foo", "foo", "bar", "bar",
... "bar", "bar", "foo", "foo", "foo"], dtype=object)
>>> b = np.array(["one", "one", "one", "two", "one", "one",
... "one", "two", "two", "two", "one"], dtype=object)
>>> c = np.array(["dull", "dull", "shiny", "dull", "dull", "shiny",
... "shiny", "dull", "shiny", "shiny", "shiny"],
... dtype=object)
>>> pd.crosstab(a, [b, c], rownames=["a"], colnames=["b", "c"])
   b  one  two
c  dull  shiny  dull  shiny
a bar   1   2   1   0
     foo   2   2   1   2
```

Here ‘c’ and ‘f’ are not represented in the data and will not be shown in the output because dropna is True by default. Set dropna=False to preserve categories with no data.

```python
>>> foo = pd.Categorical(["a", "b"], categories=["a", "b", "c"])
>>> bar = pd.Categorical(["d", "e"], categories=["d", "e", "f"])
>>> pd.crosstab(foo, bar)
col_0 d e
row_0 
a 1 0
b 0 1
>>> pd.crosstab(foo, bar, dropna=False)
col_0 d e f
row_0 
a 1 0 0
b 0 1 0
c 0 0 0
```
**pandas.cut**

```python
pandas.cut(x, bins, right=True, labels=None, retbins=False, precision=3, include_lowest=False,
          duplicates='raise', ordered=True)
```

Bin values into discrete intervals.

Use `cut` when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

**Parameters**

- **x** [array-like] The input array to be binned. Must be 1-dimensional.
- **bins** [int, sequence of scalars, or IntervalIndex] The criteria to bin by.
  - int : Defines the number of equal-width bins in the range of `x`. The range of `x` is extended by .1% on each side to include the minimum and maximum values of `x`.
  - sequence of scalars : Defines the bin edges allowing for non-uniform width. No extension of the range of `x` is done.
  - IntervalIndex : Defines the exact bins to be used. Note that IntervalIndex for `bins` must be non-overlapping.
- **right** [bool, default True] Indicates whether `bins` includes the rightmost edge or not. If `right` == True (the default), then the `bins` [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when `bins` is an IntervalIndex.
- **labels** [array or False, default None] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when `bins` is an IntervalIndex. If True, raises an error. When `ordered=False`, labels must be provided.
- **retbins** [bool, default False] Whether to return the bins or not. Useful when bins is provided as a scalar.
- **precision** [int, default 3] The precision at which to store and display the bins labels.
- **include_lowest** [bool, default False] Whether the first interval should be left-inclusive or not.
- **duplicates** [{default ‘raise’, ‘drop’}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.
- **ordered** [bool, default True] Whether the labels are ordered or not. Applies to returned types Categorical and Series (with Categorical dtype). If True, the resulting categorical will be ordered. If False, the resulting categorical will be unordered (labels must be provided).

New in version 1.1.0.

**Returns**

- **out** [Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of `x`. The type depends on the value of `labels`.
  - True (default) : returns a Series for Series `x` or a Categorical for all other inputs. The values stored within are Interval dtype.
  - sequence of scalars : returns a Series for Series `x` or a Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
  - False : returns an ndarray of integers.
bins [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when
retbins=True. For scalar or sequence bins, this is an ndarray with the computed bins. If set
duplicates=drop, bins will drop non-unique bin. For an IntervalIndex bins, this is equal to
bins.

See also:

qcut Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

Categorical Array type for storing data that come from a fixed set of values.

Series One-dimensional array with axis labels (including time series).

IntervalIndex Immutable Index implementing an ordered, sliceable set.

Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or Categorical
object.

Examples

Discretize into three equal-sized bins.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
...
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [0.994 < 3.0] ...

>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
...
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [0.994 < 3.0] ...
array([0.994, 3.0, 5.0, 7.0])
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical’s categories are
labels and is ordered.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]),
... 3, labels=['bad', 'medium', 'good'])
['bad', 'good', 'medium', 'medium', 'good', 'bad']
Categories (3, object): [bad < medium < good]
```

ordered=False will result in unordered categories when labels are passed. This parameter can be used to allow
non-unique labels:

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]),
... 3, labels=['B', 'A', 'B'], ordered=False)
['B', 'A', 'B', 'A', 'B', 'B']
Categories (2, object): [A', 'B']
```

labels=False implies you just want the bins back.

```python
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```
Passing a Series as an input returns a Series with categorical dtype:

```python
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
                   index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
...  a (1.992, 4.667]
     b (1.992, 4.667]
     c (4.667, 7.333]
     d (7.333, 10.0]
     e (7.333, 10.0]
dtype: category
Categories (3, interval[float64, right]): [(1.992, 4.667] < (4.667, ...]
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```python
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
                   index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 10], labels=False, retbins=True, right=False)
...  (a 1.0
     b 2.0
     c 3.0
     d 4.0
     e NaN
dtype: float64,
array([ 0, 2, 4, 6, 10]))
```

Use `drop` optional when bins is not unique

```python
>>> pd.cut(s, [0, 2, 4, 6, 10], labels=False, retbins=True,
         right=False, duplicates='drop')
...  (a 1.0
     b 2.0
     c 3.0
     d 3.0
     e NaN
dtype: float64,
array([ 0, 2, 4, 6, 10]))
```

Passing an IntervalIndex for `bins` results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```python
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0.0, 1.0], NaN, (2.0, 3.0], (4.0, 5.0]
Categories (3, interval[int64, right]): [(0, 1] < (2, 3] < (4, 5)]
```
pandas.qcut

Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

Parameters

- `x` [1d ndarray or Series] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. `[0, .25, .5, .75, 1.]` for quartiles.
- `q` [int or list-like of float] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. `[0, .25, .5, .75, 1.]` for quartiles.
- `labels` [array or False, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins. If True, raises an error.
- `retbins` [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.
- `precision` [int, optional] The precision at which to store and display the bins labels.
- `duplicates` [(default ‘raise’, ‘drop’), optional] If bin edges are not unique, raise ValueError or drop non-unicues.

Returns

- `out` [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.
- `bins` [ndarray of floats] Returned only if `retbins` is True.

Notes

Out of bounds values will be NA in the resulting Categorical object

Examples

```python
>>> pd.qcut(range(5), 4)
...
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64, right]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```python
>>> pd.qcut(range(5), 3, labels=['good', 'medium', 'bad'])
...
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```python
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```
pandas.merge

```
pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)
```

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

**Parameters**

- **left** [DataFrame]
- **right** [DataFrame or named Series] Object to merge with.
- **how** [{‘left’, ‘right’, ‘outer’, ‘inner’, ‘cross’}, default ‘inner’] Type of merge to be performed.
  - left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
  - right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
  - outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
  - inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
  - cross: creates the cartesian product from both frames, preserves the order of the left keys.
  
  New in version 1.2.0.

- **on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

- **left_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

- **right_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

- **left_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

- **right_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

- **sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

- **suffixes** [list-like, default is ("_x", "_y")]. A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.

- **copy** [bool, default True] If False, avoid copy if possible.
indicator [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame, “right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

• “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
• “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
• “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
• “many_to_many” or “m:m”: allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

merge_ordered Merge with optional filling/interpolation.
merge_asof Merge on nearest keys.
DataFrame.join Similar method using indices.

Notes

Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0 Support for merging named Series objects was added in version 0.24.0

Examples

```python
>>> df1 = pd.DataFrame({'
'    'lkey': ['foo', 'bar', 'baz', 'foo'],
'    'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'
'    'rkey': ['foo', 'bar', 'baz', 'foo'],
'    'value': [5, 6, 7, 8]})
>>> df1
   lkey value
0    foo   1
1    bar   2
2    baz   3
3    foo   5
>>> df2
   rkey value
0    foo   5
1    bar   6
2    baz   7
3    foo   8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.
 Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=('l_left', 'r_right'))
   lkey   value_l_left rkey   value_r_right
0  foo          1 foo         5
1  foo          1 foo         8
2  foo          5 foo         5
3  foo          5 foo         8
4  bar          2 bar         6
5  baz          3 baz         7

 Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...  ValueError: columns overlap but no suffix specified:
     Index(['value'], dtype=object)

>>> df1 = pd.DataFrame({'a': ['foo', 'bar'], 'b': [1, 2]})
>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})
>>> df1
   a  b
0  foo  1
1  bar  2
>>> df2
   a  c
0  foo  3
1  baz  4

>>> df1.merge(df2, how='inner', on='a')
   a  b  c
0  foo  1  3

>>> df1.merge(df2, how='left', on='a')
   a  b  c
0  foo  3.0
1  bar  NaN
pandas: powerful Python data analysis toolkit, Release 1.3.4

(continued from previous page)

```python
left
0  foo
1  bar
>>> df2
right
0  7
1  8

>>> df1.merge(df2, how='cross')
left  right
0  foo   7
1  foo   8
2  bar   7
3  bar   8
```

**pandas.merge_ordered**

`pandas.merge_ordered(left, right, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('_x', '_y'), how='outer')`

Perform merge with optional filling/interpolation.

Designed for ordered data like time series data. Optionally perform group-wise merge (see examples).

**Parameters**

- `left` [DataFrame]
- `right` [DataFrame]
- `on` [label or list] Field names to join on. Must be found in both DataFrames.
- `left_on` [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns.
- `right_on` [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per left_on docs.
- `left_by` [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame.
- `right_by` [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame.
- `fill_method` [{‘ffill’, None}, default None] Interpolation method for data.
- `suffixes` [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in `left` and `right` respectively. Pass a value of `None` instead of a string to indicate that the column name from `left` or `right` should be left as-is, with no suffix. At least one of the values must not be `None`.

Changed in version 0.25.0.

- `how` [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘outer’]
  - left: use only keys from left frame (SQL: left outer join)
  - right: use only keys from right frame (SQL: right outer join)
• outer: use union of keys from both frames (SQL: full outer join)
• inner: use intersection of keys from both frames (SQL: inner join).

Returns

**DataFrame** The merged DataFrame output type will be the same as `left`, if it is a subclass of DataFrame.

See also:

*merge* Merge with a database-style join.

*merge_asof* Merge on nearest keys.

**Examples**

```python
>>> df1 = pd.DataFrame(
...     {  
...         "key": ["a", "c", "e", "a", "c", "e"],  
...         "lvalue": [1, 2, 3, 1, 2, 3],  
...         "group": ["a", "a", "a", "b", "b", "b"]  
...     }  
... )

>>> df1

<table>
<thead>
<tr>
<th>key</th>
<th>lvalue</th>
<th>group</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>c</td>
<td>2</td>
<td>a</td>
</tr>
<tr>
<td>e</td>
<td>3</td>
<td>a</td>
</tr>
<tr>
<td>a</td>
<td>1</td>
<td>b</td>
</tr>
<tr>
<td>c</td>
<td>2</td>
<td>b</td>
</tr>
<tr>
<td>e</td>
<td>3</td>
<td>b</td>
</tr>
</tbody>
</table>

>>> df2 = pd.DataFrame({"key": ["b", "c", "d"], "rvalue": [1, 2, 3]})

>>> df2

<table>
<thead>
<tr>
<th>key</th>
<th>rvalue</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>1</td>
</tr>
<tr>
<td>c</td>
<td>2</td>
</tr>
<tr>
<td>d</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> merge_ordered(df1, df2, fill_method="ffill", left_by="group")

<table>
<thead>
<tr>
<th>key</th>
<th>lvalue</th>
<th>group</th>
<th>rvalue</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
<td>a</td>
<td>NaN</td>
</tr>
<tr>
<td>b</td>
<td>1</td>
<td>a</td>
<td>1.0</td>
</tr>
<tr>
<td>c</td>
<td>2</td>
<td>a</td>
<td>2.0</td>
</tr>
<tr>
<td>d</td>
<td>2</td>
<td>a</td>
<td>3.0</td>
</tr>
<tr>
<td>e</td>
<td>3</td>
<td>a</td>
<td>3.0</td>
</tr>
<tr>
<td>a</td>
<td>1</td>
<td>b</td>
<td>NaN</td>
</tr>
<tr>
<td>b</td>
<td>1</td>
<td>b</td>
<td>1.0</td>
</tr>
<tr>
<td>c</td>
<td>2</td>
<td>b</td>
<td>2.0</td>
</tr>
<tr>
<td>d</td>
<td>2</td>
<td>b</td>
<td>3.0</td>
</tr>
<tr>
<td>e</td>
<td>3</td>
<td>b</td>
<td>3.0</td>
</tr>
</tbody>
</table>
```

3.2. General functions
pandas: powerful Python data analysis toolkit, Release 1.3.4

**pandas.merge_asof**

```
pandas.merge_asof(left, right, on=None, left_on=None, right_on=None, left_index=False, right_index=False, by=None, left_by=None, right_by=None, suffixes=('x', '_y'), tolerance=None, allow_exact_matches=True, direction='backward')
```

Perform an asof merge.

This is similar to a left-join except that we match on nearest key rather than equal keys. Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

**Parameters**

- **left** [DataFrame or named Series]
- **right** [DataFrame or named Series]
- **on** [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.
- **left_on** [label] Field name to join on in left DataFrame.
- **right_on** [label] Field name to join on in right DataFrame.
- **left_index** [bool] Use the index of the left DataFrame as the join key.
- **right_index** [bool] Use the index of the right DataFrame as the join key.
- **by** [column name or list of column names] Match on these columns before performing merge operation.
- **left_by** [column name] Field names to match on in the left DataFrame.
- **right_by** [column name] Field names to match on in the right DataFrame.
- **suffixes** [2-length sequence (tuple, list, ...)] Suffix to apply to overlapping column names in the left and right side, respectively.
- **tolerance** [int or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.
- **allow_exact_matches** [bool, default True]
  - If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
  - If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than).
- **direction** ['backward' (default), 'forward', or 'nearest'] Whether to search for prior, subsequent, or closest matches.
Returns

merged [DataFrame]

See also:

merge Merge with a database-style join.
merge_ordered Merge with optional filling/interpolation.

Examples

```python
>>> left = pd.DataFrame({"a": [1, 5, 10], "left_val": ["a", "b", "c"]})
>>> left
   a  left_val
0  1    a
1  5    b
2 10    c

>>> right = pd.DataFrame({"a": [1, 2, 3, 6, 7], "right_val": [1, 2, 3, 6, 7]})
>>> right
   a  right_val
0  1     1
1  2     2
2  3     3
3  6     6
4  7     7

>>> pd.merge_asof(left, right, on="a")
   a  left_val  right_val
0  1    a         1
1  5    b         3
2 10    c        NaN

>>> pd.merge_asof(left, right, on="a", allow_exact_matches=False)
   a  left_val  right_val
0  1    a       NaN
1  5    b        3.0
2 10    c        7.0

>>> pd.merge_asof(left, right, on="a", direction="forward")
   a  left_val  right_val
0  1    a        1.0
1  5    b        6.0
2 10    c       NaN

>>> pd.merge_asof(left, right, on="a", direction="nearest")
   a  left_val  right_val
0  1    a         1
1  5    b         6
2 10    c         7
```

We can use indexed DataFrames as well.
>>> left = pd.DataFrame({"left_val": ["a", "b", "c"], index=[1, 5, 10])
>>> left
  left_val
1    a
5    b
10   c

>>> right = pd.DataFrame({"right_val": [1, 2, 3, 6, 7], index=[1, 2, 3, 6, 7])
>>> right
  right_val
1      1
2      2
3      3
6      6
7      7

Here is a real-world times-series example

>>> quotes = pd.DataFrame({
...   "time": [pd.Timestamp("2016-05-25 13:30:00.023"), pd.Timestamp("2016-05-25 13:30:00.023"),
...            pd.Timestamp("2016-05-25 13:30:00.030"), pd.Timestamp("2016-05-25 13:30:00.041"),
...            pd.Timestamp("2016-05-25 13:30:00.048"), pd.Timestamp("2016-05-25 13:30:00.049"),
...            pd.Timestamp("2016-05-25 13:30:00.072"), pd.Timestamp("2016-05-25 13:30:00.075")],
...   "ticker": ["GOOG", "MSFT", "MSFT", "MSFT", "GOOG", "AAPL", "GOOG", "MSFT"],
...   "bid": [720.50, 51.95, 51.97, 51.99, 720.50, 720.50, 720.50, 52.01],
...   "ask": [720.50, 51.95, 51.97, 51.99, 720.50, 720.50, 720.50, 52.01]
... })

(continues on next page)
0 2016-05-25 13:30:00.023 GOOG 720.50 720.93
1 2016-05-25 13:30:00.023 MSFT 51.95 51.96
2 2016-05-25 13:30:00.030 MSFT 51.97 51.98
3 2016-05-25 13:30:00.041 MSFT 51.99 52.00
4 2016-05-25 13:30:00.048 GOOG 720.50 720.93
5 2016-05-25 13:30:00.049 AAPL 97.99 98.01
6 2016-05-25 13:30:00.072 GOOG 720.50 720.88
7 2016-05-25 13:30:00.075 MSFT 52.01 52.03

```python
>>> trades = pd.DataFrame(
...     {
...         "time": [
...             pd.Timestamp("2016-05-25 13:30:00.023"),
...             pd.Timestamp("2016-05-25 13:30:00.038"),
...             pd.Timestamp("2016-05-25 13:30:00.048"),
...             pd.Timestamp("2016-05-25 13:30:00.048"),
...             pd.Timestamp("2016-05-25 13:30:00.048")
...         ],
...         "ticker": ["MSFT", "MSFT", "GOOG", "GOOG", "AAPL"],
...         "price": [51.95, 51.95, 720.77, 720.92, 98.0],
...         "quantity": [75, 155, 100, 100, 100]
...     }
... )

>>> trades
  time  ticker  price  quantity
0  2016-05-25 13:30:00.023  MSFT   51.95         75
1  2016-05-25 13:30:00.038  MSFT   51.95        155
2  2016-05-25 13:30:00.048  GOOG  720.77        100
3  2016-05-25 13:30:00.048  GOOG  720.92        100
4  2016-05-25 13:30:00.048  AAPL   98.00        100

By default we are taking the asof of the quotes

```python
>>> pd.merge_asof(trades, quotes, on="time", by="ticker")

<table>
<thead>
<tr>
<th>time</th>
<th>ticker</th>
<th>price</th>
<th>quantity</th>
<th>bid</th>
<th>ask</th>
</tr>
</thead>
<tbody>
<tr>

</table>

**pandas.concat**

```python
pandas.concat(objs, axis=0, join='outer', ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, sort=False, copy=True)
```

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

**Parameters**

- **objs** [a sequence or mapping of Series or DataFrame objects] If a mapping is passed, the sorted keys will be used as the keys argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- **axis** [{0/‘index’, 1/‘columns’}, default 0] The axis to concatenate along.

- **join** [{‘inner’, ‘outer’}, default ‘outer’] How to handle indexes on other axis (or axes).

- **ignore_index** [bool, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **keys** [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level.

- **levels** [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

- **names** [list, default None] Names for the levels in the resulting hierarchical index.

- **verify_integrity** [bool, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

- **sort** [bool, default False] Sort non-concatenation axis if it is not already aligned when join is ‘outer’. This has no effect when join='inner', which already preserves the order of the non-concatenation axis.

Changed in version 1.0.0: Changed to not sort by default.
copy  [bool, default True] If False, do not copy data unnecessarily.

Returns

object, type of objs  When concatenating all Series along the index (axis=0), a Series is returned. When objs contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (axis=1), a DataFrame is returned.

See also:

Series.append  Concatenate Series.
DataFrame.append  Concatenate DataFrames.
DataFrame.join  Join DataFrames using indexes.
DataFrame.merge  Merge DataFrames by indexes or columns.

Notes

The keys, levels, and names arguments are all optional.
A walkthrough of how this method fits in with other tools for combining pandas objects can be found here.

Examples

Combine two Series.

```python
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0  a
1  b
0  c
1  d
dtype: object
```

Clear the existing index and reset it in the result by setting the ignore_index option to True.

```python
>>> pd.concat([s1, s2], ignore_index=True)
0  a
1  b
2  c
3  d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the keys option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1  0  a
    1  b
s2  0  c
    1  d
dtype: object
```

Label the index keys you create with the names option.
Combine two DataFrame objects with identical columns.

```python
>>> df1 = pd.DataFrame([['a', 1], ['b', 2]],
                     columns=['letter', 'number'])
>>> df1
     letter number
0       a      1
1       b      2

>>> df2 = pd.DataFrame([['c', 3], ['d', 4]],
                     columns=['letter', 'number'])
>>> df2
     letter number
0       c      3
1       d      4

>>> pd.concat([df1, df2])
     letter number
0       a      1
1       b      2
0       c      3
1       d      4
```

Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```python
>>> df3 = pd.DataFrame([['c', 3, 'cat'], ['d', 4, 'dog']],
                     columns=['letter', 'number', 'animal'])
>>> df3
     letter number animal
0       c      3   cat
1       d      4   dog

>>> pd.concat([df1, df3], sort=False)
     letter number animal
0       a      1   NaN
1       b      2   NaN
0       c      3   cat
1       d      4   dog
```

Combine DataFrame objects with overlapping columns and return only those that are shared by passing inner to the join keyword argument.

```python
>>> pd.concat([df1, df3], join="inner")
     letter number animal
0       a      1   NaN
1       b      2   NaN
```
Combine DataFrame objects horizontally along the x axis by passing in axis=1.

```python
>>> df4 = pd.DataFrame([["bird", "polly"], ["monkey", "george"]],
...                    columns=["animal", "name"])
>>> pd.concat([df1, df4], axis=1)
    letter  number  animal  name
0       a        1   bird    polly
1       b        2  monkey   george
```

Prevent the result from including duplicate index values with the verify_integrity option.

```python
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df5
      0
a  1
>>> df6 = pd.DataFrame([2], index=['a'])
>>> df6
      0
a  2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
  ...:
ValueError: Indexes have overlapping values: ['a']
```

### pandas.get_dummies

`pandas.get_dummies(data, prefix=None, prefix_sep='__', dummy_na=False, columns=None, sparse=False, drop_first=False, dtype=None)`

Convert categorical variable into dummy/indicator variables.

**Parameters**

- **data** [array-like, Series, or DataFrame] Data of which to get dummy indicators.
- **prefix** [str, list of str, or dict of str, default None] String to append DataFrame column names. Pass a list with length equal to the number of columns when calling get_dummies on a DataFrame. Alternatively, `prefix` can be a dictionary mapping column names to prefixes.
- **prefix_sep** [str, default ‘_’] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with `prefix`.
- **dummy_na** [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.
- **columns** [list-like, default None] Column names in the DataFrame to be encoded. If `columns` is None then all the columns with `object` or `category` dtype will be converted.
- **sparse** [bool, default False] Whether the dummy-encoded columns should be backed by a `SparseArray` (True) or a regular NumPy array (False).
- **drop_first** [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.
- **dtype** [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.
Returns

**DataFrame** Dummy-coded data.

See also:

*Series.str.get_dummies* Convert Series to dummy codes.

Examples

```python
>>> s = pd.Series(list('abca'))

```
>>> pd.get_dummies(pd.Series(list('abcaa')), drop_first=True)
    b  c
   0  0  0
   1  1  0
   2  0  1
   3  0  0
   4  0  0

>>> pd.get_dummies(pd.Series(list('abc')), dtype=float)
    a  b  c
   0  1.0  0.0  0.0
   1  0.0  1.0  0.0
   2  0.0  0.0  1.0

**pandas.factorize**

**pandas.factorize(values, sort=False, na_sentinel=-1, size_hint=None)**

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function *pandas.factorize()*, and as a method *Series.factorize()* and *Index.factorize()*.

**Parameters**

- **values** [sequence] A 1-D sequence. Sequences that aren’t pandas objects are coerced to ndarrays before factorization.
- **sort** [bool, default False] Sort *uniques* and shuffle *codes* to maintain the relationship.
- **na_sentinel** [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

- **size_hint** [int, optional] Hint to the hashtable sizer.

**Returns**

- **codes** [ndarray] An integer ndarray that’s an indexer into *uniques*. *uniques.take(codes)* will have the same values as *values*.
- **uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

**Note:** Even if there’s a missing value in *values*, *uniques* will not contain an entry for it.

**See also:**

- **cut** Discretize continuous-valued array.
- **unique** Find the unique value in an array.
Examples

These examples all show factorize as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is the maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
>>> codes
array([ 0,  1,  0, -1])
>>> uniques
array([1., 2.])

>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([1., 2., nan])
```

**pandas.unique**

`pandas.unique(values)`

Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than numpy.unique for long enough sequences. Includes NA values.

**Parameters**

- `values` [1d array-like]

**Returns**

`numpy.ndarray` or `ExtensionArray` The return can be:

- `Index` : when the input is an Index
- `Categorical` : when the input is a Categorical dtype
- `ndarray` : when the input is a Series/ndarray

Return `numpy.ndarray` or `ExtensionArray`.

**See also:**

- `Index.unique` Return unique values from an Index.
- `Series.unique` Return unique values of Series object.

**Examples**

```python
>>> pd.unique(pd.Series([2, 1, 3, 3]))
array([2, 1, 3])

>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])

>>> pd.unique(pd.Series([pd.Timestamp("20160101"), pd.Timestamp("20160101")]))
array(['2016-01-01T00:00:00.000000000', '2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.unique(...
...     pd.Series(...
...         [
```

(continues on next page)
An unordered Categorical will return categories in the order of appearance.

>>> pd.unique(pd.Series(pd.Categorical(list("baabc")))

array(['b', 'a', 'c'], dtype=object)

An ordered Categorical preserves the category ordering.

>>> pd.unique(pd.Series(pd.Categorical(list("baabc"), categories=list("abc")), ordered=True))

array(['b', 'a', 'c'], dtype=object)

An array of tuples

>>> pd.unique(([("a", "b"), ("b", "a"), ("a", "c"), ("b", "a")])

array([('a', 'b'), ('b', 'a'), ('a', 'c')], dtype=object)
pandas: powerful Python data analysis toolkit, Release 1.3.4

pandas.

pandas.

pandas.

Wide panel to long format. Less flexible but more user-friendly than melt.

With stubnames ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2,..., B-suffix1, B-suffix2,... You specify what you want to call this suffix in the resulting long format with \( j \) (for example \( j='year' \))

Each row of these wide variables are assumed to be uniquely identified by \( i \) (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

**Parameters**

- \( df \) [DataFrame] The wide-format DataFrame.
- \( stubnames \) [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.
- \( i \) [str or list-like] Column(s) to use as id variable(s).
- \( j \) [str] Thenameofthesub-observationvariable. Whatyouwishtonameyoursuffixinthelong
  format.
- \( sep \) [str, default ‘’] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying \( sep='-' \).
- \( suffix \) [str, default ‘d+’] A regular expression capturing the wanted suffixes. ‘d+’ captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class ‘\D+’. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,..., and you have an unrelated column A-rating, you can ignore the last one by specifying \( suffix='(!?one|two)' \). When all suffixes are numeric, they are cast to int64/float64.

**Returns**

- \( DataFrame \) A DataFrame that contains each stub name as a variable, with new index (i, j).

See also:

- \( melt \) Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
- \( pivot \) Create a spreadsheet-style pivot table as a DataFrame.
- \( DataFrame.pivot \) Pivot without aggregation that can handle non-numeric data.
- \( DataFrame.pivot_table \) Generalization of pivot that can handle duplicate values for one index/column pair.
- \( DataFrame.unstack \) Pivot based on the index values instead of a column.
Notes

All extra variables are left untouched. This simply uses pandas.melt under the hood, but is hard-coded to “do the right thing” in a typical case.

Examples

```python
>>> np.random.seed(123)
>>> df = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
...       "A1980" : {0 : "d", 1 : "e", 2 : "f"},
...       "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
...       "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
...       "X" : dict(zip(range(3), np.random.randn(3)))
...     })
>>> df["id"] = df.index
>>> df
0      a      d  2.500  3.200 -1.0856  0
1      b      e  1.200  1.300  0.99734  1
2      c      f  0.700  0.100  0.28298  2
>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
X     A     B
id  year
0   1970  -1.0856  a  2.5
1   1970   0.99734  b  1.2
2   1970   0.28298  c  0.7
0   1980  -1.08563  d  3.2
1   1980   0.99734  e  1.3
2   1980   0.28297  f  0.1
```

With multiple id columns

```python
>>> df = pd.DataFrame({
...       'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...       'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...       'ht1': [2.8, 2.9, 2.2, 1.8, 1.9, 2.2, 2.3, 2.1],
...       'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
...     })
>>> df
   famid  birth  ht1  ht2
0     1     1    2.8   3.4
1     1     2    2.9   3.8
2     1     3    2.2   2.9
3     2     1    2.0   3.2
4     2     2    1.8   2.8
5     2     3    1.9   2.4
6     3     1    2.2   3.3
7     3     2    2.3   3.4
8     3     3    2.1   2.9
```

```python
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
```

(continues on next page)
...  

```python
Going from long back to wide just takes some creative use of `unstack`

```python
w = l.unstack()

w.columns = w.columns.map('\{{0}\{1|2\}'.format)

w.reset_index()
```

```bash
famid birth ht1 ht2
0 1 1 2.8 3.4
1 1 2 2.9 3.8
2 1 3 2.2 2.9
3 2 1 2.0 3.2
4 2 2 1.8 2.8
5 2 3 1.9 2.4
6 3 1 2.2 3.3
7 3 2 2.3 3.4
8 3 3 2.1 2.9
```

Less wieldy column names are also handled

```python
np.random.seed(0)

df = pd.DataFrame({'A(weekly)-2010': np.random.rand(3),
                  'A(weekly)-2011': np.random.rand(3),
                  'B(weekly)-2010': np.random.rand(3),
                  'B(weekly)-2011': np.random.rand(3),
                  'X': np.random.randint(3, size=3)})

df['id'] = df.index

df
```

<table>
<thead>
<tr>
<th>A(weekly)-2010</th>
<th>A(weekly)-2011</th>
<th>B(weekly)-2010</th>
<th>B(weekly)-2011</th>
<th>X</th>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.548814</td>
<td>0.544883</td>
<td>0.437587</td>
<td>0.383442</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0.715189</td>
<td>0.423655</td>
<td>0.891773</td>
<td>0.791725</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0.602763</td>
<td>0.645894</td>
<td>0.963663</td>
<td>0.528895</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
>>> pd.wide_to_long(df, ['A(weekly)', 'B(weekly)'], i='id',
...                j='year', sep='-',)
...
    X  A(weekly)  B(weekly)
   id   year
0  2010   0  0.548814  0.437587
1  2010   1  0.715189  0.891773
2  2010   1  0.602763  0.963663
0  2011   0  0.544883  0.383442
1  2011   1  0.423655  0.791725
2  2011   1  0.645894  0.528895
```

If we have many columns, we could also use a regex to find our stubnames and pass that list on to wide_to_long

```python
>>> stubnames = sorted(set([match[0] for match in df.columns.str.findall(r'[A-B]\([A-Za-z0-9]+\)').values if match != []])
...)
>>> list(stubnames)
['A(weekly)', 'B(weekly)']
```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```python
>>> df = pd.DataFrame({
... 'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
... 'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
... 'ht_one': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
... 'ht_two': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   famid  birth  ht_one  ht_two
0     1      1  2.8     3.4
1     1      2  2.9     3.8
2     1      3  2.2     2.9
3     2      1  2.0     3.2
4     2      2  1.8     2.8
5     2      3  1.9     2.4
6     3      1  2.2     3.3
7     3      2  2.3     3.4
8     3      3  2.1     2.9
```

```python
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',
...                     sep='_', suffix=r'\w+',)
>>> l
...
  famid  birth  age  ht
1     1      one  2.8  
      two  3.4
2     1      one  2.9  
      two  3.8
3     1      one  2.2  
      two  2.9
```

(continues on next page)
### 3.2.2 Top-level missing data

- **isna**(obj) Detect missing values for an array-like object.
- **isnull**(obj) Detect missing values for an array-like object.
- **notna**(obj) Detect non-missing values for an array-like object.
- **notnull**(obj) Detect non-missing values for an array-like object.

**pandas.isna**

`pandas.isna(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (`NaN` in numeric arrays, `None` or `NaN` in object arrays, `NaT` in datetimelike).

**Parameters**

- **obj** [scalar or array-like] Object to check for null or missing values.

**Returns**

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**

- **notna** Boolean inverse of pandas.isna.
- **Series.isna** Detect missing values in a Series.
- **DataFrame.isna** Detect missing values in a DataFrame.
- **Index.isna** Detect missing values in an Index.
Examples

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False

>>> pd.isna(pd.NA)
True

>>> pd.isna(np.nan)
True
```

dndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
"2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([[ 'ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0    1    2
0  ant  bee  cat
1  dog  None  fly
>>> pd.isna(df)
   0  1  2
0  False  False  False
1  False  True  False
```

```python
>>> pd.isna(df[1])
   0  1
0  False
1  True
Name: 1, dtype: bool
```
pandas.isnull

pandas.isnull(obj)
Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

- obj [scalar or array-like] Object to check for null or missing values.

Returns

- bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

- notna Boolean inverse of pandas.isna.
- Series.isna Detect missing values in a Series.
- DataFrame.isna Detect missing values in a DataFrame.
- Index.isna Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(pd.NA)
True
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan], [4, 5, np.nan]])
>>> array
array([[ 1., nan],
       [ 4., 5., nan]])
```

```
>>> pd.isna(array)
array([[False, True],
       [False, False, True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
                           '2017-07-08'])
```

(continues on next page)
For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0  1  2
0  ant bee cat
1  dog  None fly
>>> pd.isna(df)
   0  1  2
0  False False False
1  False True False
```

```
>>> pd.isna(df[1])
0  False
1  True
Name: 1, dtype: bool
```

### pandas.notna

`pandas.notna(obj)`     
Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is `NaN` in numeric arrays, `None` or `NaN` in object arrays, `NaT` in datetimelike).

**Parameters**

- **obj**  
  [array-like or object value] Object to check for not null or non-missing values.

**Returns**

- **bool or array-like of bool**  
  For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

- `isna`  
  Boolean inverse of pandas.notna.

- `Series.notna`  
  Detect valid values in a Series.

- `DataFrame.notna`  
  Detect valid values in a DataFrame.

- `Index.notna`  
  Detect valid values in an Index.
Examples

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.notna('dog')
True
```

```python
>>> pd.notna(pd.NA)
False
```

```python
>>> pd.notna(np.nan)
False
```

Ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None,...
                           '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
        dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True, True, False, True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([[ant, 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0 1 2
0 ant bee cat
1 dog None fly
>>> pd.notna(df)
   0 1 2
0 True True True
1 True False True
```

```python
>>> pd.notna(df[1])
0   True
1   False
Name: 1, dtype: bool
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

pandas.notnull

pandas.notnull(obj)
Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

obj [array-like or object value] Object to check for not null or non-missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

isna Boolean inverse of pandas.notna.
Series.notna Detect valid values in a Series.
DataFrame.notna Detect valid values in a DataFrame.
Index.notna Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

>>> pd.notna('dog')
True

>>> pd.notna(pd.NA)
False

>>> pd.notna(np.nan)
False

ndarrays result in an ndarray of booleans.

>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])

>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])

>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])

For indexes, an ndarray of booleans is returned.

>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
                            '2017-07-08'])

>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0  1  2
0 ant bee cat
1 dog None fly
>>> pd.notna(df)
     0  1  2
0  True True True
1  True False True
```

```python
>>> pd.notna(df[1])
0  True
1 False
Name: 1, dtype: bool
```

### 3.2.3 Top-level conversions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>to_numeric</code></td>
<td>Convert argument to a numeric type.</td>
</tr>
</tbody>
</table>

#### pandas.to_numeric

Convert argument to a numeric type.

The default return dtype is `float64` or `int64` depending on the data supplied. Use the `downcast` parameter to obtain other dtypes.

Please note that precision loss may occur if really large numbers are passed in. Due to the internal limitations of `ndarray`, if numbers smaller than -9223372036854775808 (np.iinfo(np.int64).min) or larger than 18446744073709551615 (np.iinfo(np.uint64).max) are passed in, it is very likely they will be converted to float so that they can stored in an `ndarray`. These warnings apply similarly to `Series` since it internally leverages `ndarray`.

**Parameters**

- `arg` [scalar, list, tuple, 1-d array, or Series] Argument to be converted.
- `errors` [‘ignore’, ‘raise’, ‘coerce’], default ‘raise’
  - If ‘raise’, then invalid parsing will raise an exception.
  - If ‘coerce’, then invalid parsing will be set as NaN.
  - If ‘ignore’, then invalid parsing will return the input.
- `downcast` [‘integer’, ‘signed’, ‘unsigned’, ‘float’], default None
  - If not None, and if the data has been successfully cast to a numerical dtype (or if the data was numeric to begin with), downcast that resulting data to the smallest numerical dtype possible according to the following rules:
pandas: powerful Python data analysis toolkit, Release 1.3.4

- ‘integer’ or ‘signed’: smallest signed int dtype (min.: np.int8)
- ‘unsigned’: smallest unsigned int dtype (min.: np.uint8)
- ‘float’: smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the ‘errors’ input.

In addition, downcasting will only occur if the size of the resulting data’s dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

**Returns**

ret Numeric if parsing succeeded. Return type depends on input. Series if Series, otherwise ndarray.

See also:

- `DataFrame.astype` Cast argument to a specified dtype.
- `to_datetime` Convert argument to datetime.
- `to_timedelta` Convert argument to timedelta.
- `numpy.ndarray.astype` Cast a numpy array to a specified type.
- `DataFrame.convert_dtypes` Convert dtypes.

**Examples**

Take separate series and convert to numeric, coercing when told to

```python
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
0 1.0
1 2.0
2 -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0 1.0
1 2.0
2 -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0 1
1 2
2 -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', -3])
>>> pd.to_numeric(s, errors='ignore')
0    apple
1    1.0
2     2
3     -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
```

(continues on next page)
Downcasting of nullable integer and floating dtypes is supported:

```python
>>> s = pd.Series([1, 2, 3], dtype="Int64")
>>> pd.to_numeric(s, downcast="integer")
0 1
1 2
2 3
dtype: Int8
>>> s = pd.Series([1.0, 2.1, 3.0], dtype="Float64")
>>> pd.to_numeric(s, downcast="float")
0 1.0
1 2.1
2 3.0
dtype: Float32
```

### 3.2.4 Top-level dealing with datetimelike

- **to_datetime**(arg[, errors, dayfirst, ...]) Convert argument to datetime.
- **to_timedelta**(arg[, unit, errors]) Convert argument to timedelta.
- **date_range**(start, end, periods, freq, tz, ...) Return a fixed frequency DatetimeIndex.
- **bdate_range**(start, end, periods, freq, tz, ...) Return a fixed frequency DatetimeIndex, with business day as the default frequency.
- **period_range**(start, end, periods, freq, name) Return a fixed frequency PeriodIndex.
- **timedelta_range**(start, end, periods, freq, ...) Return a fixed frequency TimedeltaIndex, with day as the default frequency.
- **infer_freq**(index[, warn]) Infer the most likely frequency given the input index.

**pandas.to_datetime**

- **pandas.to_datetime**(arg, errors='raise', dayfirst=False, yearfirst=False, utc=None, format=None, exact=True, unit=None, infer_datetime_format=False, origin='unix', cache=True) Convert argument to datetime.

**Parameters**

- **arg** [int, float, str, datetime, list, tuple, 1-d array, Series, DataFrame/dict-like] The object to convert to a datetime.
- **errors** [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]  
  - If ‘raise’, then invalid parsing will raise an exception.  
  - If ‘coerce’, then invalid parsing will be set as NaT.  
  - If ‘ignore’, then invalid parsing will return the input.
dayfirst [bool, default False] Specify a date parse order if arg is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: dayfirst=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).

yearfirst [bool, default False] Specify a date parse order if arg is str or its list-likes.

- If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.
- If both dayfirst and yearfirst are True, yearfirst is preceded (same as dateutil).

Warning: yearfirst=True is not strict, but will prefer to parse with year first (this is a known bug, based on dateutil behavior).

utc [bool, default None] Return UTC DatetimeIndex if True (converting any tz-aware datetime.datetime objects as well).

format [str, default None] The strftime to parse time, eg “%d/%m/%Y”, note that “%f” will parse all the way up to nanoseconds. See strftime documentation for more information on choices: https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior.

exact [bool, True by default] Behaves as: - If True, require an exact format match. - If False, allow the format to match anywhere in the target string.

unit [str, default ‘ns’] The unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit=’ms’ and origin=’unix’ (the default), this would calculate the number of milliseconds to the unix epoch start.

infer_datetime_format [bool, default False] If True and no format is given, attempt to infer the format of the datetime strings based on the first non-NaN element, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

origin [scalar, default ‘unix’] Define the reference date. The numeric values would be parsed as number of units (defined by unit) since this reference date.

- If ‘unix’ (or POSIX) time; origin is set to 1970-01-01.
- If ‘julian’, unit must be ‘D’, and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
- If Timestamp convertible, origin is set to Timestamp identified by origin.

cache [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets. The cache is only used when there are at least 50 values. The presence of out-of-bounds values will render the cache unusable and may slow down parsing.

Changed in version 0.25.0: - changed default value from False to True.

Returns
datetime If parsing succeeded. Return type depends on input:

- list-like: DatetimeIndex
- Series: Series of datetime64 dtype
- scalar: Timestamp

In case when it is not possible to return designated types (e.g. when any element of input is before Timestamp.min or after Timestamp.max) return will have datetime.datetime type (or corresponding array/Series).
See also:

- **DataFrame.astype** Cast argument to a specified dtype.
- **to_timedelta** Convert argument to timedelta.
- **convert_dtypes** Convert dtypes.

### Examples

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same.

```python
>>> df = pd.DataFrame({'year': [2015, 2016],
                    ...       'month': [2, 3],
                    ...       'day': [4, 5]})
>>> pd.to_datetime(df)
0 2015-02-04
1 2016-03-05
```

If a date does not meet the timestamp limitations, passing errors='ignore' will return the original input instead of raising any exception.

Passing errors='coerce' will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```python
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing `infer_datetime_format=True` can often-times speed up a parsing if its not an ISO8601 format exactly, but in a regular format.

```python
>>> s.head()
0  3/11/2000
1  3/12/2000
2  3/13/2000
3  3/11/2000
4  3/12/2000
```

```bash
%timeit pd.to_datetime(s, infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
```

```bash
%timeit pd.to_datetime(s, infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```python
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')

(continues on next page)
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')

Warning: For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

>>> pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)

In case input is list-like and the elements of input are of mixed timezones, return will have object type Index if utc=False.

>>> pd.to_datetime(['2018-10-26 12:00 -0530', '2018-10-26 12:00 -0500'], utc=True)
DatetimeIndex(['2018-10-26 17:30:00+00:00', '2018-10-26 17:00:00+00:00'], dtype='datetime64[ns, UTC]', freq=None)

pandas.to_timedelta

pandas.to_timedelta(arg=None, unit=None, errors='raise')

Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

Parameters

arg [str, timedelta, list-like or Series] The data to be converted to timedelta.

Deprecated since version 1.2: Strings with units ‘M’, ‘Y’ and ‘y’ do not represent unambiguous timedelta values and will be removed in a future version

unit [str, optional] Denotes the unit of the arg for numeric arg. Defaults to "ns".

Possible values:

- ‘W’
- ‘D’ / ‘days’ / ‘day’
- ‘hours’ / ‘hour’ / ‘hr’ / ‘h’
- ‘m’ / ‘minute’ / ‘min’ / ‘minutes’ / ‘T’
- ‘S’ / ‘seconds’ / ‘sec’ / ‘second’
- ‘ms’ / ‘millisecond’ / ’milliseconds’ / ‘milli’ / ‘millis’ / ‘L’
- ‘us’ / ‘microseconds’ / ‘microsecond’ / ‘micro’ / ‘micros’ / ‘U’
pandas: powerful Python data analysis toolkit, Release 1.3.4

- ‘ns’ / ‘nanoseconds’ / ‘nano’ / ‘nanos’ / ‘nanosecond’ / ‘N’

Changed in version 1.1.0: Must not be specified when arg context strings and errors="raise".

errors [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]
  - If ‘raise’, then invalid parsing will raise an exception.
  - If ‘coerce’, then invalid parsing will be set as NaT.
  - If ‘ignore’, then invalid parsing will return the input.

Returns
timedelta64 or numpy.array of timedelta64  Output type returned if parsing succeeded.

See also:
- DataFrame.astype  Cast argument to a specified dtype.
- to_datetime  Convert argument to datetime.
- convert_dtypes  Convert dtypes.

Notes
If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds for string inputs.

Examples
Parsing a single string to a Timedelta:

```python
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015500')
```

Parsing a list or array of strings:

```python
>>> pd.to_timedelta(['1 days 06:05:01.000030', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
                dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the *unit* keyword argument:

```python
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
                '0 days 00:00:03', '0 days 00:00:04'],
               dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

pandas.date_range

pandas.date_range(start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, **kwargs)

Return a fixed frequency DatetimeIndex.

Returns the range of equally spaced time points (where the difference between any two adjacent points is specified by the given frequency) such that they all satisfy start ≤ x ≤ end, where the first one and the last one are, resp., the first and last time points in that range that fall on the boundary of freq (if given as a frequency string) or that are valid for freq (if given as a pandas.tseries.offsets.DateOffset). (If exactly one of start, end, or freq is not specified, this missing parameter can be computed given periods, the number of timesteps in the range. See the note below.)

Parameters

- **start** [str or datetime-like, optional] Left bound for generating dates.
- **end** [str or datetime-like, optional] Right bound for generating dates.
- **periods** [int, optional] Number of periods to generate.
- **freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See here for a list of frequency aliases.
- **tz** [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong_Kong’. By default, the resulting DatetimeIndex is timezone-naive.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **name** [str, default None] Name of the resulting DatetimeIndex.
- **closed** [[None, ‘left’, ‘right’], optional] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).

**kwargs For compatibility. Has no effect on the result.

Returns

- **rng** [DatetimeIndex]

See also:

- DatetimeIndex An immutable container for datetimes.
- timedelta_range Return a fixed frequency TimedeltaIndex.
- period_range Return a fixed frequency PeriodIndex.
- interval_range Return a fixed frequency IntervalIndex.

Notes

Of the four parameters start, end, periods, and freq, exactly three must be specified. If freq is omitted, the resulting DatetimeIndex will have periods linearly spaced elements between start and end (closed on both sides).

To learn more about the frequency strings, please see this link.
Examples

Specifying the values

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`. Specify `start` and `end`, with the default daily frequency.

```python
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
       dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```python
>>> pd.date_range(start='1/1/2018', periods=8)
       dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```python
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
               '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
       dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
               '2018-04-27 00:00:00'],
       dtype='datetime64[ns]', freq=None)
```

Other Parameters

Changed the `freq` (frequency) to ‘M’ (month end frequency).

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
               '2018-05-31'],
       dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
               '2019-01-31'],
       dtype='datetime64[ns]', freq='3M')
```

`freq` can also be specified as an Offset object.

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
               '2019-01-31'],
       dtype='datetime64[ns]', freq='3M')
```
Specify tz to set the timezone.

```python
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
              '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
              '2018-01-05 00:00:00+09:00'],
   dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

closed controls whether to include start and end that are on the boundary. The default includes boundary points on either end.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
   dtype='datetime64[ns]', freq='D')
```

Use closed='left' to exclude end if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
   dtype='datetime64[ns]', freq='D')
```

Use closed='right' to exclude start if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
   dtype='datetime64[ns]', freq='D')
```

### pandas.bdate_range

pandas.bdate_range(\n    start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, \n    weekmask=None, holidays=None, closed=None, **kwargs)\n
Return a fixed frequency DatetimeIndex, with business day as the default frequency.

Parameters:

- **start** [str or datetime-like, default None] Left bound for generating dates.
- **end** [str or datetime-like, default None] Right bound for generating dates.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, default 'B' (business daily)] Frequency strings can have multiples, e.g. '5H'.
- **tz** [str or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **name** [str, default None] Name of the resulting DatetimeIndex.
- **weekmask** [str or None, default None] Weekmask of valid business days, passed to numpy.busdaycalendar; only used when custom frequency strings are passed. The default value None is equivalent to 'Mon Tue Wed Thu Fri'.
- **holidays** [list-like or None, default None] Dates to exclude from the set of valid business days, passed to numpy.busdaycalendar; only used when custom frequency strings are passed.
closed [str, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None).

**kwargs For compatibility. Has no effect on the result.

Returns

DatetimeIndex

Notes

Of the four parameters: start, end, periods, and freq, exactly three must be specified. Specifying freq is a requirement for bdate_range. Use date_range if specifying freq is not desired.

To learn more about the frequency strings, please see this link.

Examples

Note how the two weekend days are skipped in the result.

```python
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
```

pandas.period_range

pandas.period_range(start=None, end=None, periods=None, freq=None, name=None)

Return a fixed frequency PeriodIndex.

The day (calendar) is the default frequency.

Parameters

- **start** [str or period-like, default None] Left bound for generating periods.
- **end** [str or period-like, default None] Right bound for generating periods.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, optional] Frequency alias. By default the freq is taken from start or end if those are Period objects. Otherwise, the default is "D" for daily frequency.
- **name** [str, default None] Name of the resulting PeriodIndex.

Returns

PeriodIndex

3.2. General functions
Notes

Of the three parameters: start, end, and periods, exactly two must be specified.
To learn more about the frequency strings, please see this link.

Examples

```python
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05', '2017-06',
             '2017-07', '2017-08', '2017-09', '2017-10', '2017-11', '2017-12',
             '2018-01'],
            dtype='period[M]')
```

If start or end are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the period_range constructor.

```python
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
                  end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]')
```

**pandas.timedelta_range**

pandas.timedelta_range
(start=None, end=None, periods=None, freq=None, name=None, closed=None)

Return a fixed frequency TimedeltaIndex, with day as the default frequency.

Parameters

- **start** [str or timedelta-like, default None] Left bound for generating timedeltas.
- **end** [str or timedelta-like, default None] Right bound for generating timedeltas.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’.
- **name** [str, default None] Name of the resulting TimedeltaIndex.
- **closed** [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).

Returns

TimedeltaIndex

Notes

Of the four parameters start, end, periods, and freq, exactly three must be specified. If freq is omitted, the resulting TimedeltaIndex will have periods linearly spaced elements between start and end (closed on both sides).
To learn more about the frequency strings, please see this link.
Examples

```python
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```python
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the TimedeltaIndex. Only fixed frequencies can be passed, non-fixed frequencies such as 'M' (month end) will raise.

```python
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00', '1 days 18:00:00', '2 days 00:00:00'], dtype='timedelta64[ns]', freq='6H')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```python
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00', '5 days 00:00:00'], dtype='timedelta64[ns]', freq=None)
```

### pandas.infer_freq

`pandas.infer_freq(index, warn=True)`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

**Parameters**

- `index` [DatetimeIndex or TimedeltaIndex] If passed a Series will use the values of the series (NOT THE INDEX).
- `warn` [bool, default True]

**Returns**

- `str` or `None` None if no discernible frequency.

**Raises**

- `TypeError` If the index is not datetime-like.
- `ValueError` If there are fewer than three values.
3.2.5 Top-level dealing with intervals

```
>>> idx = pd.date_range(start='2020/12/01', end='2020/12/30', periods=30)
>>> pd.infer_freq(idx)
'D'
```

```
interval_range([start, end, periods, freq, ...]) Return a fixed frequency IntervalIndex.
```

**pandas.interval_range**

```
pandas.interval_range(start=None, end=None, periods=None, freq=None, name=None, closed='right')
```

Return a fixed frequency IntervalIndex.

**Parameters**

- **start** [numeric or datetime-like, default None] Left bound for generating intervals.
- **end** [numeric or datetime-like, default None] Right bound for generating intervals.
- **periods** [int, default None] Number of periods to generate.
- **freq** [numeric, str, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or ‘5H’ for datetime-like. Default is 1 for numeric and ‘D’ for datetime-like.
- **name** [str, default None] Name of the resulting IntervalIndex.
- **closed** [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

- **IntervalIndex**

**See also:**

- IntervalIndex An Index of intervals that are all closed on the same side.

**Notes**

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting IntervalIndex will have periods linearly spaced elements between `start` and `end`, inclusively.

To learn more about datetime-like frequency strings, please see this link.
Examples

Numeric start and end is supported.

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]),
dtype='interval[int64, right]')
```

Additionally, datetime-like input is also supported.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
... end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
... (2017-01-03, 2017-01-04]],
dtype='interval[datetime64[ns], right]')
```

The `freq` parameter specifies the frequency between the left and right endpoints of the individual intervals within the `IntervalIndex`. For numeric start and end, the frequency must also be numeric.

```python
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
dtype='interval[float64, right]')
```

Similarly, for datetime-like start and end, the frequency must be convertible to a DateOffset.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
... periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
... (2017-03-01, 2017-04-01]],
dtype='interval[datetime64[ns], right]')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```python
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
dtype='interval[float64, right]')
```

The `closed` parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```python
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]],
dtype='interval[int64, both]')
```

### 3.2.6 Top-level evaluation

`eval(expr[, parser, engine, truediv, ...])` Evaluate a Python expression as a string using various backends.
The following arithmetic operations are supported: +, -, *, /, **, %, // (python engine only) along with the following boolean operations: | (or), & (and), and ~ (not). Additionally, the 'pandas' parser allows the use of and, or, and not with the same semantics as the corresponding bitwise operators. Series and DataFrame objects are supported and behave as they would with plain ol’ Python evaluation.

Parameters

- **expr** [str] The expression to evaluate. This string cannot contain any Python statements, only Python expressions.
- **parser** [{‘pandas’, ‘python’}, default ‘pandas’] The parser to use to construct the syntax tree from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the enhancing performance documentation for more details.
- **engine** [{‘python’, ‘numexpr’}, default ‘numexpr’] The engine used to evaluate the expression. Supported engines are
  - None : tries to use numexpr, falls back to python
  - 'numexpr': This default engine evaluates pandas objects using numexpr for large speed ups in complex expressions with large frames.
  - 'python': Performs operations as if you had eval’d in top level python. This engine is generally not that useful.

More backends may be available in the future.

- **truediv** [bool, optional] Whether to use true division, like in Python >= 3.
  - Deprecated since version 1.0.0.
- **local_dict** [dict or None, optional] A dictionary of local variables, taken from locals() by default.
- **global_dict** [dict or None, optional] A dictionary of global variables, taken from globals() by default.
- **resolvers** [list of dict-like or None, optional] A list of objects implementing the __getitem__ special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the query() method to inject the DataFrame. index and DataFrame. columns variables that refer to their respective DataFrame instance attributes.
- **level** [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will not need to change this parameter.
- **target** [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then target must support item assignment with string keys, and if a copy is being returned, it must also support .copy().
- **inplace** [bool, default False] If target is provided, and the expression mutates target, whether to modify target inplace. Otherwise, return a copy of target with the mutation.

Returns

- ndarray, numeric scalar, DataFrame, Series, or None The completion value of evaluating the given code or None if inplace=True.
Raises

**ValueError** There are many instances where such an error can be raised:

- \( \text{target} = \text{None} \), but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:
  \[
  a = b + 1 \quad a + 2
  \]
  Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of \( a + 2 \).
- \( \text{inplace} = \text{True} \), but the expression is missing item assignment.
- Item assignment is provided, but the \text{target} does not support string item assignment.
- Item assignment is provided and \( \text{inplace} = \text{False} \), but the \text{target} does not support the .\text{copy}() method

**See also:**

- **DataFrame\_query** Evaluates a boolean expression to query the columns of a frame.
- **DataFrame\_eval** Evaluate a string describing operations on DataFrame columns.

**Notes**

The \text{dtype} of any objects involved in an arithmetic \% operation are recursively cast to `\text{float64}`.

See the *enhancing performance* documentation for more details.

**Examples**

```python
>>> df = pd.DataFrame({"animal": ["dog", "pig"], "age": [10, 20]})
>>> df
animal  age
0     dog   10
1     pig   20
```

We can add a new column using \text{pd.eval}:

```python
>>> pd.eval("double_age = df.age * 2", target=df)
animal  age  double_age
0     dog    10      20
1     pig    20      40
```
3.2.7 Hashing

util.hash_array(vals[, encoding, hash_key, ...])
Given a 1d array, return an array of deterministic integers.

util.hash_pandas_object(obj[, index, ...])
Return a data hash of the Index/Series/DataFrame.

pandas.util.hash_array

pandas.util.hash_array(vals, encoding='utf8', hash_key='0123456789123456', categorize=True)
Given a 1d array, return an array of deterministic integers.

Parameters
  vals [ndarray or ExtensionArray]
  encoding [str, default 'utf8'] Encoding for data & key when strings.
  hash_key [str, default _default_hash_key] Hash_key for string key to encode.
  categorize [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

Returns
  ndarray[np.uint64, ndim=1] Hashed values, same length as the vals.

pandas.util.hash_pandas_object

pandas.util.hash_pandas_object(obj, index=True, encoding='utf8', hash_key='0123456789123456', categorize=True)
Return a data hash of the Index/Series/DataFrame.

Parameters
  obj [Index, Series, or DataFrame]
  index [bool, default True] Include the index in the hash (if Series/DataFrame).
  encoding [str, default 'utf8'] Encoding for data & key when strings.
  hash_key [str, default _default_hash_key] Hash_key for string key to encode.
  categorize [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

Returns
  Series of uint64, same length as the object
3.2.8 Testing

```python
test(extra_args)
```

pandas.test

```python
pandas.test(extra_args=None)
```

### 3.3 Series

#### 3.3.1 Constructor

| `Series([data, index, dtype, name, copy, ...])` | One-dimensional ndarray with axis labels (including time series). |

pandas.Series

```python
class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fastpath=False)
```

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *) align values based on their associated index values— they need not be the same length. The result index will be the sorted union of the two indexes.

**Parameters**

- **data** [array-like, Iterable, dict, or scalar value] Contains data stored in Series. If data is a dict, argument order is maintained.
- **index** [array-like or Index (1d)] Values must be hashable and have the same length as `data`. Non-unique index values are allowed. Will default to RangeIndex (0, 1, 2, ..., n) if not provided. If data is dict-like and index is None, then the keys in the data are used as the index. If the index is not None, the resulting Series is reindexed with the index values.
- **dtype** [str, numpy.dtype, or ExtensionDtype, optional] Data type for the output Series. If not specified, this will be inferred from `data`. See the user guide for more usages.
- **name** [str, optional] The name to give to the Series.
- **copy** [bool, default False] Copy input data. Only affects Series or 1d ndarray input. See examples.
Examples

Constructing Series from a dictionary with an Index specified

```python
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['a', 'b', 'c'])
>>> ser
a 1
b 2
c 3
dtype: int64
```

The keys of the dictionary match with the Index values, hence the Index values have no effect.

```python
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['x', 'y', 'z'])
>>> ser
x NaN
y NaN
z NaN
dtype: float64
```

Note that the Index is first build with the keys from the dictionary. After this the Series is reindexed with the given Index values, hence we get all NaN as a result.

Constructing Series from a list with `copy=False`.

```python
>>> r = [1, 2]
>>> ser = pd.Series(r, copy=False)
>>> ser.iloc[0] = 999
>>> r
[1, 2]
>>> ser
0 999
1 2
dtype: int64
```

Due to input data type the Series has a `copy` of the original data even though `copy=False`, so the data is unchanged.

Constructing Series from a 1d ndarray with `copy=False`.

```python
>>> r = np.array([1, 2])
>>> ser = pd.Series(r, copy=False)
>>> ser.iloc[0] = 999
>>> r
array([999, 2])
>>> ser
0 999
1 2
dtype: int64
```

Due to input data type the Series has a `view` on the original data, so the data is changed as well.
Attributes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td>array</td>
<td>The ExtensionArray of the data backing this Series or Index.</td>
</tr>
<tr>
<td>at</td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td>attrs</td>
<td>Dictionary of global attributes of this dataset.</td>
</tr>
<tr>
<td>axes</td>
<td>Return a list of the row axis labels.</td>

<tr>
<td>dtype</td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td>dtypes</td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td>flags</td>
<td>Get the properties associated with this pandas object.</td>
</tr>
<tr>
<td>hasnans</td>
<td>Return if I have any nans; enables various perf speedups.</td>
</tr>
<tr>
<td>iat</td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td>iloc</td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td>index</td>
<td>The index (axis labels) of the Series.</td>
</tr>
<tr>
<td>is_monotonic</td>
<td>Return boolean if values in the object are monotonic_increasing.</td>
</tr>
<tr>
<td>is_monotonic_decreasing</td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
<tr>
<td>is_monotonic_increasing</td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td>is_unique</td>
<td>Return boolean if values in the object are unique.</td>
</tr>
<tr>
<td>loc</td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td>name</td>
<td>Return the name of the Series.</td>
</tr>
<tr>
<td>nbytes</td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td>ndim</td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td>shape</td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td>size</td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td>values</td>
<td>Return Series as ndarray or ndarray-like depending on the dtype.</td>
</tr>
</tbody>
</table>

**pandas.Series.T**

*property Series.T*

Return the transpose, which is by definition self.

**pandas.Series.array**

*property Series.array*

The ExtensionArray of the data backing this Series or Index.

**Returns**

*ExtensionArray* An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`. 

3.3. Series
.array differs .values which may require converting the data to a different form.

See also:

- **Index.to_numpy** Similar method that always returns a NumPy array.
- **Series.to_numpy** Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>DType</th>
<th>Array Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use **Series.to_numpy()** instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned.

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

**pandas.Series.at**

**property** Series.at

Access a single value for a row/column label pair.

Similar to loc, in that both provide label-based lookups. Use at if you only need to get or set a single value in a DataFrame or Series.

**Raises**

- **KeyError** If ‘label’ does not exist in DataFrame.
See also:

DataFrame.iat  Access a single value for a row/column pair by integer position.

DataFrame.loc  Access a group of rows and columns by label(s).

Series.at  Access a single value using a label.

Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                      index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```

pandas.Series.attrs

property Series.attrs
Dictionary of global attributes of this dataset.

**Warning:**  attrs is experimental and may change without warning.

See also:

DataFrame.flags  Global flags applying to this object.
pandas.Series.axes

property Series.axes
Return a list of the row axis labels.

pandas.Series.dtype

property Series.dtype
Return the dtype object of the underlying data.

pandas.Series.dtypes

property Series.dtypes
Return the dtype object of the underlying data.

pandas.Series.flags

property Series.flags
Get the properties associated with this pandas object.

The available flags are

• Flags.allows_duplicate_labels

See also:

Flags Flags that apply to pandas objects.
DataFrame.attrs Global metadata applying to this dataset.

Notes

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in DataFrame.attrs.

Examples

>>> df = pd.DataFrame("
A": [1, 2])
>>> df.flags
<Flags(allows_duplicate_labels=True)>

Flags can be get or set using .

>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False

Or by slicing with a key
pandas.Series.hasnans

**property Series.hasnans**

Return if I have any nans; enables various perf speedups.

pandas.Series.iat

**property Series.iat**

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

`IndexError` When integer position is out of bounds.

See also:

`DataFrame.at` Access a single value for a row/column label pair.

`DataFrame.loc` Access a group of rows and columns by label(s).

`DataFrame.iloc` Access a group of rows and columns by integer position(s).

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
```

```python
1
```

Set value at specified row/column pair

```python
>>> df.iat[1, 2] = 10
```

```python
>>> df.iat[1, 2]
```

```
10
```

Get value within a series
pandas.Series.iloc

**property** Series.iloc

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at *Selection by Position*.

See also:

DataFrame.iat Fast integer location scalar accessor.

DataFrame.loc Purely label-location based indexer for selection by label.

Series.iloc Purely integer-location based indexing for selection by position.

**Examples**

```python
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
             {'a': 100, 'b': 200, 'c': 300, 'd': 400},
             {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
     a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

**Indexing just the rows**

With a scalar integer.

```python
>>> type(df.iloc[0])<class 'pandas.core.series.Series'>
>>> df.iloc[0]
```

(continues on next page)
With a list of integers.

```python
>>> df.iloc[[0]]
    a  b  c  d
0  1  2  3  4

>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

With a slice object.

```python
>>> df.iloc[:3]
    a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```python
>>> df.iloc[[True, False, True]]
    a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The x passed to the lambda is the DataFrame being sliced. This selects the rows whose index label even.

```python
>>> df.iloc[lambda x: x.index % 2 == 0]
    a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000
```

**Indexing both axes**

You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

```python
>>> df.iloc[0, 1]
2
```

With lists of integers.
>>> df.iloc[[0, 2], [1, 3]]
   b  d
0  2  4
2 2000 4000

With *slice* objects.

>>> df.iloc[1:3, 0:3]
   a  b  c
1  100 200 300
2 1000 2000 3000

With a boolean array whose length matches the columns.

>>> df.iloc[:, [True, False, True, False]]
   a  c
0  1  3
1 100 300
2 1000 3000

With a callable function that expects the Series or DataFrame.

```python
>>> df.iloc[:, lambda df: [0, 2]]
   a  c
0  1  3
1 100 300
2 1000 3000
```

**pandas.Series.index**

*Series.index*

The index (axis labels) of the Series.

**pandas.Series.is_monotonic**

*property Series.is_monotonic*

Return boolean if values in the object are monotonic_increasing.

*Returns*

bool

**pandas.Series.is_monotonic_decreasing**

*property Series.is_monotonic_decreasing*

Return boolean if values in the object are monotonic_decreasing.

*Returns*

bool
**pandas.Series.is_monotonic_increasing**

**property Series.is_monotonic_increasing**

Alias for is_monotonic.

**pandas.Series.is_unique**

**property Series.is_unique**

Return boolean if values in the object are unique.

Returns

bool

**pandas.Series.loc**

**property Series.loc**

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
- An alignable Index. The Index of the returned selection will be the input.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*.

Raises

- **KeyError** If any items are not found.
- **IndexingError** If an indexed key is passed and its index is unalignable to the frame index.

See also:

- **DataFrame.at** Access a single value for a row/column label pair.
- **DataFrame.iloc** Access group of rows and columns by integer position(s).
- **DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- **Series.loc** Access group of values using labels.
Examples

Getting values

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                    index=['cobra', 'viper', 'sidewinder'],
                    columns=['max_speed', 'shield'])
>>> df
           max_speed  shield
   cobra         1       2
   viper         4       5
   sidewinder    7       8
```

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
   max_speed  shield
   viper      4       5

Name: viper, dtype: int64
```

List of labels. Note using `[]` returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
           max_speed  shield
   viper         4       5
   sidewinder    7       8
```

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc['cobra': 'viper', 'max_speed']
   cobra        1
   viper         4

Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```python
>>> df.loc[[False, False, True]]
           max_speed  shield
   sidewinder    7       8
```

Alignable boolean Series:

```python
>>> df.loc[pd.Series([False, True, False],
                    index=['viper', 'sidewinder', 'cobra'])]
           max_speed  shield
   sidewinder    7       8
```

Index (same behavior as `df.reindex`)
>>> df.loc[pd.Index(["cobra", "viper"], name="foo")]
   max_speed  shield
   foo
   cobra     1     2
   viper     4     5

Conditional that returns a boolean Series

>>> df.loc[df['shield'] > 6]
   max_speed  shield
   sidewinder 7     8

Conditional that returns a boolean Series with column labels specified

>>> df.loc[df['shield'] > 6, ['max_speed']]
   max_speed
   sidewinder 7

Callable that returns a boolean Series

>>> df.loc[lambda df: df['shield'] == 8]
   max_speed  shield
   sidewinder 7     8

Setting values

Set value for all items matching the list of labels

>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50

Set value for an entire row

>>> df.loc['cobra'] = 10

Set value for an entire column

>>> df.loc[:, 'max_speed'] = 30

Set value for rows matching callable condition
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
>>> df.loc[df['shield'] > 35] = 0
```

```python
>>> df
   max_speed  shield
cobra      30      10
viper       0       0
sidewinder  0       0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                      index=[7, 8, 9], columns=['max_speed', 'shield'])
```

```python
>>> df
   max_speed  shield
    7          1
    8          4
    9          7
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc[7:9]
   max_speed  shield
    7          1
    8          4
    9          7
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
>>> tuples = [
    ... ('cobra', 'mark i'), ('cobra', 'mark ii'),
    ... ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
    ... ('viper', 'mark ii'), ('viper', 'mark iii')
    ... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
    ... [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
```

```python
>>> df
   max_speed  shield
    cobra mark i     12
          mark ii    2
    sidewinder mark i  10
          mark ii     4
    viper  mark ii     7
          mark iii   16
```

Single label. Note this returns a DataFrame with a single index.

```python
>>> df.loc['cobra']
   max_speed  shield
    cobra mark i     12
          mark ii    2
```

(continues on next page)
Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield       4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield       2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]  
max_speed    [0 4]
shield       [4 4]
Name: (cobra, mark ii), dtype: int64
```

Single tuple for the index with a single label for the column

```
>>> df.loc[['cobra', 'mark i'], 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[['cobra', 'mark i']]:'viper']
max_speed shield
cobra mark i 12 2
mark ii 0 4
sidewinder mark i 10 20
mark ii 1 4
viper mark ii 7 1
mark iii 16 36
```

Slice from index tuple to index tuple

```
>>> df.loc[['cobra', 'mark i']]:('viper', 'mark ii')]
max_speed shield
cobra mark i 12 2
mark ii 0 4
sidewinder mark i 10 20
mark ii 1 4
viper mark ii 7 1
```
**pandas.Series.name**

**property Series.name**

Return the name of the Series.

The name of a Series becomes its index or column name if it is used to form a DataFrame. It is also used whenever displaying the Series using the interpreter.

**Returns**

- **label (hashable object)** The name of the Series, also the column name if part of a DataFrame.

**See also:**

- **Series.rename** Sets the Series name when given a scalar input.
- **Index.name** Corresponding Index property.

**Examples**

The Series name can be set initially when calling the constructor.

```python
>>> s = pd.Series([1, 2, 3], dtype=np.int64, name='Numbers')
>>> s
0 1
1 2
2 3
Name: Numbers, dtype: int64
>>> s.name = "Integers"
>>> s
0 1
1 2
2 3
Name: Integers, dtype: int64
```

The name of a Series within a DataFrame is its column name.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4], [5, 6]],
...                   columns=['Odd Numbers', 'Even Numbers'])
>>> df
   Odd Numbers  Even Numbers
0       1         2
1       3         4
2       5         6
>>> df["Even Numbers"].name
'Even Numbers'
```
**pandas.Series.nbytes**

*property* `Series.nbytes`

Return the number of bytes in the underlying data.

**pandas.Series.ndim**

*property* `Series.ndim`

Number of dimensions of the underlying data, by definition 1.

**pandas.Series.shape**

*property* `Series.shape`

Return a tuple of the shape of the underlying data.

**pandas.Series.size**

*property* `Series.size`

Return the number of elements in the underlying data.

**pandas.Series.values**

*property* `Series.values`

Return Series as ndarray or ndarray-like depending on the dtype.

```
Warning: We recommend using `Series.array` or `Series.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.
```

Returns

```
numpy.ndarray or ndarray-like
```

See also:

- `Series.array` Reference to the underlying data.
- `Series.to_numpy` A NumPy array representing the underlying data.

**Examples**

```python
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])
```

```python
>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```
```python
>>> pd.Series(list('aabc')).astype('category').values
['a', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Timezone aware datetime data is converted to UTC:

```python
>>> pd.Series(pd.date_range('20130101', periods=3,
...                           tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
       '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'],
      dtype='datetime64[ns]')
```

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>add(other[, level, fill_value, axis])</code></td>
<td>Return Addition of series and other, element-wise (binary operator <code>add</code>).</td>
</tr>
<tr>
<td><code>add_prefix(prefix)</code></td>
<td>Prefix labels with string <code>prefix</code>.</td>
</tr>
<tr>
<td><code>add_suffix(suffix)</code></td>
<td>Suffix labels with string <code>suffix</code>.</td>
</tr>
<tr>
<td><code>agg(func, axis)</code>)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>aggregate(func, axis)</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>align(other[, join, axis, level, copy, ...])</code></td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>all([axis, bool_only, skipna, level])</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>any([axis, bool_only, skipna, level])</code></td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td><code>append(to_append[, ignore_index, ...])</code></td>
<td>Concatenate two or more Series.</td>
</tr>
<tr>
<td><code>apply(func[, convert_dtype, args])</code></td>
<td>Invoke function on values of Series.</td>
</tr>
<tr>
<td><code>argmax([axis, skipna])</code></td>
<td>Return int position of the largest value in the Series.</td>
</tr>
<tr>
<td><code>argmin([axis, skipna])</code></td>
<td>Return int position of the smallest value in the Series.</td>
</tr>
<tr>
<td><code>argsort([axis, kind, order])</code></td>
<td>Return the integer indices that would sort the Series values.</td>
</tr>
<tr>
<td><code>asfreq(freq[, method, how, normalize, ...])</code></td>
<td>Convert time series to specified frequency.</td>
</tr>
<tr>
<td><code>asof(where[, subset])</code></td>
<td>Return the last row(s) without any NaNs before <code>where</code>.</td>
</tr>
<tr>
<td><code>astype(dtype[, copy, errors])</code></td>
<td>Cast a pandas object to a specified dtype <code>dtype</code>.</td>
</tr>
<tr>
<td><code>at_time(time[, asof, axis])</code></td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td><code>autocorr([lag])</code></td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td><code>backfill([axis, inplace, limit, downcast])</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method= 'bfill'.</td>
</tr>
<tr>
<td><code>between(left, right[, inclusive])</code></td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
</tbody>
</table>

<td><code>corr()</code></td>
<td>Compute correlation with <code>other</code> Series, excluding missing values.</td>
</tr>
<tr>
<td><code>count()</code></td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td><code>cov()</code></td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td><code>cummax()</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cummin()</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumprod()</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumsum()</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>describe()</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>diff()</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>div()</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>divide()</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>divmod()</code></td>
<td>Return Integer division and modulo of series and other, element-wise (binary operator <code>divmod</code>).</td>
</tr>
<tr>
<td><code>dot()</code></td>
<td>Compute the dot product between the Series and the columns of other.</td>
</tr>
<tr>
<td><code>drop()</code></td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td><code>drop_duplicates()</code></td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td><code>droplevel()</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>dropna()</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>duplicated()</code></td>
<td>Indicate duplicate Series values.</td>
</tr>
<tr>
<td><code>eq()</code></td>
<td>Return Equal to of series and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
</tbody>

Table 34 – continued from previous page

- **map**(arg[, na_action]) Map values of Series according to input correspondence.
- **mask**(cond[, other, inplace, axis, level, ...]) Replace values where the condition is True.
- **max**(axis, skipna, numeric_only) Return the maximum of the values over the requested axis.
- **mean**(axis, skipna, numeric_only) Return the mean of the values over the requested axis.
- **median**(axis, skipna, numeric_only) Return the median of the values over the requested axis.
- **memory_usage**(index, deep) Return the memory usage of the Series.
- **min**(axis, skipna, numeric_only) Return the minimum of the values over the requested axis.
- **mod**(other[, level, fill_value, axis]) Return Modulo of series and other, element-wise (binary operator mod).
- **mode**(dropna) Return the mode(s) of the Series.
- **mul**(other[, level, fill_value, axis]) Return Multiplication of series and other, element-wise (binary operator mul).
- **multiply**(other[, level, fill_value, axis]) Return Multiplication of series and other, element-wise (binary operator mul).
- **ne**(other[, level, fill_value, axis]) Return Not equal to of series and other, element-wise (binary operator ne).
- **nlargest**(n, keep) Return the largest n elements.
- **notna** Detect existing (non-missing) values.
- **notnull** Detect existing (non-missing) values.
- **nsmallest**(n, keep) Return the smallest n elements.
- **nunique**(dropna) Return number of unique elements in the object.
- **pad**(axis, inplace, limit, downcast) Synonym for DataFrame.fillna() with method='ffill'.
- **pct_change**(periods, fill_method, limit, freq) Percentage change between the current and a prior element.
- **pipe**(func, *args, **kwargs) Apply func.sell, *args, **kwargs).
- **plot** alias of pandas.plotting._core.PlotAccessor
- **pop**(item) Return item and drops from series.
- **pow**(other[, level, fill_value, axis]) Return Exponential power of series and other, element-wise (binary operator pow).
- **prod**(axis, skipna, numeric_only, ...]) Return the product of the values over the requested axis.
- **product**(axis, skipna, numeric_only, ...]) Return the product of the values over the requested axis.
- **quantile**(q, interpolation) Return value at the given quantile.
- **radd**(other[, level, fill_value, axis]) Return Addition of series and other, element-wise (binary operator radd).
- **rank**(axis, method, numeric_only, ...) Compute numerical data ranks (1 through n) along axis.
- **ravel**(order) Return the flattened underlying data as an ndarray.
- **rdiv**(other[, level, fill_value, axis]) Return Floating division of series and other, element-wise (binary operator rtruediv).
- **rdivmod**(other[, level, fill_value, axis]) Return Integer division and modulo of series and other, element-wise (binary operator rdivmod).
- **reindex**(index) Conform Series to new index with optional filling logic.

continues on next page
pandas.Series.abs

Series.abs()
Return a Series/DataFrame with absolute numeric value of each element.
This function only applies to elements that are all numeric.

Returns
abs  Series/DataFrame containing the absolute value of each element.

See also:
numpy.absolute  Calculate the absolute value element-wise.

Notes
For complex inputs, 1.2 + 1j, the absolute value is $\sqrt{a^2 + b^2}$.

Examples
Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1     2.00
2     3.33
3     4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```python
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
... })
(continues on next page)```
...  'c': [100, 50, -30, -50]
... })
>>> df
    a  b  c
0  4  10  100
1  5  20  50
2  6  30  -30
3  7  40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
    a  b  c
1  5  20  50
0  4  10  100
2  6  30  -30
3  7  40  -50

**pandas.Series.add**

*pandas.Series.add*(other, level=None, fill_value=None, axis=0)

Return Addition of series and other, element-wise (binary operator `add`).

Equivalent to `series + other`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- **Series** The result of the operation.

See also:

- **Series.radd** Reverse of the Addition operator, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
```
```python
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.add(b, fill_value=0)
a  2.0
b  1.0
c  1.0
d  1.0
e  NaN
dtype: float64
```

**pandas.Series.add_prefix**

Series.add_prefix\(prefix\)

Prefix labels with string \(prefix\).

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters**

- `prefix` \([str]\) The string to add before each label.

**Returns**

Series or DataFrame New Series or DataFrame with updated labels.

**See also:**

- Series.add_suffix Suffix row labels with string `suffix`.
- DataFrame.add_suffix Suffix column labels with string `suffix`.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```python
>>> s.add_prefix('item_')
item_0  1
item_1  2
item_2  3
item_3  4
dtype: int64
```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})

>>> df
A  B
0 1 3
1 2 4
2 3 5
3 4 6

>>> df.add_prefix('col_')
   col_A  col_B
0     1     3
1     2     4
2     3     5
3     4     6

**pandas.Series.add_suffix**

Series.add_suffix(suffix)

Suffix labels with string suffix.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**

- **suffix** [str] The string to add after each label.

**Returns**

- **Series or DataFrame** New Series or DataFrame with updated labels.

See also:

- **Series.add_prefix** Prefix row labels with string prefix.
- **DataFrame.add_prefix** Prefix column labels with string prefix.

**Examples**

>>> s = pd.Series([1, 2, 3, 4])

>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_suffix('_col')
   A_col  B_col
0      1      3
1      2      4
2      3      5
3      4      6
```

### pandas.Series.agg

`Series.agg(func=None, axis=0, *args, **kwargs)`
Aggregate using one or more operations over the specified axis.

**Parameters**
- `func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.
  
  Accepted combinations are:
  - function
  - string function name
  - list of functions and/or function names, e.g. `[np.sum, 'mean']`
  - dict of axis labels -> functions, function names or list of such.

- `axis` `{0 or 'index'}` Parameter needed for compatibility with DataFrame.
- `*args` Positional arguments to pass to `func`.
- `**kwargs` Keyword arguments to pass to `func`.

**Returns**
- `scalar, Series or DataFrame` The return can be:
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**
- `Series.apply` Invoke function on a Series.
- `Series.transform` Transform function producing a Series with like indexes.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
min  1
max  4
dtype: int64
```

**pandas.Series.aggregate**

`Series.aggregate(func=None, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

**Parameters**

- `func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.
  
  Accepted combinations are:
  
  • function
  
  • string function name
  
  • list of functions and/or function names, e.g. `[np.sum, 'mean']`
  
  • dict of axis labels -> functions, function names or list of such.

- `axis` `{0 or 'index'}` Parameter needed for compatibility with DataFrame.

- `*args` Positional arguments to pass to `func`.

- `**kwargs` Keyword arguments to pass to `func`.

**Returns**

- scalar, Series or DataFrame The return can be:
  
  • scalar : when Series.agg is called with single function

3.3. Series
Series : when DataFrame.agg is called with a single function
DataFrame : when DataFrame.agg is called with several functions
Return scalar, Series or DataFrame.

See also:

**Series.apply** Invoke function on a Series.
**Series.transform** Transform function producing a Series with like indexes.

**Notes**

*agg* is an alias for *aggregate*. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
    min  max
0     1    4
```

**pandas.Series.align**

*pandas.Series.align*(*other*, *join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None*)

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

**Parameters**

- **other** [DataFrame or Series]
- **join** [‘outer’, ‘inner’, ‘left’, ‘right’], default ‘outer’
- **axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
**level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.

**copy** [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

**fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘fill’, None}, default None] Method to use for filling holes in reindexed Series:
  - pad / fill: propagate last valid observation forward to next valid.
  - backfill / bfill: use NEXT valid observation to fill gap.

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill_axis** [{0 or ‘index’}, default 0] Filling axis, method and limit.

**broadcast_axis** [{0 or ‘index’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

**Returns**

(left, right) [(Series, type of other)] Aligned objects.

### pandas.Series.all

**Series.all**(axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

**Parameters**

**axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
  - 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
  - None : reduce all axes, return a scalar.

**bool_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.
Returns

*scalar or Series* If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

*Series.all* Return True if all elements are True.

*DataFrame.any* Return True if one (or more) elements are True.

Examples

### Series

```python
>>> pd.Series([True, True]).all()
True
```

```python
>>> pd.Series([True, False]).all()
False
```

```python
>>> pd.Series([], dtype="float64").all()
True
```

```python
>>> pd.Series([np.nan]).all(skipna=False)
True
```

### DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({"col1": [True, True], "col2": [True, False]})
```

```python
def
<table>
<thead>
<tr>
<th>col1</th>
<th>col2</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
```

```python
col1  True
col2  False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
```

```python
0   True
1   False
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
```

```python
False
```
**Series.any**

`Series.any(axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

**Parameters**

- **axis** [(0 or ‘index’, 1 or ‘columns’, None), default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
  - 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
  - None : reduce all axes, return a scalar.
- **bool_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.
- **skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **kwargs** [any, default=None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- scalar or Series  If level is specified, then, Series is returned; otherwise, scalar is returned.

**See also:**

- numpy.any  Numpy version of this method.
- Series.any  Return whether any element is True.
- Series.all  Return whether all elements are True.
- DataFrame.any  Return whether any element is True over requested axis.
- DataFrame.all  Return whether all elements are True over requested axis.

**Examples**

**Series**

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.4

(continued from previous page)

False
>>> pd.Series([np.nan]).any(skipna=False)
True
DataFrame
Whether each column contains at least one True element (the default).
>>> df =
>>> df
A B
0 1 0
1 2 2

pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
C
0
0

>>> df.any()
A
True
B
True
C
False
dtype: bool
Aggregating over the columns.
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
A B
0
True 1
1 False 2
>>> df.any(axis='columns')
0
True
1
True
dtype: bool
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
A B
0
True 1
1 False 0
>>> df.any(axis='columns')
0
True
1
False
dtype: bool
Aggregating over the entire DataFrame with axis=None.
>>> df.any(axis=None)
True
any for an empty DataFrame is an empty Series.
>>> pd.DataFrame([]).any()
Series([], dtype: bool)

1186

Chapter 3. API reference


pandas.Series.append

Series.append(to_append, ignore_index=False, verify_integrity=False)
Concatenate two or more Series.

Parameters

to_append [Series or list/tuple of Series] Series to append with self.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

verify_integrity [bool, default False] If True, raise Exception on creating index with duplicates.

Returns

Series Concatenated Series.

See also:

concat General function to concatenate DataFrame or Series objects.

Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

Examples

```python
gt>> s1 = pd.Series([1, 2, 3])
gt>> s2 = pd.Series([4, 5, 6])
gt>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
gt>> s1.append(s2)
               0  
            1  1
            2  2
            0  4
            1  5
            2  6
dtype: int64

gt>> s1.append(s3)
               0  
            1  1
            2  2
            0  4
            1  5
            2  6
            3  4
            4  5
            5  6
dtype: int64
```

With `ignore_index` set to True:

```python
gt>> s1.append(s2, ignore_index=True)
               0  
            0  1
```

(continues on next page)
With `verify_integrity` set to True:

```python
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...  
ValueError: Indexes have overlapping values: [0, 1, 2]
```

### pandas.Series.apply

Series.apply(func, convert_dtype=True, args=(), **kwargs)

Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

**Parameters**

- `func` [function] Python function or NumPy ufunc to apply.
- `convert_dtype` [bool, default True] Try to find better dtype for elementwise function results.
  - If False, leave as dtype=object. Note that the dtype is always preserved for some extension array dtypes, such as Categorical.
- `args` [tuple] Positional arguments passed to func after the series value.
- `**kwargs` Additional keyword arguments passed to func.

**Returns**

Series or DataFrame If func returns a Series object the result will be a DataFrame.

See also:

- Series.map For element-wise operations.
- Series.agg Only perform aggregating type operations.
- Series.transform Only perform transforming type operations.

**Notes**

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.
Examples

Create a series with typical summer temperatures for each city.

```python
>>> s = pd.Series([20, 21, 12],
                 index=['London', 'New York', 'Helsinki'])
```

```python
>>> s
London   20
New York 21
Helsinki 12
dtype: int64
```

Square the values by defining a function and passing it as an argument to `apply()`.

```python
>>> def square(x):
...     return x ** 2
```

```python
>>> s.apply(square)
London   400
New York 441
Helsinki 144
dtype: int64
```

Square the values by passing an anonymous function as an argument to `apply()`.

```python
>>> s.apply(lambda x: x ** 2)
London   400
New York 441
Helsinki 144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```python
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value
```

```python
>>> s.apply(subtract_custom_value, args=(5,))
London   15
New York 16
Helsinki  7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply()`.

```python
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x
```

```python
>>> s.apply(add_custom_values, june=30, july=20, august=25)
London   95
New York 96
Helsinki 87
dtype: int64
```
Use a function from the Numpy library.

```python
gg s.apply(np.log)
London     2.995732
New York   3.044522
Helsinki  2.484907
dtype: float64
```

**pandas.Series.argmax**

`Series.argmax(axis=None, skipna=True, *args, **kwargs)`

Return int position of the largest value in the Series.

If the maximum is achieved in multiple locations, the first row position is returned.

**Parameters**

- `axis` [[None]] Dummy argument for consistency with Series.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

**Returns**

- `int` Row position of the maximum value.

**See also:**

- `Series.argmax` Return position of the maximum value.
- `Series.argmin` Return position of the minimum value.
- `numpy.ndarray.argmax` Equivalent method for numpy arrays.
- `Series.idxmax` Return index label of the maximum values.
- `Series.idxmin` Return index label of the minimum values.

**Examples**

Consider dataset containing cereal calories

```python
gg s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,  
...                   'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
```
The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

**pandas.Series.argmin**

`Series.argmin(axis=None, skipna=True, *args, **kwargs)`

Return int position of the smallest value in the Series. If the minimum is achieved in multiple locations, the first row position is returned.

**Parameters**

- `axis` [{None}] Dummy argument for consistency with Series.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

**Returns**

- `int` Row position of the minimum value.

See also:

- `Series.argmin` Return position of the minimum value.
- `Series.argmax` Return position of the maximum value.
- `numpy.ndarray.argmin` Equivalent method for numpy arrays.
- `Series.idxmax` Return index label of the maximum values.
- `Series.idxmin` Return index label of the minimum values.

**Examples**

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...    'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
```

```python
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch    120.0
Cocoa Puff        110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
**pandas.Series.argsort**

`Series.argsort(axis=0, kind='quicksort', order=None)`

Return the integer indices that would sort the Series values.

Override ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

**Parameters**

- **axis** ([0 or “index”]) Has no effect but is accepted for compatibility with numpy.
- **kind** [{'mergesort', 'quicksort', 'heapsort', 'stable'}, default 'quicksort'] Choice of sorting algorithm. See `numpy.sort()` for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms.
- **order** [None] Has no effect but is accepted for compatibility with numpy.

**Returns**

Series[np.intp] Positions of values within the sort order with -1 indicating NaN values.

**See also:**

- `numpy.ndarray.argsort` Returns the indices that would sort this array.

---

**pandas.Series.asfreq**

`Series.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this Series is a `PeriodIndex`, the new index is the result of transforming the original index with `PeriodIndex.asfreq` (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to `pd.date_range(start, end, freq=freq)` where `start` and `end` are, respectively, the first and last entries in the original index (see `pandas.date_range()`). The values corresponding to any timesteps in the new index which were not present in the original index will be null (NaN), unless a method for filling such unknowns is provided (see the `method` parameter below).

The `resample()` method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

**Parameters**

- **freq** [DateOffset or str] Frequency `DateOffset` or string.
- **method** [{‘backfill’/’bfill’, ‘pad’/’ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  - ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
  - ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.
- **how** [{‘start’, ‘end’}, default end] For PeriodIndex only (see `PeriodIndex.asfreq`).
- **normalize** [bool, default False] Whether to reset output index to midnight.
- **fill_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).
Returns

Series  Series object reindexed to the specified frequency.

See also:

reindex  Conform DataFrame to new index with optional filling logic.

Notes

To learn more about the frequency strings, please see [this link](#).

Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df
     s
2000-01-01 00:00:00  0.0
2000-01-01 00:01:00  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:03:00  3.0
```

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
     s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a fill value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
     s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```

Upsample again, providing a method.
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
>>> df.asfreq(freq='30S', method='bfill')
Series
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

**pandas.Series.asof**

```python
Series.asof(where, subset=None)
```

Return the last row(s) without any NaNs before `where`.

The last row (for each element in `where`, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not `None`)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

**Parameters**

- **where** [date or array-like of dates] Date(s) before which the last row(s) are returned.
- **subset** [str or array-like of str, default `None`] For DataFrame, if not `None`, only use these columns to check for NaNs.

**Returns**

- **scalar, Series, or DataFrame** The return can be:
  - scalar: when `self` is a Series and `where` is a scalar
  - Series: when `self` is a Series and `where` is an array-like, or when `self` is a DataFrame and `where` is a scalar
  - DataFrame: when `self` is a DataFrame and `where` is an array-like

Return scalar, Series, or DataFrame.

**See also:**

- `merge_asof` Perform an asof merge. Similar to left join.

**Notes**

Dates are assumed to be sorted. Raises if this is not the case.
Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
```

```plaintext
10 1.0
20 2.0
30 NaN
40 4.0
```

dtype: float64

```python
>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.

```python
>>> s.asof([5, 20])
5 NaN
20 2.0
```

dtype: float64

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```python
>>> s.asof(30)
2.0
```

Take all columns into consideration

```python
df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
                   'b': [None, None, None, None, 500],
                   index=pd.DatetimeIndex(['2018-02-27 09:01:00',
                                           '2018-02-27 09:02:00',
                                           '2018-02-27 09:03:00',
                                           '2018-02-27 09:04:00',
                                           '2018-02-27 09:05:00'])})
```

```python
df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
                           '2018-02-27 09:04:30']))
```

```plaintext
a b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```python
df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
                           '2018-02-27 09:04:30']),
       subset=['a'])
```

```plaintext
a b
2018-02-27 09:03:30 30.0 NaN
2018-02-27 09:04:30 40.0 NaN
```
pandas.Series.astype

**Series.astype**(*dtype*, *copy=True*, *errors='raise'*)

Cast a pandas object to a specified dtype *dtype*.

**Parameters**

- **dtype** [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

- **copy** [bool, default True] Return a copy when *copy=True* (be very careful setting *copy=False* as changes to values then may propagate to other pandas objects).

- **errors** [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.
  - **raise**: allow exceptions to be raised
  - **ignore**: suppress exceptions. On error return original object.

**Returns**

casted [same type as caller]

**See also:**

to_datetime

to_timedelta

to_numeric

**numpy.ndarray.astype** Cast a numpy array to a specified type.

**Notes**

Deprecated since version 1.3.0: Using **astype** to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use **Series.dt.tz_localize()** instead.

**Examples**

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
```

```plaintext
col1  int64
col2  int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
```

```plaintext
col1  int32
col2  int32
dtype: object
```
Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
        col1    col2  dtype: object
       int32    int64
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0     1
1     2
dtype: int32
>>> ser.astype('int64')
0     1
1     2
dtype: int64
```

Convert to categorical type:

```python
>>> ser.astype('category')
0     1
1     2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype(...
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0     1
1     2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using copy=False and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1  # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0  2020-01-01
1  2020-01-02
```

(continues on next page)
pandas.Series.at_time

Series.at_time(time, asof=False, axis=None)
Select values at particular time of day (e.g., 9:30AM).

Parameters
- **time** [datetime.time or str]
- **axis** [{0 or 'index', 1 or 'columns'}, default 0]

Returns
Series or DataFrame

Raises
- **TypeError** If the index is not a DatetimeIndex

See also:
- **between_time** Select values between particular times of the day.
- **first** Select initial periods of time series based on a date offset.
- **last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer_at_time** Get just the index locations for values at particular time of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
     A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4

>>> ts.at_time('12:00')
     A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```
pandas.Series.autocorr

Series.autocorr(lag=1)

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

Parameters

lag [int, default 1] Number of lags to apply before performing autocorrelation.

Returns

float The Pearson correlation between self and self.shift(lag).

See also:

Series.corr Compute the correlation between two Series.
Series.shift Shift index by desired number of periods.
DataFrame.corr Compute pairwise correlation of columns.
DataFrame.corrwith Compute pairwise correlation between rows or columns of two DataFrame objects.

Notes

If the Pearson correlation is not well defined return ‘NaN’.

Examples

```python
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr()
0.10355...
>>> s.autocorr(lag=2)
-0.99999...
```

If the Pearson correlation is not well defined, then ‘NaN’ is returned.

```python
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

pandas.Series.backfill

Series.backfill(axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='bfill'.

Returns

Series/DataFrame or None Object with missing values filled or None if inplace=True.
pandas.Series.between

Series.between(left, right, inclusive='both')
Return boolean Series equivalent to left <= series <= right.

This function returns a boolean vector containing True wherever the corresponding Series element is between the boundary values left and right. NA values are treated as False.

Parameters

- left [scalar or list-like] Left boundary.
- right [scalar or list-like] Right boundary.
- inclusive [{“both”, “neither”, “left”, “right”}] Include boundaries. Whether to set each bound as closed or open.

Returns

Series Series representing whether each element is between left and right (inclusive).

See also:

Series.gt Greater than of series and other.
Series.lt Less than of series and other.

Notes

This function is equivalent to (left <= ser) & (ser <= right)

Examples

```python
>>> s = pd.Series([2, 0, 4, 8, np.nan])
```
Boundary values are included by default:

```python
>>> s.between(1, 4)
0    True
1   False
2    True
3   False
4   False
dtype: bool
```

With inclusive set to "neither" boundary values are excluded:

```python
>>> s.between(1, 4, inclusive="neither")
0    True
1   False
2   False
3   False
4   False
dtype: bool
```
left and right can be any scalar value:

```python
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0    False
1     True
2     True
3    False
dtype: bool
```

**pandas.Series.between_time**

`Series.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting start_time to be later than end_time, you can get the times that are not between the two times.

**Parameters**

- `start_time` [datetime.time or str] Initial time as a time filter limit.
- `end_time` [datetime.time or str] End time as a time filter limit.
- `include_start` [bool, default True] Whether the start time needs to be included in the result.
- `include_end` [bool, default True] Whether the end time needs to be included in the result.
- `axis` [{0 or 'index', 1 or 'columns'}, default 0] Determine range time on index or columns value.

**Returns**

- `Series` or `DataFrame` Data from the original object filtered to the specified dates range.

**Raises**

- `TypeError` If the index is not a `DatetimeIndex`

**See also:**

- `at_time` Select values at a particular time of the day.
- `first` Select initial periods of time series based on a date offset.
- `last` Select final periods of time series based on a date offset.
- `DatetimeIndex.indexer_between_time` Get just the index locations for values between particular times of the day.
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
          A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4

>>> ts.between_time('0:15', '0:45')
          A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```python
>>> ts.between_time('0:45', '0:15')
          A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4
```

**pandas.Series.bfill**

Series.bfill(axis=None, inplace=False, limit=None, downcast=None) Synonym for DataFramefillna() with method='bfill'.

Returns

Series/DataFrame or None Object with missing values filled or None if inplace=True.

**pandas.Series.bool**

Series.bool() Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool The value in the Series or DataFrame.

See also:

Series.astype Change the data type of a Series, including to boolean.
DataFrame.astype Change the data type of a DataFrame, including to boolean.
numpy.bool_ NumPy boolean data type, used by pandas for boolean values.
Examples

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

```python
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.Series.cat

Series.cat()

Accessor object for categorical properties of the Series values.

Be aware that assigning to categories is a inplace operation, while all methods return new categorical data per default (but can be called with inplace=True).

**Parameters**

- **data** [Series or CategoricalIndex]

**Examples**

```python
>>> s = pd.Series(list('abbccc')).astype('category')
>>> s
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```python
>>> s.cat.categories
Index(['a', 'b', 'c'], dtype='object')
```

```python
>>> s.cat.rename_categories(list('cba'))
0  c
1  b
2  b
3  a
4  a
5  a
dtype: category
Categories (3, object): ['c', 'b', 'a']
```
>>> s.cat.reorder_categories(list("cba"))
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['c', 'b', 'a']

>>> s.cat.add_categories(['d', 'e'])
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']

>>> s.cat.remove_categories(['a', 'c'])
0    NaN
1    b
2    b
3    NaN
4    NaN
5    NaN
dtype: category
Categories (1, object): ['b']

>>> s1 = s.cat.add_categories(['d', 'e'])
>>> s1.cat.remove_unused_categories()
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a', 'b', 'c']

>>> s.cat.set_categories(list("abcde"))
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']
```python
>>> s.cat.as_ordered()
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']

>>> s.cat.as_unordered()
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

**pandas.Series.clip**

*Series.clip*(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)*

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- **lower** [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g. NA) will not clip the value.
- **upper** [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g. NA) will not clip the value.
- **axis** [int or str axis name, optional] Align object with lower and upper along the given axis.
- **inplace** [bool, default False] Whether to perform the operation in place on the data.
- ***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

*Series* or *DataFrame* or *None* Same type as calling object with the values outside the clip boundaries replaced or None if *inplace=True*.

**See also:**

- *Series.clip* Trim values at input threshold in series.
- *DataFrame.clip* Trim values at input threshold in dataframe.
- *numpy.clip* Clip (limit) the values in an array.
Examples

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9    -2
1     -3    -7
2      0     6
3     -1     8
4      5    -5

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3     -4
2      0     6
3     -1     6
4      5    -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64

>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3     -4
2      0      3
3      6      8
4      5      3
```

Clips using specific lower threshold per column element, with missing values:

```python
>>> t = pd.Series([2, -4, np.NaN, 6, 3])
>>> t
0  2.0
1 -4.0
2  NaN
3  6.0
4  3.0
dtype: float64
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

>>> df.clip(t, axis=0)
col_0  col_1
0     9     2
1    -3    -4
2     0     6
3     6     8
4     5     3

pandas.Series.combine

Series.combine(other, func, fill_value=None)
Combine the Series with a Series or scalar according to func.

Combine the Series and other using func to perform elementwise selection for combined Series. fill_value is assumed when value is missing at some index from one of the two objects being combined.

Parameters

other [Series or scalar] The value(s) to be combined with the Series.
func [function] Function that takes two scalars as inputs and returns an element.
fill_value [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

Returns

Series The result of combining the Series with the other object.

See also:

Series.combine_first Combine Series values, choosing the calling Series’ values first.

Examples

Consider 2 Datasets s1 and s2 containing highest clocked speeds of different birds.

>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon  330.0
eagle  160.0
dtype: float64

>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon  345.0
eagle  200.0
duck  30.0
dtype: float64

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

>>> s1.combine(s2, max)
duck       NaN
eagle  200.0

(continues on next page)
In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set fill_value=0, so the maximum value returned will be the value from some dataset.

```python
>>> s1.combine(s2, max, fill_value=0)
duck   30.0
eagle  200.0
falcon 345.0
dtype: float64
```

**pandas.Series.combine_first**

`Series.combine_first(other)`

Update null elements with value in the same location in ‘other’.

Combine two Series objects by filling null values in one Series with non-null values from the other Series. Result index will be the union of the two indexes.

**Parameters**

- `other` [Series] The value(s) to be used for filling null values.

**Returns**

- `Series` The result of combining the provided Series with the other object.

**See also:**

- `Series.combine` Perform element-wise operation on two Series using a given function.

**Examples**

```python
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4, 5])
>>> s1.combine_first(s2)
0  1.0
1  4.0
2  5.0
dtype: float64
```

Null values still persist if the location of that null value does not exist in `other`

```python
>>> s1 = pd.Series({'falcon': np.nan, 'eagle': 160.0})
>>> s2 = pd.Series({'eagle': 200.0, 'duck': 30.0})
>>> s1.combine_first(s2)
duck   30.0
eagle  160.0
falcon  NaN
dtype: float64
```
pandas.Series.compare

Series.compare(other, align_axis=1, keep_shape=False, keep_equal=False)

Compare to another Series and show the differences.

New in version 1.1.0.

Parameters

other  [Series] Object to compare with.

align_axis  [{0 or ‘index’, 1 or ‘columns’}, default 1] Determine which axis to align the comparison on.

• 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.

• 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.

keep_shape  [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

keep_equal  [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

Series or DataFrame If axis is 0 or ‘index’ the result will be a Series. The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

If axis is 1 or ‘columns’ the result will be a DataFrame. It will have two columns namely ‘self’ and ‘other’.

See also:

DataFrame.compare  Compare with another DataFrame and show differences.

Notes

Matching NaNs will not appear as a difference.

Examples

```python
>>> s1 = pd.Series(['a', 'b', 'c', 'd', 'e'])
>>> s2 = pd.Series(['a', 'a', 'c', 'b', 'e'])
```

Align the differences on columns

```python
>>> s1.compare(s2)
   self other
1   b   a
3   d   b
```

Stack the differences on indices
>>> s1.compare(s2, align_axis=0)
1 self  b
  other  a
3 self  d
  other  b
dtype: object

Keep all original rows

>>> s1.compare(s2, keep_shape=True)
     self  other
 0   NaN     NaN
 1    b      a
 2   NaN     NaN
 3    d      b
 4   NaN     NaN

Keep all original rows and also all original values

>>> s1.compare(s2, keep_shape=True, keep_equal=True)
     self  other
 0    a      a
 1    b      a
 2    c      c
 3    d      b
 4    e      e

pandas.Series.convert_dtypes

Series.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True,
                      convert_boolean=True, convert_floating=True)

Convert columns to best possible dtypes using dtypes supporting pd.NA.

New in version 1.0.0.

Parameters

infer_objects [bool, default True] Whether object dtypes should be converted to the best possible types.

convert_string [bool, default True] Whether object dtypes should be converted to StringDtype().

convert_integer [bool, default True] Whether, if possible, conversion can be done to integer extension types.

convert_boolean [bool, default True] Whether object dtypes should be converted to BooleanDtypes().

convert_floating [bool, default True] Whether, if possible, conversion can be done to floating extension types. If convert_integer is also True, preference will be give to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

Returns
**Series or DataFrame** Copy of input object with new dtype.

**See also:**

- `infer_objects` Infer dtypes of objects.
- `to_datetime` Convert argument to datetime.
- `to_timedelta` Convert argument to timedelta.
- `to_numeric` Convert argument to a numeric type.

**Notes**

By default, `convert_dtypes` will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, `convert_boolean` and `convert_boolean`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types, `BooleanDtype` or floating extension types, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer or floating extension type, otherwise leave as `object`.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

**Examples**

```python
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )
```

Start with a DataFrame with default dtypes.

```python
>>> df
   a  b   c  d  e  f
0  1  x  True  10.0  NaN
1  2  y  False  1.0  100.5
2  3  z   NaN  NaN  20.0  200.0
```
Convert the DataFrame to use best possible dtypes.

```python
>>> dfn = df.convert_dtypes()

>>> dfn
  a  b  c  d  e  f
0  1  x  True  h  10   <NA>
1  2  y  False  i  <NA>  100.5
2  3  z  <NA>  <NA>  20  200.0
```

Start with a Series of strings and missing data represented by `np.nan`.

```python
>>> s = pd.Series(["a", "b", np.nan])

>>> s
0   a
1   b
2  NaN
  dtype: object
```

Obtain a Series with dtype `StringDtype`.

```python
>>> s.convert_dtypes()
 0   a
1   b
2   <NA>
  dtype: string
```
**pandas.Series.copy**

`Series.copy(deep=True)`

Make a copy of this object’s indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

**Parameters**

- `deep` [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

**Returns**

- `copy` [Series or DataFrame] Object type matches caller.

**Notes**

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

**Examples**

```python
generate code here
```

Shallow copy versus default (deep) copy:

```python
generate code here
```

Shallow copy shares data and index with original.
Deep copy has own copy of data and index.

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.
**pandas.Series.corr**

`Series.corr(other, method='pearson', min_periods=None)`  
Compute correlation with `other` Series, excluding missing values.

**Parameters**

- `other` [Series] Series with which to compute the correlation.
- `method` [[`pearson`, ‘kendall’, ‘spearman’] or callable] Method used to compute correlation:
  - `pearson` : Standard correlation coefficient
  - `kendall` : Kendall Tau correlation coefficient
  - `spearman` : Spearman rank correlation
  - `callable`: Callable with input two 1d ndarrays and returning a float.

**Warning:** Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

- `min_periods` [int, optional] Minimum number of observations needed to have a valid result.

**Returns**

- `float` Correlation with other.

**See also:**

- `DataFrame.corr` Compute pairwise correlation between columns.
- `DataFrame.corrwith` Compute pairwise correlation with another DataFrame or Series.

**Examples**

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v

>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```
**pandas.Series.count**

Series.count(level=None)

Return number of non-NA/null observations in the Series.

Parameters

- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series.

Returns

- **int or Series (if level specified)** Number of non-null values in the Series.

See also:

- **DataFrame.count** Count non-NA cells for each column or row.

Examples

```python
>>> s = pd.Series([0.0, 1.0, np.nan])
>>> s.count()
2
```

**pandas.Series.cov**

Series.cov(other, min_periods=None, ddof=1)

Compute covariance with Series, excluding missing values.

Parameters

- **other** [Series] Series with which to compute the covariance.

- **min_periods** [int, optional] Minimum number of observations needed to have a valid result.

- **ddof** [int, default 1] Delta degrees of freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

Returns

- **float** Covariance between Series and other normalized by N-1 (unbiased estimator).

See also:

- **DataFrame.cov** Compute pairwise covariance of columns.
Examples

```python
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

**pandas.Series.cummax**

`Series.cummax(axis=None, skipna=True, *args, **kwargs)`

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

**Parameters**

- `axis`  
  [0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

- `skipna`  
  [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- `*args, **kwargs`  
  Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- `scalar` or `Series`  
  Return cumulative maximum of scalar or Series.

**See also:**

- `core.window.Expanding.max`  
  Similar functionality but ignores NaN values.

- `Series.max`  
  Return the maximum over Series axis.

- `Series.cummax`  
  Return cumulative maximum over Series axis.

- `Series.cummin`  
  Return cumulative minimum over Series axis.

- `Series.cumsum`  
  Return cumulative sum over Series axis.

- `Series.cumprod`  
  Return cumulative product over Series axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.
To include NA values in the operation, use `skipna=False`

```python
>>> s.cummax(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
```

dtype: float64

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
```

```python
>>> df
   A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummax()
   A   B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```python
>>> df.cummax(axis=1)
   A   B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```
pandas.Series.cummin

Series.cummin(axis=None, skipna=True, *args, **kwargs)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative minimum of scalar or Series.

See also:

core.window.Expanding.min Similar functionality but ignores NaN values.

Series.min Return the minimum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use skipna=False
>>> s.cummin(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

DataFrame

By default, iterates over rows and finds the minimum in each column. This is equivalent to axis=None or axis='index'.

>>> df.cummin()
     A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

To iterate over columns and find the minimum in each row, use axis=1

>>> df.cummin(axis=1)
   A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

pandas.Series.cumprod

Series.cumprod(axis=None, skipna=True, *args, **kwargs)
Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis [(0 or ‘index’, 1 or ‘columns’), default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.
scalar or Series  Return cumulative product of scalar or Series.

See also:

core.window.Expanding.prod  Similar functionality but ignores NaN values.

Series.prod  Return the product over Series axis.

Series.cummax  Return cumulative maximum over Series axis.

Series.cummin  Return cumulative minimum over Series axis.

Series.cumsum  Return cumulative sum over Series axis.

Series.cumprod  Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
dtype: float64
```

To include NA values in the operation, use skipna=False

```python
>>> s.cumprod(skipna=False)
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
```

(continues on next page)
By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumprod()
     A    B
0    2.0  1.0
1    6.0  NaN
2    6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```python
>>> df.cumprod(axis=1)
     A    B
0    2.0  2.0
1    3.0  NaN
2    1.0  0.0
```

### pandas.Series.cumsum

`Series.cumsum(axis=None, skipna=True, *args, **kwargs)`  
Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

**Parameters**

- `axis` {0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- `scalar or Series` Return cumulative sum of scalar or Series.

**See also:**

- `core.window.Expanding.sum` Similar functionality but ignores NaN values.
- `Series.sum` Return the sum over Series axis.
- `Series.cummax` Return cumulative maximum over Series axis.
- `Series.cummin` Return cumulative minimum over Series axis.
- `Series.cumsum` Return cumulative sum over Series axis.
- `Series.cumprod` Return cumulative product over Series axis.
**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0 2.0
1 NaN
2 5.0
3 -1.0
4 0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0  2.0
1  NaN
2  7.0
3  6.0
4  6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumsum(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
                    ...                   [3.0, np.nan],
                    ...                   [1.0, 0.0]],
                    ... columns=list('AB'))
>>> df
     A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumsum()
     A  B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
>>> df.cumsum(axis=1)
   A  B
0  2.0 3.0
1  3.0 NaN
2  1.0 1.0
```

**pandas.Series.describe**

`Series.describe(percentiles=None, include=None, exclude=None, datetime_is_numeric=False)`

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

- **percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.
- **include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
  - 'all': All columns of the input will be included in the output.
  - A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O']))). To select pandas categorical columns, use 'category'
  - None (default): The result will include all numeric columns.
- **exclude** [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
  - A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O']))). To exclude pandas categorical columns, use 'category'
  - None (default): The result will exclude nothing.
- **datetime_is_numeric** [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

**Returns**

- **Series or DataFrame** Summary statistics of the Series or Dataframe provided.

**See also:**

- `DataFrame.count` Count number of non-NA/null observations.
**DataFrame.max**  Maximum of the values in the object.

**DataFrame.min**  Minimum of the values in the object.

**DataFrame.mean**  Mean of the values.

**DataFrame.std**  Standard deviation of the observations.

**DataFrame.select_dtypes**  Subset of a DataFrame including/excluding columns based on their dtype.

**Notes**

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the count and top results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

**Examples**

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count   3.0
mean    2.0
std     1.0
min     1.0
25%     1.5
50%     2.0
75%     2.5
max     3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count   4
unique  3
top     a
tfreq   2
dtype: object
```
Describing a timestamp Series.

```python
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01"),
... ])
>>> s.describe(datetime_is_numeric=True)
count 3
mean 2006-09-01 08:00:00
min 2000-01-01 00:00:00
25% 2004-12-31 12:00:00
50% 2010-01-01 00:00:00
75% 2010-01-01 00:00:00
max 2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame(
...     {
...         'categorical': pd.Categorical(['d', 'e', 'f']),
...         'numeric': [1, 2, 3],
...         'object': ['a', 'b', 'c']
...     })
>>> df.describe()
count 3 3.0 3
unique 3 NaN 3
top f NaN a
freq 1 NaN 1
mean NaN 2.0 NaN
std NaN 1.0 NaN
min NaN 1.0 NaN
25% NaN 1.5 NaN
50% NaN 2.0 NaN
75% NaN 2.5 NaN
max NaN 3.0 NaN
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
count 3 3.0 3 3
unique 3 NaN 3 3
top f NaN a NaN
freq 1 NaN 1 NaN
mean NaN 2.0 NaN NaN
std NaN 1.0 NaN NaN
min NaN 1.0 NaN NaN
25% NaN 1.5 NaN NaN
50% NaN 2.0 NaN NaN
75% NaN 2.5 NaN NaN
max NaN 3.0 NaN NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
count 3.0
```
Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
```
```
numeric
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
Name: numeric, dtype: float64
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=['object'])
```
```
object
count 3
unique 3
top a
freq 1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
```
```
categorical
count 3
unique 3
top d
freq 1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
```
```
categorical object
count 3 3
unique 3 3
top f a
freq 1 1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=['object'])
```
```
categorical numeric
```
pandas.Series.diff

Series.diff(periods=1)

First discrete difference of element.

Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

Returns

Series First differences of the Series.

See also:

Series.pct_change Percent change over given number of periods.
Series.shift Shift index by desired number of periods with an optional time freq.
DataFrame.diff First discrete difference of object.

Notes

For boolean dtypes, this uses operator.xor() rather than operator.sub(). The result is calculated according to current dtype in Series, however dtype of the result is always float64.

Examples

Difference with previous row

```python
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0   NaN
1     0.0
2     1.0
3     1.0
4     2.0
5     3.0
dtype: float64
```
Difference with 3rd previous row

```python
>>> s.diff(periods=3)
0   NaN
1   NaN
2   NaN
3    2.0
4    4.0
5    6.0
dtype: float64
```

Difference with following row

```python
>>> s.diff(periods=-1)
0    0.0
1   -1.0
2   -1.0
3   -2.0
4   -3.0
5     NaN
dtype: float64
```

Overflow in input dtype

```python
>>> s = pd.Series([1, 0], dtype=np.uint8)
```  
```python
>>> s.diff()
0   NaN
1   255.0
dtype: float64
```

**pandas.Series.div**

*pandas.Series.div*(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to series / other, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other**  [Series or scalar value]
- **fill_value**  [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level**  [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- **Series**  The result of the operation.

**See also:**

- **Series.rtruediv**  Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0  
b  1.0  
c  1.0  
d  NaN
dtype: float64
```  
```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0  
b  NaN  
d  1.0  
e  NaN
dtype: float64
```  
```python
>>> a.divide(b, fill_value=0)
a  1.0  
b  inf  
c  inf  
d  0.0  
e  NaN
```

**pandas.Series.divide**

`Series.divide(other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator `truediv`).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.rtruediv` Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64

>>> a.divide(b, fill_value=0)
da    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

`pandas.Series.divmod`

Series.divmod(other, level=None, fill_value=None, axis=0)

Return Integer division and modulo of series and other, element-wise (binary operator `divmod`).

Equivalent to `divmod(series, other)`, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

2-Tuple of Series The result of the operation.

See also:

`Series.rdivmod` Reverse of the Integer division and modulo operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64

>>> a.divmod(b, fill_value=0)
(a 1.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64,
(a 0.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64)
```

`pandas.Series.dot`

`Series.dot(other)`

Compute the dot product between the Series and the columns of other.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using `self @ other` in Python >= 3.5.

Parameters

- **other** [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

Returns

- **scalar, Series or numpy.ndarray** Return the dot product of the Series and other if other is a Series, the Series of the dot product of Series and each rows of other if other is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

See also:

- `Dataframe.dot` Compute the matrix product with the DataFrame.
**Series.mul**  Multiplication of series and other, element-wise.

**Notes**

The Series and other has to share the same index if other is a Series or a DataFrame.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other
8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])
```

**pandas.Series.drop**

**Series.drop**(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

**Parameters**

- **labels**  [single label or list-like] Index labels to drop.
- **axis**  [0, default 0] Redundant for application on Series.
- **index**  [single label or list-like] Redundant for application on Series, but ‘index’ can be used instead of ‘labels’.
- **columns**  [single label or list-like] No change is made to the Series; use ‘index’ or ‘labels’ instead.
- **level**  [int or level name, optional] For MultiIndex, level for which the labels will be removed.
- **inplace**  [bool, default False] If True, do operation inplace and return None.
- **errors**  [‘ignore’, ‘raise’] If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

- **Series or None**  Series with specified index labels removed or None if inplace=True.

**Raises**
### KeyError
If none of the labels are found in the index.

**See also:**

- **Series.reindex** Return only specified index labels of Series.
- **Series.dropna** Return series without null values.
- **Series.drop_duplicates** Return Series with duplicate values removed.
- **DataFrame.drop** Drop specified labels from rows or columns.

#### Examples

```python
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A 0
B 1
C 2
dtype: int64

Drop labels B en C

```python
>>> s.drop(labels=['B', 'C'])
A 0
dtype: int64
```

Drop 2nd level label in MultiIndex Series

```python
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                          ['speed', 'weight', 'length']],
...                       codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                          [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
...                index=midx)
>>> s
lama  speed   45.0
      weight  200.0
      length  1.2
cow   speed   30.0
      weight  250.0
      length  1.5
falcon speed  320.0
      weight   1.0
      length  0.3
dtype: float64
```

```python
>>> s.drop(labels='weight', level=1)
lama  speed  45.0
      length  1.2
     cow   speed  30.0
      length  1.5
falcon speed  320.0
      length  0.3
```
**pandas.Series.drop_duplicates**

`Series.drop_duplicates(keep='first', inplace=False)`

Return Series with duplicate values removed.

**Parameters**

- **keep** [‘first’, ‘last’, False], default ‘first’ Method to handle dropping duplicates:
  - ‘first’: Drop duplicates except for the first occurrence.
  - ‘last’: Drop duplicates except for the last occurrence.
  - False: Drop all duplicates.

- **inplace** [bool, default False] If True, performs operation inplace and returns None.

**Returns**

Series or None Series with duplicates dropped or None if inplace=True.

**See also:**

- **Index.drop_duplicates** Equivalent method on Index.
- **DataFrame.drop_duplicates** Equivalent method on DataFrame.
- **Series.duplicated** Related method on Series, indicating duplicate Series values.

**Examples**

Generate a Series with duplicated entries.

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
                 name='animal')
>>> s
   0 lama
   1 cow
   2 lama
   3 beetle
   4 lama
   5 hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```python
>>> s.drop_duplicates()
   0 lama
   1 cow
   3 beetle
   5 hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.
>>> s.drop_duplicates(keep='last')
1    cow
3   beetle
4    lama
5    hippo
Name: animal, dtype: object

The value False for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to True performs the operation inplace and returns None.

>>> s.drop_duplicates(keep=False, inplace=True)

pandas.Series.droplevel

Series.droplevel(level, axis=0)
Return Series/DataFrame with requested index / column level(s) removed.

Parameters

level [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the level(s) is removed:
• 0 or ‘index’: remove level(s) in column.
• 1 or ‘columns’: remove level(s) in row.

Returns

Series/DataFrame Series/DataFrame with requested index / column level(s) removed.

Examples

>>> df = pd.DataFrame(
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ).set_index([0, 1]).rename_axis(["a", "b"])

>>> df.columns = pd.MultiIndex.from_tuples(
...     ("c", "e"), ("d", "f"),
...     names=["level_1", "level_2"]
... )

>>> df
level_1  c  d
level_2  e  f
a  b

(continues on next page)
pandas.Series.dropna

Series.dropna(axis=0, inplace=False, how=None)

Return a new Series with missing values removed.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or ‘index’}, default 0] There is only one axis to drop values from.

inplace [bool, default False] If True, do operation inplace and return None.

Returns

Series or None Series with NA entries dropped from it or None if inplace=True.

See also:

Series.isna Indicate missing values.

Series.notna Indicate existing (non-missing) values.

Series.fillna Replace missing values.

DataFrame.dropna Drop rows or columns which contain NA values.

Index.dropna Drop missing indices.
Examples

```python
code
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0  1.0
1  2.0
2  NaN
dtype: float64

Drop NA values from a Series.

```python
>>> ser.dropna()
0  1.0
1  2.0
dtype: float64
```

Keep the Series with valid entries in the same variable.

```python
>>> ser.dropna(inplace=True)
>>> ser
0  1.0
1  2.0
dtype: float64
```

Empty strings are not considered NA values. `None` is considered an NA value.

```python
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0   NaN
1   2.0
2    NaT
3
4   None
5    I stay
dtype: object

```python
>>> ser.dropna()
1   2
3
5    I stay
dtype: object
```
**pandas.Series.dt**

*Series.dt()*

Accessor object for datetimelike properties of the Series values.

**Examples**

```python
>>> seconds_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="s"))
>>> seconds_series
0 2000-01-01 00:00:00
1 2000-01-01 00:00:01
2 2000-01-01 00:00:02
dtype: datetime64[ns]
>>> seconds_series.dt.second
0 0
1 1
2 2
dtype: int64

>>> hours_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="h"))
>>> hours_series
0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
>>> hours_series.dt.hour
0 0
1 1
2 2
dtype: int64

>>> quarters_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="q"))
>>> quarters_series
0 2000-03-31
1 2000-06-30
2 2000-09-30
dtype: datetime64[ns]
>>> quarters_series.dt.quarter
0 1
1 2
2 3
dtype: int64
```

Returns a Series indexed like the original Series. Raises TypeError if the Series does not contain datetimelike values.
pandas.Series.duplicated

Series.duplicated(keep='first')

Indicate duplicate Series values.

Duplicated values are indicated as True values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

**Parameters**

- **keep** [{‘first’, ‘last’, False}, default ‘first’] Method to handle dropping duplicates:
  - ‘first’ : Mark duplicates as True except for the first occurrence.
  - ‘last’ : Mark duplicates as True except for the last occurrence.
  - False : Mark all duplicates as True.

**Returns**

- **Series[bool]** Series indicating whether each value has occurred in the preceding values.

**See also:**

- Index.duplicated Equivalent method on pandas.Index.
- DataFrame.duplicated Equivalent method on pandas.DataFrame.
- Series.drop_duplicates Remove duplicate values from Series.

**Examples**

By default, for each set of duplicated values, the first occurrence is set on False and all others on True:

```python
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1     False
2      True
3     False
4      True
dtype: bool
```

which is equivalent to

```python
>>> animals.duplicated(keep='first')
0    False
1     False
2      True
3     False
4      True
dtype: bool
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> animals.duplicated(keep='last')
0      True
1     False
```

(continues on next page)
By setting keep on False, all duplicates are True:

```python
>>> animals.duplicated(keep=False)
0   True
1  False
2   True
3  False
4   True
dtype: bool
```

**pandas.Series.eq**

`Series.eq(other, level=None, fill_value=None, axis=0)`

Return Equal to of series and other, element-wise (binary operator `eq`).

Equivalent to `series == other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

`Series` The result of the operation.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
c    1.0
```

(continues on next page)
pandas.Series.equals

Series.equals(other)
Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal. Corresponding columns must be of the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

testing.assert_frame_equal Like assert_series_equal, but targets DataFrames.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Examples

```python
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
   1  2
0 10 20
```

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.
```python
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1  2
0  10  20
>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return True.

```python
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0  10.0  20.0
>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```python
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1  2
0  10.0  20.0
>>> df.equals(different_data_type)
False
```

**pandas.Series.ewm**

Series.ewm(com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None)

Provide exponential weighted (EW) functions.

Available EW functions: mean(), var(), std(), corr(), cov().

Exactly one parameter: `com`, `span`, `halflife`, or `alpha` must be provided.

**Parameters**

- `com` [float, optional] Specify decay in terms of center of mass, \( \alpha = 1/(1 + com) \), for \( com \geq 0 \).
- `span` [float, optional] Specify decay in terms of span, \( \alpha = 2/(span + 1) \), for \( span \geq 1 \).
- `halflife` [float, str, timedelta, optional] Specify decay in terms of half-life, \( \alpha = 1 - \exp(-\ln(2)/halflife) \), for \( halflife > 0 \).

If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()` and halflife value will not apply to the other functions.

New in version 1.1.0.

- `alpha` [float, optional] Specify smoothing factor \( \alpha \) directly, \( 0 < \alpha \leq 1 \).
- `min_periods` [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).
adjust  [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

- When adjust=True (default), the EW function is calculated using weights \( w_t = (1 - \alpha)^t \). For example, the EW moving average of the series \([x_0, x_1, ..., x_t]\) would be:

\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ... + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t}
\]

- When adjust=False, the exponentially weighted function is calculated recursively:

\[
y_0 = x_0 \\
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]

ignore_na  [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

- When ignore_na=False (default), weights are based on absolute positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, \text{None}, x_2]\) are \((1 - \alpha)^2\) and 1 if adjust=True, and \((1 - \alpha)^2\) and \(\alpha\) if adjust=False.

- When ignore_na=True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, \text{None}, x_2]\) are \(1 - \alpha\) and 1 if adjust=True, and \(1 - \alpha\) and \(\alpha\) if adjust=False.

axis  [(0, 1), default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

times  [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and datetime64[ns] dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to mean().

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

rolling Provides rolling window calculations.

expanding Provides expanding transformations.
Notes

More details can be found at: *Exponentially weighted windows*.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0
1  1
2  2
3  NaN
4  4

>>> df.ewm(com=0.5).mean()
   B
0  0
1  0.75
2  1.615385
3  1.615385
4  3.670213

Specifying times with a timedelta `halflife` when computing mean.

```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-
˓→17']

>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
   B
0  0
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

**pandas.Series.expanding**

Series.expanding(*min_periods=1, center=None, axis=0, method='single*)

Provide expanding transformations.

Parameters

- **min_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).
- **center** [bool, default False] Set the labels at the center of the window.
- **axis** [int or str, default 0]
- **method** [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying engine='numba' in the method call.
New in version 1.3.0.

Returns

a Window sub-classed for the particular operation

See also:

rolling Provides rolling window calculations.
ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

Examples

```python
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.expanding(2).sum()
   B
0  NaN
1   1.0
2   3.0
3   3.0
4   7.0
```

pandas.Series.explode

Series.explode(ignite_index=False)

Transform each element of a list-like to a row.

New in version 0.25.0.

Parameters

- ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.1.0.

Returns

Series Exploded lists to rows; index will be duplicated for these rows.

See also:
**Series.str.split**  Split string values on specified separator.

**Series.unstack**  Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame.

**DataFrame.melt**  Unpivot a DataFrame from wide format to long format.

**DataFrame.explode**  Explode a DataFrame from list-like columns to long format.

**Notes**

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of elements in the output will be non-deterministic when exploding sets.

**Examples**

```python
>>> s = pd.Series([[1, 2, 3], 'foo', [], [3, 4]])
>>> s
0   [1, 2, 3]
1     foo
2      []
3   [3, 4]
dtype: object

>>> s.explode()
0  1
0  2
0  3
1   foo
2    NaN
3   3
3   4
dtype: object
```

**pandas.Series.factorize**

**Series.factorize**(sort=False, na_sentinel=-1)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. factorize is available as both a top-level function pandas.factorize(), and as a method Series.factorize() and Index.factorize().

**Parameters**

- **sort**  [bool, default False] Sort uniques and shuffle codes to maintain the relationship.

- **na_sentinel**  [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

**Returns**

- **changed in version 1.1.2.**
codes [ndarray] An integer ndarray that's an indexer into uniques. uniques.
take(codes) will have the same values as values.

uniques [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in values, uniques will not contain an entry for it.

See also:
cut Discretize continuous-valued array.
unique Find the unique value in an array.

Examples

These examples all show factorize as a top-level method like pd.factorize(values). The results are identical for methods like Series.factorize().

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With sort=True, the uniques will be sorted, and codes will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in codes with na_sentinel (-1 by default). Note that missing values are never included in uniques.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of uniques will differ. For Categoricals, a Categorical is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
```

(continues on next page)
Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([1., 2.])
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])
```

**pandas.Series.ffill**

Series.ffill(*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for `DataFrame.fillna()` with `method='ffill'`.

Returns

Series/DataFrame or None  Object with missing values filled or None if `inplace=True`.

**pandas.Series.fillna**

Series.fillna(*value=None, method=None, axis=None, inplace=False, limit=None, downcast=None*)

Fill NA/Nan values using the specified method.

Parameters

- **value** [scalar, dict, Series, or DataFrame]  Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a
Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **method** [['backfill', 'bfill', 'pad', 'ffill', None], default None]  Method to use for filling holes in reindexed Series pad / fill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.
**pandas: powerful Python data analysis toolkit, Release 1.3.4**

**axis**  [0 or ‘index’] Axis along which to fill missing values.

**inplace**  [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

**limit**  [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**downcast**  [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**

Series or None  Object with missing values filled or None if inplace=True.

**See also:**

*interpolate* Fill NaN values using interpolation.

*reindex* Conform object to new index.

*asfreq* Convert TimeSeries to specified frequency.

**Examples**

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                    columns=list("ABCD"))
```

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
   A  B  C  D
0  0.0 2.0 NaN 0
1  3.0 4.0 NaN 1
2  NaN NaN NaN 5
3  NaN 3.0 NaN 4
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method="ffill")
   A   B   C   D
0  NaN 2.0 NaN 0
1  3.0 4.0 NaN 1
```

(continues on next page)
Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A  B  C  D
0  0  2  2  0
1  3  4  2  1
2  0  1  2  5
3  0  3  2  4
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
   A  B  C  D
0  0  2  2  0
1  3  4  NaN 1
2  NaN 1 NaN 5
3  NaN 3 NaN 4
```

When filling using a DataFrame, replacement happens along the same column names and same indices.

```python
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list('ABCE'))
>>> df.fillna(df2)
   A  B  C  D
0  0  2  0  0
1  3  4  NaN 1
2  NaN 1 NaN 5
3  NaN 3 NaN 4
```

**pandas.Series.filter**

`Series.filter(items=None, like=None, regex=None, axis=None)`

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items** [list-like] Keep labels from axis which are in items.
- **like** [str] Keep labels from axis for which “like in label == True”.
- **regex** [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

**Returns**

same type as input object
See also:

*DataFrame.loc*  Access a group of rows and columns by label(s) or a boolean array.

**Notes**

The *items*, *like*, and *regex* parameters are enforced to be mutually exclusive.

*axis* defaults to the info axis that is used when indexing with [].

**Examples**

```python
>>> df = pd.DataFrame(np.array(((1, 2, 3), (4, 5, 6))),
                    index=['mouse', 'rabbit'],
                    columns=['one', 'two', 'three'])
>>> df
          one  two  three
mouse     1    2    3
rabbit    4    5    6
```

```python
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
          one  three
mouse     1    3
rabbit    4    6
```

```python
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
          one  three
mouse     1    3
rabbit    4    6
```

```python
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
          one  two  three
rabbit    4    5    6
```

*Series.first*

*Series.first*(offset)

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

**Parameters**

- *offset* [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

**Returns**
Series or DataFrame  A subset of the caller.

Raises

TypeError  If the index is not a DatetimeIndex

See also:

last  Select final periods of time series based on a date offset.
at_time  Select values at a particular time of the day.
between_time  Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
   A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.Series.first_valid_index

Series.first_valid_index()

Return index for first non-NA value or None, if no NA value is found.

Returns

scalar  [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.
pandas.Series.floordiv

Series.floordiv(other, level=None, fill_value=None, axis=0)

Return Integer division of series and other, element-wise (binary operator floordiv).

Equivalent to series // other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rfloordiv Reverse of the Integer division operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.floordiv(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```
pandas.Series.ge

Series.ge(other, level=None, fill_value=None, axis=0)

Return Greater than or equal to of series and other, element-wise (binary operator ge).

Equivalent to series >= other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a 1.0
b 1.0
     c 1.0
d 1.0
     e 1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a 0.0
b 1.0
    0.0
d 1.0
f 1.0
dtype: float64
>>> a.ge(b, fill_value=0)
a   True
b   True
c   False
d  NaN
     True
f  NaN
     False
dtype: bool
```
pandas.Series.get

Series.get(key, default=None)
Get item from object for given key (ex: DataFrame column).
Returns default value if not found.

Parameters
key [object]

Returns
value [same type as items contained in object]

pandas.Series.groupby

Series.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True,
squeeze=NoDefault.no_default, observed=False, dropna=True)
Group Series using a mapper or by a Series of columns.
A groupby operation involves some combination of splitting the object, applying a function, and combining
the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters
by [mapping, function, label, or list of labels] Used to determine the groups for the
groupby. If by is a function, it’s called on each value of the object’s index. If a dict or
Series is passed, the Series or dict VALUES will be used to determine the groups (the
Series’ values are first aligned; see .align() method). If an ndarray is passed, the
values are used as-is to determine the groups. A label or list of labels may be passed
to group by the columns in self. Notice that a tuple is interpreted as a (single) key.
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Split along rows (0) or columns (1).
level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hier-
archical), group by a particular level or levels.
as_index [bool, default True] For aggregated output, return object with group labels as the
index. Only relevant for DataFrame input. as_index=False is effectively “SQL-style”
grouped output.
sort [bool, default True] Sort group keys. Get better performance by turning this off. Note
this does not influence the order of observations within each group. Groupby preserves
the order of rows within each group.
group_keys [bool, default True] When calling apply, add group keys to index to identify
pieces.
squeeze [bool, default False] Reduce the dimensionality of the return type if possible,
otherwise return a consistent type.
    Deprecated since version 1.1.0.
observed [bool, default False] This only applies if any of the groupers are Categoricals.
    If True: only show observed values for categorical groupers. If False: show all values
    for categorical groupers.
dropna [bool, default True] If True, and if group keys contain NA values, NA values
together with row/column will be dropped. If False, NA values will also be treated as
the key in groups.
New in version 1.1.0.

**Returns**

**SeriesGroupBy** Returns a groupby object that contains information about the groups.

**See also:**

`resample` Convenience method for frequency conversion and resampling of time series.

**Notes**

See the user guide for more.

**Examples**

```python
>>> ser = pd.Series([390., 350., 30., 20.],
...                   index=['Falcon', 'Falcon', 'Parrot', 'Parrot'], name="Max Speed")
>>> ser
Falcon  390.0
Falcon  350.0
Parrot  30.0
Parrot  20.0
Name: Max Speed, dtype: float64
>>> ser.groupby(\["a", "b", "a", "b"]\).mean()
a  210.0
b  185.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level=0).mean()
Falcon  370.0
Parrot  25.0
Name: Max Speed, dtype: float64
>>> ser.groupby(ser > 100).mean()
Max Speed
False  25.0
True  370.0
Name: Max Speed, dtype: float64
```

**Grouping by Indexes**

We can groupby different levels of a hierarchical index using the `level` parameter:

```python
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...            ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=\('Animal', 'Type'\))
>>> ser = pd.Series([390., 350., 30., 20.], index=index, name="Max Speed")
>>> ser
Animal  Type
Falcon  Captive  390.0
        Wild       350.0
Parrot  Captive  30.0
        Wild       20.0
Name: Max Speed, dtype: float64
```
>>> ser.groupby(level=0).mean()
Animal
Falcon 370.0
Parrot 25.0
Name: Max Speed, dtype: float64

>>> ser.groupby(level="Type").mean()
Type
Captive 210.0
Wild 185.0
Name: Max Speed, dtype: float64

We can also choose to include NA in group keys or not by defining dropna parameter, the default setting is True:

>>> ser = pd.Series([1, 2, 3, 3], index=\["a", 'a', 'b', np.nan\])

>>> ser.groupby(level=0).sum()
a 3
b 3
dtype: int64

>>> ser.groupby(level=0, dropna=False).sum()
a 3
b 3
NaN 3
dtype: int64

>>> arrays = ['Falcon', 'Falcon', 'Parrot', 'Parrot']

>>> ser = pd.Series([390., 350., 30., 20.], index=arrays, name="Max Speed")

>>> ser.groupby(\["a", "b", "a", np.nan\]).mean()
a 210.0
b 350.0
Name: Max Speed, dtype: float64

>>> ser.groupby(\["a", "b", "a", np.nan\], dropna=False).mean()
a 210.0
b 350.0
NaN 20.0
Name: Max Speed, dtype: float64

pandas.Series.gt

Series.gt(other, level=None, fill_value=None, axis=0)

Return Greater than of series and other, element-wise (binary operator gt).

Equivalent to series > other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before
computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

**Series** The result of the operation.

**Examples**

```python
>>> a = pd.Series([1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
e 1.0
dtype: float64
```

```python
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a 0.0
b 1.0
c 2.0
d NaN
f 1.0
dtype: float64
```

```python
>>> a.gt(b, fill_value=0)
a  True
b  False
c  False
d  False
e  True
f  False
dtype: bool
```

### pandas.Series.head

**Series.head**(n=5)

Return the first n rows.

This function returns the first n rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of n, this function returns all rows except the last n rows, equivalent to `df[:n]`.

**Parameters**

- n [int, default 5] Number of rows to select.

**Returns**

- same type as caller The first n rows of the caller object.

**See also:**
DataFrame.tail  Returns the last n rows.

Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
...                          'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1     bee
2   falcon
3     lion
4   monkey
5   parrot
6     shark
7   whale
8    zebra

Viewing the first 5 lines

```python
>>> df.head()
   animal
0  alligator
1     bee
2   falcon
3     lion
4   monkey

Viewing the first n lines (three in this case)

```python
>>> df.head(3)
   animal
0  alligator
1     bee
2   falcon

For negative values of n

```python
>>> df.head(-3)
   animal
0  alligator
1     bee
2   falcon
pandas.Series.hist

Series.hist(by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, backend=None, legend=False, **kwargs)
Draw histogram of the input series using matplotlib.

Parameters
by [object, optional] If passed, then used to form histograms for separate groups.
ax [matplotlib axis object] If not passed, uses gca().
grid [bool, default True] Whether to show axis grid lines.
xlabelsize [int, default None] If specified changes the x-axis label size.
xrot [float, default None] Rotation of x axis labels.
ylabelsize [int, default None] If specified changes the y-axis label size.
yrot [float, default None] Rotation of y axis labels.
figsize [tuple, default None] Figure size in inches by default.
bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, 'matplotlib'. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend. New in version 1.0.0.
legend [bool, default False] Whether to show the legend. New in version 1.1.0.

**kwargs To be passed to the actual plotting function.

Returns
matplotlib.AxesSubplot A histogram plot.

See also:
matplotlib.axes.Axes.hist Plot a histogram using matplotlib.

pandas.Series.idxmax

Series.idxmax(axis=0, skipna=True, *args, **kwargs)
Return the row label of the maximum value.
If multiple values equal the maximum, the first row label with that value is returned.

Parameters
axis [int, default 0] For compatibility with DataFrame.idxmax. Redundant for application on Series.
skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.
*args, **kwargs Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **Index**: Label of the maximum value.

**Raises**

- **ValueError**: If the Series is empty.

**See also:**

- `numpy.argmax`: Return indices of the maximum values along the given axis.
- `DataFrame.idxmax`: Return index of first occurrence of maximum over requested axis.
- `Series.idxmin`: Return index label of the first occurrence of minimum of values.

**Notes**

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

**Examples**

```python
>>> s = pd.Series(data=[1, None, 4, 3, 4],
                 index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B   NaN
C    4.0
D    3.0
E    4.0
dtype: float64

>>> s.idxmax()
'C'

If `skipna` is False and there is an NA value in the data, the function returns `nan`.

>>> s.idxmax(skipna=False)
nan
```

**pandas.Series.idxmin**

`Series.idxmin(axis=0, skipna=True, *args, **kwargs)`

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

**Parameters**

- **axis** [int, default 0] For compatibility with DataFrame.idxmin. Redundant for application on Series.
skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

*args, **kwargs Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the minimum value.

Raises

ValueError If the Series is empty.

See also:

numpy.argmin Return indices of the minimum values along the given axis.
DataFrame.idxmin Return index of first occurrence of minimum over requested axis.
Series.idxmax Return index label of the first occurrence of maximum of values.

Notes

This method is the Series version of ndarray.argmin. This method returns the label of the minimum, while ndarray.argmin returns the position. To get the position, use series.values.argmin().

Examples

```python
gp = pd.Series(data=[1, None, 4, 1],
               index=['A', 'B', 'C', 'D'])
gp
A  1.0
B  NaN
C  4.0
D  1.0
dtype: float64

>>> gp.idxmin()
'A'

If skipna is False and there is an NA value in the data, the function returns nan.

>>> gp.idxmin(skipna=False)
nan
```
pandas.Series.infer_objects

Series.infer_objects()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns

converted [same type as input object]

See also:

to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric Convert argument to numeric type.
convert_dtypes Convert argument to best possible dtype.

Examples

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
0  1
1  1
2  1
3  3

>>> df.dtypes
A object
dtype: object

>>> df.infer_objects().dtypes
A  int64
dtype: object
```

pandas.Series.interpolate

Series.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)

Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default ‘linear’] Interpolation technique to use. One of:

- ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
• ‘index’, ‘values’: use the actual numerical values of the index.
• ‘pad’: Fill in NaNs using existing values.
• ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’:Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method=’polynomial’, order=5).
• ‘from_derivatives’: Refers to scipy.interpolate.BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [{{0 or ‘index’, 1 or ‘columns’, None}}, default None] Axis to interpolate along.
limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.
inplace [bool, default False] Update the data in place if possible.
limit_direction [{{‘forward’, ‘backward’, ‘both’}}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:
• If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
• If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:
• If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
• else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area [{{None, ‘inside’, ‘outside’}}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.
• None: No fill restriction.
• ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).
downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

````kwags```` [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

See also:

fillna Fill missing values using different methods.
scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).
scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.
**scipy.interpolate.interp1d** Interpolate a 1-D function.

**scipy.interpolate.KroghInterpolator** Interpolate polynomial (Krogh interpolator).

**scipy.interpolate.PchipInterpolator** PCHIP 1-d monotonic cubic interpolation.

**scipy.interpolate.CubicSpline** Cubic spline data interpolator.

**Notes**

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

**Examples**

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ...
... "fill_two_more", np.nan, np.nan, np.nan, ...
... 4.71, np.nan])
>>> s
0    NaN
1    single_one
2    NaN
3    fill_two_more
4    NaN
5    NaN
6    NaN
7    4.71
8    NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0    NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
```

(continues on next page)
Filling in NaN in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an order (int).

```python
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Using polynomial interpolation.

```python
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3    16.0
Name: d, dtype: float64
```
pandas.Series.isin

Series.isin(values)
Whether elements in Series are contained in values.
Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of values exactly.

Parameters
values [set or list-like] The sequence of values to test. Passing in a single string will raise a TypeError. Instead, turn a single string into a list of one element.

Returns
Series Series of booleans indicating if each element is in values.

Raises
TypeError
• If values is a string

See also:
DataFrame.isin Equivalent method on DataFrame.

Examples

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0    True
1    True
2    True
3   False
4    True
5   False
Name: animal, dtype: bool
```

Passing a single string as s.isin('lama') will raise an error. Use a list of one element instead:

```python
>>> s.isin(['lama'])
0    True
1    False
2    True
3   False
4    True
5   False
Name: animal, dtype: bool
```

Strings and integers are distinct and are therefore not comparable:

```python
>>> pd.Series([1]).isin([1])
0   False
dtype: bool
```

```python
>>> pd.Series([1.1]).isin(['1.1'])
(continues on next page)```
pandas.Series.isna

Series.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.Nan, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is an NA value.

See also:

Series.isnull Alias of isna.
Series.notna Boolean inverse of isna.
Series.dropna Omit axes labels with missing values.

Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                     born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                           pd.Timestamp('1940-04-25')],
...                     name=['Alfred', 'Batman', ''],
...                     toy=[None, 'Batmobile', 'Joker']))
>>> df
     age      born      name     toy
0     5.0      NaT    Alfred    None
1     6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25     Joker
```

```python
>>> df.isna()
     age      born      name     toy
0   False     True    False   True
1   False    False    False   False
2    True    False    False   False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
```

(continues on next page)
pandas.Series.isnull

Series.isnull()
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.Nan, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is an NA value.

See also:

Series.isnull Alias of isna.
Series.notna Boolean inverse of isna.
Series.dropna Omit axes labels with missing values.

Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.nan],
  ...                     born=[pd.NaT, pd.Timestamp('1939-05-27'),
  ...                     pd.Timestamp('1940-04-25')],
  ...                     name=['Alfred', 'Batman', ''],
  ...                     toy=[None, 'Batmobile', 'Joker']))
>>> df
    age  born     name    toy
0  5.0   NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2 NaN 1940-04-25  Joker
```
```python
>>> df.isna()
  age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False

Show which entries in a Series are NA.
```n
```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0   5.0
1   6.0
2   NaN
dtype: float64

>>> ser.isna()
0  False
1  False
2   True
dtype: bool
```

**pandas.Series.item**

Series.item()  
Return the first element of the underlying data as a Python scalar.

**Returns**

- scalar  The first element of $(klass)$.  

**Raises**

- ValueError  If the data is not length-1.

**pandas.Series.items**

Series.items()  
Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

**Returns**

- iterable  Iterable of tuples containing the (index, value) pairs from a Series.

**See also:**

- `DataFrame.items`  Iterate over (column name, Series) pairs.
- `DataFrame.iterrows`  Iterate over DataFrame rows as (index, Series) pairs.
Examples

```python
>>> s = pd.Series(['A', 'B', 'C'])
```
```python
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}"
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

**pandas.Series.iteritems**

`Series.iteritems()` Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

**Returns**

- `iterable` Iterable of tuples containing the (index, value) pairs from a Series.

**See also:**

- `DataFrame.items` Iterate over (column name, Series) pairs.
- `DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.

Examples

```python
>>> s = pd.Series(['A', 'B', 'C'])
```
```python
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}"
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

**pandas.Series.keys**

`Series.keys()` Return alias for index.

**Returns**

- `Index` Index of the Series.
pandas.Series.kurt

Series.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.
Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis ([index (0)]) Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.kurtosis

Series.kurtosis(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.
Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis ([index (0)]) Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.last

Series.last(offset)
Select final periods of time series data based on a date offset.
For a DataFrame with a sorted DatetimeIndex, this function selects the last few rows based on a date offset.

Parameters

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘3D’ will display all the rows having their index within the last 3 days.
Returns

Series or DataFrame  A subset of the caller.

Raises

TypeError  If the index is not a DatetimeIndex

See also:

first  Select initial periods of time series based on a date offset.
at_time  Select values at a particular time of the day.
between_time  Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
```  
```
2018-04-09 1
2018-04-11 2
2018-04-13 3
2018-04-15 4
```

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
```

```
2018-04-13 3
2018-04-15 4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

pandas.Series.last_valid_index

Series.last_valid_index()
Return index for last non-NA value or None, if no NA value is found.

Returns

scalar  [type of index]
Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.Series.le**

Series.le(other, level=None, fill_value=None, axis=0)

Return Less than or equal to of series and other, element-wise (binary operator `le`).

Equivalent to `series <= other`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]

- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- **Series** The result of the operation.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d   NaN
f    1.0
dtype: float64
>>> a.le(b, fill_value=0)
a   False
b   True
c   True
d  False
e  False
f   True
dtype: bool
```
pandas.Series.lt

Series.lt(other, level=None, fill_value=None, axis=0)

  Return Less than of series and other, element-wise (binary operator lt).
  Equivalent to series < other, but with support to substitute a fill_value for missing data in either one of the inputs.

  Parameters

    other [Series or scalar value]
    fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
    level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

  Returns

    Series The result of the operation.

  Examples

```python
g = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>> g
  a    1.0
  b    1.0
  c    1.0
  d  NaN
  e    1.0
  dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
  a    0.0
  b    1.0
  c    2.0
  d  NaN
  f    1.0
  dtype: float64
>>> a.lt(b, fill_value=0)
  a    False
  b    False
  c     True
  d    False
  e    False
  f     True
  dtype: bool```
**pandas.Series.mad**

```python
Series.mad(axis=None, skipna=None, level=None)
```

Return the mean absolute deviation of the values over the requested axis.

**Parameters**

- **axis** [{index (0)}] Axis for the function to be applied on.
- **skipna** [bool, default None] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**Returns**

- scalar or Series (if level specified)

**pandas.Series.map**

```python
Series.map(arg, na_action=None)
```

Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a `dict` or a `Series`.

**Parameters**

- **arg** [function, collections.abc.Mapping subclass or Series] Mapping correspondence.
- **na_action** [{None, ‘ignore’}, default None] If ‘ignore’, propagate NaN values, without passing them to the mapping correspondence.

**Returns**

- **Series** Same index as caller.

**See also:**

- `Series.apply` For applying more complex functions on a Series.
- `DataFrame.apply` Apply a function row-/column-wise.
- `DataFrame.applymap` Apply a function elementwise on a whole DataFrame.

**Notes**

When `arg` is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a `dict` subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN.
Examples

```python
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0    cat
1    dog
2   NaN
3  rabbit
dtype: object
```

map accepts a dict or a Series. Values that are not found in the dict are converted to NaN, unless the dict has a default value (e.g. defaultdict):

```python
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0  kitten
1    puppy
2    NaN
3    NaN
dtype: object
```

It also accepts a function:

```python
>>> s.map('I am a {}.format)
0   I am a cat
1   I am a dog
2     I am a nan
3   I am a rabbit
dtype: object
```

To avoid applying the function to missing values (and keep them as NaN) `na_action='ignore'` can be used:

```python
>>> s.map('I am a {}.format, na_action='ignore')
0   I am a cat
1   I am a dog
2       NaN
3   I am a rabbit
dtype: object
```

**pandas.Series.mask**

The `Series.mask` function allows replacing values where the condition is True.

```python
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0    cat
1    dog
2   NaN
3  rabbit
dtype: object
```

**Parameters**

- **cond** [bool Series/DataFrame, array-like, or callable] Where `cond` is False, keep the original value. Where True, replace with corresponding value from `other`. If `cond` is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
other [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

• ‘raise’ : allow exceptions to be raised.
• ‘ignore’ : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecation since version 1.3.0: Manually cast back if necessary.

Returns
Same type as caller or None if inplace=True.

See also:

DataFrame.where() Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is False the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the mask documentation in indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```
```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0     0
1     1
2    10
3    10
4    10
dtype: int64

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0 -1  1
1 -2  3
2 -4 -5
3 -6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```
**pandas.Series.max**

```
Series.max(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
```

Return the maximum of the values over the requested axis.

If you want the index of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

- scalar or Series (if level specified)

See also:

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays(['warm', 'warm', 'cold', 'cold'],
...                                ['dog', 'falcon', 'fish', 'spider'],
...                                names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded    animal
  warm     dog  4
   falcon  2
cold       fish  0
       spider  8
Name: legs, dtype: int64
```
pandas.Series.mean

Series.mean(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return the mean of the values over the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.median

Series.median(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return the median of the values over the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)
pandas.Series.memory_usage

Series.memory_usage(index=True, deep=False)

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of object dtype.

Parameters

- **index** [bool, default True] Specifies whether to include the memory usage of the Series index.
- **deep** [bool, default False] If True, introspect the data deeply by interrogating object dtypes for system-level memory consumption, and include it in the returned value.

Returns

- **int** Bytes of memory consumed.

See also:

- numpy.ndarray.nbytes Total bytes consumed by the elements of the array.
- DataFrame.memory_usage Bytes consumed by a DataFrame.

Examples

```python
>>> s = pd.Series(range(3))
>>> s.memory_usage()
152
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```python
>>> s.memory_usage(index=False)
24
```

The memory footprint of object values is ignored by default:

```python
>>> s = pd.Series(["a", "b"])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
144
>>> s.memory_usage(deep=True)
244
```

pandas.Series.min

Series.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the minimum of the values over the requested axis.

If you want the index of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

Parameters

- **axis** ([index (0)]) Axis for the function to be applied on.
skipna  [bool, default True] Exclude NA/null values when computing the result.
level  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count
along a particular level, collapsing into a scalar.
numeric_only  [bool, default None] Include only float, int, boolean columns. If None, will
attempt to use everything, then use only numeric data. Not implemented for Series.
**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:
Series.sum  Return the sum.
Series.min  Return the minimum.
Series.max  Return the maximum.
Series.idxmin  Return the index of the minimum.
Series.idxmax  Return the index of the maximum.
DataFrame.sum  Return the sum over the requested axis.
DataFrame.min  Return the minimum over the requested axis.
DataFrame.max  Return the maximum over the requested axis.
DataFrame.idxmin  Return the index of the minimum over the requested axis.
DataFrame.idxmax  Return the index of the maximum over the requested axis.

Examples

```python
>>> idx = pd.MultiIndex.from_arrays([
... ['warm', 'warm', 'cold', 'cold'],
... ['dog', 'falcon', 'fish', 'spider']],
... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
warm    dog  4
       falcon  2
cold   fish  0
       spider  8
Name: legs, dtype: int64
```

```python
>>> s.min()
0
```
pandas.Series.mod

Series.mod(other, level=None, fill_value=None, axis=0)
Return Modulo of series and other, element-wise (binary operator mod).
Equivalent to `series % other`, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rmod Reverse of the Modulo operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b   NaN
c   NaN
d    0.0
e   NaN
dtype: float64
```
pandas.Series.mode

Series.mode(dropna=True)
Return the mode(s) of the Series.

The mode is the value that appears most often. There can be multiple modes.
Always returns Series even if only one value is returned.

Parameters

dropna [bool, default True] Don’t consider counts of NaN/NaT.

Returns

Series Modes of the Series in sorted order.

pandas.Series.mul

Series.mul(other, level=None, fill_value=None, axis=0)
Return Multiplication of series and other, element-wise (binary operator mul).

Equivalent to series * other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

Series.rmul Reverse of the Multiplication operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a   1.0
b   1.0
c   1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
```
pandas.Series.multiply

Series.multiply(other, level=None, fill_value=None, axis=0)
Return Multiplication of series and other, element-wise (binary operator `mul`).
Equivalent to `series * other`, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns
Series The result of the operation.

See also:

Series.rmul Reverse of the Multiplication operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
```
pandas.Series.ne

Series.ne(other, level=None, fill_value=None, axis=0)

Return Not equal to of series and other, element-wise (binary operator ne).

Equivalent to series != other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b  NaN
d    1.0
e  NaN
dtype: float64
>>> a.ne(b, fill_value=0)
a   False
b  True
```
pandas.Series.nlargest

Series.nlargest(n=5, keep='first')
Return the largest n elements.

Parameters

n [int, default 5] Return this many descending sorted values.
keep [‘first’, ‘last’, ‘all’], default ‘first’ When there are duplicate values that cannot all
fit in a Series of n elements:
• first [return the first n occurrences in order] of appearance.
• last [return the last n occurrences in reverse] order of appearance.
• all [keep all occurrences. This can result in a Series of] size larger than n.

Returns

Series The n largest values in the Series, sorted in decreasing order.

See also:

Series.nsmallest Get the n smallest elements.
Series.sort_values Sort Series by values.
Series.head Return the first n rows.

Notes

Faster than .sort_values(ascending=False).head(n) for small n relative to the size of the Series
object.

Examples

```python
>>> countries_population = {
    "Italy": 59000000, "France": 65000000,
    ...
    "Malta": 434000, "Maldives": 434000,
    ...
    "Brunei": 434000, "Iceland": 337000,
    ...
    "Nauru": 11300, "Tuvalu": 11300,
    ...
    "Anguilla": 11300, "Montserrat": 5200
}
>>> s = pd.Series(countries_population)
>>> s
Italy       59000000
France     65000000
Malta       434000
Maldives    434000
Brunei     434000
```
The $n$ largest elements where $n=5$ by default.

```python
>>> s.nlargest()
France  65000000
Italy   59000000
Malta   43400000
Maldives 4340000
Brunei  43400000
dtype: int64
```

The $n$ largest elements where $n=3$. Default `keep` value is `first` so Malta will be kept.

```python
>>> s.nlargest(3)
France  65000000
Italy   59000000
Malta   43400000
```

The $n$ largest elements where $n=3$ and keeping the last duplicates. Brunei will be kept since it is the last with value 43400000 based on the index order.

```python
>>> s.nlargest(3, keep='last')
France  65000000
Italy   59000000
Brunei  43400000
```

The $n$ largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```python
>>> s.nlargest(3, keep='all')
France  65000000
Italy   59000000
Malta   43400000
Maldives 43400000
Brunei  43400000
```

</table>
pandas.Series.notna

Series.notna()
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.nan, get mapped to False values.

Returns
Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:
Series.notnull Alias of notna.
Series.isna Boolean inverse of notna.
Series.dropna Omit axes labels with missing values.
notna Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```python
df = pd.DataFrame(dict(age=[5, 6, np.nan],
                          pd.Timestamp('1940-04-25')],
                    name=['Alfred', 'Batman', ''],
                    toy=[None, 'Batmobile', 'Joker']))
```

```
<table>
<thead>
<tr>
<th>age</th>
<th>born</th>
<th>name</th>
<th>toy</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>NaT</td>
<td>Alfred</td>
<td>None</td>
</tr>
<tr>
<td>6.0</td>
<td>1939-05-27</td>

<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>False</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
</tbody>
</table>
```

Show which entries in a Series are not NA.

```python
ser = pd.Series([5, 6, np.nan])
```

```
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0 5.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1 6.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2 NaN</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

dtype: float64
pandas.Series.notnull

Series.notnull()
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns
Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.notnull Alias of notna.
Series.isna Boolean inverse of notna.
Series.dropna Omit axes labels with missing values.
notna Top-level notna.

Examples
Show which entries in a DataFrame are not NA.

```python
def = pd.DataFrame(dict(age=[5, 6, np.nan],
                          pd.Timestamp('1940-04-25')],
                    name=['Alfred', 'Batman', ''],
                    toy=[None, 'Batmobile', 'Joker']))
def
age  born  name  toy
0   5.0   NaT  Alfred  None
1   6.0  1939-05-27  Batman  Batmobile
2   NaN  1940-04-25  Joker

>>> df.notna()
age  born  name  toy
0   True  False  True  False
1   True  True   True  True
2   False True   True  True
```

Show which entries in a Series are not NA.
```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64

>>> ser.notna()
0    True
1    True
2    False
dtype: bool
```

### pandas.Series.nsmallest

**Series.nsmallest(n=5, keep='first')**

Return the smallest n elements.

**Parameters**

- **n** [int, default 5] Return this many ascending sorted values.
- **keep** [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of n elements:
  - **first** [return the first n occurrences in order] of appearance.
  - **last** [return the last n occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than n.

**Returns**

- **Series** The n smallest values in the Series, sorted in increasing order.

**See also:**

- **Series.nlargest** Get the n largest elements.
- **Series.sort_values** Sort Series by values.
- **Series.head** Return the first n rows.

**Notes**

Faster than .sort_values().head(n) for small n relative to the size of the Series object.
Examples

```python
>>> countries_population = {
    "Italy": 59000000, "France": 65000000,
    "Brunei": 434000, "Malta": 434000,
    "Maldives": 434000, "Iceland": 337000,
    "Nauru": 11300, "Tuvalu": 11300,
    "Anguilla": 11300, "Montserrat": 5200
}

>>> s = pd.Series(countries_population)

>>> s
Italy    59000000
France   65000000
Brunei   434000
Malta    434000
Maldives 434000
Iceland  337000
Nauru    11300
Tuvalu   11300
Anguilla 11300
Montserrat 5200
dtype: int64

The \( n \) smallest elements where \( n=5 \) by default.

```python
>>> s.nsmallest()
Montserrat   5200
Nauru        11300
Tuvalu       11300
Anguilla     11300
Iceland      337000
dtype: int64

The \( n \) smallest elements where \( n=3 \). Default keep value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)
Montserrat   5200
Nauru        11300
Tuvalu       11300
dtype: int64

The \( n \) smallest elements where \( n=3 \) and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')
Montserrat   5200
Anguilla     11300
Tuvalu       11300
dtype: int64

The \( n \) smallest elements where \( n=3 \) with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest(3, keep='all')
Montserrat   5200
Nauru        11300
```
**pandas.Series.nunique**

Series.nunique(dropna=True)

Return number of unique elements in the object.

Excludes NA values by default.

Parameters

- dropna [bool, default True] Don’t include NaN in the count.

Returns

- int

See also:

DataFrame.nunique  Method nunique for DataFrame.

Series.count  Count non-NA/null observations in the Series.

Examples

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```

**pandas.Series.pad**

Series.pad(axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='ffill'.

Returns

- Series/DataFrame or None  Object with missing values filled or None if inplace=True.
**pandas.Series.pct_change**

<pandas.Series.pct_change>(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters**

- **periods** [int, default 1] Periods to shift for forming percent change.
- **fill_method** [str, default 'pad'] How to handle NAs before computing percent changes.
- **limit** [int, default None] The number of consecutive NAs to fill before stopping.
- **freq** [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
- ****kwargs Additional keyword arguments are passed into DataFrame.shift or Series.shift.

**Returns**

- **chg** [Series or DataFrame] The same type as the calling object.

See also:

- **Series.diff** Compute the difference of two elements in a Series.
- **DataFrame.diff** Compute the difference of two elements in a DataFrame.
- **Series.shift** Shift the index by some number of periods.
- **DataFrame.shift** Shift the index by some number of periods.

**Examples**

**Series**

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0 90
1 91
2 85
dtype: int64

>>> s.pct_change()
0   NaN
1  0.011111
2 -0.065934
dtype: float64

>>> s.pct_change(periods=2)
0   NaN
1   NaN
2 -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.
```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2      NaN
3    85.0
dtype: float64

>>> s.pct_change(fill_method='ffill')
0     NaN
1  0.011111
2  0.000000
3 -0.065934
dtype: float64

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

>>> df = pd.DataFrame(
...     {'FR': [4.0405, 4.0963, 4.3149],
...      'GR': [1.7246, 1.7482, 1.8519],
...      'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
    FR     GR     IT
1980-01-01 4.0405 1.7246 804.74
1980-02-01 4.0963 1.7482 810.01
1980-03-01 4.3149 1.8519 860.13

>>> df.pct_change()
     FR     GR     IT
1980-01-01 NaN  NaN   NaN
1980-02-01 0.013810 0.013684 0.006549
1980-03-01 0.053365 0.059318 0.061876

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

>>> df = pd.DataFrame(
...     {'2016': [1769950, 30586265],
...      '2015': [1500923, 40912316],
...      '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
   2016  2015  2014
GOOG  1769950 1500923 1371819
APPL  30586265 40912316 41403351

>>> df.pct_change(axis='columns', periods=-1)
   2016  2015  2014
GOOG  0.179241 0.094112  NaN
APPL -0.252395 -0.011860  NaN
```
pandas.Series.pipe

Series.pipe(func, *args, **kwargs)
    Apply func(self, *args, **kwargs).

Parameters
    func [function] Function to apply to the Series/DataFrame. args, and kwargs are
    passed into func. Alternatively a (callable, data_keyword) tuple where
    data_keyword is a string indicating the keyword of callable that expects the Se-
    ries/DataFrame.
    args [iterable, optional] Positional arguments passed into func.
    kwargs [mapping, optional] A dictionary of keyword arguments passed into func.

Returns
    object [the return type of func.]

See also:
    DataFrame.apply Apply a function along input axis of DataFrame.
    DataFrame.applymap Apply a function elementwise on a whole DataFrame.
    Series.map Apply a mapping correspondence on a Series.

Notes

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead
of writing

```python
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(func, arg2=b, arg3=c)
...)
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which
keyword expects the data. For example, suppose \( f \) takes its data as \( \text{arg2} \):

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((func, 'arg2'), arg1=a, arg3=c)
...)
```
pandas.Series.plot

`Series.plot(*args, **kwargs)`

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

**Parameters**

- **data** [Series or DataFrame] The object for which the method is called.
- **x** [label or position, default None] Only used if data is a DataFrame.
- **y** [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.
- **kind** [str] The kind of plot to produce:
  - ‘line’ : line plot (default)
  - ‘bar’ : vertical bar plot
  - ‘barh’ : horizontal bar plot
  - ‘hist’ : histogram
  - ‘box’ : boxplot
  - ‘kde’ : Kernel Density Estimation plot
  - ‘density’ : same as ‘kde’
  - ‘area’ : area plot
  - ‘pie’ : pie plot
  - ‘scatter’ : scatter plot (DataFrame only)
  - ‘hexbin’ : hexbin plot (DataFrame only)
- **ax** [matplotlib axes object, default None] An axes of the current figure.
- **subplots** [bool, default False] Make separate subplots for each column.
- **sharex** [bool, default True if ax is None else False] In case `subplots=True`, share x axes and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and `sharex=True` will alter all x axis labels for all axis in a figure.
- **sharey** [bool, default False] In case `subplots=True`, share y axis and set some y axis labels to invisible.
- **layout** [tuple, optional] (rows, columns) for the layout of subplots.
- **figsize** [a tuple (width, height) in inches] Size of a figure object.
- **use_index** [bool, default True] Use index as ticks for x axis.
- **title** [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and `subplots` is True, print each item in the list above the corresponding subplot.
- **grid** [bool, default None (matlab style default)] Axis grid lines.
- **legend** [bool or ‘reverse’] Place legend on axis subplots.
- **style** [list or dict] The matplotlib line style per column.
**logx** [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. .. version-changed:: 0.25.0

**logy** [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. .. version-changed:: 0.25.0

**loglog** [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y axes. .. version-changed:: 0.25.0

**xticks** [sequence] Values to use for the xticks.

**yticks** [sequence] Values to use for the yticks.

**xlim** [2-tuple/list] Set the x limits of the current axes.

**ylim** [2-tuple/list] Set the y limits of the current axes.

**xlabel** [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel, or the x-column name for planar plots.

  New in version 1.1.0.

  Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

**ylabel** [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel, or the y-column name for planar plots.

  New in version 1.1.0.

  Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

**rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

**fontsize** [int, default None] Font size for xticks and yticks.

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

**position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

**table** [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

**xerr** [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

**stacked** [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

**sort_columns** [bool, default False] Sort column names to determine plot ordering.

**secondary_y** [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

**mark_right** [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

**include_bool** [bool, default is False] If True, boolean values can be plotted.
**backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`. New in version 1.0.0.

**kwargs Options to pass to matplotlib plotting method.

**Returns**

- `matplotlib.axes.Axes` or `numpy.ndarray` of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

**Notes**

- See matplotlib documentation online for more on this subject
- If `kind` = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by `position` keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**pandas.Series.pop**

*Series.pop(item)*

Return item and drops from series. Raise KeyError if not found.

**Parameters**

- `item` [label] Index of the element that needs to be removed.

**Returns**

Value that is popped from series.

**Examples**

```python
>>> ser = pd.Series([1,2,3])
>>> ser.pop(0)
1
```

```python
>>> ser
1  2
2  3
dtype: int64
```
pandas.Series.pow

Series.pow(other, level=None, fill_value=None, axis=0)

Return Exponential power of series and other, element-wise (binary operator pow).

Equivalent to `series ** other`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

Series The result of the operation.

**See also:**

Series.rpow Reverse of the Exponential power operator, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a    1.0
b   1.0
c    1.0
d    0.0
e   NaN
dtype: float64
```
**pandas.Series.prod**

`Series.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the product of the values over the requested axis.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
- ****kwargs Additional keyword arguments to be passed to the function.

**Returns**

- scalar or Series (if level specified)

**See also:**

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.

**Examples**

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.
```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.Series.product**

Series.product\((axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)\)
Return the product of the values over the requested axis.

**Parameters**

- `axis`\([\{index (0)\}]\) Axis for the function to be applied on.
- `skipna`\([\text{bool, default True}]\) Exclude NA/null values when computing the result.
- `level`\([\text{int or level name, default None}]\) If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- `numeric_only`\([\text{bool, default None}]\) Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `min_count`\([\text{int, default 0}]\) The required number of valid values to perform the operation.
  If fewer than \text{min\_count} non-NA values are present the result will be NA.
- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

- scalar or Series (if level specified)

**See also:**

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

`pandas.Series.quantile`

`Series.quantile(q=0.5, interpolation='linear')`

Return value at the given quantile.

Parameters

- `q` [float or array-like, default 0.5 (50% quantile)] The quantile(s) to compute, which can lie in range: 0 <= q <= 1.
- `interpolation` [\{’linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’\}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:
  - linear: \(i + (j - i) \times \text{fraction}\), where fraction is the fractional part of the index surrounded by i and j.
  - lower: i.
  - higher: j.
  - nearest: i or j whichever is nearest.
  - midpoint: (i + j) / 2.

Returns

- float or Series If q is an array, a Series will be returned where the index is q and the values are the quantiles, otherwise a float will be returned.

See also:

- `core.window.Rolling.quantile` Calculate the rolling quantile.
- `numpy.percentile` Returns the q-th percentile(s) of the array elements.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25 1.75
0.50 2.50
0.75 3.25
dtype: float64
```

**pandas.Series.radd**

Series.radd(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Addition of series and other, element-wise (binary operator radd).

Equivalent to other + series, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

Series The result of the operation.

**See also:**

*Series.add* Element-wise Addition, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
```

```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
```
```python
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```

**pandas.Series.rank**

`Series.rank(axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)`

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

**Parameters**

- **axis** [[0 or 'index', 1 or 'columns'], default 0] Index to direct ranking.
- **method** [[‘average’, ‘min’, ‘max’, ‘first’, ‘dense’], default ‘average’] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups.
- **numeric_only** [bool, optional] For DataFrame objects, rank only numeric columns if set to True.
- **na_option** [[‘keep’, ‘top’, ‘bottom’], default ‘keep’] How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign lowest rank to NaN values
  - bottom: assign highest rank to NaN values
- **ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.
- **pct** [bool, default False] Whether or not to display the returned rankings in percentile form.

**Returns**

- **same type as caller** Return a Series or DataFrame with data ranks as values.

**See also:**

- `core.groupby.GroupBy.rank` Rank of values within each group.
Examples

```python
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                           'spider', 'snake'],
...                        'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
  Animal  Number_legs
 0  cat      4.0
 1 penguin  2.0
 2   dog      4.0
 3  spider     8.0
 4   snake  NaN
```

The following example shows how the method behaves with the above parameters:

- **default_rank**: this is the default behaviour obtained without using any parameter.
- **max_rank**: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)
- **NA_bottom**: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- **pct_rank**: when setting `pct = True`, the ranking is expressed as percentile rank.

```python
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
  Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
 0  cat       4.0       2.5         3.0       2.5      0.625
 1 penguin  2.0         1.0         1.0       1.0      0.250
 2   dog      4.0       2.5         3.0       2.5      0.625
 3  spider     8.0       4.0         4.0       4.0      1.000
 4   snake  NaN        NaN        NaN      NaN       NaN
```

**pandas.Series.ravel**

Series.ravel(order='C')

Return the flattened underlying data as an ndarray.

**Returns**

numpy.ndarray or ndarray-like Flattened data of the Series.

**See also:**

numpy.ndarray.ravel Return a flattened array.
pandas.Series.rdiv

Series.rdiv(other, level=None, fill_value=None, axis=0)
Return Floating division of series and other, element-wise (binary operator /). Equivalent to other / series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters
other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns
Series The result of the operation.

See also:
Series.truediv Element-wise Floating division, see Python documentation for more details.

Examples

```python
code=
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```
pandas.Series.rdivmod

```
Series.rdivmod(other, level=None, fill_value=None, axis=0)
```

Return integer division and modulo of series and other, element-wise (binary operator `rdivmod`). Equivalent to `other divmod series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

2-Tuple of Series The result of the operation.

See also:

- `Series.divmod` Element-wise integer division and modulo, see Python documentation for more details.

**Examples**

```python
g>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
g>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
g>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
g>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
g>>> a.rdivmod(b, fill_value=0)
g(a 1.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64,
a 0.0
b NaN
c NaN
d 0.0)
```
pandas.Series.reindex

Series.reindex(index=None, **kwargs)
Conform Series to new index with optional filling logic.
Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

Parameters

- **index** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.
- **method** [[None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’]] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: Propagate last valid observation forward to next valid.
  - backfill / bfill: Use next valid observation to fill gap.
  - nearest: Use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
- **limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs(index[indexer] - target)} \leq \text{tolerance} \).
  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

Series with changed index.

See also:

- DataFrame.set_index Set row labels.
- DataFrame.reset_index Remove row labels or move them to new columns.
- DataFrame.reindex_like Change to same indices as other DataFrame.
Examples

DataFrame.reindex supports two calling conventions

• `(index=index_labels, columns=column_labels, ...)`

• `(labels, axis={'index', 'columns'}, ...)`

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
                              'http_status': [200, 200, 404, 404, 301],
                              'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
                              index=index)
>>> df
     http_status response_time
Firefox       200          0.04
Chrome        200          0.02
Safari        404          0.07
IE10          404          0.08
Konqueror     301          1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10', 'Chrome']
>>> df.reindex(new_index)
     http_status response_time
Safari       404.0        0.07
Iceweasel    NaN          NaN
Comodo Dragon NaN          NaN
IE10         404.0        0.08
Chrome       200.0        0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
     http_status response_time
Safari       404          0.07
Iceweasel    0            0.00
Comodo Dragon 0          0.00
IE10         404          0.08
Chrome       200          0.02
```

```python
>>> df.reindex(new_index, fill_value='missing')
     http_status response_time
Safari       404          0.07
Iceweasel  missing      missing
Comodo Dragon missing      missing
IE10         404          0.08
Chrome       200          0.02
```
We can also reindex the columns.

```
>>> df.reindex(columns=["http_status", 'user_agent'])
    http_status    user_agent
Firefox       200        NaN
Chrome        200        NaN
Safari        404        NaN
IE10          404        NaN
Konqueror     301        NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(["http_status", 'user_agent'], axis="columns")
    http_status    user_agent
Firefox       200        NaN
Chrome        200        NaN
Safari        404        NaN
IE10          404        NaN
Konqueror     301        NaN
```

To further illustrate the filling functionality in reindex, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({'prices': [100, 101, np.nan, 100, 89, 88]}, index=date_index)
...  >>> df2
     prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03         NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
     prices
2009-12-29         NaN
2009-12-30         NaN
2009-12-31         NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03         NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07         NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass bfill as an argument to
the method keyword.

```python
>>> df2.reindex(date_index2, method='bfill')
prices
2009-12-29  100.0
2009-12-30  100.0
2009-12-31  100.0
2010-01-01  100.0
2010-01-02  101.0
2010-01-03  NaN
2010-01-04  100.0
2010-01-05  89.0
2010-01-06  88.0
2010-01-07  NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the user guide for more.

**pandas.Series.reindex_like**

Series.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.
- **method** [{None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation \( \text{abs(index[indexer] - target)} \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,
array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

Series or DataFrame  Same type as caller, but with changed indices on each axis.

See also:

DataFrame.set_index  Set row labels.
DataFrame.reset_index  Remove row labels or move them to new columns.
DataFrame.reindex  Change to new indices or expand indices.

Notes

Same as calling .reindex(index=other.index, columns=other.columns,...).

Examples

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
                    [31, 87.8, 'high'],
                    [22, 71.6, 'medium'],
                    [35, 95, 'medium']],
                   columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
                   index=pd.date_range(start='2014-02-12',
                                        end='2014-02-15', freq='D'))
>>> df1
临时celsius  temp_fahrenheit  windspeed
2014-02-12  24.3           75.7      high
2014-02-13  31.0           87.8      high
2014-02-14  22.0           71.6    medium
2014-02-15  35.0           95.0    medium

>>> df2 = pd.DataFrame([[28, 'low'],
                     [30, 'low'],
                     [35.1, 'medium']],
                    columns=['temp_celsius', 'windspeed'],
                    index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
                                             '2014-02-15']))
>>> df2
临时celsius  windspeed
2014-02-12   28.0       low
2014-02-13   30.0       low
2014-02-15  35.1    medium

>>> df2.reindex_like(df1)
临时celsius  temp_fahrenheit  windspeed
2014-02-12  28.0       NaN      low
```

(continues on next page)
pandas.Series.rename

```python
Series.rename(index=None, *, axis=None, copy=True, inplace=False, level=None, errors='ignore')
```

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

Alternatively, change `Series.name` with a scalar value.

See the `user guide` for more.

**Parameters**

- `axis` [{0 or “index”}] Unused. Accepted for compatibility with DataFrame method only.
- `index` [scalar, hashable sequence, dict-like or function, optional] Functions or dict-like are transformations to apply to the index. Scalar or hashable sequence-like will alter the `Series.name` attribute.
- `**kwargs` Additional keyword arguments passed to the function. Only the “inplace” keyword is used.

**Returns**

`Series` or `None` Series with index labels or name altered or None if `inplace=True`.

See also:

- `DataFrame.rename` Corresponding DataFrame method.
- `Series.rename_axis` Set the name of the axis.

**Examples**

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0 1
1 2
2 3
dtype: int64
>>> s.rename("my_name") # scalar, changes Series.name
0 1
1 2
2 3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2) # function, changes labels
0 1
1 2
4 3
dtype: int64
```
>>>
s.rename({1: 3, 2: 5}) # mapping, changes labels
0   1
3   2
5   3
dtype: int64

pandas.Series.rename_axis

Series.rename_axis(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)
Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.
index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values. Note that the columns parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.
Use either mapper and axis to specify the axis to target with mapper, or index and/or columns.
axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.
copy [bool, default True] Also copy underlying data.
inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if inplace=True.

See also:

Series.rename Alter Series index labels or name.
DataFrame.rename Alter DataFrame index labels or name.
Index.rename Set new names on index.

Notes

DataFrame.rename_axis supports two calling conventions

- (index=index_mapper, columns=columns_mapper, ...)
- (mapper, axis=('index', 'columns'), ...)
The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter copy is ignored.
The second calling convention will modify the names of the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis labels.
We highly recommend using keyword arguments to clarify your intent.
Examples

Series

```python
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0   dog
1    cat
2   monkey
dtype: object
>>> s.rename_axis("animal")
animal
0   dog
1    cat
2   monkey
dtype: object
```

DataFrame

```python
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
... "num_arms": [0, 0, 2]},
... ["dog", "cat", "monkey"]))
>>> df
      num_legs num_arms
dog        4        0
cat        4        0
monkey     2        2
>>> df = df.rename_axis("animal")
>>> df
      num_legs num_arms
animal
  dog        4        0
  cat        4        0
  monkey     2        2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
      limbs num_legs num_arms
animal
  dog        4        0
  cat        4        0
  monkey     2        2
```

MultiIndex

```python
>>> df.index = pd.MultiIndex.from_product([['mammal'],
... ['dog', 'cat', 'monkey']],
... names=['type', 'name'])
>>> df
      limbs num_legs num_arms
type name
mammal dog        4        0
   cat        4        0
  monkey     2        2
```
pandas: powerful Python data analysis toolkit, Release 1.3.4

```python
>>> df.rename_axis(index={'type': 'class'})
limbs          num_legs  num_arms
class         name
mammal       dog       4       0
              cat       4       0
              monkey    2       2

>>> df.rename_axis(columns=str.upper)
LIMBS          num_legs  num_arms
type         name
mammal       dog       4       0
              cat       4       0
              monkey    2       2
```

**pandas.Series.reorder_levels**

`Series.reorder_levels(order)`
Rearrange index levels using input order.
May not drop or duplicate levels.

**Parameters**
- `order` [list of int representing new level order] Reference level by number or key.

**Returns**
- type of caller (new object)

**pandas.Series.repeat**

`Series.repeat(repeats, axis=None)`
Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

**Parameters**
- `repeats` [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.
- `axis` [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**
- `Series` Newly created Series with repeated elements.

**See also:**
- `Index.repeat` Equivalent function for Index.
- `numpy.repeat` Similar method for `numpy.ndarray`. 

---

3.3. Series 1319
## Examples

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
>>> s.repeat(2)
0    a
   a
1    b
   b
2    c
   c
dtype: object
>>> s.repeat([1, 2, 3])
0    a
   a
1    b
   b
2    c
   c
2    c
   c
dtype: object
```

### pandas.Series.replace

The function `Series.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')` is used to replace values given in `to_replace` with `value`. Values of the Series are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

**Parameters**

- `to_replace` [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
  - numeric: numeric values equal to `to_replace` will be replaced with `value`
  - str: string exactly matching `to_replace` will be replaced with `value`
  - regex: regexs matching `to_replace` will be replaced with `value`
  - list of str, regex, or numeric:
    - First, if `to_replace` and `value` are both lists, they must be the same length.
    - Second, if `regex=True` then all of the strings in both lists will be interpreted as regexes otherwise they will match directly. This doesn't matter much for `value` since there are only a few possible substitution regexes you can use.
  - dict:
    - str, regex and numeric rules apply as above.
```
- **Dicts can be used to specify different replacement values** for different existing values. For example, `{ 'a': 'b', 'y': 'z'}` replaces the value `a` with `b` and `y` with `z`. To use a dict in this way the `value` parameter should be `None`.

- **For a DataFrame a dict can specify that different values** should be replaced in different columns. For example, `{ 'a': 1, 'b': 'z'}` looks for the value `1` in column `'a'` and the value `'z'` in column `'b'` and replaces these values with whatever is specified in `value`. The `value` parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.

- **For a DataFrame nested dictionaries, e.g., `{a: {b: np.nan}}`, are read as follows:** look in column `'a'` for the value `'b'` and replace it with NaN. The `value` parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.

  - None:
    - **This means that the regex argument must be a string**, compiled regular expression, or list, dict, ndarray or Series of such elements. If `value` is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

- **value** [scalar, dict, list, str, regex, default `None`] Value to replace any values matching `to_replace` with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

- **inplace** [bool, default `False`] If True, performs operation inplace and returns None.

- **limit** [int, default `None`] Maximum size gap to forward or backward fill.

- **regex** [bool or same types as `to_replace`, default `False`] Whether to interpret `to_replace` and/or `value` as regular expressions. If this is `True` then `to_replace` must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case `to_replace` must be `None`.

- **method** [[`{'pad', 'ffill', 'bfill', 'None'}`]] The method to use when for replacement, when `to_replace` is a scalar, list or tuple and `value` is `None`.

  Changed in version 0.23.0: Added to DataFrame.

**Returns**

- **Series** Object after replacement.

**Raises**

- **AssertionError**
  - If `regex` is not a `bool` and `to_replace` is not `None`.

- **TypeError**
  - If `to_replace` is not a scalar, array-like, dict, or `None`
  - If `to_replace` is a `dict` and `value` is not a list, dict, ndarray, or Series
  - If `to_replace` is `None` and `regex` is not compilable into a regular expression or is a list, dict, ndarray, or Series.
• When replacing multiple bool or datetime64 objects and the arguments to `to_replace` does not match the type of the value being replaced

ValueError

• If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

See also:

`Series.fillna` Fill NA values.

`Series.where` Replace values based on boolean condition.

`Series.str.replace` Simple string replacement.

Notes

• Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When dict is used as the `to_replace` value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`:

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0 5
1 1
2 2
3 3
4 4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
```

```python
>>> df.replace(0, 5)
A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

• When replacing multiple bool or datetime64 objects and the arguments to `to_replace` does not match the type of the value being replaced

ValueError

• If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

See also:

`Series.fillna` Fill NA values.

`Series.where` Replace values based on boolean condition.

`Series.str.replace` Simple string replacement.

Notes

• Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When dict is used as the `to_replace` value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`:

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0 5
1 1
2 2
3 3
4 4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
```

```python
>>> df.replace(0, 5)
A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```
List-like `to_replace`

```python
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```python
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```python
>>> s.replace([1, 2], method='bfill')
0     0
1     3
2     3
3     3
4     4
dtype: int64
```

dict-like `to_replace`

```python
>>> df.replace({0: 10, 1: 100})
   A  B  C
0 10  5  a
1 100  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  400  9  e
```

Regular expression `to_replace`

```python
>>> df.replace('A')
```

3.3. Series 1323
```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
                   'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new  abc
1    foo  new
2   bait  xyz
```

```python
>>> df.replace({r'^ba.$': 'new'})
   A  B
0  new  abc
1    foo  new
2   bait  xyz
```

```python
>>> df.replace(regex={r'^ba.$': 'new'}, value='new')
   A  B
0  new  abc
1    foo  new
2   bait  xyz
```

```python
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new  abc
1    new  new
2   bait  xyz
```

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0  10
1  None
2  None
3   b
4  None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:
```python
>>> s.replace('a', None)
0 10
1 10
2 10
3 b
4 b
dtype: object
```

**pandas.Series.resample**

The function `Series.resample()` is used to resample time-series data. It provides a convenient method for frequency conversion and resampling of time series. The object must have a datetime-like index (`DatetimeIndex`, `PeriodIndex`, or `TimedeltaIndex`), or the caller must pass the label of a datetime-like series/index to the `on` or `level` keyword parameter.

**Parameters**

- `rule` ([DateOffset, Timedelta or str]) The offset string or object representing target conversion.
- `axis` ([0 or 'index', 1 or 'columns'], default 0) Which axis to use for up- or down-sampling. For `Series` this will default to 0, i.e. along the rows. Must be `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`.
- `closed` ([{'right', 'left'}, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.
- `label` ([{'right', 'left'}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.
- `convention` ([{'start', 'end', 's', 'e'}, default 'start'] For `PeriodIndex` only, controls whether to use the start or end of `rule`.
- `kind` ([‘timestamp’, ‘period’], optional, default None] Pass ‘timestamp’ to convert the resulting index to a `DateTimeIndex` or ‘period’ to convert it to a `PeriodIndex`. By default the input representation is retained.
- `loffset` [timedelta, default None] Adjust the resampled time labels. Deprecated since version 1.1.0: You should add the loffset to the `df.index` after the resample. See below.
- `base` [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0. Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.
- `on` [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.
- `level` [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. `level` must be datetime-like.
**origin** [[‘epoch’, ‘start’, ‘start_day’, ‘end’, ‘end_day’], Timestamp] or str, default ‘start_day’ The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: *origin* is 1970-01-01
- ‘start’: *origin* is the first value of the timeseries
- ‘start_day’: *origin* is the first day at midnight of the timeseries

New in version 1.1.0.

- ‘end’: *origin* is the last value of the timeseries
- ‘end_day’: *origin* is the ceiling midnight of the last day

New in version 1.3.0.

**offset** [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

**Returns**

`pandas.core.Resampler` Resampler object.

**See also:**

- `Series.resample` Resample a Series.
- `DataFrame.resample` Resample a DataFrame.
- `groupby` Group Series by mapping, function, label, or list of labels.
- `asfreq` Reindex a Series with the given frequency without grouping.

**Notes**

See the user guide for more.

To learn more about the offset strings, please see this link.

**Examples**

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
  2000-01-01 00:00:00    0
  2000-01-01 00:01:00    1
  2000-01-01 00:02:00    2
  2000-01-01 00:03:00    3
  2000-01-01 00:04:00    4
  2000-01-01 00:05:00    5
  2000-01-01 00:06:00    6
  2000-01-01 00:07:00    7
  2000-01-01 00:08:00    8
Freq: T, dtype: int64
```
Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00    12
2000-01-01 00:06:00    21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00    12
2000-01-01 00:09:00    21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00    15
2000-01-01 00:09:00    15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```python
>>> series.resample('30S').bfill()[0:5]
(continues on next page)
Pass a custom function via apply

```python
>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
...  
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00     8
2000-01-01 00:03:00    17
2000-01-01 00:06:00    26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of `rule`.

Resample a year by quarter using 'start' `convention`. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                freq='A',
...                periods=2))
>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64

>>> s.resample('Q', convention='start').asfreq()
2012Q1 1.0
2012Q2 NaN
2012Q3 NaN
2012Q4 NaN
2013Q1 2.0
2013Q2 NaN
2013Q3 NaN
2013Q4 NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' `convention`. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                freq='Q',
...                periods=4))
>>> q
2018Q1 1
2018Q2 2
2018Q3 3
2018Q4 4
Freq: Q-DEC, dtype: int64

>>> q.resample('M', convention='end').asfreq()
2018-03 1.0
```

(continues on next page)
For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
       ...     'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
                                      ...     periods=8,
                                      ...     freq='W')
>>> df
   price  volume  week_starting
0     10      50   2018-01-07
1     11      60   2018-01-14
2      9      40   2018-01-21
3     13     100   2018-01-28
4     14      50   2018-02-04
5     18     100   2018-02-11
6     17      40   2018-02-18
7     19      50   2018-02-25
>>> df.resample('M', on='week_starting').mean()
   price  volume
week_starting
2018-01-31  10.75  62.5
2018-02-28  17.00  60.0
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
       ...     'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(d2,
                     ...     index=pd.MultiIndex.from_product([days, ['morning', 'afternoon']])
                     ... )
>>> df2
   price  volume
2000-01-01 morning     10      50
                         afternoon  11      60
```
If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64

```
If you want to adjust the start of the bins with an `offset` Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
