<td>Return a Dataframe of the components of the Timedeltas.</td>
</tr>
</tbody>
</table>

pandas.Series.dt.days

Series.dt.days
    Number of days for each element.

pandas.Series.dt.seconds

Series.dt.seconds
    Number of seconds (>= 0 and less than 1 day) for each element.

pandas.Series.dt.microseconds

Series.dt.microseconds
    Number of microseconds (>= 0 and less than 1 second) for each element.

pandas.Series.dt.nanoseconds

Series.dt.nanoseconds
    Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
Series.dt.components

Series.dt.components
Return a DataFrame of the components of the Timedeltas.

Returns
DataFrame

Examples

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0    0 days 00:00:00
1    1 days 00:00:01
2    2 days 00:00:02
3    3 days 00:00:03
4    4 days 00:00:04
dtype: timedelta64[ns]

>>> s.dt.components
                        days       hours       minutes     seconds   milliseconds   microseconds     nanoseconds
0                  0          0            0           0               0                 0                0
1                  0          0            0           1               0                 0                0
2                  0          0            0           2               0                 0                0
3                  0          0            0           3               0                 0                0
4                  0          0            0           4               0                 0                0
```

Timedelta methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.to_pytimedelta()</td>
<td>Return an array of native <code>datetime.timedelta</code> objects.</td>
</tr>
<tr>
<td>Series.dt.total_seconds(*args, **kwargs)</td>
<td>Return total duration of each element expressed in seconds.</td>
</tr>
</tbody>
</table>

pandas.Series.dt.to_pytimedelta

Series.dt.to_pytimedelta()
Return an array of native `datetime.timedelta` objects.

Python’s standard `datetime` library uses a different representation `timedelta`’s. This method converts a Series of pandas Timedeltas to `datetime.timedelta` format with the same length as the original Series.

Returns

- `numpy.ndarray`: Array of 1D containing data with `datetime.timedelta` type.

See also:

- `datetime.timedelta`: A duration expressing the difference between two date, time, or datetime.
Examples

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]

>>> s.dt.to_pytimedelta()
array([timedelta(0), timedelta(days=1),
          timedelta(days=2), timedelta(days=3),
          timedelta(days=4)], dtype=object)
```

**pandas.Series.dt.total_seconds**

Series.dt.total_seconds(*args, **kwargs)

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the .dt namespace.

**Returns**

seconds [[ndarray, Float64Index, Series]] When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type float64 whose index is the same as the original.

**See also:**

datetime.timedelta.total_seconds Standard library version of this method.

TimedeltaIndex.components Return a DataFrame with components of each Timedelta.

Examples

Series

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]

>>> s.dt.total_seconds()
0     0.0
1   86400.0
2  172800.0
3  259200.0
4  345600.0
dtype: float64
```
TimedeltaIndex

```python
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

```python
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.0000000003, 345600.0],
              dtype='float64')
```

String handling

Series.str can be used to access the values of the series as strings and apply several methods to it. These can be accessed like Series.str.<function/property>.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>

</table>
**pandas.Series.str.capitalize**

Series.str.\texttt{capitalize}()  
Convert strings in the Series/Index to be capitalized.  
Equivalent to \texttt{str.capitalize()}.  
returns  
Series or Index of object

See also:  
\texttt{Series.str.lower} Converts all characters to lowercase.  
\texttt{Series.str.upper} Converts all characters to uppercase.  
\texttt{Series.str.title} Converts first character of each word to uppercase and remaining to lowercase.  
\texttt{Series.str.capitalize} Converts first character to uppercase and remaining to lowercase.  
\texttt{Series.str.swapcase} Converts uppercase to lowercase and lowercase to uppercase.  
\texttt{Series.str.casefold} Removes all case distinctions in the string.

**Examples**

```python  
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])  
>>> s  
0    lower  
1   CAPITALS  
2  this is a sentence  
3   SwApCaSe  
dtype: object  

>>> s.str.lower()  
0    lower  
1   capitals  
2  this is a sentence  
3   swapcase  
dtype: object  

>>> s.str.upper()  
0    LOWER  
1   CAPITALS  
2  THIS IS A SENTENCE  
3   SWAPCASE  
dtype: object  

>>> s.str.title()  
0    Lower  
1   Capitals  
2  This Is A Sentence  
3   Swapcase  
dtype: object  

>>> s.str.capitalize()  
0    Lower  
1   Capitals  
2  This is a sentence  
3   Swapcase  
dtype: object  
```
pandas.Series.str.casefold

Series.str.casefold()
Convert strings in the Series/Index to be casefolded.
New in version 0.25.0.
Equivalent to str.casefold().
Returns
Series or Index of object
See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0       lower
1  CAPITALS
2  this is a sentence
3       SwApCaSe
dtype: object
```

```python
>>> s.str.lower()
0 lower
1 capitals
2 this is a sentence
3 swapcase
```

```python
>>> s.str.upper()
0 LOWER
1 CAPITALS
2 THIS IS A SENTENCE
3 SWAPCASE
```

```python
>>> s.str.title()
0 Lower
(continues on next page)
```
1 Capitals
2 This Is A Sentence
3 Swapcase
dtype: object

```python
>>> s.str.capitalize()
0 Lower
1 Capitals
2 This is a sentence
3 Swapcase
dtype: object
```

```python
>>> s.str.swapcase()
0 LOWER
1 capitals
2 THIS IS A SENTENCE
3 sWaPcAsE
dtype: object
```

**pandas.Series.str.cat**

Series.str.cat( **others=None, sep=None, na_rep=None, join='left'** )

Concatenate strings in the Series/Index with given separator.

If **others** is specified, this function concatenates the Series/Index and elements of **others** element-wise. If **others** is not passed, then all values in the Series/Index are concatenated into a single string with a given **sep**.

**Parameters**

- **others** [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if **join** is not None.

If others is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If others is None, the method returns the concatenation of all strings in the calling Series/Index.

- **sep** [str, default ‘’] The separator between the different elements/columns. By default the empty string ‘’ is used.

- **na_rep** [str or None, default None] Representation that is inserted for all missing values:
  - If **na_rep** is None, and **others** is None, missing values in the Series/Index are omitted from the result.
  - If **na_rep** is None, and **others** is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

- **join** [‘left’, ‘right’, ‘outer’, ‘inner’], default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in **others** (objects without an index need to match the length of the calling Series/Index). To disable alignment, use .values on any Series/Index/DataFrame in **others**.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of **join** from None to ‘left’.

1312 Chapter 3. API reference
Returns

str, Series or Index  If others is None, str is returned, otherwise a Series/Index (same type as caller) of objects is returned.

See also:
split  Split each string in the Series/Index.
join  Join lists contained as elements in the Series/Index.

Examples

When not passing others, all values are concatenated into a single string:

```python
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using na_rep, they can be given a representation:

```python
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If others is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0 a,A
1 b,B
2 NaN
3 d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using na_rep

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep='?', na_rep='--')
0 a,A
1 b,B
2 --,C
3 d,D
dtype: object
```

If sep is not specified, the values are concatenated without separation.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0 aA
1 bB
2 -,C
3 dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The join-keyword works as in other methods.

```python
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0 aa
1 b-
2 -,C
3 dd
dtype: object
```

(continues on next page)
dtype: object

>>> s.str.cat(t, join='outer', na_rep='-')
0    aa
1   -b
2    -c
3     dd
4    -e
dtype: object

>>> s.str.cat(t, join='inner', na_rep='-')
0    aa
2    -c
3     dd
dtype: object

>>> s.str.cat(t, join='right', na_rep='-')
3     dd
0    aa
4    -e
2    -c
dtype: object

For more examples, see here.

**pandas.Series.str.center**

Series.str.center(width, fillchar='')

Pad left and right side of strings in the Series/Index.

Equivalent to str.center().

Parameters

- **width** [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- **fillchar** [str] Additional character for filling, default is whitespace.

Returns

filled [Series/Index of objects.]

**pandas.Series.str.contains**

Series.str.contains(pat, case=True, flags=0, na=None, regex=True)

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

Parameters

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.
na [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

regex [bool, default True] If True, assumes the pat is a regular expression. If False, treats the pat as a literal string.

Returns
Series or Index of boolean values A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

See also:
macth Analogous, but stricter, relying on re.match instead of re.search.
Series.str.startswith Test if the start of each string element matches a pattern.
Series.str.endswith Same as startswith, but tests the end of string.

Examples
Returning a Series of booleans using only a literal pattern.

```python
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0   False
1   True
2   False
3   False
4     NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```python
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using case.

```python
>>> s1.str.contains('oG', case=True, regex=True)
0   False
1   False
2   False
3   False
4     NaN
dtype: object
```

Specifying na to be False instead of NaN replaces NaN values with False. If Series or Index does not contain NaN values the resultant dtype will be bool, otherwise, an object dtype.

```python
>>> s1.str.contains('og', na=False, regex=True)
0   False
1   True
2   False
3   False
4   False
dtype: bool
```

Returning ‘house’ or ‘dog’ when either expression occurs in a string.
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4     NaN
dtype: object

Ignoring case sensitivity using flags with regex.

>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0   False
1   False
2     True
3    False
4     NaN
dtype: object

Returning any digit using regular expression.

>>> s1.str.contains('\\d', regex=True)
0   False
1   False
2   False
3     True
4     NaN
dtype: object

Ensure pat is a not a literal pattern when regex is set to True. Note in the following example one might expect only s2[1] and s2[3] to return True. However, ".0" as a regex matches any character followed by a 0.

>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0    True
1    True
2   False
3    True
4   False
dtype: bool

pandas.Series.str.count

Series.str.count (pat, flags=0)
Count occurrences of pattern in each string of the Series/Index.
This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the Series.

Parameters

pat [str] Valid regular expression.
flags [int, default 0, meaning no flags] Flags for the re module. For a complete list, see here.
**kwargs For compatibility with other string methods. Not used.

Returns
Series or Index  Same type as the calling object containing the integer counts.

See also:

- re Standard library module for regular expressions.
- str.count Standard library version, without regular expression support.

Notes

Some characters need to be escaped when passing in pat. eg. '\$' has a special meaning in regex and must be escaped when finding this literal character.

Examples

```python
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape '\$' to find the literal dollar sign.

```python
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\\$')
0   1
1   0
2   1
3   2
4   2
5   0
dtype: int64
```

This is also available on Index.

```python
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

pandas.Series.str.decode

Series.str.decode(encoding, errors='strict')

Decode character string in the Series/Index using indicated encoding.

Equivalent to str.decode() in python2 and bytes.decode() in python3.

Parameters

- encoding  [str]
- errors     [str, optional]

Returns

Series or Index
pandas.Series.str.encode

Series.str.encode (encoding, errors='strict')
   Encode character string in the Series/Index using indicated encoding.
   Equivalent to str.encode().
   Parameters
   encoding [str]
   errors [str, optional]
   Returns
   encoded [Series/Index of objects]

pandas.Series.str.endswith

Series.str.endswith (pat, na=None)
   Test if the end of each string element matches a pattern.
   Equivalent to str.endswith().
   Parameters
   pat [str] Character sequence. Regular expressions are not accepted.
   na [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.
   Returns
   Series or Index of bool  A Series of booleans indicating whether the given pattern matches the end of each string element.
   See also:
   str.endswith Python standard library string method.
   Series.str.startswith Same as endswith, but tests the start of string.
   Series.str.contains Tests if string element contains a pattern.

Examples

```python
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
  0  bat
  1  bear
  2  caT
  3  NaN
  dtype: object

>>> s.str.endswith('t')
  0  True
  1  False
  2  False
  3  NaN
  dtype: object
```

Specifying na to be False instead of NaN.
pandas.Series.str.extract

Series.str.extract \( (\text{pat, flags=}0, \text{expand=}True) \)
Extract capture groups in the regex \( \text{pat} \) as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression \( \text{pat} \).

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] Flags from the \( \text{re} \) module, e.g. \( \text{re.IGNORECASE} \), that modify regular expression matching for things like case, spaces, etc. For more details, see \( \text{re} \).
- **expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

**Returns**

- **DataFrame or Series or Index** A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression \( \text{pat} \) will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If \( \text{expand=}\text{False} \) and \( \text{pat} \) has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

**See also:**

- **extractall** Returns all matches (not just the first match).

**Examples**

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```python
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'\[(ab)\](\d)')
    0  1
   --- ---
0  a  1
1  b  2
2  NaN NaN
```

A pattern may contain optional groups.

```python
>>> s.str.extract(r'\[(ab)\]?\d')
    0  1
   --- ---
0  a  1
1  b  2
2  NaN 3
```

Named groups will become column names in the result.
```python
>>> s.str.extract(r'(?P<letter>[ab]) (?P<digit>\d)')
   letter digit
0     a     1
1     b     2
2    NaN  NaN

A pattern with one group will return a DataFrame with one column if expand=True.

```  

```python
>>> s.str.extract(r'\[ab\](\d)', expand=True)
   0
0  1
1  2
2 NaN

A pattern with one group will return a Series if expand=False.

```  

```python
>>> s.str.extract(r'\[ab\](\d)', expand=False)
   0
0  1
1  2
2 NaN

dtype: object
```

### pandas.Series.str.extractall

**DataFrame**  
Extract capture groups in the regex `pat` as columns in DataFrame.  

For each subject string in the Series, extract groups from all matches of regular expression `pat`. When each subject string in the Series has exactly one match, `extractall(pat).xs(0, level='match')` is the same as `extract(pat)`.

**Parameters**

- `pat`  
  [str] Regular expression pattern with capturing groups.

- `flags`  
  [int, default 0 (no flags)] A `re` module flag, for example `re.IGNORECASE`. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example `re.IGNORECASE | re.MULTILINE`.

**Returns**

- `DataFrame`  
  A DataFrame with one row for each match, and one column for each group. Its rows have a `MultiIndex` with first levels that come from the subject `Series`. The last level is named ‘match’ and indexes the matches in each item of the `Series`. Any capture group names in regular expression `pat` will be used for column names; otherwise capture group numbers will be used.

**See also:**

- `extract`  
  Returns first match only (not all matches).
Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```python
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)"
                     
        0
match
A 0 1
1 2
B 0 1
```

Capture group names are used for column names of the result.

```python
>>> s.str.extractall(r"[ab](?P<digit>\d)"
                     
        digit
match
A 0 1
1 2
B 0 1
```

A pattern with two groups will return a DataFrame with two columns.

```python
>>> s.str.extractall(r"(?P<letter>[ab])\(?P<digit>\d)"
                     
  letter digit
match
A 0 a 1
1 a 2
B 0 b 1
```

Optional groups that do not match are NaN in the result.

```python
>>> s.str.extractall(r"(?P<letter>[ab])\(?P<digit>\d)"
                     
  letter digit
match
A 0 a 1
1 a 2
B 0 b 1
C 0 NaN 1
```

**pandas.Series.str.find**

Series.str.\textbf{find}(\textit{sub, start=0, end=None})

Return lowest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between \texttt{[start:end]}.

Return -1 on failure. Equivalent to standard \texttt{str.find()}.

**Parameters**

- \textit{sub} \[str\] Substring being searched.
- \textit{start} \[int\] Left edge index.
- \textit{end} \[int\] Right edge index.

**Returns**

Series or Index of int.

See also:

- `rfind` Return highest indexes in each strings.

**pandas.Series.str.findall**

```python
Series.str.findall(pat, flags=0)
```

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

**Parameters**

- `pat` [str] Pattern or regular expression.
- `flags` [int, default 0] Flags from `re` module, e.g. `re.IGNORECASE` (default is 0, which means no flags).

**Returns**

- **Series/Index of lists of strings** All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

**See also:**

- `count` Count occurrences of pattern or regular expression in each string of the Series/Index.
- `extractall` For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.
- `re.findall` The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

**Examples**

```python
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern ‘Monkey’ returns one match:

```python
>>> s.str.findall('Monkey')
0    []
1  [Monkey]
2    []
dtype: object
```

On the other hand, the search for the pattern ‘MONKEY’ doesn’t return any match:

```python
>>> s.str.findall('MONKEY')
0    []
1    []
2    []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern ‘MONKEY’ ignoring the case:

```python
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0    []
```

(continues on next page)
When the pattern matches more than one string in the Series, all matches are returned:

```python
>>> s.str.findall('on')
0    [on]
1    [on]
2     []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word ‘on’ is shown next:

```python
>>> s.str.findall('on$')
0    [on]
1     []
2     []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```python
>>> s.str.findall('b')
0     []
1     []
2    [b, b]
dtype: object
```

### pandas.Series.str.get

**Series.str.get(i)**

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

**Parameters**

- **i** [int] Position of element to extract.

**Returns**

Series or Index

**Examples**

```python
>>> s = pd.Series(["String",
...                 (1, 2, 3),
...                 ["a", "b", "c"],
...                 123,
...                 -456,
...                 {1: "Hello", "2": "World"}])
>>> s
0    String
1    (1, 2, 3)
2    [a, b, c]
3       123
4      -456
5  {1: "Hello", "2": "World"}
```
In [3]: s.str.get(1)
Out[3]

0  t
1  2
2  b
3  NaN
4  NaN
5  Hello

dtype: object

In [4]: s.str.get(-1)
Out[4]

0  g
1  3
2  c
3  NaN
4  NaN
5  None

dtype: object

**pandas.Series.str.index**

`Series.str.index(sub, start=0, end=None)`

Return lowest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.index`.

**Parameters**

- `sub` [str] Substring being searched.
- `start` [int] Left edge index.
- `end` [int] Right edge index.

**Returns**

Series or Index of object

**See also:**

`rindex` Return highest indexes in each strings.
pandas.Series.str.join

Series.str.join(sep)
Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to str.join().

Parameters

sep [str] Delimiter to use between list entries.

Returns

Series/Index: object The list entries concatenated by intervening occurrences of the delimiter.

Raises

AttributeError If the supplied Series contains neither strings nor lists.

See also:
str.join Standard library version of this method.
Series.str.split Split strings around given separator/delimiter.

Notes

If any of the list items is not a string object, the result of the join will be NaN.

Examples

Example with a list that contains non-string elements.

```python
>>> s = pd.Series([['lion', 'elephant', 'zebra'],
...                  [1.1, 2.2, 3.3],
...                  ['cat', np.nan, 'dog'],
...                  ['cow', 4.5, 'goat'],
...                  ['duck', ['swan', 'fish'], 'guppy']])
```

Join all lists using a ‘-‘. The lists containing object(s) of types other than str will produce a NaN.

```python
>>> s.str.join('-')
0   lion-elephant-zebra
1           NaN
2         NaN
3         NaN
4         NaN
```

3.3. Series 1325
pandas.Series.str.len

Series.str.len()
Compute the length of each element in the Series/Index.

   The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

Returns

Series or Index of int  A Series or Index of integer values indicating the length of each element in the Series or Index.

See also:

str.len  Python built-in function returning the length of an object.
Series.size  Returns the length of the Series.

Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```python
>>> s = pd.Series(['dog', 
... '', 
... 5, 
... ('foo' : 'bar'), 
... [2, 3, 5, 7], 
... {'one' : 'two', 'three'}])

>>> s
0    dog
1    
2    5
3   {'foo': 'bar'}
4    [2, 3, 5, 7]
5  {'one': 'two', 'three'}

dtype: object
```

```python
>>> s.str.len()
0   3.0
1   0.0
2  NaN
3   1.0
4   4.0
5   3.0

dtype: float64
```

pandas.Series.str.ljust

Series.str.ljust(width, fillchar='')
Pad right side of strings in the Series/Index.

Equivalent to str.ljust().

Parameters

width  [int]  Minimum width of resulting string; additional characters will be filled with fillchar.

fillchar  [str]  Additional character for filling, default is whitespace.

Returns
filled  [Series/Index of objects.]

pandas.Series.str.lower

Series.str.lower()
Convert strings in the Series/Index to lowercase.
Equivalent to str.lower().
Returns
Series or Index of object

See also:
Series.str.lower  Converts all characters to lowercase.
Series.str.upper  Converts all characters to uppercase.
Series.str.title  Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize  Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase  Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold  Removes all case distinctions in the string.

Examples

>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0   lower
1  CAPITALS
2  this is a sentence
3    SwApCaSe
dtype: object

>>> s.str.lower()
0   lower
1  capitals
2  this is a sentence
3  swapcase
dtype: object

>>> s.str.upper()
0   LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  SWAPCASE
dtype: object

>>> s.str.title()
0   Lower
1   Capitals
2  This Is A Sentence
3    Swapcase
dtype: object

>>> s.str.capitalize()
0   Lower
1   Capitals

(continues on next page)
| 2 | This is a sentence          |
| 3 | Swapcase                  |
|   | dtype: object             |

```python
>>> s.str.swapcase()
0    LOWER
1   capitals
2  THIS IS A SENTENCE
3    sWaPcAsE
dtype: object
```

### pandas.Series.str.lstrip

**Series.str.lstrip**(to\_strip=None)  
Remove leading characters.  

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

#### Parameters

- **to\_strip** : [str or None, default None]  
  Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

#### Returns

Series or Index of object

**See also:**

- `Series.str.strip`  
  Remove leading and trailing characters in Series/Index.
- `Series.str.lstrip`  
  Remove leading characters in Series/Index.
- `Series.str.rstrip`  
  Remove trailing characters in Series/Index.

#### Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?\t', np.nan])

0    1. Ant.
1    Bee!
2    Cat?
3  NaN
dtype: object

>>> s.str.strip()
0    1. Ant.
1    Bee!
2    Cat?
3  NaN
dtype: object

>>> s.str.lstrip('123.')
0    Ant.
1    Bee!
```

(continues on next page)
pandas.Series.str.match

Series.str.match (pat, case=True, flags=0, na=None)
Determine if each string starts with a match of a regular expression.

Parameters
- pat [str] Character sequence or regular expression.
- case [bool, default True] If True, case sensitive.
- flags [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.
- na [scalar, optional] Fill value for missing values. The default depends on dtype of the array.
  For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

Returns
Series/array of boolean values

See also:
- fullmatch Stricter matching that requires the entire string to match.
- contains Analogous, but less strict, relying on re.search instead of re.match.
- extract Extract matched groups.

pandas.Series.str.normalize

Series.str.normalize(form)
Return the Unicode normal form for the strings in the Series/Index.

For more information on the forms, see the unicodedata.normalize().

Parameters

Returns
- normalized [Series/Index of objects]
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.Series.str.pad**

Series.str.pad(width, side='left', fillchar=' ')

Pad strings in the Series/Index up to width.

**Parameters**

- **width** [int] Minimum width of resulting string; additional characters will be filled with character defined in `fillchar`.
- **side** [{'left', 'right', 'both'}, default 'left'] Side from which to fill resulting string.
- **fillchar** [str, default ' '] Additional character for filling, default is whitespace.

**Returns**

Series or Index of object Returns Series or Index with minimum number of char in object.

**See also:**

- `Series.str.rjust` Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.
- `Series.str.ljust` Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.
- `Series.str.center` Fills both sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.
- `Series.str.zfill` Pad strings in the Series/Index by prepending '0' character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.

**Examples**

```python
>>> s = pd.Series(['caribou', 'tiger'])
>>> s
0    caribou
1     tiger
dtype: object

>>> s.str.pad(width=10)
0  caribou
1   tiger
dtype: object

>>> s.str.pad(width=10, side='right', fillchar='-')
0  caribou-----
1   tiger-----
dtype: object

>>> s.str.pad(width=10, side='both', fillchar='-')
0 -caribou-----
1 --tiger------
dtype: object
```
**pandas.Series.str.partition**

Series.str.partition(sep=' ', expand=True)

Split the string at the first occurrence of sep.

This method splits the string at the first occurrence of sep, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

**Parameters**

- `sep` [str, default whitespace] String to split on.
- `expand` [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

**Returns**

DataFrame/MultiIndex or Series/Index of objects

**See also:**

- `rpartition` Split the string at the last occurrence of sep.
- `Series.str.split` Split strings around given separators.
- `str.partition` Standard library version.

**Examples**

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object

>>> s.str.partition()
   0  1  2
0  Linda   van der Berg
1  George   Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
   0  1  2
0  Linda van der Berg
1  George Pitt-Rivers
```

To partition by something different than a space:

```python
>>> s.str.partition('-')
   0  1  2
0  Linda van der Berg
1  George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
   0 (Linda van der Berg, , )
   1 (George Pitt, -, Rivers)
```

```
Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
            ('Y', ' ', '999')],
           )
```

Or an index with tuples with `expand=False`:

```python
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

### pandas.Series.str.repeat

**Series.str.repeat** (*repeats*)

Duplicate each string in the Series or Index.

**Parameters**

- **repeats** [int or sequence of int] Same value for all (int) or different value per (sequence).

**Returns**

- **Series or Index of object** Series or Index of repeated string objects specified by input parameter repeats.

**Examples**

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0 a
1 b
2 c
dtype: object
```

**Single int repeats string in Series**

```python
>>> s.str.repeat(repeats=2)
0  aa
1  bb
2  cc
dtype: object
```

**Sequence of int repeats corresponding string in Series**

```python
>>> s.str.repeat(repeats=[1, 2, 3])
0  a
1  bb
2  ccc
dtype: object
```
pandas.Series.str.replace

Series.str.replace(pat, repl, n=-1, case=None, flags=0, regex=None)
Replace each occurrence of pattern/regex in the Series/Index.

Equivalent to str.replace() or re.sub(), depending on the regex value.

Parameters

- **pat** [str or compiled regex] String can be a character sequence or regular expression.
- **repl** [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See re.sub().
- **n** [int, default -1 (all)] Number of replacements to make from start.
- **case** [bool, default None] Determines if replace is case sensitive:
  - If True, case sensitive (the default if pat is a string)
  - Set to False for case insensitive
  - Cannot be set if pat is a compiled regex.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE. Cannot be set if pat is a compiled regex.
- **regex** [bool, default True] Determines if assumes the passed-in pattern is a regular expression:
  - If True, assumes the passed-in pattern is a regular expression.
  - If False, treats the pattern as a literal string
  - Cannot be set to False if pat is a compiled regex or repl is a callable.

New in version 0.23.0.

Returns

- **Series or Index of object** A copy of the object with all matching occurrences of pat replaced by repl.

Raises

- **ValueError**
  - if regex is False and repl is a callable or pat is a compiled regex
  - if pat is a compiled regex and case or flags is set

Notes

When pat is a compiled regex, all flags should be included in the compiled regex. Use of case, flags, or regex=False with a compiled regex will raise an error.
Examples

When `pat` is a string and `regex` is True (the default), the given `pat` is compiled as a regex. When `repl` is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0  bao
1  baz
2  NaN
dtype: object
```

When `pat` is a string and `regex` is False, every `pat` is replaced with `repl` as with `str.replace()`:

```python
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0  bao
1  fuz
2  NaN
dtype: object
```

When `repl` is a callable, it is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0  <re.Match object; span=(0, 1), match='f'>oo
1  <re.Match object; span=(0, 1), match='f'>uz
2  NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```python
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0  oof 123
1  rab zab
2  NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```python
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0  tWO
1  bAR
dtype: object
```

Using a compiled regex with flags

```python
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0  foo
1  bar
2  NaN
dtype: object
```
pandas.Series.str.rfind

Series.str.rfind(sub, start=0, end=None)
Return highest indexes in each strings in the Series/Index.
Each of returned indexes corresponds to the position where the substring is fully contained between [start:end].
Return -1 on failure. Equivalent to standard str.rfind().

Parameters
- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

Returns
Series or Index of int.

See also:
- find Return lowest indexes in each strings.

pandas.Series.str.rindex

Series.str.rindex(sub, start=0, end=None)
Return highest indexes in each string in Series/Index.
Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as str.rfind except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard str.rindex.

Parameters
- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

Returns
Series or Index of object

See also:
- index Return lowest indexes in each strings.

pandas.Series.str.rjust

Series.str.rjust(width, fillchar=' ')
Pad left side of strings in the Series/Index.
Equivalent to str.rjust().

Parameters
- width [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- fillchar [str] Additional character for filling, default is whitespace.

Returns
filled [Series/Index of objects.]
pandas.Series.str.rpartition

Series.str.rpartition(sep='\', expand=True)

Split the string at the last occurrence of sep.

This method splits the string at the last occurrence of sep, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

Parameters

- sep [str, default whitespace] String to split on.
- expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

- partition Split the string at the first occurrence of sep.
- Series.str.split Split strings around given separators.
- str.partition Standard library version.

Examples

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0   Linda van der Berg
1     George Pitt-Rivers
dtype: object

>>> s.str.partition()
    0      1      2
0  Linda    van der Berg
1    George   Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
    0      1      2
0  Linda    van der Berg
1    George   Pitt-Rivers
``` 

To partition by something different than a space:

```python
>>> s.str.partition('-')
    0      1      2
0  Linda    van der Berg
1    George   Pitt - Rivers
``` 

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
    0      1      2
0  (Linda van der Berg, )
1  (George Pitt, -, Rivers)
dtype: object
```
Also available on indices:

```python
>>> idx = pd.Index(["X 123", 'Y 999'])
>>> idx
Index(["X 123", 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([("X", ' ', '123'),
            ('Y', ' ', '999')],
           )
```

Or an index with tuples with `expand=False`:

```python
>>> idx.str.partition(expand=False)
Index(["X", ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

**pandas.Series.str.rstrip**

`Series.str.rstrip(to_strip=None)`

Remove trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

**Parameters**

- `to_strip` [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

Series or Index of object

**See also:**

- `Series.str.strip` Remove leading and trailing characters in Series/Index.
- `Series.str.lstrip` Remove leading characters in Series/Index.
- `Series.str.rstrip` Remove trailing characters in Series/Index.

**Examples**

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?\t', np.nan])
>>> s
0   1. Ant.
1   2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s.str.strip()
0   1. Ant.
1   2. Bee!
2   3. Cat?
3     NaN
dtype: object
```
>>> s.str.lstrip('123.')</br>0  Ant.  1  Bee!
2  Cat?
3  NaN  dtype: object

>>> s.str.rstrip('.!? \n\t')
0  1. Ant  1  2. Bee
2  3. Cat  2  3  NaN  dtype: object

>>> s.str.strip('123.!?
	')
0  Ant  1  Bee  2  Cat  3  NaN  dtype: object

pandas.Series.str.slice

Series.str.slice(start=None, stop=None, step=None)
Slice substrings from each element in the Series or Index.

Parameters

- **start** [int, optional] Start position for slice operation.
- **stop** [int, optional] Stop position for slice operation.
- **step** [int, optional] Step size for slice operation.

Returns

Series or Index of object  Series or Index from sliced substring from original string object.

See also:

Series.str.slice_replace  Replace a slice with a string.
Series.str.get  Return element at position. Equivalent to Series.str.slice(start=i, stop=i+1) with i being the position.

Examples

>>> s = pd.Series(['koala', 'fox', 'chameleon'])
>>> s
0  koala  1  fox
2  chameleon  dtype: object

>>> s.str.slice(start=1)
0  oala  1  ox
(continues on next page)
```
2 hameleon
dtype: object
```

```
>>> s.str.slice(start=-1)
0  a
1  x
2  n
dtype: object
```

```
>>> s.str.slice(stop=2)
0  ko
1  fo
2  ch
dtype: object
```

```
>>> s.str.slice(step=2)
0  kaa
1  fx
2  caeen
dtype: object
```

```
>>> s.str.slice(start=0, stop=5, step=3)
0  kl
1  f
2  cm
dtype: object
```

Equivalent behaviour to:

```
>>> s.str[0:5:3]
0  kl
1  f
2  cm
dtype: object
```

**pandas.Series.str.slice_replace**

Series.str.slice_replace(start=None, stop=None, repl=None)

Replace a positional slice of a string with another value.

**Parameters**

- **start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.
- **stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.
- **repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

**Returns**

Series or Index  Same type as the original object.

**See also:**

Series.str.slice  Just slicing without replacement.
### Examples

```python
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0   a
1  ab
2  abc
3  abdc
4  abcde
dtype: object
```

Specify just `start`, meaning replace `start` until the end of the string with `repl`.

```python
>>> s.str.slice_replace(1, repl='X')
0  aX
1  aX
2  aX
3  aX
4  aX
```

Specify just `stop`, meaning the start of the string to `stop` is replaced with `repl`, and the rest of the string is included.

```python
>>> s.str.slice_replace(stop=2, repl='X')
0  X
1  X
2  Xc
3  Xdc
4  Xcde
```

Specify `start` and `stop`, meaning the slice from `start` to `stop` is replaced with `repl`. Everything before or after `start` and `stop` is included as is.

```python
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0  aX
1  aX
2  aX
3  aXc
4  aXcde
```

### pandas.Series.str.split

`Series.str.split(pat=None, n=-1, expand=False)`

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

**Parameters**

- `pat` [str, optional] String or regular expression to split on. If not specified, split on whitespace.
- `n` [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
expand [bool, default False] Expand the split strings into separate columns.

- If True, return DataFrame/MultiIndex expanding dimensionality.
- If False, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless expand=True (see Notes).

See also:

Series.str.split Split strings around given separator/delimiter.
Series.str.rsplit Splits string around given separator/delimiter, starting from the right.
Series.str.join Join lists contained as elements in the Series/Index with passed delimiter.
str.split Standard library version for split.
str.rsplit Standard library version for rsplit.

Notes

The handling of the $n$ keyword depends on the number of found splits:

- If found splits > $n$, make first $n$ splits only
- If found splits <= $n$, make all splits
- If for a certain row the number of found splits < $n$, append None for padding up to $n$ if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```python
>>> s = pd.Series(
    ... [
    ...     "this is a regular sentence",
    ...     "https://docs.python.org/3/tutorial/index.html",
    ...     np.nan
    ... ]
    ...
)
>>> s
0    this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2     NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```python
>>> s.str.split()
0    [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2        NaN
dtype: object
```

Without the $n$ parameter, the outputs of rsplit and split are identical.

```python
>>> s.str.rsplit()
0    [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2        NaN
dtype: object
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

The n parameter can be used to limit the number of splits on the delimiter. The outputs of split and rsplit are
different.
>>> s.str.split(n=2)
0
[this, is, a regular sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2
NaN
dtype: object
>>> s.str.rsplit(n=2)
0
[this is a, regular, sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2

**pandas.Series.str.rsplit**

Series.str.rsplit \( (\text{pat=None, } n=-1, \text{ expand=False}) \)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to \textit{str.rsplit}.

**Parameters**

- \textbf{pat} [str, optional] String or regular expression to split on. If not specified, split on whitespace.
- \textbf{n} [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
- \textbf{expand} [bool, default False] Expand the split strings into separate columns.
  - If True, return DataFrame/MultiIndex expanding dimensionality.
  - If False, return Series/Index, containing lists of strings.

**Returns**

Series, Index, DataFrame or MultiIndex Type matches caller unless \texttt{expand=True} (see Notes).

**See also:**

- \textit{Series.str.split} Split strings around given separator/delimiter.
- \textit{Series.str.rsplit} Splits string around given separator/delimiter, starting from the right.
- \textit{Series.str.join} Join lists contained as elements in the Series/Index with passed delimiter.
- \textit{str.split} Standard library version for split.
- \textit{str.rsplit} Standard library version for rsplit.

**Notes**

The handling of the \textit{n} keyword depends on the number of found splits:

- If found splits > \textit{n}, make first \textit{n} splits only
- If found splits <= \textit{n}, make all splits
- If for a certain row the number of found splits < \textit{n}, append \textit{None} for padding up to \textit{n} if \texttt{expand=True}

If using \texttt{expand=True}, Series and Index callers return DataFrame and MultiIndex objects, respectively.

**Examples**

```python
>>> s = pd.Series(
...   [  
...     "this is a regular sentence",  
...     "https://docs.python.org/3/tutorial/index.html",  
...     np.nan  
...   ]
... )

>>> s
0  this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2     NaN
dtype: object
```

In the default setting, the string is split by whitespace.

Chapter 3. API reference


```
>>> s = pd.Series(['1+1=2'])
>>> s
0  1+1=2
dtype: object
>>> s.str.split(r'\+|=\', expand=True)
          0   1   2
        0  1  1  2
```

**pandas.Series.str.startswith**

Series.str.

**startswith\( (\text{pat, na=\text{None}}) \)**

Test if the start of each string element matches a pattern.

Equivalent to \text{str.startwith()}.  

**Parameters**

\( \text{pat} \) [str] Character sequence. Regular expressions are not accepted.

\( \text{na} \) [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, \text{numpy.nan} is used. For \text{StringDtype}, pandas.NA is used.

**Returns**

\text{Series or Index of bool} A Series of booleans indicating whether the given pattern matches the start of each string element.

**See also:**

\text{str.startwith} Python standard library string method.

\text{Series.str.endwith} Same as startwith, but tests the end of string.

\text{Series.str.contains} Tests if string element contains a pattern.

**Examples**

```
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0   bat
1    Bear
2     cat
3      NaN
dtype: object

>>> s.str.startswith('b')
0   True
1  False
2  False
3     NaN
dtype: object

Specifying \text{na} to be \text{False} instead of NaN.
```

```
>>> s.str.startswith('b', na=False)
0   True
1  False
2  False
3     NaN
```
pandas.Series.str.strip

Series.str.strip(to_strip=None)
Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from
left and right sides. Equivalent to str.strip().

Parameters

   to_strip [str or None, default None] Specifying the set of characters to be removed. All
          combinations of this set of characters will be stripped. If None then whitespaces are
          removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?><t', np.nan])
>>> s
0   1. Ant. 
1   2. Bee!
2   3. Cat?><t
3     NaN
dtype: object

>>> s.str.strip()
0   1. Ant. 
1   2. Bee!
2   3. Cat?><t
3     NaN
dtype: object

>>> s.str.lstrip('123.‘
')
0    Ant. 
1    Bee!
2    Cat?><t
3     NaN
dtype: object

>>> s.str.rstrip('!.? \n\t')
0   1. Ant
1   2. Bee
2   3. Cat
```
pandas.Series.str.swapcase

Series.str.swapcase()
Convert strings in the Series/Index to be swapcased.

Equivalent to str.swapcase().

Returns
Series or Index of object

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
```

```python
>>> s
0    lower
1  CAPITALS
2   this is a sentence
3   SwApCaSe
dtype: object
```

```python
>>> s.str.lower()
0    lower
1  capitals
2   this is a sentence
3   swapcase
dtype: object
```

```python
>>> s.str.upper()
0  LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  SWAPCASE
dtype: object
```

3.3. Series
>>> s.str.title()
0   Lower
1   Capitals
2   This Is A Sentence
3   Swapcase
dtype: object

>>> s.str.capitalize()
0   Lower
1   Capitals
2   This is a sentence
3   Swapcase
dtype: object

>>> s.str.swapcase()
0   LOWER
1   capitals
2   THIS IS A SENTENCE
3   sWaPcAsE
dtype: object

pandas.Series.str.title

Series.str.title()  
Convert strings in the Series/Index to titlecase.  
Equivalent to str.title().

Returns

Series or Index of object

See also:

Series.str.lower  
Converts all characters to lowercase.

Series.str.upper  
Converts all characters to uppercase.

Series.str.title  
Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize  
Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase  
Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold  
Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
```

```python
>>> s
0   lower
1   CAPITALS
2   this is a sentence
3   SwApCaSe
dtype: object
```

```python
>>> s.str.lower()
0   lower
1   capitals
2   this is a sentence
```

(continues on next page)
pandas.Series.str.translate

Series.str.translate(table)
Map all characters in the string through the given mapping table.
Equivalent to standard str.translate().
Parameters

    table [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None.
    Unmapped characters are left untouched. Characters mapped to None are deleted.
    str.maketrans() is a helper function for making translation tables.

Returns

    Series or Index
pandas.Series.str.upper

Series.str.upper()
Convert strings in the Series/Index to uppercase.
Equivalent to str.upper().
Returns
Series or Index of object

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0   lower
1   CAPITALS
2   this is a sentence
3   SwApCaSe
dtype: object

>>> s.str.lower()
0   lower
1   capitals
2   this is a sentence
3   swapcase
dtype: object

>>> s.str.upper()
0   LOWER
1   CAPITALS
2   THIS IS A SENTENCE
3   SWAPCASE
dtype: object

>>> s.str.title()
0   Lower
1   Capitals
2   This Is A Sentence
3   Swapcase
dtype: object

>>> s.str.capitalize()
0   Lower
1   Capitals
2   This is a sentence
3   Swapcase
dtype: object
```
>>> s.str.swapcase()
0    LOWER
1  capitals
2  THIS IS A SENTENCE
3   sWaPcAsE
dtype: object

pandas.Series.str.wrap

Series.str.wrap(width, **kwargs)
Wrap strings in Series/Index at specified line width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

Parameters

- **width** [int] Maximum line width.
- **expand_tabs** [bool, optional] If True, tab characters will be expanded to spaces (default: True).
- **replace_whitespace** [bool, optional] If True, each whitespace character (as defined by string.whitespace) remaining after tab expansion will be replaced by a single space (default: True).
- **drop_whitespace** [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).
- **break_long_words** [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).
- **break_on_hyphens** [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set break_long_words to false if you want truly inseparable words (default: True).

Returns

- Series or Index

Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R’s stringr library str_wrap function, use the arguments:
  • expand_tabs = False
  • replace_whitespace = True
  • drop_whitespace = True
  • break_long_words = False
  • break_on_hyphens = False
Examples

```python
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0          line to be
          wrapped
1 another line to be
          wrapped
dtype: object
```

pandas.Series.str.zfill

Series.str.zfill(width)

Pad strings in the Series/Index by prepending ‘0’ characters.

Strings in the Series/Index are padded with ‘0’ characters on the left of the string to reach a total string length width. Strings in the Series/Index with length greater or equal to width are unchanged.

Parameters

width [int] Minimum length of resulting string; strings with length less than width be prepended with ‘0’ characters.

Returns

Series/Index of objects.

See also:

Series.str.rjust Fills the left side of strings with an arbitrary character.
Series.str.ljust Fills the right side of strings with an arbitrary character.
Series.str.pad Fills the specified sides of strings with an arbitrary character.
Series.str.center Fills both sides of strings with an arbitrary character.

Notes

Differs from str.zfill() which has special handling for ‘+’/’-’ in the string.

Examples

```python
>>> s = pd.Series([-1, 1, '1000', 10, np.nan])
>>> s
0    -1
1     1
2   1000
3    10
4    NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in ‘-1’ is treated as a regular character and the zero is added to the left of it (str.zfill() would have moved it to the left). 1000 remains unchanged as it is longer than width.

```python
>>> s.str.zfill(3)
0     0-1
1     001
2   1000
3    NaN
```
4 NaN
dtype: object

pandas.Series.str.isalnum

Series.str.isalnum()

Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method str.isalnum() for each element of the Series/Index.

If a string has zero characters, False is returned for that check.

**Returns**

Series or Index of bool  Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha  Check whether all characters are alphabetic.
Series.str.isnumeric  Check whether all characters are numeric.
Series.str.isalnum  Check whether all characters are alphanumeric.
Series.str.isdigit  Check whether all characters are digits.
Series.str.isdecimal  Check whether all characters are decimal.
Series.str.isspace  Check whether all characters are whitespace.
Series.str.islower  Check whether all characters are lowercase.
Series.str.isupper  Check whether all characters are uppercase.
Series.str.istitle  Check whether all characters are titlecase.

**Examples**

Checks for Alphabetic and Numeric Characters

```python
>>> sl = pd.Series(['one', 'one1', '1', ''])

>>> sl.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> sl.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

>>> sl.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```
Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```
```python
>>> s5.str.islower()
0   True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2   True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1   True
2   False
3   False
dtype: bool
```

### pandas.Series.str.isalpha

**Series.str.isalpha()**

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(["one", "one1", "1", "]

>>> s1.str.isalpha()
0   True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2   True
3   False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(["A B", "1.5", "3,000"])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(["23", ",", ",", "]

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0   True
(continues on next page)```
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool
```

### Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

### Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```
pandas.Series.str.isdigit

Series.str.isdigit()

Series or Index of bool

Check whether all characters in each string are digits.

This is equivalent to running the Python string method \texttt{str.isdigit()} for each element of the Series/Index. If a string has zero characters, \texttt{False} is returned for that check.

**Returns**

Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- \texttt{Series.str.isalpha}
- \texttt{Series.str.isnumeric}
- \texttt{Series.str.isalnum}
- \texttt{Series.str.isdigit}
- \texttt{Series.str.isdecimal}
- \texttt{Series.str.isspace}
- \texttt{Series.str.islower}
- \texttt{Series.str.isupper}
- \texttt{Series.str.istitle}

**Examples**

**Checks for Alphabetic and Numeric Characters**

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
```

dtype: bool

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
```

dtype: bool

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0   True
1   True
2   False
3   False
```

dtype: bool

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '	\n', ''])

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2    False
3    False
dtype: bool
```

### pandas.Series.str.isspace

`Series.str.isspace()` checks whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- **Series or Index of bool**  
  Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha`  
  Check whether all characters are alphabetic.
- `Series.str.isnumeric`  
  Check whether all characters are numeric.
- `Series.str.isalnum`  
  Check whether all characters are alphanumeric.
- `Series.str.isdigit`  
  Check whether all characters are digits.
- `Series.str.isdecimal`  
  Check whether all characters are decimal.
- `Series.str.isspace`  
  Check whether all characters are whitespace.
- `Series.str.islower`  
  Check whether all characters are lowercase.
- `Series.str.isupper`  
  Check whether all characters are uppercase.
- `Series.str.istitle`  
  Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
Series.str.islower()  
Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool  Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha`  Check whether all characters are alphabetic.
- `Series.str.isnumeric`  Check whether all characters are numeric.
- `Series.str.isalnum`  Check whether all characters are alphanumeric.
- `Series.str.isdigit`  Check whether all characters are digits.
- `Series.str.isdecimal`  Check whether all characters are decimal.
- `Series.str.isspace`  Check whether all characters are whitespace.
- `Series.str.islower`  Check whether all characters are lowercase.
- `Series.str.isupper`  Check whether all characters are uppercase.
- `Series.str.istitle`  Check whether all characters are titlecase.

**Examples**

**Checks for Alphabetic and Numeric Characters**

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['2', '³', '', ''])
```

The `s.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
>>> s5.str.isupper()
0   False
1   True
2   True
3   False
dtype: bool

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool

**pandas.Series.str.isupper**

`Series.str.isupper()` Check whether all characters in each string are uppercase.

This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- **Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '³', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '\t\n ', ''])
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
>>> s5.str.islower()
0   True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2   True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1   True
2   False
3   False
dtype: bool
```
pandas.Series.str.istitle

Series.str.istitle()

Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method `str.istitle()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

**Examples**

**Checks for Alphabetic and Numeric Characters**

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s3.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s3.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\rn ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

### pandas.Series.str.isnumeric

`Series.str.isnumeric()` checks whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- **Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
3
```
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n ', ''])
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

>>> s5.str.islower()
0   True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s5.str.isupper()
0   False
1   False
2   True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1   True
2   False
3   False
dtype: bool
```
pandas.Series.str.isdecimal

Series.str.isdecimal()
Check whether all characters in each string are decimal.

This is equivalent to running the Python string method str.isdecimal() for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

>>> s2 = pd.Series(['A B', '1.5', '3,000'])

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

>>> s3 = pd.Series(['23', '3', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool

The `s3.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool

The `s3.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

### pandas.Series.str.get_dummies

Series.str.get_dummies(sep=\'|\')  
Return DataFrame of dummy/indicator variables for Series.  
Each string in Series is split by sep and returned as a DataFrame of dummy/indicator variables.  

**Parameters**

- **sep** [str, default \'|\'] String to split on.

**Returns**

- **DataFrame** Dummy variables corresponding to values of the Series.

**See also:**

- `get_dummies` Convert categorical variable into dummy/indicator variables.

**Examples**

```python
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1

>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```
Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.cat.categories</code></td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td><code>Series.cat.ordered</code></td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td><code>Series.cat.codes</code></td>
<td>Return Series of codes as well as the index.</td>
</tr>
</tbody>
</table>

**pandas.Series.cat.categories**

`Series.cat.categories`

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

**pandas.Series.cat.ordered**

`Series.cat.ordered`

Whether the categories have an ordered relationship.

**pandas.Series.cat.codes**

`Series.cat.codes`

Return Series of codes as well as the index.

```
Series.cat.rename_categories(*args, **kwargs) Rename categories.
```

```
Series.cat.reorder_categories(*args, **kwargs) Reorder categories as specified in new_categories.
```

```
Series.cat.add_categories(*args, **kwargs) Add new categories.
```

```
Series.cat.remove_categories(*args, **kwargs) Remove the specified categories.
```

```
Series.cat.remove_unused_categories(*args) Remove categories which are not used.
```

continues on next page
Table 48 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.cat.set_categories(*args, **kwargs)</td>
<td>Set the categories to the specified new_categories.</td>
</tr>
<tr>
<td>Series.cat.as_ordered(*args, **kwargs)</td>
<td>Set the Categorical to be ordered.</td>
</tr>
<tr>
<td>Series.cat.as_unordered(*args, **kwargs)</td>
<td>Set the Categorical to be unordered.</td>
</tr>
</tbody>
</table>

**pandas.Series.cat.rename_categories**

```python
Series.cat.rename_categories(*args, **kwargs)
```

Rename categories.

**Parameters**

- **new_categories** [list-like, dict-like or callable] New categories which will replace old categories.
  - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
  - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
  - callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

- **inplace** [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**

- **ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

**See also:**

- **reorder_categories** Reorder categories.
- **add_categories** Add new categories.
- **remove_categories** Remove the specified categories.
- **remove_unused_categories** Remove categories which are not used.
- **set_categories** Set the categories to the specified ones.

**Examples**

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories

**3.3. Series**

1377
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']

pandas.Series.cat.reorder_categories

Series.cat.reorder_categories(*args, **kwargs)
Reorder categories as specified in new_categories.

new_categories need to include all old categories and no new category items.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, optional] Whether or not the categorical is treated as a ordered categorical.
If not given, do not change the ordered information.

inplace [bool, default False] Whether or not to reorder the categories inplace or return a copy
of this categorical with reordered categories.

Returns

cat [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError If the new categories do not contain all old category items or any new ones

See also:

rename_categories Rename categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.Series.cat.add_categories

Series.cat.add_categories(*args, **kwargs)
Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this
call.

Parameters

new_categories [category or list-like of category] The new categories to be included.

inplace [bool, default False] Whether or not to add the categories inplace or return a copy
of this categorical with added categories.

Returns

cat [Categorical or None] Categorical with new categories added or None if inplace=True.

Raises

ValueError If the new categories include old categories or do not validate as categories

See also:

rename_categories Rename categories.
reorder_categories  Reorder categories.
remove_categories  Remove the specified categories.
remove_unused_categories  Remove categories which are not used.
set_categories  Set the categories to the specified ones.

pandas.Series.cat.remove_categories

Series.cat.remove_categories(*args, **kwargs)
Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals  [category or list of categories] The categories which should be removed.
ineplace  [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Returns
cat  [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError  If the removals are not contained in the categories

See also:
rename_categories  Rename categories.
reorder_categories  Reorder categories.
add_categories  Add new categories.
remove_unused_categories  Remove categories which are not used.
set_categories  Set the categories to the specified ones.

pandas.Series.cat.remove_unused_categories

Series.cat.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

inplace  [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Deprecation since version 1.2.0.

Returns

cat  [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:
rename_categories  Rename categories.
reorder_categories  Reorder categories.
add_categories  Add new categories.
remove_categories  Remove the specified categories.
set_categories  Set the categories to the specified ones.
pandas.Series.cat.set_categories

Series.cat.set_categories(*args, **kwargs)
Set the categories to the specified new_categories.

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- **rename** [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.
- **inplace** [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

**Returns**
Categorical with reordered categories or None if inplace.

**Raises**
ValueError If new_categories does not validate as categories

See also:
- rename_categories Rename categories.
- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.

pandas.Series.cat.as_ordered

Series.cat.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

- **inplace** [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

**Returns**
Categorical or None Ordered Categorical or None if inplace=True.
**pandas.Series.cat.as_unordered**

Series.cat.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

**Parameters**

inplace  [bool, default False] Whether or not to set the ordered attribute in-place or return a
        copy of this categorical with ordered set to False.

**Returns**

Categorical or None  Unordered Categorical or None if inplace=True.

**Sparse accessor**

Sparse-dtype specific methods and attributes are provided under the Series.sparse accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.sparse.npoints</td>
<td>The number of non-fill_value points.</td>
</tr>
<tr>
<td>Series.sparse.density</td>
<td>The percent of non-fill_value points, as decimal.</td>
</tr>
<tr>
<td>Series.sparse.fill_value</td>
<td>Elements in data that are fill_value are not stored.</td>
</tr>
<tr>
<td>Series.sparse.sp_values</td>
<td>An ndarray containing the non-fill_value values.</td>
</tr>
</tbody>
</table>

**pandas.Series.sparse.npoints**

Series.sparse.npoints
The number of non-fill_value points.

**Examples**

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

**pandas.Series.sparse.density**

Series.sparse.density
The percent of non-fill_value points, as decimal.

**Examples**

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```
pandas.Series.sparse.fill_value

Series.sparse.fill_value

Elements in data that are fill_value are not stored.

For memory savings, this should be the most common value in the array.

pandas.Series.sparse.sp_values

Series.sparse.sp_values

An ndarray containing the non-fill_value values.

Examples

```python
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

pandas.Series.sparse.from_coo

classmethod Series.sparse.from_coo(A, dense_index=False)

Create a Series with sparse values from a scipy.sparse.coo_matrix.

Parameters

- A : scipy.sparse.coo_matrix

- dense_index : bool, default False If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

Returns

- s : Series A Series with sparse values.

Examples

```python
>>> from scipy import sparse

>>> A = sparse.coo_matrix((... (3.0, 1.0, 2.0), ([1, 0, 0], [0, 2, 3])), shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'

with 3 stored elements in COOrdinate format>
```
>>> A.todense()
matrix([[0., 0., 1., 2.],
       [3., 0., 0., 0.],
       [0., 0., 0., 0.]])

>>> ss = pd.Series.sparse.from_coo(A)
>>> ss
0    2    1.0
   3    2.0
1    0    3.0
dtype: Sparse[default, nan]

pandas.Series.sparse.to_coo

Series.sparse.to_coo(row_levels=(0), column_levels=(1), sort_labels=False)
Create a scipy.sparse.coo_matrix from a Series with MultiIndex.

Use row_levels and column_levels to determine the row and column coordinates respectively. row_levels and
column_levels are the names (labels) or numbers of the levels. {row_levels, column_levels} must be a partition
of the MultiIndex level names (or numbers).

Parameters
    row_levels [tuple/list]
    column_levels [tuple/list]
    sort_labels [bool, default False] Sort the row and column labels before forming the sparse
              matrix.

Returns
    y [scipy.sparse.coo_matrix]
    rows [list (row labels)]
    columns [list (column labels)]

Examples

>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples(
...     [1, 2, "a", 0),
...     [1, 2, "a", 1),
...     [1, 1, "b", 0),
...     [1, 1, "b", 1),
...     [2, 1, "b", 0),
...     [2, 1, "b", 1)  
...     ],
...     names=["A", "B", "C", "D"],
...     )
>>> s
A B C D
1 2 a 0 3.0
   1 NaN
1 b 0 1.0 
Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in `Series.attrs`.

<table>
<thead>
<tr>
<th>Flags</th>
<th>obj, *, allows_duplicate_labels</th>
<th>Flags that apply to pandas objects.</th>
</tr>
</thead>
</table>

**Flags**

```python
Flags(obj, *, allows_duplicate_labels)

Flags that apply to pandas objects.
```

pandas.Flags

**class** pandas.Flags(obj, *, allows_duplicate_labels)

Flags that apply to pandas objects.

New in version 1.2.0.

**Parameters**

- `obj` [Series or DataFrame] The object these flags are associated with.
- `allows_duplicate_labels` [bool, default True] Whether to allow duplicate labels in this object. By default, duplicate labels are permitted. Setting this to `False` will cause an `errors.DuplicateLabelError` to be raised when `index` (or columns for
DataFrame) is not unique, or any subsequent operation on introduces duplicates. See *Disallowing Duplicate Labels* for more.

**Warning:** This is an experimental feature. Currently, many methods fail to propagate the `allows_duplicate_labels` value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate `allows_duplicate_labels`.

### Notes

Attributes can be set in two ways

```python
>>> df = pd.DataFrame()
>>> df.flags
<Flags(allows_duplicate_labels=True)>
>>> df.flags.allows_duplicate_labels = False
>>> df.flags
<Flags(allows_duplicate_labels=False)>
>>> df.flags['allows_duplicate_labels'] = True
>>> df.flags
<Flags(allows_duplicate_labels=True)>
```

### Attributes

<table>
<thead>
<tr>
<th><code>allows_duplicate_labels</code></th>
<th>Whether this object allows duplicate labels.</th>
</tr>
</thead>
</table>

**pandas.Flags.allows_duplicate_labels**

**property Flags.allows_duplicate_labels**

Whether this object allows duplicate labels.

Setting `allows_duplicate_labels=False` ensures that the index (and columns of a DataFrame) are unique. Most methods that accept and return a Series or DataFrame will propagate the value of `allows_duplicate_labels`.

See *Duplicate Labels* for more.

See also:

- `DataFrame.attrs` Set global metadata on this object.
- `DataFrame.set_flags` Set global flags on this object.
Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]}, index=['a', 'a'])
>>> df.allows_duplicate_labels
True
>>> df.allows_duplicate_labels = False
Traceback (most recent call last):
  ...  
pandas.errors.DuplicateLabelError: Index has duplicates.
  positions
  label
  a [0, 1]
```

Metadata

`Series.attrs` is a dictionary for storing global metadata for this Series.

**Warning:** `Series.attrs` is considered experimental and may change without warning.

<table>
<thead>
<tr>
<th><code>Series.attrs</code></th>
<th>Dictionary of global attributes of this dataset</th>
</tr>
</thead>
</table>

3.3.14 Plotting

`Series.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `Series.plot.<kind>`.

<table>
<thead>
<tr>
<th><code>Series.plot([kind, ax, figsize,...])</code></th>
<th>Series plotting accessor and method</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.plot.area([x, y])</code></td>
<td>Draw a stacked area plot.</td>
</tr>
<tr>
<td><code>Series.plot.bar([x, y])</code></td>
<td>Vertical bar plot.</td>
</tr>
<tr>
<td><code>Series.plot.barh([x, y])</code></td>
<td>Make a horizontal bar plot.</td>
</tr>
<tr>
<td><code>Series.plot.box([by])</code></td>
<td>Make a box plot of the DataFrame columns.</td>
</tr>
<tr>
<td><code>Series.plot.density([bw_method, ind])</code></td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td><code>Series.plot.hist([by, bins])</code></td>
<td>Draw one histogram of the DataFrame’s columns.</td>
</tr>
<tr>
<td><code>Series.plot.kde([bw_method, ind])</code></td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td><code>Series.plot.line([x, y])</code></td>
<td>Plot Series or DataFrame as lines.</td>
</tr>
<tr>
<td><code>Series.plot.pie(**kwargs)</code></td>
<td>Generate a pie plot.</td>
</tr>
</tbody>
</table>
pandas.Series.plot.area

Series.plot.area(x=None, y=None, **kwargs)
Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

x [label or position, optional] Coordinates for the X axis. By default uses the index.

y [label or position, optional] Column to plot. By default uses all columns.

stacked [bool, default True] Area plots are stacked by default. Set to False to create a un-stacked plot.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

See also:

DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                        freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass stacked=False:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```
**pandas.Series.plot.bar**

Series.plot.bar(x=None, y=None, **kwargs)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called \( a \) and \( b \), then passing \{‘a’: ‘green’, ‘b’: ‘red’\} will color bars for column \( a \) in green and bars for column \( b \) in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().**

**Returns**

- matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

**See also:**

DataFrame.plot.barh Horizontal bar plot.
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.bar Make a bar plot with matplotlib.

**Examples**

Basic plot.

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
  'rabbit', 'giraffe', 'coyote', 'horse']
```
Plot stacked bar charts for the DataFrame:

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
>>> axes = df.plot.bar(
...    rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
...)
>>> axes[1].legend(loc=2)
```

Plot a single column.
speed

lifespan

snail  pig  elephant  rabbit  giraffe  coyote  horse
>>> ax = df.plot.bar(y='speed', rot=0)

Plot only selected categories for the DataFrame.

>>> ax = df.plot.bar(x='lifespan', rot=0)

**pandas.Series.plot.barh**

Series.plot.barh(x=None, y=None, **kwargs)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a9d19’.

A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively.

A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.bar Vertical bar plot.
DataFrame.plot Make plots of DataFrame using matplotlib.
matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
                     ...
                     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```python
>>> ax = df.plot.barh(color={'speed': "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
```
3.3. Series
The diagram shows a comparison of speed and lifespan for various animals:

- Horse: High speed, moderate lifespan
- Coyote: High speed, moderate lifespan
- Giraffe: Moderate speed, high lifespan
- Rabbit: Low speed, high lifespan
- Elephant: Low speed, very high lifespan
- Pig: Low speed, moderate lifespan
- Snail: Very low speed, very low lifespan

Legend:
- Red: speed
- Green: lifespan
```python
...    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')

Plot DataFrame versus the desired column

```
pandas.Series.plot.box

Series.plot.box(by=None, **kwargs)
Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

**kwargs Additional keywords are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.Series.plot.density

Series.plot.density(bw_method=None, ind=None, **kwargs)
Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

```python
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```
pandas.Series.plot.hist

Series.plot.hist(by=None, bins=10, **kwargs)

Draw one histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame’s Series are in a similar scale.

**Parameters**

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

**Returns**

class:matplotlib.AxesSubplot Return a histogram plot.

See also:

DataFrame.hist Draw histograms per DataFrame’s Series.

Series.hist Draw a histogram with Series’ data.

**Examples**

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

pandas.Series.plot.kde

Series.plot.kde(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().

**Returns**

%(this-datatype)s.plot().

3.3. Series
matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
```
```python
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
```
```python
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```
**pandas.Series.plot.line**

Series.plot.line(x=None, y=None, **kwargs)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance [‘green’,’yellow’] each column’s line will be filled in green or yellow, alternatively.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {‘a’:‘green’,’b’:‘red’} will color lines for column a in green and lines for column b in red.

New in version 1.1.0.

**kwargs** Additional keyword arguments are documented in DataFrame.plot().

**Returns**

- matplotlib.axes.Axes or np.ndarray of them

An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

**See also:**

- matplotlib.pyplot.plot
- pandas.DataFrame.plot

**Examples**

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame({'pig': [20, 18, 489, 675, 1776],
...                     'horse': [4, 25, 281, 600, 1900]
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).
>>> axes = df.plot.line(
...
subplots=True, color={"pig": "pink", "horse": "#742802"}
... )

The following example shows the relationship between both populations.
>>> lines = df.plot.line(x='pig', y='horse')

pandas.Series.plot.pie
Series.plot.pie(**kwargs)
Generate a pie plot.
A pie plot is a proportional representation of the numerical data in a column. This function wraps
matplotlib.pyplot.pie() for the specified column.
If no column reference is passed and
subplots=True a pie plot is drawn for each numerical column independently.
Parameters
y [int or label, optional] Label or position of the column to plot.
subplots=True argument must be passed.

If not provided,

**kwargs Keyword arguments to pass on to DataFrame.plot().

3.3. Series

1431


Returns

matplotlib.axes.Axes or np.ndarray of them  A NumPy array is returned when subplots is True.

See also:

Series.plot.pie  Generate a pie plot for a Series.
DataFrame.plot  Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
... 'radius': [2439.7, 6051.8, 6378.1]})
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```python
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

```python
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```
Series.hist(by, ax, grid, xlabelsize, ...) Draw histogram of the input series using matplotlib.

3.3.15 Serialization / IO / conversion

Series.to_pickle(path[, compression, ...]) Pickle (serialize) object to file.
Series.to_csv([path_or_buf, sep, na_rep, ...]) Write object to a comma-separated values (csv) file.
Series.to_dict([into]) Convert Series to {label -> value} dict or dict-like object.
Series.to_excel(excel_writer[, sheet_name, ...]) Write object to an Excel sheet.
Series.to_frame([name]) Convert Series to DataFrame.
Series.to_xarray() Return an xarray object from the pandas object.
Series.to_hdf(path_or_buf, key[, mode, ...]) Write the contained data to an HDF5 file using HDFStore.
Series.to_sql(name, con[, schema, ...]) Write records stored in a DataFrame to a SQL database.
Series.to_json([path_or_buf, orient, ...]) Convert the object to a JSON string.
Series.to_string([buf, na_rep, ...]) Render a string representation of the Series.
Series.to_clipboard([excel, sep]) Copy object to the system clipboard.
Series.to_latex([buf, columns, col_space, ...]) Render object to a LaTeX tabular, longtable, or nested table/tabular.
Series.to_markdown([buf, mode, index, ...]) Print Series in Markdown-friendly format.

3.4 DataFrame

3.4.1 Constructor

DataFrame([data, index, columns, dtype, copy]) Two-dimensional, size-mutable, potentially heterogeneous tabular data.
**dtype** [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer.

**copy** [bool, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input.

See also:

*DataFrame.from_records* Constructor from tuples, also record arrays.
*DataFrame.from_dict* From dicts of Series, arrays, or dicts.
*read_csv* Read a comma-separated values (csv) file into DataFrame.
*read_table* Read general delimited file into DataFrame.
*read_clipboard* Read text from clipboard into DataFrame.

**Examples**

Constructing DataFrame from a dictionary.

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1 col2
0    1    3
1    2    4
```

Notice that the inferred dtype is int64.

```python
>>> df.dtypes
col1     int64
col2     int64
dtype: object
```

To enforce a single dtype:

```python
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```python
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
... columns=['a', 'b', 'c'])
```

```python
>>> df2
    a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

Constructing DataFrame from dataclass:

```python
>>> from dataclasses import make_dataclass
>>> Point = make_dataclass("Point", [("x", int), ("y", int)])
>>> pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
   x  y
0  0  0
1  0  3
2  2  3
```
Attributes

- `at`: Access a single value for a row/column label pair.
- `attrs`: Dictionary of global attributes of this dataset.
- `axes`: Return a list representing the axes of the DataFrame.
- `columns`: The column labels of the DataFrame.
- `dtypes`: Return the dtypes in the DataFrame.
- `empty`: Indicator whether DataFrame is empty.
- `flags`: Get the properties associated with this pandas object.
- `iat`: Access a single value for a row/column pair by integer position.
- `iloc`: Purely integer-location based indexing for selection by position.
- `index`: The index (row labels) of the DataFrame.
- `loc`: Access a group of rows and columns by label(s) or a boolean array.
- `ndim`: Return an int representing the number of axes / array dimensions.
- `shape`: Return a tuple representing the dimensionality of the DataFrame.
- `size`: Return an int representing the number of elements in this object.
- `style`: Returns a Styler object.
- `values`: Return a Numpy representation of the DataFrame.

**pandas.DataFrame.at**

**property** `DataFrame.at`
Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

- `KeyError` If ‘label’ does not exist in DataFrame.

**See also:**

- `DataFrame.iat` Access a single value for a row/column pair by integer position.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `Series.at` Access a single value using a label.
Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                    index=[4, 5, 6], columns=['A', 'B', 'C'])
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>10</td>
<td>20</td>
</tr>
</tbody>
</table>

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```

pandas.DataFrame.attrs

**property** pandas.DataFrame.attrs

Dictionary of global attributes of this dataset.

**Warning:** attrs is experimental and may change without warning.

See also:

- **Dataframe.flags** Global flags applying to this object.

pandas.DataFrame.axes

**property** pandas.DataFrame.axes

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.
Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

```python
pandas.DataFrame.columns
```

**DataFrame.columns**: *Index*

The column labels of the DataFrame.

```python
pandas.DataFrame.dtypes
```

**property DataFrame.dtypes**

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

**Returns**

```python
pandas.Series
```

The data type of each column.

Examples

```python
>>> df = pd.DataFrame({'float': [1.0],
...                     'int': [1],
...                     'datetime': [pd.Timestamp('20180310')],
...                     'string': ['foo']})
>>> df.dtypes
float       float64
int         int64
datetime    datetime64[ns]
string      object
dtype: object
```

```python
pandas.DataFrame.empty
```

**property DataFrame.empty**

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

**Returns**

```python
bool
```

If DataFrame is empty, return True, if not return False.

**See also:**

```python
Series.dropna
```

Return series without null values.

```python
DataFrame.dropna
```

Return DataFrame with labels on given axis omitted where (all or any) data are missing.
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []

>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
  A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

pandas.DataFrame.flags

**property** DataFrame.flags

Get the properties associated with this pandas object.

The available flags are

- `Flags.allows_duplicate_labels`

See also:

- `Flags` Flags that apply to pandas objects.
- `DataFrame.attrs` Global metadata applying to this dataset.

Notes

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`. 
Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags
<Flags(allow_duplicate_labels=True)>
```

Flags can be get or set using .

```python
>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False
```

Or by slicing with a key

```python
>>> df.flags["allows_duplicate_labels"]
False
>>> df.flags["allows_duplicate_labels"] = True
```

```
pandas.DataFrame.iat

property DataFrame.iat
Access a single value for a row/column pair by integer position.
Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

Raises

    IndexError  When integer position is out of bounds.

See also:

    DataFrame.at  Access a single value for a row/column label pair.
    DataFrame.loc  Access a group of rows and columns by label(s).
    DataFrame.iloc  Access a group of rows and columns by integer position(s).

Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...       columns=['A', 'B', 'C'])
```

```
    A  B  C
  0  0  2  3
  1  0  4  1
  2 10 20 30
```

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
```

```
1
```

Set value at specified row/column pair
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> df.iat[1, 2] = 10
```

Get value within a series

```python
>>> df.loc[0].iat[1]
```

**pandas.DataFrame.iloc**

**property DataFrame.iloc**

Purely integer-location based indexing for selection by position.

```
.loc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.
```

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except `slice` indexers which allow out-of-bounds indexing (this conforms with python/numpy `slice` semantics).

See more at Selection by Position.

See also:

- **DataFrame.iat** Fast integer location scalar accessor.
- **DataFrame.loc** Purely label-location based indexer for selection by label.
- **Series.iloc** Purely integer-location based indexing for selection by position.

**Examples**

```python
mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
          {'a': 100, 'b': 200, 'c': 300, 'd': 400},
          {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
```

```python
df = pd.DataFrame(mydict)
```

Indexing just the rows

With a scalar integer.
With a list of integers.

```python
>>> df.iloc[[0]]
a b c d
0 1 2 3 4
```

```python
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

With a slice object.

```python
>>> df.iloc[:3]
a b c d
0 1 2 3 4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```python
>>> df.iloc[[True, False, True]]
a b c d
0 1 2 3 4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The x passed to the `lambda` is the DataFrame being sliced. This selects the rows whose index label even.

```python
>>> df.iloc[lambda x: x.index % 2 == 0]
a b c d
0 1 2 3 4
2 1000 2000 3000 4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

```python
>>> df.iloc[0, 1]
2
```
```python
>>> df.iloc[[0, 2], [1, 3]]
   b  d
0  2  4
2 2000 4000
```

With *slice* objects.

```python
>>> df.iloc[1:3, 0:3]
   a  b  c
1  100 200 300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```python
>>> df.iloc[:, [True, False, True, False]]
   a  c
0  1  3
1 100 300
2 1000 3000
```

With a callable function that expects the Series or DataFrame.

```python
>>> df.iloc[:, lambda df: [0, 2]]
   a  c
0  1  3
1 100 300
2 1000 3000
```

**pandas.DataFrame.index**

Dataframe.index: *Index*

The index (row labels) of the DataFrame.

**pandas.DataFrame.loc**

Property dataframe.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and never as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, both the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
• An alignable Index. The Index of the returned selection will be the input.

• A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at Selection by Label.

Raises

- **KeyError** If any items are not found.
- **IndexingError** If an indexed key is passed and its index is unalignable to the frame index.

See also:

- **DataFrame.at** Access a single value for a row/column label pair.
- **DataFrame.iloc** Access group of rows and columns by integer position(s).
- **DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- **Series.loc** Access group of values using labels.

**Examples**

**Getting values**

```
>>> df = pd.DataFrame([ [1, 2], [4, 5], [7, 8]],
...                     index=['cobra', 'viper', 'sidewinder'],
...                     columns=['max_speed', 'shield'])
>>> df
          max_speed  shield
   cobra       1       2
   viper       4       5
   sidewinder  7       8
```

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed  4
shield     5
Name: viper, dtype: int64
```

List of labels. Note using [[]] returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
      max_speed  shield
viper        4       5
sidewinder   7       8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.
>>> df.loc['cobra':'viper', 'max_speed']
cobra 1
viper 4
Name: max_speed, dtype: int64

Boolean list with the same length as the row axis

>>> df.loc[[False, False, True]]
max_speed   shield
sidewinder  7    8

Alignable boolean Series:

>>> df.loc[pd.Series([False, True, False], index=['viper', 'sidewinder', 'cobra'])]
max_speed   shield
sidewinder  7    8

Index (same behavior as `df.reindex`)

>>> df.loc[pd.Index(["cobra", "viper"], name="foo")]
max_speed   shield
foo          
cobra 1 2
viper 4 5

Conditional that returns a boolean Series

>>> df.loc[df["shield"] > 6]
max_speed   shield
sidewinder  7    8

Conditional that returns a boolean Series with column labels specified

>>> df.loc[df["shield"] > 6, ["max_speed"]]
max_speed
sidewinder 7

Callable that returns a boolean Series

>>> df.loc[lambda df: df["shield"] == 8]
max_speed   shield
sidewinder  7    8

Setting values

Set value for all items matching the list of labels

>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
max_speed   shield
cobra 1 2
viper 4 50
sidewinder 7 50

Set value for an entire row
Set value for an entire column

```python
>>> df.loc[:, 'max_speed'] = 30
>>> df
 max_speed  shield
 cobra       30     10
 viper       30      50
 sidewinder  30      50
```

Set value for rows matching callable condition

```python
>>> df.loc[df['shield'] > 35] = 0
>>> df
 max_speed  shield
 cobra       30     10
 viper       0       0
 sidewinder  0       0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
 max_speed  shield
 7           1     2
 8           4     5
 9           7     8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc[7:9]
 max_speed  shield
 7           1     2
 8           4     5
 9           7     8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
>>> tuples = [
...    ('cobra', 'mark i'), ('cobra', 'mark ii'),
...    ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...    ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...            [1, 4], [7, 1], [16, 36]]
```
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>max_speed</td>
<td>shield</td>
<td></td>
</tr>
<tr>
<td>cobra</td>
<td>mark i</td>
<td>12</td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>sidewinder</td>
<td>mark i</td>
<td>10</td>
</tr>
<tr>
<td>mark ii</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>viper</td>
<td>mark ii</td>
<td>7</td>
</tr>
<tr>
<td>mark i</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>mark iii</td>
<td>16</td>
<td>36</td>
</tr>
</tbody>
</table>

Single label. Note this returns a DataFrame with a single index.

>>> df.loc['cobra']

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>max_speed</td>
<td>shield</td>
</tr>
<tr>
<td>mark i</td>
<td>12</td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
</tr>
</tbody>
</table>

Single index tuple. Note this returns a Series.

>>> df.loc[('cobra', 'mark ii')]

max_speed 0
shield 4
Name: (cobra, mark ii), dtype: int64

Single label for row and column. Similar to passing in a tuple, this returns a Series.

>>> df.loc['cobra', 'mark i']

max_speed 12
shield 2
Name: (cobra, mark i), dtype: int64

Single tuple. Note using [] returns a DataFrame.

>>> df.loc[['cobra', 'mark ii']]

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>max_speed</td>
<td>shield</td>
<td></td>
</tr>
<tr>
<td>cobra</td>
<td>mark ii</td>
<td>0</td>
</tr>
</tbody>
</table>

Single tuple for the index with a single label for the column

>>> df.loc[['cobra', 'mark i'], 'shield']

2

Slice from index tuple to single label

>>> df.loc[['cobra', 'mark i':'viper']

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>max_speed</td>
<td>shield</td>
<td></td>
</tr>
<tr>
<td>cobra</td>
<td>mark i</td>
<td>12</td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>sidewinder</td>
<td>mark i</td>
<td>10</td>
</tr>
<tr>
<td>mark ii</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>viper</td>
<td>mark ii</td>
<td>7</td>
</tr>
<tr>
<td>mark i</td>
<td>16</td>
<td>36</td>
</tr>
</tbody>
</table>

Slice from index tuple to index tuple
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
          max_speed  shield
    cobra   mark i   12   2
             mark ii   0   4
  sidewinder   mark i  10  20
             mark ii   1   4
    viper   mark ii   7   1

pandas.DataFrame.ndim

**property DataFrame.ndim**

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

**See also:**

*ndarray.ndim* Number of array dimensions.

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

pandas.DataFrame.shape

**property DataFrame.shape**

Return a tuple representing the dimensionality of the DataFrame.

**See also:**

*ndarray.shape* Tuple of array dimensions.

**Examples**

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
                    'col3': [5, 6]})
>>> df.shape
(2, 3)
```
pandas.DataFrame.size

property DataFrame.size
Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

ndarray.size Number of elements in the array.

Examples

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

pandas.DataFrame.style

property DataFrame.style
Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame.

See also:

io.formats.style.Styler Helps style a DataFrame or Series according to the data with HTML and CSS.

pandas.DataFrame.values

property DataFrame.values
Return a Numpy representation of the DataFrame.

Warning: We recommend using DataFrame.to_numpy() instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

Returns

numpy.ndarray The values of the DataFrame.

See also:

DataFrame.to_numpy Recommended alternative to this method.
DataFrame.index Retrieve the index labels.
DataFrame.columns Retrieving the column names.
Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```python
>>> df = pd.DataFrame({'age': [ 3, 29],
... 'height': [94, 170],
... 'weight': [31, 115]})
>>> df
   age  height  weight
0    3      94      31
1   29     170     115
>>> df.dtypes
age    int64
height  int64
weight  int64
dtype: object
>>> df.values
array([[ 3, 94, 31],
       [29, 170, 115]])
```

A DataFrame with mixed type columns (e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```python
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
... ('lion', 80.5, 1),
... ('monkey', np.nan, None)],
... columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name     object
max_speed  float64
rank      object
dtype: object
>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)
```
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>add(other[, axis, level, fill_value])</td>
<td>Get Addition of dataframe and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td>add_prefix(prefix)</td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td>add_suffix(suffix)</td>
<td>Suffix labels with string suffix.</td>
</tr>

<tr>
<td><code>eq(other[, axis, level])</code></td>
<td>Get Equal to of dataframe and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>eval(expr[, inplace])</code></td>
<td>Evaluate a string describing operations on DataFrame columns.</td>
</tr>
<tr>
<td><code>ewm([com, span, halflife, alpha, . . . ])</code></td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
<tr>
<td><code>expanding([min_periods, center, axis])</code></td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td><code>explode(column[, ignore_index])</code></td>
<td>Transform each element of a list-like to a row, replicating index values.</td>
</tr>
<tr>
<td><code>ffill([axis, inplace, limit, downcast])</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>fillna([value, method, axis, inplace, . . . ])</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>filter([items, like, regex, axis])</code></td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td><code>first(offset)</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>first_valid_index()</code></td>
<td>Return index for first non-NA/null value.</td>
</tr>
<tr>
<td><code>floordiv(other[, axis, level, fill_value])</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>from_dict(data[, orient, dtype, columns])</code></td>
<td>Construct DataFrame from dict of array-like or dicts.</td>
</tr>
<tr>
<td><code>from_records(data[, index, exclude, . . . ])</code></td>
<td>Convert structured or record ndarray to DataFrame.</td>
</tr>
<tr>
<td><code>ge(other[, axis, level])</code></td>
<td>Get Greater than or equal to of dataframe and other, element-wise (binary operator <code>ge</code>).</td>
</tr>
<tr>
<td><code>get(key[, default])</code></td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>

pandas.DataFrame.abs

DataFrame.abs()

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs Series/DataFrame containing the absolute value of each element.

See also:

numpy.absolute Calculate the absolute value element-wise.

Notes

For complex inputs, \(1.2 + 1j\), the absolute value is \(\sqrt{a^2 + b^2}\).

Examples

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

3.4. DataFrame
```python
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
  a  b  c
0 4 10 100
1 5 20 50
2 6 30 -30
3 7 40 -50
```

```python
>>> df.loc[(df.c - 43).abs().argsort()]
  a  b  c
1 5 20 50
0 4 10 100
2 6 30 -30
3 7 40 -50
```

**pandas.DataFrame.add**

DataFrame.add (other, axis='columns', level=None, fill_value=None)

Get Addition of dataframe and other, element-wise (binary operator add).

Equivalent to dataframe + other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, radd.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [(0 or ‘index’, 1 or ‘columns’)] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also:**

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
**DataFrame.mod**  Calculate modulo (remainder after division).

**DataFrame.pow**  Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                    ... 'degrees': [360, 180, 360],
                    ... index=['circle', 'triangle', 'rectangle'])
>>> df
          angles  degrees
    circle        0      360
    triangle      3      180
    rectangle     4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
          angles  degrees
    circle        1      361
    triangle      4      181
    rectangle     5      361
```

```python
>>> df.add(1)
          angles  degrees
    circle        1      361
    triangle      4      181
    rectangle     5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
          angles  degrees
    circle   0.00    36.00
    triangle 0.30    18.00
    rectangle 0.40   36.00
```

```python
>>> df.rdiv(10)
          angles  degrees
    circle    inf    0.02
    triangle  3.33    0.05
    rectangle 2.50    0.03
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
          angles  degrees
    circle   -1      358
    triangle    2      178
    rectangle    3      358
```
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])

other

other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])

df * other

df.mul(other, fill_value=0)
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             'index':['A', 'A', 'A', 'B', 'B', 'B'],
                             ['circle', 'triangle', 'rectangle',
                              'square', 'pentagon', 'hexagon']})

df_multindex

df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             'index':['A', 'A', 'A', 'B', 'B', 'B'],
                             ['circle', 'triangle', 'rectangle',
                              'square', 'pentagon', 'hexagon']})

df.div(df_multindex, level=1, fill_value=0)

(df_continues on next page)
pandas.DataFrame.add_prefix

DataFrame.add_prefix(prefix)
Prefix labels with string prefix.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame  New Series or DataFrame with updated labels.

See also:

Series.add_suffix  Suffix row labels with string suffix.

DataFrame.add_suffix  Suffix column labels with string suffix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_prefix('item_')
item_0  1
item_1  2
item_2  3
item_3  4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A   B
0  1   3
1  2   4
2  3   5
3  4   6

>>> df.add_prefix('col_')
   col_A  col_B
0     1     3
1     2     4
```

(continues on next page)
pandas.DataFrame.add_suffix

DataFrame.add_suffix(suffix)
Suffix labels with string suffix.
For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters
suffix [str] The string to add after each label.

Returns
Series or DataFrame New Series or DataFrame with updated labels.

See also:
Series.add_prefix Prefix row labels with string prefix.
DataFrame.add_prefix Prefix column labels with string prefix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_suffix('_col')
   A_col B_col
0    1     3
1    2     4
2    3     5
3    4     6
```
pandas.DataFrame.agg

DataFrame.agg(func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply. Accepted combinations are:

• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

axis [0 or 'index', 1 or 'columns'], default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:

• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened array, e.g., numpy.mean(arr_2d) as opposed to numpy.mean(arr_2d, axis=0).

agg is an alias for aggregate. Use the alias.

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.
Notes

agg is an alias for aggregate. Use the alias.
A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
...                     [4, 5, 6],
...                     [7, 8, 9],
...                     [np.nan, np.nan, np.nan]],
...                     columns=['A', 'B', 'C'])

Aggregate these functions over the rows.
```  

```python
>>> df.agg(['sum', 'min'])

A   B   C
--- --- ---
sum 12.0 15.0 18.0
min 1.0  2.0  3.0

Different aggregations per column.
```  

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})

A   B
--- ---
sum 12.0 NaN
min 1.0  2.0
max NaN  8.0

Aggregate different functions over the columns and rename the index of the resulting DataFrame.
```  

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))

A   B   C
--- --- ---
x   7.0 NaN NaN
y   NaN  2.0 NaN
z   NaN  NaN  6.0

Aggregate over the columns.
```  

```python
>>> df.agg("mean", axis="columns")

       0   1   2
0  2.0  5.0  8.0
1  NaN  NaN  NaN
dtype: float64
```
pandas.DataFrame.aggregate

DataFrame.aggregate (func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply. Accepted combinations are:
• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:
• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened array, e.g., numpy.mean(arr_2d) as opposed to numpy.mean(arr_2d, axis=0).

agg is an alias for aggregate. Use the alias.

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.
Notes

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
...                     [4, 5, 6],
...                     [7, 8, 9],
...                     [np.nan, np.nan, np.nan]],
...                     columns=['A', 'B', 'C'])

Aggregate these functions over the rows.

```python
>>> df.agg(['sum', 'min'])

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>12.0</td>
<td>15.0</td>
<td>18.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>
```

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>12.0</td>
<td>NaN</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
</tr>
<tr>
<td>max</td>
<td>NaN</td>
<td>8.0</td>
</tr>
</tbody>
</table>
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>7.0</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>y</td>
<td>NaN</td>
<td>2.0</td>
<td>NaN</td>
</tr>
<tr>
<td>z</td>
<td>NaN</td>
<td>NaN</td>
<td>6.0</td>
</tr>
</tbody>
</table>
```

Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2.0</td>
<td>5.0</td>
<td>8.0</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

```
pandas.DataFrame.align

DataFrame.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)

Align two objects on their axes with the specified join method. Join method is specified for each axis Index.

Parameters

- other [Dataframe or Series]
- join [{‘outer’, ‘inner’, ‘left’, ‘right’}, default ‘outer’]
- axis [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
- level [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.
- copy [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.
- fill_value [scalar, default np.NA] Value to use for missing values. Defaults to NA, but can be any “compatible” value.
  - pad / ffill: propagate last valid observation forward to next valid.
  - backfill / bfill: use NEXT valid observation to fill gap.
- limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.
- fill_axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Filling axis, method and limit.
- broadcast_axis [{0 or ‘index’, 1 or ‘columns’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(DataFrame, type of other)] Aligned objects.

pandas.DataFrame.all

DataFrame.all(axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

- axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

**bool_only** [bool, default None] Include only boolean columns. If None, will attempt
to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA
and skipna is True, then the result will be True, as for an empty row/column. If
skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count
along a particular level, collapsing into a Series.

**kwargs** [any, default None] Additional keywords have no effect but might be ac-
cepted for compatibility with NumPy.

Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Se-
ries is returned.

See also:

*Series.all* Return True if all elements are True.

*DataFrame.any* Return True if one (or more) elements are True.

**Examples**

**Series**

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

**DataFrames**

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True  True
1  True  False

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
   col1  col2
0  True  True
1  True False
dtype: bool
```
Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0   True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

**pandas.DataFrame.any**

DataFrame .any (axis=0, bool_only=None, skipna=True, level=None, **kwags)

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
  - 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
  - None : reduce all axes, return a scalar.

- **bool_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

- **skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

- ****kwags [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

*Series or DataFrame* If level is specified, then, DataFrame is returned; otherwise, Series is returned.

**See also:**

- **numpy.any** Numpy version of this method.
- **Series.any** Return whether any element is True.
- **Series.all** Return whether all elements are True.
- **DataFrame.any** Return whether any element is True over requested axis.
- **DataFrame.all** Return whether all elements are True over requested axis.
pandas: powerful Python data analysis toolkit, Release 1.2.2

Examples
Series
For Series input, the output is a scalar indicating whether any element is True.
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True

DataFrame
Whether each column contains at least one True element (the default).
>>> df =
>>> df
A B
0 1 0
1 2 2

pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
C
0
0

>>> df.any()
A
True
B
True
C
False
dtype: bool

Aggregating over the columns.
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
A B
0
True 1
1 False 2
>>> df.any(axis='columns')
0
True
1
True
dtype: bool
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
A B
0
True 1
1 False 0
>>> df.any(axis='columns')
0
True
1
False
dtype: bool

Aggregating over the entire DataFrame with axis=None.
1470

Chapter 3. API reference


any for an empty DataFrame is an empty Series.

```python
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

### pandas.DataFrame.append

DataFrame. `append` *(other, ignore_index=False, verify_integrity=False, sort=False)*

Append rows of `other` to the end of caller, returning a new object.

Columns in `other` that are not in the caller are added as new columns.

**Parameters**

- `other` [DataFrame or Series/dict-like object, or list of these] The data to append.
- `ignore_index` [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
- `verify_integrity` [bool, default False] If True, raise ValueError on creating index with duplicates.
- `sort` [bool, default False] Sort columns if the columns of `self` and `other` are not aligned.

Changed in version 1.0.0: Changed to not sort by default.

**Returns**

DataFrame

**See also:**

- `concat` General function to concatenate DataFrame or Series objects.

**Notes**

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

**Examples**

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
>>> df
   A  B
0  1  2
1  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
>>> df.append(df2)
A  B
0  1  2
1  3  4
2  5  6
3  7  8
```
With `ignore_index` set to True:

```python
>>> df.append(df2, ignore_index=True)
    A  B
0  0  1
1  1  2
2  2  3
3  3  4
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```python
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4
```

More efficient:

```python
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
            ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

*pandas.DataFrame.apply*

DataFrame.apply (func, axis=0, raw=False, result_type=None, args=(), **kwds)

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame’s index (`axis=0`) or the DataFrame’s columns (`axis=1`). By default (`result_type=None`), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the `result_type` argument.

**Parameters**

- **func** [function] Function to apply to each column or row.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the function is applied:
• 0 or ‘index’: apply function to each column.
• 1 or ‘columns’: apply function to each row.

**raw** [bool, default False] Determines if row or column is passed as a Series or ndarray object:
• False: passes each row or column as a Series to the function.
• True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

**result_type** [[‘expand’, ‘reduce’, ‘broadcast’, None], default None] These only act when axis=1 (columns):
• ‘expand’: list-like results will be turned into columns.
• ‘reduce’: returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
• ‘broadcast’: results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

**args** [tuple] Positional arguments to pass to func in addition to the array/series.

**kwds** Additional keyword arguments to pass as keywords arguments to func.

Returns

Series or DataFrame Result of applying func along the given axis of the DataFrame.

See also:

*DataFrame.applymap* For elementwise operations.
*DataFrame.aggregate* Only perform aggregating type operations.
*DataFrame.transform* Only perform transforming type operations.

Examples

```python
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9

Using a numpy universal function (in this case the same as np.sqrt(df)):

```python
>>> df.apply(np.sqrt)
   A  B
0  2.0 3.0
1  2.0 3.0
2  2.0 3.0
```

Using a reducing function on either axis
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> df.apply(np.sum, axis=0)
A  12
B  27
dtype: int64

>>> df.apply(np.sum, axis=1)
0  13
1  13
2  13
dtype: int64

Returning a list-like will result in a Series

```python
>>> df.apply(lambda x: [1, 2], axis=1)
0  [1, 2]
1  [1, 2]
2  [1, 2]
dtype: object
```

Passing result_type='expand' will expand list-like results to columns of a Dataframe

```python
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   A   B
0  1  2
1  1  2
2  1  2
```

Returning a Series inside the function is similar to passing result_type='expand'. The resulting column names will be the Series index.

```python
>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
0   1  2
1   1  2
2   1  2
```

Passing result_type='broadcast' will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```python
>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A   B
0  1  2
1  1  2
2  1  2
```

**pandas.DataFrame.applymap**

DataFrame.applymap(func, na_action=None)
Apply a function to a Dataframe elementwise.
This method applies a function that accepts and returns a scalar to every element of a DataFrame.

**Parameters**

- **func** [callable] Python function, returns a single value from a single value.
na_action  [[None, ‘ignore’], default None] If ‘ignore’, propagate NaN values, without
passing them to func.

New in version 1.2.

Returns

DataFrame  Transformed DataFrame.

See also:

DataFrame.apply  Apply a function along input axis of DataFrame.

Examples

```python
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0    1
0  1.000 2.120
1  3.356 4.567
```

```python
def.applymap(lambda x: len(str(x)))
   0    1
0     3   4
1     5   5
```

Like Series.map, NA values can be ignored:

```python
def_copy = df.copy()
def_copy.iloc[0, 0] = pd.NA
def_copy.applymap(lambda x: len(str(x)), na_action='ignore')
   0     1
0  <NA>   4
1     5   5
```

Note that a vectorized version of `func` often exists, which will be much faster. You could square each
number elementwise.

```python
def.applymap(lambda x: x**2)
   0    1
0  1.000000 4.494400
1 11.262736 20.857489
```

But it’s better to avoid applymap in that case.

```python
def ** 2
   0    1
0  1.000000 4.494400
1 11.262736 20.857489
```
pandas.DataFrame.asfreq

DataFrame.asfreq(freq=None, how=None, normalize=False, fill_value=None)

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. resample is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset or str] Frequency DateOffset or string.

method [{‘backfill’/’bfill’, ‘pad’/’ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
- ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.

how [{‘start’, ‘end’}, default end] For PeriodIndex only (see PeriodIndex.asfreq).

normalize [bool, default False] Whether to reset output index to midnight.

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

Same type as caller Object converted to the specified frequency.

See also:

reindex Conform DataFrame to new index with optional filling logic.

Notes

To learn more about the frequency strings, please see this link.

Examples

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
   s
2000-01-01 00:00:00 0.0
2000-01-01 00:01:00 NaN
2000-01-01 00:02:00 2.0
2000-01-01 00:03:00 3.0
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
   s
2000-01-01 00:00:00 0.0
```

(continues on next page)
Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
```

### pandas.DataFrame.asof

DataFrame.asof(where, subset=None)

Return the last row(s) without any NaNs before `where`.

The last row (for each element in `where`, if list) without any NaN is taken. In case of a DataFrame, the last row without NaN considering only the subset of columns (if not None)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

**Parameters**

- **where** [date or array-like of dates] Date(s) before which the last row(s) are returned.
- **subset** [str or array-like of str, default None] For DataFrame, if not None, only use these columns to check for NaNs.

**Returns**

scalar, Series, or DataFrame  The return can be:

- scalar : when `self` is a Series and `where` is a scalar
- Series: when `self` is a Series and `where` is an array-like, or when `self` is a DataFrame and `where` is a scalar
- DataFrame : when `self` is a DataFrame and `where` is an array-like
Return scalar, Series, or DataFrame.

See also:

merge_asof  Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10  1.0
20  2.0
30  NaN
40  4.0
dtype: float64

>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.

```python
>>> s.asof([5, 20])
5  NaN
20  2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```python
>>> s.asof(30)
2.0
```

Take all columns into consideration

```python
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                     'b': [None, None, None, None, 500],
...                     'c': [2018-02-27 09:01:00, 2018-02-27 09:02:00, 2018-02-27 09:03:00, 2018-02-27 09:04:00, 2018-02-27 09:05:00]})

>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30', '2018-02-27 09:04:30']))
a   b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...     '2018-02-27 09:04:30']),
...     subset=['a'])

   a     b
2018-02-27 09:03:30 30.0  NaN
2018-02-27 09:04:30 40.0  NaN

### pandas.DataFrame.assign

DataFrame.assign(**kwargs)

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are reassigned will be overwritten.

**Parameters**

**kwargs [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn’t check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

**Returns**

DataFrame A new DataFrame with the new columns in addition to all the existing columns.

### Notes

Assigning multiple columns within the same assign is possible. Later items in ‘**kwargs’ may refer to newly created or modified columns in ‘df’; items are computed and assigned into ‘df’ in order.

### Examples

```python
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
...                    index=['Portland', 'Berkeley'])
>>> df
   temp_c
Portland  17.0
Berkeley  25.0

Where the value is a callable, evaluated on df:

```python
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
      temp_c  temp_f
Portland    17.0     62.6
Berkeley    25.0     77.0
```  

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```python
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
      temp_c  temp_f
temp_c    17.0     62.6
temp_c    25.0     77.0
```
You can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```python
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...           temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
```

<table>
<thead>
<tr>
<th></th>
<th>temp_c</th>
<th>temp_f</th>
<th>temp_k</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portland</td>
<td>17.0</td>
<td>62.6</td>
<td>290.15</td>
</tr>
<tr>
<td>Berkeley</td>
<td>25.0</td>
<td>77.0</td>
<td>298.15</td>
</tr>
</tbody>
</table>

### pandas.DataFrame.astype

DataFrame. **astype**(dtype, copy=True, errors='raise')

Cast a pandas object to a specified dtype dtype.

**Parameters**

- **dtype** [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

- **copy** [bool, default True] Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

- **errors** [['raise', 'ignore'], default 'raise'] Control raising of exceptions on invalid data for provided dtype.
  - raise: allow exceptions to be raised
  - ignore: suppress exceptions. On error return original object.

**Returns**

- **casted** [same type as caller]

**See also:**

- **to_datetime** Convert argument to datetime.
- **to_timedelta** Convert argument to timedelta.
- **to_numeric** Convert argument to a numeric type.
- **numpy.ndarray.astype** Cast a numpy array to a specified type.
Examples

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0 1
1 2
dtype: int32
>>> ser.astype('int64')
0 1
1 2
dtype: int64
```

Convert to categorical type:

```python
>>> ser.astype('category')
0 1
1 2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> cat_dtype = pd.api.types.CategoricalDtype(
...    categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0 1
1 2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using copy=False and changing data on a new pandas object may propagate changes:
Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0    2020-01-01
1    2020-01-02
2    2020-01-03
dtype: datetime64[ns]
```

Datetimes are localized to UTC first before converting to the specified timezone:

```python
>>> ser_date.astype('datetime64[ns, US/Eastern]')
0  2019-12-31 19:00:00-05:00
1  2020-01-01 19:00:00-05:00
2  2020-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

**pandas.DataFrame.at_time**

```python
dataframe.at_time(time, asof=False, axis=None)
```

Select values at particular time of day (e.g., 9:30AM).

**Parameters**

- `time` [datetime.time or str]
- `axis` [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

**Returns**

Series or DataFrame

**Raises**

TypeError If the index is not a DatetimeIndex

See also:

- **between_time** Select values between particular times of the day.
- **first** Select initial periods of time series based on a date offset.
- **last** Select final periods of time series based on a date offset.
- **DatetimeIndex.indexer_at_time** Get just the index locations for values at particular time of the day.
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]})
>>> ts
   A
2018-04-09 00:00:00 1
2018-04-09 12:00:00 2
2018-04-10 00:00:00 3
2018-04-10 12:00:00 4

>>> ts.at_time('12:00')
   A
2018-04-09 12:00:00 2
2018-04-10 12:00:00 4
```

**pandas.DataFrame.backfill**

DataFrame.backfill(axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='bfill'.

Returns

{klass} or None Object with missing values filled or None if inplace=True.

**pandas.DataFrame.between_time**

DataFrame.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are not between the two times.

Parameters

- **start_time** [datetime.time or str] Initial time as a time filter limit.
- **end_time** [datetime.time or str] End time as a time filter limit.
- **include_start** [bool, default True] Whether the start time needs to be included in the result.
- **include_end** [bool, default True] Whether the end time needs to be included in the result.
- **axis** {[0 or ‘index’, 1 or ‘columns’], default 0] Determine range time on index or columns value.

New in version 0.24.0.

Returns

Series or DataFrame Data from the original object filtered to the specified dates range.

Raises

TypeError If the index is not a `DatetimeIndex`
See also:

**at_time** Select values at a particular time of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer_between_time** Get just the index locations for values between particular times of the day.

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
     A
2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4

>>> ts.between_time('0:15', '0:45')
     A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3

You get the times that are not between two times by setting `start_time` later than `end_time`:

```python
>>> ts.between_time('0:45', '0:15')
     A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4
```

**pandas.DataFrame.bfill**

DataFrame.bfill(*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for `DataFrame.fillna()` with method='bfill'.

Returns

{klass} or None Object with missing values filled or None if `inplace=True`.

**pandas.DataFrame.bool**

DataFrame.bool()

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool The value in the Series or DataFrame.
See also:

Series.astype Change the data type of a Series, including to boolean.

DataFrame.astype Change the data type of a DataFrame, including to boolean.
numpy.bool_ NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

```python
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.DataFrame.boxplot

DataFrame.boxplot (column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, backend=None, **kwargs)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR = Q3 - Q1) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia’s entry for boxplot.

Parameters

- column [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to pandas.DataFrame.groupby().
- by [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.groupby(). One box-plot will be done per value of columns in by.
- ax [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.
- fontsize [float or str] Tick label font size in points or as a string (e.g., large).
- rot [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.
- grid [bool, default True] Setting this to True will show the grid.
- figsize [A tuple (width, height) in inches] The size of the figure to create in matplotlib.
- layout [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.
**return_type** [[‘axes’, ‘dict’, ‘both’] or None, default ‘axes’] The kind of object to return. The default is axes.

- ‘axes’ returns the matplotlib axes the boxplot is drawn on.
- ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
- ‘both’ returns a namedtuple with the axes and dict.
- when grouping with *by*, a Series mapping columns to *return_type* is returned.

If *return_type* is *None*, a NumPy array of axes with the same shape as *layout* is returned.

**backend** [str, default None] Backend to use instead of the backend specified in the option *plotting.backend*. For instance, ‘matplotlib’. Alternatively, to specify the *plotting.backend* for the whole session, set *pd.options.plotting.backend*.

New in version 1.0.0.

**kwargs** All other plotting keyword arguments to be passed to *matplotlib.pyplot.boxplot()*.

Returns

result See Notes.

See also:

*Series.plot.hist* Make a histogram.

*matplotlib.pyplot.boxplot* Matplotlib equivalent plot.

**Notes**

The return type depends on the *return_type* parameter:

- ‘axes’ : object of class matplotlib.axes.Axes
- ‘dict’ : dict of matplotlib.lines.Line2D objects
- ‘both’ : a namedtuple with structure (*ax*, *lines*)

For data grouped with *by*, return a Series of the above or a numpy array:

- *Series*
- *array* (for *return_type* = None)

Use *return_type*='dict' when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.
Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
...                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                    columns=['Col1', 'Col2', 'Col3'])
```
The layout of boxplot can be adjusted giving a tuple to `layout`:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
```

```
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:
```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
... >>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
... >>> type(boxplot)
<class 'numpy.ndarray'>
```

### pandas.DataFrame.clip

`DataFrame.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)`

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- `lower` [float or array_like, default None] Minimum threshold value. All values below this threshold will be set to it.
- `upper` [float or array_like, default None] Maximum threshold value. All values above this threshold will be set to it.
- `axis` [int or str axis name, optional] Align object with lower and upper along the given axis.
- `inplace` [bool, default False] Whether to perform the operation in place on the data.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

- `Series or DataFrame or None` Same type as calling object with the values outside the clip boundaries replaced or None if `inplace=True`.

**See also:**

- `Series.clip` Trim values at input threshold in series.
- `DataFrame.clip` Trim values at input threshold in data frame.
- `numpy.clip` Clip (limit) the values in an array.
### Examples

```python
data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0 col_1
0      9   -2
1     -3   -7
2      0     6
3     -1     8
4      5   -5
```

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
   col_0 col_1
0      6   -2
1     -3   -4
2      0     6
3     -1     6
4      5   -4
```

Clips using specific lower and upper thresholds per column element:

```python
t = pd.Series([2, -4, -1, 6, 3])
>>> t
0  2
1 -4
2 -1
3  6
4  3
   dtype: int64

>>> df.clip(t, t + 4, axis=0)
   col_0 col_1
0      6   -2
1     -3   -4
2      0     3
3      6     8
4      5     3
```

---

**pandas.DataFrame.combine**

`DataFrame.combined РФ other, func, fill_value=None, overwrite=True`  
Perform column-wise combine with another DataFrame.

Combines a DataFrame with `other` DataFrame using `func` to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

### Parameters

- **other** [DataFrame] The DataFrame to merge column-wise.
- **func** [function] Function that takes two series as inputs and return a Series or a scalar. Used to merge the two dataframes column by columns.
- **fill_value** [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.
overwrite [bool, default True] If True, columns in self that do not exist in other will be overwritten with NaNs.

Returns

DataFrame Combination of the provided DataFrames.

See also:

DataFrame.combine_first Combine two DataFrame objects and default to non-null values in frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```python
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3  
1  0  3  
```

Example using a true element-wise combine function.

```python
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
   A  B
0  1  2  
1  0  3  
```

Using fill_value fills Nones prior to passing the column to the merge function.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0 -5.0
1  0  4.0
```

However, if the same element in both dataframes is None, that None is preserved

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0 -5.0
1  0  3.0
```

Example that demonstrates the use of overwrite and behavior when the axis differ between the dataframes.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], 'index': [1, 2]})
>>> df1.combine(df2, take_smaller, overwrite=True)
   A  B  C
0  0  4.0
1  0  3.0
```
pandas.DataFrame.combine_first

DataFrame.combine_first(other)
Update null elements with value in the same location in other.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters
other [DataFrame] Provided DataFrame to use to fill null values.

Returns
DataFrame

See also:

DataFrame.combine Perform series-wise operation on two DataFrames using a given function.
Examples

```python
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
     A  B
0  1.0  3.0
1  0.0  4.0

Null values still persist if the location of that null value does not exist in `other`

```python
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df1.combine_first(df2)
     A   B   C
0  NaN  4.0  NaN
1  0.0  3.0  1.0
2  NaN  3.0  1.0
```

pandas.DataFrame.compare

DataFrame.compare(other, align_axis=1, keep_shape=False, keep_equal=False)

Compare to another DataFrame and show the differences.

New in version 1.1.0.

**Parameters**

- **other** [DataFrame] Object to compare with.
- **align_axis** [{0 or ‘index’, 1 or ‘columns’}, default 1] Determine which axis to align the comparison on.
  - 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
  - 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.
- **keep_shape** [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.
- **keep_equal** [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

**Returns**

DataFrame DataFrame that shows the differences stacked side by side.

The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

**Raises**

ValueError When the two DataFrames don’t have identical labels or shape.

**See also:**

- Series.compare Compare with another Series and show differences.
- DataFrame.equals Test whether two objects contain the same elements.
Notes

Matching NaNs will not appear as a difference.

Can only compare identically-labeled (i.e. same shape, identical row and column labels) DataFrames

Examples

```python
>>> df = pd.DataFrame({
...     "col1": ["a", "a", "b", "b", "a"],
...     "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
...     "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
... },
... columns=["col1", "col2", "col3"],
...
}
```

```bash
>>> df
col1  col2  col3
0   a    1.0  1.0
1   a    2.0  2.0
2   b    3.0  3.0
3   b    NaN 4.0
4   a    5.0  5.0
```

```bash
>>> df2 = df.copy()
>>> df2.loc[0, 'col1'] = 'c'
>>> df2.loc[2, 'col3'] = 4.0
```

```bash
>>> df2
col1  col2  col3
0   c    1.0  1.0
1   a    2.0  2.0
2   b    3.0  4.0
3   b    NaN 4.0
4   a    5.0  5.0
```

Align the differences on columns

```bash
>>> df.compare(df2)
coll  col3
self  other self  other
0   a    NaN   NaN
2   NaN  3.0    4.0
```

Stack the differences on rows

```bash
>>> df.compare(df2, align_axis=0)
coll  col3
self  a    NaN
other c    NaN
2    NaN  3.0
other NaN  4.0
```

Keep the equal values

```bash
>>> df.compare(df2, keep_equal=True)
coll  col3
(continues on next page)
```
Keep all original rows and columns

```python
>>> df.compare(df2, keep_shape=True)
   col1  col2  col3
0   a    c    NaN  NaN  NaN  NaN
1   NaN  NaN  NaN  NaN  NaN  NaN
2   NaN  NaN  NaN   3  0   4  0
3   NaN  NaN  NaN  NaN  NaN  NaN
4   NaN  NaN  NaN  NaN  NaN  NaN
```

Keep all original rows and columns and also all original values

```python
>>> df.compare(df2, keep_shape=True, keep_equal=True)
   col1  col2  col3
0   a    c    1  0   1  0
1   a    a    2  0   2  0
2   b    b    3  0   3  0
3   b    b  NaN  NaN  4  0
4   a    a    5  0   5  0
```

**pandas.DataFrame.convert_dtypes**

DataFrame.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True, convert_floating=True)

Convert columns to best possible dtypes using dtypes supporting pd.NA.

New in version 1.0.0.

**Parameters**

- **infer_objects** [bool, default True] Whether object dtypes should be converted to the best possible types.
- **convert_string** [bool, default True] Whether object dtypes should be converted to StringDtype().
- **convert_integer** [bool, default True] Whether, if possible, conversion can be done to integer extension types.
- **convert_boolean** [bool, defaults True] Whether object dtypes should be converted to BooleanDtypes().
- **convert_floating** [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If convert_integer is also True, preference will be give to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

**Returns**

- **Series or DataFrame** Copy of input object with new dtype.
infer_objects  Infer dtypes of objects.

to_datetime  Convert argument to datetime.

to_timedelta  Convert argument to timedelta.

to_numeric  Convert argument to a numeric type.

Notes

By default, convert_dtypes will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support pd.NA. By using the options convert_string, convert_integer, convert_boolean and convert_boolean, it is possible to turn off individual conversions to StringDtype, the integer extension types, BooleanDtype or floating extension types, respectively.

For object-dtyped columns, if infer_objects is True, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to StringDtype, BooleanDtype or an appropriate integer or floating extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support pd.NA, the results of this method will change to support those new dtypes.

Examples

```python
>>> df = pd.DataFrame(
...     {       
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )

Start with a DataFrame with default dtypes.

```
Convert the DataFrame to use best possible dtypes.

```python
>>> dfn = df.convert_dtypes()
>>> dfn
   a  b  c  d  e  f
0  1  x  True  h  10 <NA>
1  2  y  False  i  <NA>  100.5
2  3  z  <NA>  <NA>  20  200.0
```

```python
>>> dfn.dtypes
a     Int32
b   string
c    boolean
d   string
e     Int64
f    Float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`.

```python
>>> s = pd.Series(['a', 'b', np.nan])
>>> s
0    a
1    b
2  NaN
dtype: object
```

Obtain a Series with dtype `StringDtype`.

```python
>>> s.convert_dtypes()
0    a
1    b
2   <NA>
dtype: string
```

**pandas.DataFrame.copy**

`DataFrame.copy(deep=True)`

Make a copy of this object’s indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

**Parameters**

`deep` [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.
Returns

```
copy [Series or DataFrame] Object type matches caller.
```

Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=['a', 'b'])
>>> s
a  1
b  2
dtype: int64

>>> s_copy = s.copy()
>>> s_copy
a  1
b  2
dtype: int64

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=['a', 'b'])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)

Shallow copy shares data and index with original.

```
>>> s is shallow
False
```

```
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
```

```
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
```

(continues on next page)
Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
s = pd.Series([[1, 2], [3, 4]])
deep = s.copy()
s[0][0] = 10
s
0   [10, 2]
1   [3, 4]
dtype: object
deep
0   [10, 2]
1   [3, 4]
dtype: object
```

## pandas.DataFrame.corr

**DataFrame.corr**( method='pearson', min_periods=1 )  
Compute pairwise correlation of columns, excluding NA/null values.

**Parameters**

- **method** [‘pearson’, ‘kendall’, ‘spearman’] or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.
    New in version 0.24.0.

- **min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

**Returns**

- **DataFrame** Correlation matrix.

**See also:**

- **DataFrame.corrwith** Compute pairwise correlation with another DataFrame or Series.
- **Series.corr** Compute the correlation between two Series.
Examples

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v

>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
... columns=['dogs', 'cats'])

>>> df.corr(method=histogram_intersection)
   dogs  cats
dogs  1.0  0.3
cats  0.3  1.0
```

**pandas.DataFrame.corr**

`DataFrame.corr()` Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters**

- **other** [DataFrame, Series] Object with which to compute correlations.
- **axis** [0 or 'index', 1 or 'columns'], default 0] The axis to use. 0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise.
- **drop** [bool, default False] Drop missing indices from result.
- **method** [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float.

New in version 0.24.0.

**Returns**

Series Pairwise correlations.

**See also:**

- DataFrame.corr Compute pairwise correlation of columns.

**pandas.DataFrame.count**

`DataFrame.count()` Count non-NA cells for each column or row.

The values `None`, `NaN`, `NaT`, and optionally `numpy.inf` (depending on pandas.options.mode.use_inf_as_na) are considered NA.

**Parameters**
axis [(0 or 'index', 1 or 'columns'), default 0] If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each row.

level [int or str, optional] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame. A str specifies the level name.

numeric_only [bool, default False] Include only float, int or boolean data.

Returns

Series or DataFrame For each column/row the number of non-NA/null entries. If level is specified returns a DataFrame.

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.value_counts Count unique combinations of columns.

DataFrame.shape Number of DataFrame rows and columns (including NA elements).

DataFrame.isna Boolean same-sized DataFrame showing places of NA elements.

Examples

Constructing DataFrame from a dictionary:

```python
>>> df = pd.DataFrame({"Person": [
... "John", "Myla", "Lewis", "John", "Myla"],
... "Age": [24., np.nan, 21., 33, 26],
... "Single": [False, True, True, True, False]})

>>> df
Person  Age  Single
0  John  24.0  False
1  Myla  NaN   True
2  Lewis 21.0  True
3  John  33.0  True
4  Myla  26.0  False
```

Notice the uncounted NA values:

```python
>>> df.count()
Person    5
Age       4
Single    5
dtype: int64
```

Counts for each row:

```python
>>> df.count(axis='columns')
0  3
1  2
2  3
3  3
4  3
dtype: int64
```

Counts for one level of a MultiIndex:
>>> df.set_index(["Person", "Single"]).count(level="Person")

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Age</td>
<td></td>
</tr>
<tr>
<td>Person</td>
<td></td>
</tr>
<tr>
<td>John</td>
<td>2</td>
</tr>
<tr>
<td>Lewis</td>
<td>1</td>
</tr>
<tr>
<td>Myla</td>
<td>1</td>
</tr>
</tbody>
</table>

### pandas.DataFrame.cov

**DataFrame.cov** *(min_periods=None, ddof=1)*

Compute the pairwise covariance of columns, excluding NA/null values.

- **Parameters**
  - `min_periods` [int, optional] Minimum number of observations required per pair of columns to have a valid result.
  - `ddof` [int, default 1] Delta degrees of freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

- **Returns**
  - **DataFrame** The covariance matrix of the series of the DataFrame.

**See also:**

- `Series.cov` Compute covariance with another Series.
- `core.window.ExponentialMovingWindow.cov` Exponential weighted sample covariance.
- `core.window.Expanding.cov` Expanding sample covariance.
- `core.window.Rolling.cov` Rolling sample covariance.

**Notes**

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by \( N-ddof \).

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.
Examples

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                   columns=['dogs', 'cats'])
>>> df.cov()
dogs   cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                   columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
   a         b         c         d         e
a 0.998438 -0.020161  0.059277 -0.008943  0.014144
b-0.020161  1.059352 -0.008543 -0.024738  0.009826
c 0.059277 -0.008543  1.010670 -0.001486 -0.000271
d-0.008943 -0.024738 -0.001486  0.921297 -0.013692
e 0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
   a       b       c
a 0.316741 NaN -0.150812
b NaN 1.248003  0.191417
c-0.150812  0.191417  0.895202
```

```
pandas.DataFrame.cummax
```

DataFrame.cummax (axis=None, skipna=True, *args, **kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

- **axis** [0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **args**, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative maximum of Series or DataFrame.

See also:
**core.window.Expanding.max** Similar functionality but ignores NaN values.

**DataFrame.max** Return the maximum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

### Examples

#### Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
```

```
   0    2.0
   1   NaN
   2    5.0
   3   -1.0
   4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
```

```
   0    2.0
   1   NaN
   2    5.0
   3    5.0
   4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummax(skipna=False)
```

```
   0    2.0
   1   NaN
   2   NaN
   3   NaN
   4   NaN
dtype: float64
```

#### DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
                     [3.0, np.nan],
                     [1.0, 0.0]],
                    columns=list('AB'))
```

```
   A  B
   0  2.0  1.0
   1  3.0   NaN
   2  1.0   0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None`

or `axis='index'`.
To iterate over columns and find the maximum in each row, use `axis=1`:

```python
>>> df.cummax(axis=1)
     A   B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

**pandas.DataFrame.cummin**

`DataFrame.cummin(axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

**Parameters**

- `axis` [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- Series or DataFrame Return cumulative minimum of Series or DataFrame.

**See also:**

- `core.window.Expanding.min` Similar functionality but ignores NaN values.
- `DataFrame.min` Return the minimum over DataFrame axis.
- `DataFrame.cummax` Return cumulative maximum over DataFrame axis.
- `DataFrame.cummin` Return cumulative minimum over DataFrame axis.
- `DataFrame.cumsum` Return cumulative sum over DataFrame axis.
- `DataFrame.cumprod` Return cumulative product over DataFrame axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
     A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummin()
     A  B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```python
>>> df.cummin(axis=1)
     A  B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```
pandas.DataFrame.cumprod

DataFrame.cumprod(axis=None, skipna=True, *args, **kwargs)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **args**, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative product of Series or DataFrame.

See also:

- DataFrame.cummax Return cumulative maximum over DataFrame axis.
- DataFrame.cummin Return cumulative minimum over DataFrame axis.
- DataFrame.cumsum Return cumulative sum over DataFrame axis.
- DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0   2.0
1   NaN
2   5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.
```python
>>> s.cumprod()
0    2.0
1    NaN
2    10.0
3   -10.0
4    -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
```

```python
>>> df
   A    B
0  2.0  1.0
1  3.0   NaN
2  1.0   0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumprod()
   A    B
0  2.0  2.0
1  6.0   NaN
2  6.0   0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```python
>>> df.cumprod(axis=1)
   A    B
0  2.0  2.0
1  3.0   NaN
2  1.0   0.0
```
pandas.DataFrame.cumsum

DataFrame.cumsum (axis=None, skipna=True, *args, **kwargs)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative sum of Series or DataFrame.

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

DataFrame.sum Return the sum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0   2.0
1  NaN
2   5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0   2.0
1  NaN
2   7.0
3   6.0
4   6.0
dtype: float64
```

To include NA values in the operation, use skipna=False
>>> s.cumsum(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))

By default, iterates over rows and finds the sum in each column. This is equivalent to axis=None or axis='index'.

>>> df.cumsum()
   A  B
0  2.0  1.0
1  5.0   NaN
2  6.0  1.0

To iterate over columns and find the sum in each row, use axis=1

>>> df.cumsum(axis=1)
   A  B
0  2.0  3.0
1  3.0   NaN
2  1.0  1.0

pandas.DataFrame.describe

DataFrame.describe(percentiles=None, include=None, exclude=None, date-time_is_numeric=False)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
• ‘all’ : All columns of the input will be included in the output.

• A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=[’O’])`). To select pandas categorical columns, use ‘category’

• None (default) : The result will include all numeric columns.

`exclude` [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

• A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=[’O’])`). To exclude pandas categorical columns, use ‘category’

• None (default) : The result will exclude nothing.

`datetime_is_numeric` [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

_dataframe.count Count number of non-NA/null observations.
_dataframe.max Maximum of the values in the object.
_dataframe.min Minimum of the values in the object.
_dataframe.mean Mean of the values.
_dataframe.std Standard deviation of the observations.
_dataframe.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result’s index will include `count,mean,std,min,max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count,unique,top,and freq`. The top is the most common value. The freq is the most common value’s frequency. Times-
tamps also include the first and last items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns,
the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count 4
unique 3
top a
top freq 2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([...
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count 3
mean 2006-09-01 08:00:00
min 2000-01-01 00:00:00
25% 2004-12-31 12:00:00
50% 2010-01-01 00:00:00
75% 2010-01-01 00:00:00
max 2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...     'numeric': [1, 2, 3],
...     'object': ['a', 'b', 'c']})
>>> df.describe()
numeric
```

(continues on next page)
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
categorical  numeric  object
count 3.0  3.0  3
unique 3.0  NaN  3
top f  NaN  a
freq 1.0  NaN  1
mean NaN  2.0  NaN
std NaN  1.0  NaN
min NaN  1.0  NaN
25% NaN  1.5  NaN
50% NaN  2.0  NaN
75% NaN  2.5  NaN
max NaN  3.0  NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
numeric
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
object
count 3
```
Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
categorical
    count   3
    unique   3
top   d  
    freq   1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
categorical object
    count   3   3
    unique   3   3
top   f   a  
    freq   1   1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[object])
categorical numeric
    count   3   3.0
    unique   3   NaN
top   f   NaN
    freq   1   NaN
mean  NaN   2.0
std   NaN   1.0
min   NaN   1.0
25%   NaN   1.5
50%   NaN   2.0
75%   NaN   2.5
max   NaN   3.0
```

**pandas.DataFrame.diff**

```
DataFrame.diff(periods=1, axis=0)
First discrete difference of element.
```

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

**Parameters**

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Take difference over rows (0) or columns (1).

**Returns**

- **Dataframe** First differences of the Series.
See also:

**Dataframe.pct_change**  Percent change over given number of periods.

**Dataframe.shift**  Shift index by desired number of periods with an optional time freq.

**Series.diff**  First discrete difference of object.

**Notes**

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

**Examples**

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                   'b': [1, 1, 2, 3, 5, 8],
...                   'c': [1, 4, 9, 16, 25, 36]})

>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36

>>> df.diff()
   a   b   c
0  NaN NaN NaN
1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

Difference with previous column

```python
>>> df.diff(axis=1)
   a  b  c
0  NaN 0  0
1 NaN -1  3
2 NaN -1  7
3 NaN -1 13
4 NaN  0 20
5 NaN  2 28
```

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
   a  b  c
0  NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
```

(continues on next page)
Difference with following row

```python
>>> df.diff(periods=-1)
a  b  c
0 -1.0 0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5 NaN NaN NaN
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
a
0  NaN
1  255
```

### pandas.DataFrame.div

DataFrame.div(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
... 'degrees': [360, 180, 360]},
... index=['circle', 'triangle', 'rectangle'])
>>> df
angles  degrees
circle    0   360
triangle   3   180
rectangle  4   360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
angles  degrees
circle    1   361
triangle   4   181
rectangle  5   361
```n

```python
>>> df.add(1)
angles  degrees
circle    1   361
triangle   4   181
rectangle  5   361
```n

Divide by constant with reverse version.

```python
>>> df.div(10)
angles  degrees
circle    0.0 36.0
triangle  0.3 18.0
rectangle 0.4 36.0
```n

```python
>>> df.rdiv(10)
angles  degrees
circle   inf 0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```n

Subtract a list and Series by axis with operator version.
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> df * other
   angles  degrees
circle   0   NaN
triangle  9   NaN
rectangle 16   NaN
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon']})
>>> df_multindex
   angles  degrees
A circle   0     360
    triangle 3     180
       rectangle 4     360
B square   4     360
       pentagon 5     540
     hexagon 6     720
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

```
>>> df.div(df_multindex, level=1, fill_value=0)
    angles  degrees
A   circle    NaN   1.0
     triangle  1.0   1.0
     rectangle 1.0   1.0
B    square   0.0   0.0
     pentagon  0.0   0.0
     hexagon  0.0   0.0
```

**pandas.DataFrame.divide**

DataFrame .divide (other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator `truediv`).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rtruediv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame  Result of the arithmetic operation.

**See also:**

- `DataFrame.add`  Add DataFrames.
- `DataFrame.sub`  Subtract DataFrames.
- `DataFrame.mul`  Multiply DataFrames.
- `DataFrame.div`  Divide DataFrames (float division).
- `DataFrame.truediv`  Divide DataFrames (float division).
- `DataFrame.floordiv`  Divide DataFrames (integer division).
- `DataFrame.mod`  Calculate modulo (remainder after division).
- `DataFrame.pow`  Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    'index':['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle   1      361
triangle  4      181
rectangle 5      361
```

```python
>>> df.add(1)
   angles  degrees
circle   1      361
triangle  4      181
rectangle 5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle  0.0     36.0
triangle 0.3    18.0
rectangle 0.4   36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf   0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle  -1     358
triangle   2     178
rectangle  3     358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle  -1     358
triangle   2     178
rectangle  3     358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle 0
triangle 3
rectangle 4

>>> df + other
angles  degrees
circle 0.0     NaN
triangle 9.0     NaN
rectangle 16.0    NaN

>>> df.mul(other, fill_value=0)
angles  degrees
circle   0.0
triangle   0.0
rectangle   0.0

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=['A', 'A', 'A', 'B', 'B', 'B'],
...                               ['circle', 'triangle', 'rectangle',
...                                'square', 'pentagon', 'hexagon'])
>>> df_multindex
angles  degrees
A circle 0      360
triangle 3      180
rectangle 4      360
B square 4      360
pentagon 5      540
hexagon 6      720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle  NaN     1.0
triangle   1.0     1.0
rectangle   1.0     1.0
B square   0.0     0.0
pentagon   0.0     0.0
hexagon   0.0     0.0
```
pandas.DataFrame.dot

DataFrame.dot(other)
Compute the matrix multiplication between the DataFrame and other.
This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.
It can also be called using self @ other in Python >= 3.5.

Parameters

other [Series, DataFrame or array-like] The other object to compute the matrix product with.

Returns

Series or DataFrame If other is a Series, return the matrix product between self and other as a Series. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

See also:

Series.dot Similar method for Series.

Notes

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.
The dot method for Series computes the inner product, instead of the matrix product here.

Examples

Here we multiply a DataFrame with a Series.

```python
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0   -4
1    5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```python
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
     0  1
0  0   1
1  1   4
2  1   2
```

Note that the dot method give the same result as @

```python
>>> df @ other
     0  1
0  0   1
1  1   4
2  1   2
```
The dot method works also if other is an np.array.

```python
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
   0  1
0  1  4
1  2  2
```

Note how shuffling of the objects does not change the result.

```python
>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
   0  -4
   1   5
dtype: int64
```

### pandas.DataFrame.drop

DataFrame.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level.

**Parameters**

- `labels` [single label or list-like] Index or column labels to drop.
- `axis` [[0 or ‘index’, 1 or ‘columns’], default 0] Whether to drop labels from the index (0 or ‘index’) or columns (1 or ‘columns’).
- `index` [single label or list-like] Alternative to specifying axis (labels, axis=0 is equivalent to index=labels).
- `columns` [single label or list-like] Alternative to specifying axis (labels, axis=1 is equivalent to columns=labels).
- `level` [int or level name, optional] For MultiIndex, level from which the labels will be removed.
- `inplace` [bool, default False] If False, return a copy. Otherwise, do operation inplace and return None.
- `errors` [['ignore', ‘raise’], default ‘raise’] If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

DataFrame or None DataFrame without the removed index or column labels or None if inplace=True.

** Raises **

- **KeyError** If any of the labels is not found in the selected axis.

See also:

- DataFrame.loc Label-location based indexer for selection by label.
**DataFrame.dropna** Return DataFrame with labels on given axis omitted where (all or any) data are missing.

**DataFrame.drop_duplicates** Return DataFrame with duplicate rows removed, optionally only considering certain columns.

**Series.drop** Return Series with specified index labels removed.

**Examples**

```python
def df = pd.DataFrame(np.arange(12).reshape(3, 4),
    columns=['A', 'B', 'C', 'D'])
```

```text
A   B   C   D
0   0   1   2   3
1   4   5   6   7
2   8   9   10  11
```

**Drop columns**

```python
def.drop(['B', 'C'], axis=1)
```

```text
A   D
0   3
1   7
2   11
```

```python
def.drop(columns=['B', 'C'])
```

```text
A   D
0   3
1   7
2   11
```

**Drop a row by index**

```python
def.drop([0, 1])
```

```text
A   B   C   D
2   8   9   10  11
```

**Drop columns and/or rows of MultiIndex DataFrame**

```python
midx = pd.MultiIndex(levels=[["lama", 'cow', 'falcon'],
    ['speed', 'weight', 'length']],
    codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
    [0, 1, 2, 0, 1, 2, 0, 1, 2]])
def = pd.DataFrame(index=midx, columns=['big', 'small'],
    data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
    [250, 150], [1.5, 0.8], [320, 250],
    [1, 0.8], [0.3, 0.2]])
```

```text
lama speed 45.0 30.0
weight 200.0 100.0
length 1.5 1.0
cow speed 30.0 20.0
weight 250.0 150.0
length 1.5 0.8
falcon speed 320.0 250.0
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.2.2

weight 1.0 0.8
length 0.3 0.2

```python
>>> df.drop(index='cow', columns='small')
   big
lama speed 45.0
   weight 200.0
   length 1.5
falcon speed 320.0
   weight 1.0
   length 0.3
```

```python
>>> df.drop(index='length', level=1)
   big   small
lama speed  45.0  30.0
   weight  200.0  100.0
cow  speed  30.0  20.0
   weight  250.0  150.0
falcon speed 320.0 250.0
   weight  1.0  0.8
```

**pandas.DataFrame.drop_duplicates**

DataFrame.drop_duplicates(subset=None, keep='first', inplace=False, ignore_index=False)  
Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

Parameters

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- **keep** [{‘first’, ‘last’, False}, default ‘first’] Determines which duplicates (if any) to keep. - first : Drop duplicates except for the first occurrence. - last : Drop duplicates except for the last occurrence. - False : Drop all duplicates.
- **inplace** [bool, default False] Whether to drop duplicates in place or to return a copy.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

Returns

DataFrame or None  DataFrame with duplicates removed or None if inplace=True.

See also:

- **DataFrame.value_counts**  Count unique combinations of columns.
Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame(dict(
...     brand=['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     style=['cup', 'cup', 'cup', 'pack', 'pack'],
...     rating=[4, 4, 3.5, 15, 5]
... )
```

By default, it removes duplicate rows based on all columns.

```python
>>> df.drop_duplicates()
```

To remove duplicates on specific column(s), use `subset`.

```python
>>> df.drop_duplicates(subset=['brand'])
```

To remove duplicates and keep last occurrences, use `keep`.

```python
>>> df.drop_duplicates(subset=['brand', 'style'], keep='last')
```

`pandas.DataFrame.droplevel`

`DataFrame.droplevel(level, axis=0)`

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

Parameters

- **level** [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the level(s) is removed:
  - 0 or ‘index’: remove level(s) in column.
  - 1 or ‘columns’: remove level(s) in row.
Returns

DataFrame DataFrame with requested index / column level(s) removed.

Examples

```python
>>> df = pd.DataFrame(
...   [[1, 2, 3, 4],
...    [5, 6, 7, 8],
...    [9, 10, 11, 12]]
... ).set_index([0, 1]).rename_axis(['a', 'b'])
>>> df.columns = pd.MultiIndex.from_tuples(
...   [('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
>>> df
   level_1  c  d  
  level_2  e  f  
    a  b
   1  2  3  4  
   5  6  7  8  
   9 10 11 12
>>> df.droplevel('a')
   level_1  c  d  
  level_2  e  f  
    b
   2  3  4  
   6  7  8  
  10 11 12
>>> df.droplevel('level_2', axis=1)
   level_1  c  d  
  level_2  e  f  
    a  b
   1  2  3  4  
   5  6  7  8  
   9 10 11 12
```

pandas.DataFrame.dropna

DataFrame.dropna(axis=0, how='any', thresh=None, subset=None, inplace=False)

Remove missing values.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Determine if rows or columns which contain missing values are removed.

- 0, or ‘index’ : Drop rows which contain missing values.
- 1, or ‘columns’ : Drop columns which contain missing value.
Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

**how** [{‘any’, ‘all’}, default ‘any’] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.
- ‘any’: If any NA values are present, drop that row or column.
- ‘all’: If all values are NA, drop that row or column.

**thresh** [int, optional] Require that many non-NA values.

**subset** [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

**inplace** [bool, default False] If True, do operation inplace and return None.

**Returns**
DataFrame or None DataFrame with NA entries dropped from it or None if inplace=True.

**See also:**

*DataFrame.isna* Indicate missing values.
*DataFrame.notna* Indicate existing (non-missing) values.
*DataFrame.fillna* Replace missing values.
*Series.dropna* Drop missing values.
*Index.dropna* Drop missing indices.

**Examples**

```python
>>> df = pd.DataFrame({'name': ['Alfred', 'Batman', 'Catwoman'],
                     'toy': [np.nan, 'Batmobile', 'Bullwhip'],
                     'born': [pd.NaT, pd.Timestamp('1940-04-25'),
                              pd.NaT]})
>>> df
     name     toy     born
0    Alfred    NaN      NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip     NaT

Drop the rows where at least one element is missing.
```

```python
>>> df.dropna()
     name     toy     born
1  Batman  Batmobile  1940-04-25
```

Drop the columns where at least one element is missing.

```python
>>> df.dropna(axis='columns')
     name
0    Alfred
1  Batman
2  Catwoman
```

Drop the rows where all elements are missing.

```python
```
Keep only the rows with at least 2 non-NA values.

```python
>>> df.dropna(thresh=2)
   name   toy   born
0  Alfred   NaN   NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip   NaT
```

Define in which columns to look for missing values.

```python
>>> df.dropna(subset=['name', 'toy'])
   name   toy   born
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip   NaT
```

Keep the DataFrame with valid entries in the same variable.

```python
>>> df.dropna(inplace=True)
>>> df
   name   toy   born
1  Batman  Batmobile  1940-04-25
```

### pandas.DataFrame.duplicated

DataFrame.duplicated(subset=None, keep='first')

Return boolean Series denoting duplicate rows.

Considering certain columns is optional.

**Parameters**

- `subset` [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- `keep` [{'first', 'last', False}, default 'first'] Determines which duplicates (if any) to mark.
  - **first**: Mark duplicates as True except for the first occurrence.
  - **last**: Mark duplicates as True except for the last occurrence.
  - **False**: Mark all duplicates as True.

**Returns**

- `Series` Boolean series for each duplicated rows.

**See also:**

* Index.duplicated  Equivalent method on index.
* Series.duplicated  Equivalent method on Series.
* Series.drop_duplicates  Remove duplicate values from Series.
* DataFrame.drop_duplicates  Remove duplicate values from DataFrame.
Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame({
    'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
    'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
    'rating': [4, 4, 3.5, 15, 5]
})

>>> df
   brand style  rating
0  Yum Yum   cup    4.0
1  Yum Yum   cup    4.0
2  Indomie   cup    3.5
3  Indomie   pack  15.0
4  Indomie   pack    5.0
```

By default, for each set of duplicated values, the first occurrence is set on False and all others on True.

```python
>>> df.duplicated()
0  False
1   True
2  False
3   False
4   False
dtype: bool
```

By using `last`, the last occurrence of each set of duplicated values is set on False and all others on True.

```python
>>> df.duplicated(keep='last')
0   True
1  False
2  False
3  False
4  False
dtype: bool
```

By setting `keep` on `False`, all duplicates are True.

```python
>>> df.duplicated(keep=False)
0   True
1   True
2  False
3  False
4  False
dtype: bool
```

To find duplicates on specific column(s), use `subset`.

```python
>>> df.duplicated(subset=['brand'])
0  False
1   True
2  False
3   True
4   True
dtype: bool
```
pandas.DataFrame.eq

Dataframe.eq (other, axis='columns', level=None)

Get Equal to of dataframe and other, element-wise (binary operator eq).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [(0 or 'index', 1 or 'columns'), default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300],
...                    'index': ['A', 'B', 'C'])
>>> df
   cost  revenue
A  250     100
B  150     250
C  100     300

Comparison with a scalar, using either the operator or method:

```
When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
     cost  revenue
  A    True    True
  B    True    False
  C   False    True

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
     cost  revenue
  A   True    False
  B   True    True
  C   True    True
  D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```python
>>> df == [250, 100]
     cost  revenue
  A    True    True
  B   False    False
  C   False    False

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
     cost  revenue
  A   True    False
  B   False    True
  C    True    False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])

>>> df.gt(other)
     cost  revenue
  A    False    False
  B    True    True
  C    True    False
  D    True    True
```

(continues on next page)
Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                           'revenue': [100, 250, 300, 200, 175, 225],
...                           'index': [['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                     ['A', 'B', 'C', 'A', 'B', 'C']])
```

```python
>>> df_multindex
   cost  revenue
Q1 A    250     100
    B    150     250
    C    100     300
Q2 A    150     200
    B    300     175
    C    220     225
```

```python
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A   True    True
    B   True    True
    C   True    True
Q2 A  False    True
    B   True    False
    C   True    False
```

**pandas.DataFrame.equals**

`DataFrame.equals(other)`

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal. Corresponding columns must be of the same dtype.

**Parameters**

- `other` [Series or DataFrame] The other Series or DataFrame to be compared with the first.

**Returns**

- `bool` True if all elements are the same in both objects, False otherwise.

**See also:**

- `Series.eq` Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

- `DataFrame.eq` Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.
**testing.assert_series_equal** Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

**testing.assert_frame_equal** Like assert_series_equal, but targets DataFrames.

**numpy.array_equal** Return True if two arrays have the same shape and elements, False otherwise.

### Examples

```python
def = pd.DataFrame({1: [10], 2: [20]})
def
1  2
0  10 20

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.

```python
exactly_equal = pd.DataFrame({1: [10], 2: [20]})
exactly_equal
1  2
0  10 20
def.equals(exactly_equal)
True
```

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

```python
different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
different_column_type
1.0  2.0
0   10 20
def.equals(different_column_type)
True
```

DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```python
different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
different_data_type
1  2
0  10.0 20.0
def.equals(different_data_type)
False
```

**pandas.DataFrame.eval**

DataFrame.eval(expr, inplace=False, **kwargs)
Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows eval to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

**Parameters**

- `expr` [str] The expression string to evaluate.
inplace [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

**kwargs See the documentation for eval() for complete details on the keyword arguments accepted by query().

Returns

ndarray, scalar, pandas object, or None The result of the evaluation or None if inplace=True.

See also:

DataFrame.query Evaluates a boolean expression to query the columns of a frame.

DataFrame.assign Can evaluate an expression or function to create new values for a column.

eval Evaluate a Python expression as a string using various backends.

Notes

For more details see the API documentation for eval(). For detailed examples see enhancing performance with eval.

Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1  10
1  2   8
2  3   6
3  4   4
4  5   2
>>> df.eval('A + B')
   0  1
0 11 10
1  9  8
2  6  4
3  4  2
4  2  0
dtype: int64
```

Assignment is allowed though by default the original DataFrame is not modified.

```python
>>> df.eval('C = A + B')
   A  B  C
0  1  10 11
1  2   8 10
2  3   6  9
3  4   4  8
4  5   2  7
>>> df
   A  B
0  1  10
1  2   8
2  3   6
(continues on next page)
```
Use `inplace=True` to modify the original DataFrame.

```python
>>> df.eval('C = A + B', inplace=True)
>>> df
   A  B  C
0  1  10 11
1  2   8 10
2  3   6  9
3  4   4  8
4  5   2  7
```

Multiple columns can be assigned to using multi-line expressions:

```python
>>> df.eval('''
... C = A + B
... D = A - B
... '''
...)
   A  B  C  D
0  1 10 11 -9
1  2  8 10 -6
2  3  6  9 -3
3  4  4  8  0
4  5  2  7  3
```

### pandas.DataFrame.ewm

DataFrame.ewm(  
    com=None,  
    span=None,  
    halflife=None,  
    alpha=None,  
    min_periods=0,  
    adjust=True,  
    ignore_na=False,  
    axis=0,  
    times=None  
)  

Provide exponential weighted (EW) functions.

Available EW functions: mean(), var(), std(), corr(), cov().

Exactly one parameter: `com`, `span`, `halflife`, or `alpha` must be provided.

**Parameters**

- **com** [float, optional] Specify decay in terms of center of mass, \( \alpha = 1/(1 + \text{com}) \), for \( \text{com} \geq 0 \).

- **span** [float, optional] Specify decay in terms of span, \( \alpha = 2/(\text{span} + 1) \), for \( \text{span} \geq 1 \).

- **halflife** [float, str, timedelta, optional] Specify decay in terms of half-life, \( \alpha = 1 - \exp\left(-\ln(2)/\text{halflife}\right) \), for \( \text{halflife} > 0 \).

  If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()` and `halflife` value will not apply to the other functions.

  New in version 1.1.0.

- **alpha** [float, optional] Specify smoothing factor \( \alpha \) directly, \( 0 < \alpha \leq 1 \).

- **min_periods** [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).
adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

- When adjust=True (default), the EW function is calculated using weights:
  \[ w_i = (1 - \alpha)^i \]
  For example, the EW moving average of the series \([x_0, x_1, ..., x_t]\) would be:
  \[ y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ... + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t} \]

- When adjust=False, the exponentially weighted function is calculated recursively:
  \[ y_0 = x_0 \]
  \[ y_t = (1 - \alpha)y_{t-1} + \alpha x_t, \]

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

- When ignore_na=False (default), weights are based on absolute positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, None, x_2]\) are \((1 - \alpha)^2\) and \(1\) if adjust=True, and \((1 - \alpha)^2\) and \(\alpha\) if adjust=False.

- When ignore_na=True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, None, x_2]\) are \(1 - \alpha\) and \(1\) if adjust=True, and \(1 - \alpha\) and \(\alpha\) if adjust=False.

axis [0, 1], default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

times [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and datetime64[ns] dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to mean().

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

rolling Provides rolling window calculations.

expanding Provides expanding transformations.
Notes

More details can be found at: *Exponentially weighted windows*.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0
1  1
2  2
3 NaN
4  4

>>> df.ewm(com=0.5).mean()
   B
0  0
1  0.750000
2  1.615385
3  1.615385
4  3.670213

Specifying times with a timedelta halflife when computing mean.

```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
   B
0  0
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

*pandas.DataFrame.expanding*

```
DataFrame.expanding (min_periods=1, center=None, axis=0)
```

Provide expanding transformations.

**Parameters**

- `min_periods` [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).
- `center` [bool, default False] Set the labels at the center of the window.
- `axis` [int or str, default 0] Set the labels at the center of the window.

**Returns**

- a Window sub-classed for the particular operation

**See also:**

- `rolling` Provides rolling window calculations.
- `ewm` Provides exponential weighted functions.
Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```python
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.expanding(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

`pandas.DataFrame.explode`

`DataFrame.explode(column, ignore_index=False)`

Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

**Parameters**

- `column` [str or tuple] Column to explode.
- `ignore_index` [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.1.0.

**Returns**

`DataFrame` Exploded lists to rows of the subset columns; index will be duplicated for these rows.

**Raises**

`ValueError` [] if columns of the frame are not unique.

**See also:**

`DataFrame.unstack` Pivot a level of the (necessarily hierarchical) index labels.

`DataFrame.melt` Unpivot a DataFrame from wide format to long format.

`Series.explode` Explode a DataFrame from list-like columns to long format.
Notes

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of rows in the output will be non-deterministic when exploding sets.

Examples

```python
>>> df = pd.DataFrame({'A': [[1, 2, 3], 'foo', [], [3, 4]], 'B': 1})
>>> df
   A  B
0 [1, 2, 3] 1
1   foo  1
2     []  1
3   [3, 4] 1

>>> df.explode('A')
   A  B
0 1  1
0 2  1
0 3  1
1 foo  1
2  NaN  1
3  3  1
3  4  1
```

pandas.DataFrame.ffill

DataFrame.ffill (axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='ffill'.

Returns

{klass} or None Object with missing values filled or None if inplace=True.

pandas.DataFrame.fillna

DataFrame.fillna (value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)

Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

axis [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.
inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None Object with missing values filled or None if inplace=True.

See also:

interpolate Fill NaN values using interpolation.
reindex Conform object to new index.
asfreq Convert TimeSeries to specified frequency.

Examples

```python
def = pd.DataFrame([[np.nan, 2, np.nan, 0],
                    [3, 4, np.nan, 1],
                    [np.nan, np.nan, np.nan, 5],
                    [np.nan, 3, np.nan, 4]],
                    columns=list('ABCD'))
def
    A   B   C   D
0  NaN 2.0  NaN  0
1   3.0  4.0  NaN  1
2  NaN  NaN  NaN  5
3  NaN  3.0  NaN  4

Replace all NaN elements with 0s.
```

```python
def.fillna(0)
    A   B   C   D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```python
def.fillna(method='ffill')
    A   B   C   D
0  NaN  2.0  NaN  0
1   3.0  4.0  NaN  1
2   3.0  4.0  NaN  5
3   3.0  3.0  NaN  4
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
    A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 2.0 1
2  0.0 1.0 2.0 5
3  0.0 3.0 2.0 4

Only replace the first NaN element.

>>> df.fillna(value=values, limit=1)
    A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0  NaN 1
2  NaN 1.0  NaN 5
3  NaN 3.0  NaN 4

### pandas.DataFrame.filter

Dataframe.filter(items=None, like=None, regex=None, axis=None)

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items** (list-like) Keep labels from axis which are in items.
- **like** (str) Keep labels from axis for which “like in label == True”.
- **regex** (str (regular expression)) Keep labels from axis for which re.search(regex, label) == True.
- **axis** ([0 or ‘index’, 1 or ‘columns’, None], default None) The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

**Returns**

same type as input object

**See also:**

*_dataframe.loc* Access a group of rows and columns by label(s) or a boolean array.

**Notes**

The items, like, and regex parameters are enforced to be mutually exclusive.

axis defaults to the info axis that is used when indexing with [].
Examples

```python
>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])
>>> df
    one two three
mouse  1  2  3
rabbit 4  5  6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
    one three
mouse  1  3
rabbit 4  6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
    one three
mouse  1  3
rabbit 4  6

>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
    one two three
rabbit 4  5  6
```

`pandas.DataFrame.first`

`DataFrame.first(offset)`

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

- `offset` [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

Returns

- Series or DataFrame A subset of the caller.

Raises

- TypeError If the index is not a DatetimeIndex

See also:

- `last` Select final periods of time series based on a date offset.
- `at_time` Select values at a particular time of the day.
- `between_time` Select values between particular times of the day.
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09    1
2018-04-11    2
2018-04-13    3
2018-04-15    4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
   A
2018-04-09    1
2018-04-11    2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

**pandas.DataFrame.first_valid_index**

Dataframe.`first_valid_index`()

Return index for first non-NA/null value.

Returns

    scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.DataFrame.floordiv**

Dataframe.`floordiv` (other, axis='columns', level=None, fill_value=None)

Get Integer division of dataframe and other, element-wise (binary operator `floordiv`).

Equivalent to `dataframe // other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `rfloordiv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

    other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

    axis [(0 or 'index', 1 or 'columns')] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

    level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
**fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also:**

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
gf = pd.DataFrame({'angles': [0, 3, 4],
                   'degrees': [360, 180, 360],
                   'index': ['circle', 'triangle', 'rectangle'])
gf
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>triangle</td>
<td>360</td>
</tr>
<tr>
<td>360</td>
<td></td>
</tr>
<tr>
<td>360</td>
<td></td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
<tr>
<td>180</td>
<td></td>
</tr>
<tr>
<td>360</td>
<td></td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
gf + 1
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>triangle</td>
<td>360</td>
</tr>
<tr>
<td>361</td>
<td></td>
</tr>
<tr>
<td>361</td>
<td></td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
<tr>
<td>181</td>
<td></td>
</tr>
<tr>
<td>361</td>
<td></td>
</tr>
</tbody>
</table>

```python
gf.add(1)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>
<tr>
<td>triangle</td>
<td>181</td>
</tr>
<tr>
<td>181</td>
<td></td>
</tr>
<tr>
<td>181</td>
<td></td>
</tr>
<tr>
<td>rectangle</td>
<td>361</td>
</tr>
<tr>
<td>361</td>
<td></td>
</tr>
<tr>
<td>361</td>
<td></td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.
Divide by a MultiIndex by level.

Subtract a list and Series by axis with operator version.

Multiply a DataFrame of different shape with operator version.

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
... 'degrees': [360, 180, 360, 360, 540, 720]},
... index=[['A', 'A', 'A', 'B', 'B', 'B'],
... ['circle', 'triangle', 'rectangle',
... 'square', 'pentagon', 'hexagon']])
```

```
angles  degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
>>> df_multindex
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```
angles  degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```

**pandas.DataFrame.from_dict**

*classmethod* `DataFrame.from_dict(data, orient='columns', dtype=None, columns=None)`  
Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

**Parameters**

- `data` [dict] Of the form {field : array-like} or {field : dict}.
- `orient` [{‘columns’, ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.
- `dtype` [dtype, default None] Data type to force, otherwise infer.
- `columns` [list, default None] Column labels to use when orient=’index’. Raises a `ValueError` if used with orient=’columns’.

**Returns**

- `DataFrame`

**See also:**

- `DataFrame.from_records` DataFrame from structured ndarray, sequence of tuples or dicts, or DataFrame.
- `DataFrame` DataFrame object creation using constructor.
Examples

By default the keys of the dict become the DataFrame columns:

```python
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0     3     a
1     2     b
2     1     c
3     0     d
```

Specify `orient='index'` to create the DataFrame using dictionary keys as rows:

```python
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']
>>> pd.DataFrame.from_dict(data, orient='index')
    0  1  2  3
row_1 3  2  1  0
row_2 a  b  c  d
```

When using the ‘index’ orientation, the column names can be specified manually:

```python
>>> pd.DataFrame.from_dict(data, orient='index',
... columns=['A', 'B', 'C', 'D'])
     A  B  C  D
row_1 3  2  1  0
row_2 a  b  c  d
```

**pandas.DataFrame.from_records**

`classmethod DataFrame.from_records(data, index=None, exclude=None, columns=None, coerce_float=False, nrows=None)`

Convert structured or record ndarray to DataFrame.

Creates a DataFrame object from a structured ndarray, sequence of tuples or dicts, or DataFrame.

**Parameters**

- `data` [structured ndarray, sequence of tuples or dicts, or DataFrame] Structured input data.
- `index` [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.
- `exclude` [sequence, default None] Columns or fields to exclude.
- `columns` [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).
- `coerce_float` [bool, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
- `nrows` [int, default None] Number of rows to read if data is an iterator.

**Returns**

DataFrame
See also:

**DataFrame.from_dict** DataFrame from dict of array-like or dicts.

**DataFrame** DataFrame object creation using constructor.

**Examples**

Data can be provided as a structured ndarray:

```python
>>> data = np.array([(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')],
                  dtype=[('col_1', 'i4'), ('col_2', 'U1')])
>>> pd.DataFrame.from_records(data)
   col_1 col_2
0     3     a
1     2     b
2     1     c
3     0     d
```

Data can be provided as a list of dicts:

```python
>>> data = [{'col_1': 3, 'col_2': 'a'},
           {'col_1': 2, 'col_2': 'b'},
           {'col_1': 1, 'col_2': 'c'},
           {'col_1': 0, 'col_2': 'd'}]
>>> pd.DataFrame.from_records(data)
   col_1 col_2
0     3     a
1     2     b
2     1     c
3     0     d
```

Data can be provided as a list of tuples with corresponding columns:

```python
>>> data = [(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')]
>>> pd.DataFrame.from_records(data, columns=['col_1', 'col_2'])
   col_1 col_2
0     3     a
1     2     b
2     1     c
3     0     d
```

**pandas.DataFrame.ge**

DataFrame.ge(other, axis='columns', level=None)

Get Greater than or equal to of dataframe and other, element-wise (binary operator ge).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns')

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

*DataFrame of bool* Result of the comparison.

**See also:**

*DataFrame.eq* Compare DataFrames for equality elementwise.

*DataFrame.ne* Compare DataFrames for inequality elementwise.

*DataFrame.le* Compare DataFrames for less than inequality or equality elementwise.

*DataFrame.lt* Compare DataFrames for strictly less than inequality elementwise.

*DataFrame.ge* Compare DataFrames for greater than inequality or equality elementwise.

*DataFrame.gt* Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

**Examples**

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                   'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

Comparison with a scalar, using either the operator or method:

```python
def == 100
   cost  revenue
A   False   True
B   False   False
C   True    False
```
Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A    True     False
B    True      True
C    True      True
D    True      True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```
>>> df == [250, 100]
   cost  revenue
A  True      True
B False     False
C False     False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A False     False
B False     True
C  True     False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
```

```
>>> df.gt(other)
   cost  revenue
A False     False
B False     False
C  False      True
D False     False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225]},
                              index=['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'])
```

```
>>> df_multindex
    cost  revenue
  Q1  A  250  100
(continues on next page)```
B  150  250
C  100  300
Q2 A  150  200
    B  300  175
    C  220  225

>>> df.le(df_multindex, level=1)
   cost  revenue
Q1  A    True  True
    B    True  True
    C    True  True
Q2  A   False  True
    B    True  False
    C    True  False

pandas.DataFrame.get

DataFrame.get(key, default=None)

    Get item from object for given key (ex: DataFrame column).
    Returns default value if not found.

    Parameters
        key [object]
    Returns
        value [same type as items contained in object]

pandas.DataFrame.groupby

DataFrame.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=<object object>, observed=False, dropna=True)

    Group DataFrame using a mapper or by a Series of columns.
    A groupby operation involves some combination of splitting the object, applying a function, and combing the results. This can be used to group large amounts of data and compute operations on these groups.

    Parameters
        by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If by is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see .align() method). If an ndarray is passed, the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in self. Notice that a tuple is interpreted as a (single) key.
        axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Split along rows (0) or columns (1).
        level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.
as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. as_index=False is effectively “SQL-style” grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling apply, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

Deprecated since version 1.1.0.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

dropna [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

New in version 1.1.0.

Returns

DataFrameGroupBy Returns a groupby object that contains information about the groups.

See also:

resample Convenience method for frequency conversion and resampling of time series.

Notes

See the user guide for more.

Examples

```python
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...                     'Max Speed': [380., 370., 24., 26.])
>>> df
   Animal  Max Speed
0   Falcon     380.0
1   Falcon     370.0
2   Parrot      24.0
3   Parrot      26.0
>>> df.groupby(["Animal"]).mean()
   Max Speed
Animal
Falcon     375.0
Parrot     25.0
```

Hierarchical Indexes

We can groupby different levels of a hierarchical index using the level parameter:
arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
          ['Captive', 'Wild', 'Captive', 'Wild']]
index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
                  index=index)
df

<table>
<thead>
<tr>
<th>Animal</th>
<th>Type</th>
<th>Max Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Falcon</td>
<td>Captive</td>
<td>390.0</td>
</tr>
<tr>
<td></td>
<td>Wild</td>
<td>350.0</td>
</tr>
<tr>
<td>Parrot</td>
<td>Captive</td>
<td>30.0</td>
</tr>
<tr>
<td></td>
<td>Wild</td>
<td>20.0</td>
</tr>
</tbody>
</table>

df.groupby(level=0).mean()

<table>
<thead>
<tr>
<th>Animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Falcon</td>
</tr>
<tr>
<td>Parrot</td>
</tr>
</tbody>
</table>

df.groupby(level="Type").mean()

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Captive</td>
</tr>
<tr>
<td>Wild</td>
</tr>
</tbody>
</table>

We can also choose to include NA in group keys or not by setting dropna parameter, the default setting is True:

l = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
df = pd.DataFrame(l, columns=['a', 'b', 'c'])
df.groupby(by=['b']).sum()

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>2</td>
</tr>
<tr>
<td>1.0</td>
<td>2</td>
</tr>
<tr>
<td>2.0</td>
<td>2</td>
</tr>
</tbody>
</table>

df.groupby(by=['b'], dropna=False).sum()

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>2</td>
</tr>
<tr>
<td>1.0</td>
<td>2</td>
</tr>
<tr>
<td>2.0</td>
<td>2</td>
</tr>
<tr>
<td>NaN</td>
<td>1</td>
</tr>
</tbody>
</table>

l = [['a', 12, 12], [None, 12.3, 33.], ['b', 12.3, 123], ['a', 1, 1]]
df = pd.DataFrame(l, columns=['a', 'b', 'c'])
df.groupby(by="a").sum()

<table>
<thead>
<tr>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>13.0</td>
</tr>
<tr>
<td>b</td>
<td>12.3</td>
</tr>
</tbody>
</table>

df.groupby(by="a", dropna=False).sum()

<table>
<thead>
<tr>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>13.0</td>
</tr>
</tbody>
</table>

pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DataFrame.gt

DataFrame.gt(other, axis='columns', level=None)

Get Greater than of dataframe and other, element-wise (binary operator gt).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                     index=['A', 'B', 'C'])
>>> df
   cost  revenue
  A   250     100
  B   150     250
  C   100     300
```
Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False     True
B  False    False
C   True    False
```

```python
>>> df.eq(100)
   cost  revenue
A  False     True
B  False    False
C   True    False
```

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A  True    False
B  True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A   True     True
B  False    False
C  False    False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A  True    False
B  False     True
C   True    False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                       index=['A', 'B', 'C', 'D'])
```

3.4. DataFrame
```python
>>> df.gt(other)
    cost  revenue
  A  False    False
  B  False    False
  C  False     True
  D  False    False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
   ...               'revenue': [100, 250, 300, 200, 175, 225],
   ...           index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
   ...              ['A', 'B', 'C', 'A', 'B', 'C']])
```

```python
>>> df_multindex
   cost  revenue
  Q1   A    250    100
       B    150    250
       C    100    300
  Q2   A    150    200
       B    300    175
       C    220    225
```

```python
>>> df.le(df_multindex, level=1)
    cost  revenue
  Q1   A   True   True
       B   True   True
       C   True   True
  Q2   A  False   True
       B   True  False
       C   True  False
```

### pandas.DataFrame.head

DataFrame.head(n=5)

Return the first n rows.

This function returns the first $n$ rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of $n$, this function returns all rows except the last $n$ rows, equivalent to `df[:-n]`.

**Parameters**

- **n** [int, default 5] Number of rows to select.

**Returns**

- **same type as caller** The first $n$ rows of the caller object.

**See also:**

*DataFrame.tail* Returns the last $n$ rows.
Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
         'monkey', 'parrot', 'shark', 'whale', 'zebra']})

>>> df
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey
5  parrot
6  shark
7  whale
8  zebra

Viewing the first 5 lines

```python
>>> df.head()
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey

Viewing the first \(n\) lines (three in this case)

```python
>>> df.head(3)
animal
0  alligator
1    bee
2  falcon

For negative values of \(n\)

```python
>>> df.head(-3)
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey
5  parrot

pandas.DataFrame.hist

DataFrame.hist(column=None, by=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, backend=None, legend=False, **kwargs)

Make a histogram of the DataFrame’s.

A histogram is a representation of the distribution of data. This function calls matplotlib.pyplot.hist(), on each series in the DataFrame, resulting in one histogram per column.

Parameters
data  [DataFrame] The pandas object holding the data.
column  [str or sequence] If passed, will be used to limit data to a subset of columns.
by  [object, optional] If passed, then used to form histograms for separate groups.
grid  [bool, default True] Whether to show axis grid lines.
xlabels  [int, default None] If specified changes the x-axis label size.
xrot  [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
ylabels  [int, default None] If specified changes the y-axis label size.
yrot  [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
ax  [Matplotlib axes object, default None] The axes to plot the histogram on.
sharex  [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
sharey  [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
figsize  [tuple] The size in inches of the figure to create. Uses the value in matplotlib.rcParams by default.
layout  [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
bins  [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
backend  [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

legend  [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib.pyplot.hist().

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

matplotlib.pyplot.hist  Plot a histogram using matplotlib.
Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins.

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1],
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

**pandas.DataFrame.idxmax**

DataFrame.[idxmax](https://pandas.pydata.org/pandas-docs/stable/generated/pandas.DataFrame.idxmax.html) *(axis=0, skipna=True)*

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

**Parameters**

- **axis** *[0 or ‘index’, 1 or ‘columns’], default 0]* The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

- **skipna** *[bool, default True]* Exclude NA/null values. If an entire row/column is NA, the result will be NA.
Returns

Series  Indexes of maxima along the specified axis.

Raises

ValueError

• If the row/column is empty

See also:

Series.idxmax  Return index of the maximum element.

Notes

This method is the DataFrame version of ndarray.argmax.

Examples

Consider a dataset containing food consumption in Argentina.

```python
def = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
                   'co2_emissions': [37.2, 19.66, 1712]},
                   index=['Pork', 'Wheat Products', 'Beef'])
```

By default, it returns the index for the maximum value in each column.

```python
def.idxmax()
```

<table>
<thead>
<tr>
<th>consumption</th>
<th>co2_emissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pork</td>
<td>10.51</td>
</tr>
<tr>
<td>Wheat Products</td>
<td>103.11</td>
</tr>
<tr>
<td>Beef</td>
<td>55.48</td>
</tr>
<tr>
<td></td>
<td>37.20</td>
</tr>
<tr>
<td></td>
<td>19.66</td>
</tr>
<tr>
<td></td>
<td>1712.00</td>
</tr>
</tbody>
</table>

```
dtype: object
```

To return the index for the maximum value in each row, use `axis="columns"`.

```python
def.idxmax(axis="columns")
```

<table>
<thead>
<tr>
<th>Pork</th>
<th>co2_emissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>co2_emissions</td>
<td>consumption</td>
</tr>
<tr>
<td>Beef</td>
<td>co2_emissions</td>
</tr>
</tbody>
</table>

```
dtype: object
```
pandas.DataFrame.idxmin

DataFrame.idxmin (axis=0, skipna=True)
Return index of first occurrence of minimum over requested axis.
NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.

Raises

ValueError
• If the row/column is empty

See also:

Series.idxmin Return index of the minimum element.

Notes

This method is the DataFrame version of ndarray.argmin.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({
'consumption': [10.51, 103.11, 55.48],
... 'co2_emissions': [37.2, 19.66, 1712]},
... index=['Pork', 'Wheat Products', 'Beef'])
```

By default, it returns the index for the minimum value in each column.

```python
>>> df.idxmin()
consumption    Pork
co2_emissions  Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`. 
pandas.DataFrame.infer_objects

DataFrame.infer_objects()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns

converted [same type as input object]

See also:

to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric Convert argument to numeric type.
convert_dtypes Convert argument to best possible dtype.

Examples

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
0  1
1  2
2  3

>>> df.dtypes
A object
dtype: object

>>> df.infer_objects().dtypes
   A
dtype: int64
```

pandas.DataFrame.info

DataFrame.info(verbosede=None, buf=None, max_cols=None, memory_usage=None, show_counts=None, null_counts=None)

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and columns, non-null values and memory usage.

Parameters

- data [DataFrame] DataFrame to print information about.
- verbose [bool, optional] Whether to print the full summary. By default, the setting in pandas.options.display.max_info_columns is followed.
- buf [writable buffer, defaults to sys.stdout] Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.
- max_cols [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than max_cols columns, the truncated output is used. By default, the setting in pandas.options.display.max_info_columns is used.
- memory_usage [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the pandas.options.display.memory_usage setting.

   True always show memory usage. False never shows memory usage. A value of ‘deep’ is equivalent to “True with deep introspection”. Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

- show_counts [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than pandas.options.display.max_info_rows and pandas.options.display.max_info_columns. A value of True always shows the counts, and False never shows the counts.

- null_counts [bool, optional] Deprecated since version 1.2.0: Use show_counts instead.

Returns

None This method prints a summary of a DataFrame and returns None.

See also:

- DataFrame.describe Generate descriptive statistics of DataFrame columns.
- DataFrame.memory_usage Memory usage of DataFrame columns.
Examples

```python
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({'int_col': int_values, 'text_col': text_values,
...                     'float_col': float_values})
>>> df
    int_col   text_col float_col
0       1      alpha     0.00
1       2      beta      0.25
2       3     gamma      0.50
3       4     delta      0.75
4       5    epsilon      1.0
```

Prints information of all columns:

```python
>>> df.info( verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
   # Column Non-Null Count Dtype
      ---       -------- -----
      0 int_col      5 non-null int64
      1 text_col     5 non-null object
      2 float_col    5 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```python
>>> df.info( verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```python
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w",
...         encoding="utf-8") as f:
...     f.write(s)
260
```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```python
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
...     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
...                })
```

(continues on next page)
... })
>>>
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column   Non-Null Count   Dtype
--- -------- -------------- ------
0 column_1 1000000 non-null object
1 column_2 1000000 non-null object
2 column_3 1000000 non-null object
dtypes: object(3)
memory usage: 22.9+ MB

>>>
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column   Non-Null Count   Dtype
--- -------- -------------- ------
0 column_1 1000000 non-null object

2 column_3 1000000 non-null object
dtypes: object(3)
memory usage: 165.9 MB

pandas.DataFrame.insert

DataFrame.insert(loc, column, value, allow_duplicates=False)
Insert column into DataFrame at specified location.

Raises a ValueError if column is already contained in the DataFrame, unless allow_duplicates is set to True.

Parameters

loc [int] Insertion index. Must verify 0 <= loc <= len(columns).

column [str, number, or hashable object] Label of the inserted column.

value [int, Series, or array-like]

allow_duplicates [bool, optional]

pandas.DataFrame.interpolate

DataFrame.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)
Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default ‘linear’] Interpolation technique to use. One of:

• ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
pandas: powerful Python data analysis toolkit, Release 1.2.2

- ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
- ‘index’, ‘values’: use the actual numerical values of the index.
- ‘pad’: Fill in NaNs using existing values.
- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
- ‘from_derivatives’: Refers to scipy.interpolate.BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.
limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.
inplace [bool, default False] Update the data in place if possible.

limit_direction [{‘forward’, ‘backward’, ‘both’}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:
- If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
- If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backward’.

If ‘limit’ is not specified:
- If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
- else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area [{None, ‘inside’, ‘outside’}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.
- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

`**kwargs` [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None  Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

See also:

fillna Fill missing values using different methods.
scipy.interpolate.Akima1DInterpolator  Piecewise cubic polynomials (Akima interpolator).
scipy.interpolate.BPoly.from_derivatives  Piecewise polynomial in the Bernstein basis.
scipy.interpolate.interp1d  Interpolate a 1-D function.
scipy.interpolate.KroghInterpolator  Interpolate polynomial (Krogh interpolator).
scipy.interpolate.PchipInterpolator  PCHIP 1-d monotonic cubic interpolation.
scipy.interpolate.CubicSpline  Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0  0.0
1  1.0
2  NaN
3  3.0
dtype: float64
```
```python
>>> s.interpolate()
0  0.0
1  1.0
2  2.0
3  3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ...
...     "fill_two_more", np.nan, np.nan, np.nan,
...     4.71, np.nan])
>>> s
0      NaN
1  single_one
2      NaN
3  fill_two_more
4      NaN
5      NaN
6      NaN
7  4.71
8      NaN
dtype: object
```
```python
>>> s.interpolate(method='pad', limit=2)
0      NaN
1  single_one
```
(continues on next page)
Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).

```python
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0   0.000000
1   2.000000
2   4.666667
3   8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```python
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                     (np.nan, 2.0, np.nan, np.nan),
...                     (2.0, 3.0, np.nan, 9.0),
...                     (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a   b   c   d
0  0.0  NaN -1.0  1.0
1  NaN  2.0  NaN  NaN
2  2.0  3.0  NaN  9.0
3  NaN  4.0  -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a   b   c   d
0  0.0  NaN -1.0  1.0
1  1.0  2.0  -2.0  5.0
2  2.0  3.0  -3.0  9.0
3  2.0  4.0  -4.0 16.0
```

Using polynomial interpolation.

```python
>>> df['d'].interpolate(method='polynomial', order=2)
0   1.0
1   4.0
2   9.0
3  16.0
Name: d, dtype: float64
```
**pandas.DataFrame.isin**

Dataframe.isin(values)  
Whether each element in the Dataframe is contained in values.

**Parameters**

values [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If values is a Series, that’s the index. If values is a dict, the keys must be the column names, which must match. If values is a DataFrame, then both the index and column labels must match.

**Returns**

DataFrame DataFrame of booleans showing whether each element in the DataFrame is contained in values.

See also:

- **DataFrame.eq** Equality test for DataFrame.
- **Series.isin** Equivalent method on Series.
- **Series.str.contains** Test if pattern or regex is contained within a string of a Series or Index.

**Examples**

```python
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
                    index=['falcon', 'dog'])
>>> df
            num_legs  num_wings
falcon         2          2
dog            4          0
```

When values is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```python
>>> df.isin([0, 2])
            num_legs  num_wings
falcon     True         True
dog       False         True
```

When values is a dict, we can pass values to check for each column separately:

```python
>>> df.isin({'num_wings': [0, 3]})
            num_legs  num_wings
falcon    False         False
dog       False         True
```

When values is a Series or DataFrame the index and column must match. Note that ‘falcon’ does not match based on the number of legs in df2.

```python
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
                        index=['spider', 'falcon'])
>>> df.isin(other)
            num_legs  num_wings
falcon     True         True
dog       False         False
```
**pandas.DataFrame.isna**

```python
DataFrame.isna()
```

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or `numpy.Nan`, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

- **DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

**See also:**

- **DataFrame.isnull** Alias of isna.
- **DataFrame.notna** Boolean inverse of isna.
- **DataFrame.dropna** Omit axes labels with missing values.
- **isna** Top-level isna.

**Examples**

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
... born=[pd.NaT, pd.Timestamp('1939-05-27'),
... pd.Timestamp('1940-04-25')],
... name=['Alfred', 'Batman', ''],
... toy=[None, 'Batmobile', 'Joker']))
```

```
age born name toy
0 5.0 NaT Alfred None
1 6.0 1939-05-27 Batman Batmobile
2 NaN 1940-04-25 Joker
```

```python
>>> df.isna()
```

```
    age  born  name  toy
0 False  True  False  True
1 False  False  False  False
2  True  False  False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
```

```
dtype: float64
```

```python
>>> ser.isna()
```

```
0  False
```

(continues on next page)
pandas.DataFrame.isnull

DataFrame.isnull()
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

DataFrame  Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

See also:

DataFrame.isnull  Alias of isna.
DataFrame.notna  Boolean inverse of isna.
DataFrame.dropna  Omit axes labels with missing values.
isna  Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
... born=[pd.NaT, pd.Timestamp('1939-05-27'),
... pd.Timestamp('1940-04-25')],
... name=['Alfred', 'Batman', ''],
... toy=[None, 'Batmobile', 'Joker']))

>>> df
   age  born     name   toy
0  5.0  NaT     Alfred   None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25    Joker

>>> df.isna()
   age  born     name   toy
0 False  True   False  True
1 False  False  False  False
2  True  False  False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])

>>> ser
0 5.0
```
>>> ser.isna()
0    False
1     False
2      True
dtype: bool

pandas.DataFrame.items

DataFrame.items()
Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

label [object] The column names for the DataFrame being iterated over.

content [Series] The column entries belonging to each label, as a Series.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

Examples

>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000]},
...                   index=['panda', 'polar', 'koala'])

>>> df
        species population
panda    bear       1864
polar    bear       22000
koala    marsupial  80000

>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='\n')

label: species
content: panda    bear
 content: polar    bear
 content: koala    marsupial
Name: species, dtype: object

label: population
content: panda    1864
 content: polar    22000
 content: koala    80000
Name: population, dtype: int64
pandas.DataFrame.iteritems

```python
dataframe.iteritems()
Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

- **label** [object] The column names for the DataFrame being iterated over.
- **content** [Series] The column entries belonging to each label, as a Series.

See also:

- **DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.
- **DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.
```

Examples

```python
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                     'population': [1864, 22000, 80000],
...                     'index': ['panda', 'polar', 'koala']})
>>> df
      species  population
panda    bear       1864
polar    bear      22000
koala  marsupial   80000

>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='
')
...     print()

label: species
content:
panda    bear
polar    bear
koala  marsupial
Name: species, dtype: object

label: population
content:
panda   1864
polar   22000
koala   80000
Name: population, dtype: int64
```
**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

**DataFrame.items** Iterate over (column name, Series) pairs.

**Notes**

1. Because `iterrows` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int   1.0
float 1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

**pandas.DataFrame.itertuples**

```python
DataFrame.itertuples(index=True, name='Pandas')
```

Iterate over DataFrame rows as namedtuples.

**Parameters**

- `index` [bool, default True] If True, return the index as the first element of the tuple.
- `name` [str or None, default “Pandas”] The name of the returned namedtuples or None to return regular tuples.

**Returns**

- `iterator` An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

**See also:**

- `DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.
- `DataFrame.items` Iterate over (column name, Series) pairs.
Notes

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).

Examples

```python
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
                     index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog        4          0
hawk       2          2
```

```python
>>> for row in df.itertuples():
...   print(row)
...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the `index` parameter to `False` we can remove the index as the first element of the tuple:

```python
>>> for row in df.itertuples(index=False):
...   print(row)
...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the `name` parameter set we set a custom name for the yielded namedtuples:

```python
>>> for row in df.itertuples(name='Animal'):
...   print(row)
...
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

`pandas.DataFrame.join`

DataFrame.join(other, on=None, how='left', lsuffix='', rsuffix='', sort=False)

Join columns of another DataFrame.

Join columns with `other` DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

Parameters

- **other** [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.
- **on** [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in `other`, otherwise joins index-on-index. If multiple values given, the `other` DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.
how [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] How to handle the operation of the two objects.

- left: use calling frame’s index (or column if on is specified)
- right: use other’s index.
- outer: form union of calling frame’s index (or column if on is specified) with other’s index, and sort it lexicographically.
- inner: form intersection of calling frame’s index (or column if on is specified) with other’s index, preserving the order of the calling’s one.

lsuffix [str, default ‘’] Suffix to use from left frame’s overlapping columns.

rsuffix [str, default ‘’] Suffix to use from right frame’s overlapping columns.

sort [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns

DataFrame A dataframe containing columns from both the caller and other.

See also:

DataFrame.merge For column(s)-on-column(s) operations.

Notes

Parameters on, lsuffix, and rsuffix are not supported when passing a list of DataFrame objects.

Support for specifying index levels as the on parameter was added in version 0.23.0.

Examples

```python
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
...                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})

>>> df
   key  A
0   K0  A0
1   K1  A1
2   K2  A2
3   K3  A3
4   K4  A4
5   K5  A5

>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
...                        'B': ['B0', 'B1', 'B2']})

>>> other
   key  B
0   K0  B0
1   K1  B1
2   K2  B2

Join DataFrames using their indexes.
If we want to join using the key columns, we need to set key to be the index in both `df` and `other`. The joined DataFrame will have key as its index.

```python
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller A   key_other B
0     K0    A0    K0    B0
1     K1    A1    K1    B1
2     K2    A2    K2    B2
3     K3    A3      NaN  NaN
4     K4    A4      NaN  NaN
5     K5    A5      NaN  NaN
```

Another option to join using the key columns is to use the `on` parameter. DataFrame.join always uses `other`’s index but we can use any column in `df`. This method preserves the original DataFrame’s index in the result.

```python
>>> df.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```

### `pandas.DataFrame.keys`

DataFrame[keys]()

Get the ‘info axis’ (see Indexing for more).

This is index for Series, columns for DataFrame.

**Returns**

- **Index** Info axis.
pandas.DataFrame.kurt

DataFrame.kurt (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [[index (0), columns (1)]] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.kurtosis

DataFrame.kurtosis (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [[index (0), columns (1)]] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)
pandas.DataFrame.last

DataFrame.last(offset)
Select final periods of time series data based on a date offset.
When having a DataFrame with dates as index, this function can select the last few rows based on a date offset.

Parameters

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘3D’ will display all the rows having their index within the last 3 days.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a DatetimeIndex

See also:

first Select initial periods of time series based on a date offset.
at_time Select values at a particular time of the day.
between_time Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
          A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the last 3 days:
```n
```python
>>> ts.last('3D')
          A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.
pandas.DataFrame.last_valid_index

DataFrame.last_valid_index()
Return index for last non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.le

DataFrame.le(other, axis='columns', level=None)
Get Less than or equal to of dataframe and other, element-wise (binary operator le).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. \textit{NaN} values are considered different (i.e. \textit{NaN} \neq \textit{NaN}).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
... 'revenue': [100, 250, 300]},
... index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A   False    True
B   False    False
C   True    False
```

```python
>>> df.eq(100)
   cost  revenue
A   False    True
B   False    False
C   True    False
```

When \textit{other} is a \textit{Series}, the columns of a DataFrame are aligned with the index of \textit{other} and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True    True
B   True    False
C   False    True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A   True    False
B   True    True
C   False    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in \textit{other}:

```python
>>> df == [250, 100]
   cost  revenue
A   True    True
B   False    False
C   False    False
```

Use the method to control the axis:
```python
>>> df.eq([250, 250, 100], axis='index')
  cost  revenue
A  True   False
B  False  True
C  True   False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150],
...                        index=['A', 'B', 'C', 'D'])
>>> other
revenue
A   300
B   250
C   100
D   150
```

```python
>>> df.gt(other)
  cost  revenue
A   False  False
B   False  False
C   False  True
D   False  False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225],
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
```

```python
>>> df_multindex
  cost  revenue
Q1 A  250   100
  B  150   250
  C  100   300
Q2 A  150   200
  B  300   175
  C  220   225
```

```python
>>> df.le(df_multindex, level=1)
  cost  revenue
Q1 A  True  True
  B  True  True
  C  True  True
Q2 A  False True
  B  True  False
  C  True  False
```
pandas.DataFrame.lookup

DataFrame.lookup(row_labels, col_labels)
Label-based “fancy indexing” function for DataFrame. Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

Deprecated since version 1.2.0: DataFrame.lookup is deprecated, use DataFrame.melt and DataFrame.loc instead. For an example see lookup() in the user guide.

Parameters

row_labels [sequence] The row labels to use for lookup.

col_labels [sequence] The column labels to use for lookup.

Returns

numpy.ndarray The found values.

pandas.DataFrame.lt

DataFrame.lt(other, axis='columns', level=None)
Get Less than of dataframe and other, element-wise (binary operator lt).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [[0 or ‘index’, 1 or ‘columns’], default ‘columns’) Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost   revenue
  A  False  True
  B  False  False
  C   True  False
```

```python
>>> df.eq(100)
   cost   revenue
  A  False  True
  B  False  False
  C   True  False
```

When other is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost   revenue
  A   True   True
  B   True  False
  C  False   True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost   revenue
  A  True  False
  B  True   True
  C  True   True
  D  True   True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in other:

```python
>>> df == [250, 100]
   cost   revenue
  A   True   True
  B  False  False
  C  False  False
```

Use the method to control the axis:
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
  A   True    False
  B   False   True
  C   True    False

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A   300
B   250
C   100
D   150

``` python
```python
>>> df.gt(other)
   cost  revenue
  A    False   False
  B    False   False
  C    False   True
  D    False   False

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
   cost  revenue
Q1 A  250   100
     B  150   250
     C  100   300
Q2 A  150   200
     B  300   175
     C  220   225
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A    True    True
     B    True    True
     C    True    True
Q2 A   False    True
     B    True    False
     C    True    False
```
pandas.DataFrame.mad

DataFrame.mad (axis=None, skipna=None, level=None)
Return the mean absolute deviation of the values over the requested axis.

Parameters

- **axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna** [bool, default None] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.mask

DataFrame.mask (cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)
Replace values where the condition is True.

Parameters

- **cond** [bool Series/DataFrame, array-like, or callable] Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **other** [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **inplace** [bool, default False] Whether to perform the operation in place on the data.
- **axis** [int, default None] Alignment axis if needed.
- **level** [int, default None] Alignment level if needed.
- **errors** [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.
  - ‘raise’ : allow exceptions to be raised.
  - ‘ignore’ : suppress exceptions. On error return original object.
- **try_cast** [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller or None if inplace=True.

See also:

DataFrame.where() Return an object of same shape as self.
Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2).

For further details and examples see the `mask` documentation in `indexing`.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1     1.0
2     2.0
3     3.0
4     4.0
dtype: float64
>>> s.mask(s > 0)
0     0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64

>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0     0
1     1
2    10
3    10
4    10
dtype: int64

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.2.2

```
1  -2  3
2  -4  -5
3   6  -7
4  -8  9
```

```python
>>> df.where(m, -df) == np.where(m, df, -df)
A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True

>>> df.where(m, -df) == df.mask(~m, -df)
A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

**pandas.DataFrame.max**

`DataFrame.max (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the maximum of the values over the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

**Parameters**

- `axis` [[index (0), columns (1)]] Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

- `Series` or `DataFrame` (if level specified)

See also:

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays(
    ... ['warm', 'warm', 'cold', 'cold'],
    ... ['dog', 'falcon', 'fish', 'spider'],
    ... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded   animal
  warm    dog   4
  falcon   2
  cold     fish  0
  spider   8
Name: legs, dtype: int64

>>> s.max()
8

Max using level names, as well as indices.

>>> s.max(level='blooded')
blooded
  warm   4
  cold   8
Name: legs, dtype: int64

>>> s.max(level=0)
blooded
  warm   4
  cold   8
Name: legs, dtype: int64
```

**pandas.DataFrame.mean**

**DataFrame.mean** *(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)*

Return the mean of the values over the requested axis.

**Parameters**

- **axis** *(index (0), columns (1)))* Axis for the function to be applied on.
- **skipna** *(bool, default True)* Exclude NA/null values when computing the result.
- **level** *(int or level name, default None)* If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** *(bool, default None)* Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.
pandas: powerful Python data analysis toolkit, Release 1.2.2

Returns

Series or DataFrame (if level specified)

**pandas.DataFrame.median**

DataFrame.median(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the median of the values over the requested axis.

**Parameters**

- **axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

**pandas.DataFrame.melt**

DataFrame.melt(id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

**Parameters**

- **id_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.
- **value_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.
- **var_name** [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.
- **value_name** [scalar, default ‘value’] Name to use for the ‘value’ column.
- **col_level** [int or str, optional] If columns are a MultiIndex then use this level to melt.
- **ignore_index** [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

DataFrame Unpivoted DataFrame.

See also:
**melt** Identical method.

**pivot_table** Create a spreadsheet-style pivot table as a DataFrame.

**DataFrame.pivot** Return reshaped DataFrame organized by given index / column values.

**DataFrame.explode** Explode a DataFrame from list-like columns to long format.

### Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
                      'B': {0: 1, 1: 3, 2: 5},
                      'C': {0: 2, 1: 4, 2: 6}})
```

```plaintext
A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```python
>>> df.melt(id_vars=['A'], value_vars=['B'])
```

```plaintext
A  variable  value
0  a          B  1
1  b          B  3
2  c          B  5
```

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
```

```plaintext
A  variable  value
0  a          B  1
1  b          B  3
2  c          B  5
3  a          C  2
4  b          C  4
5  c          C  6
```

The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'],
          var_name='myVarname', value_name='myValname')
```

```plaintext
A  myVarname  myValname
0  a          B  1
1  b          B  3
2  c          B  5
```

Original index values can be kept around:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
```

```plaintext
A  variable  value
0  a          B  1
1  b          B  3
2  c          B  5
0  a          C  2
1  b          C  4
2  c          C  6
```

If you have multi-index columns:
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
    A  B  C  D  E  F
0  a  1  2  
1  b  3  4  
2  c  5  6  

>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
   A  variable  value
0  a    B    1
1  b    B    3
2  c    B    5

>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D)  variable_0  variable_1  value
0   a    B    E    1
1   b    B    E    3
2   c    B    E    5

pandas.DataFrame.memory_usage

DataFrame.memory_usage(index=True, deep=False)
Return the memory usage of each column in bytes.
The memory usage can optionally include the contribution of the index and elements of object dtype.
This value is displayed in DataFrame.info by default. This can be suppressed by setting pandas.options.display.memory_usage to False.

Parameters

- **index** [bool, default True] Specifies whether to include the memory usage of the DataFrame’s index in returned Series. If index=True, the memory usage of the index is the first item in the output.
- **deep** [bool, default False] If True, introspect the data deeply by interrogating object dtypes for system-level memory consumption, and include it in the returned values.

Returns

- **Series** A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

See also:

- **numpy.ndarray.nbytes** Total bytes consumed by the elements of an ndarray.
- **Series.memory_usage** Bytes consumed by a Series.
- **Categorical** Memory-efficient array for string values with many repeated values.
- **DataFrame.info** Concise summary of a DataFrame.
Examples

```python
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000, dtype=t).astype(t))
...             for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
   int64  float64  complex128  object  bool
0     1       1.0     1.0+0.0j     1      True
1     1       1.0     1.0+0.0j     1      True
2     1       1.0     1.0+0.0j     1      True
3     1       1.0     1.0+0.0j     1      True
4     1       1.0     1.0+0.0j     1      True
```

```python
>>> df.memory_usage()
Index   128
int64   40000
float64 40000
complex128  80000
object  40000
bool    5000
dtype: int64
```

```python
>>> df.memory_usage(index=False)
int64   40000
float64 40000
complex128  80000
object  40000
bool    5000
dtype: int64
```

The memory footprint of `object` dtype columns is ignored by default:

```python
>>> df.memory_usage(deep=True)
Index   128
int64   40000
float64 40000
complex128  80000
object  180000
bool    5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```python
>>> df['object'].astype('category').memory_usage(deep=True)
5244
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DataFrame.merge

DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

Parameters

right [DataFrame or named Series] Object to merge with.

how [‘left’, ‘right’, ‘outer’, ‘inner’, ‘cross’], default ‘inner’ Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
- cross: creates the cartesian product from both frames, preserves the order of the left keys.

New in version 1.2.0.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.
copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame, “right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

merge_ordered Merge with optional filling/interpolation.

merge_asof Merge on nearest keys.

DataFrame.join Similar method using indices.

Notes

Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```python
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
                      'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
                      'value': [5, 6, 7, 8]})
```

```
>>> df1
lkey  value
0   foo      1
1   bar      2
2   baz      3
3   foo      5
```

```
>>> df2
rkey  value
0   foo      5
1   bar      6
2   baz      7
3   foo      8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=('left', 'right'))
   lkey  value_left  rkey  value_right
0  foo           1  foo           5
1  foo           1  foo           8
2  foo           5  foo           5
3  foo           5  foo           8
4  bar           2  bar           6
5  baz           3  baz           7

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
  ... 
ValueError: columns overlap but no suffix specified:
    Index(['value'], dtype='object')

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

>>> df1 = pd.DataFrame({'a': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})

>>> df1.merge(df2, how='inner', on='a')
   a  b  c
0  foo  1  3
1  bar  2  NaN

>>> df1.merge(df2, how='left', on='a')
   a  b  c
0  foo  1  3.0
1  bar  2  NaN

>>> df1 = pd.DataFrame({'left': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'right': [7, 8]})

**pandas.DataFrame.min**

`DataFrame.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the minimum of the values over the requested axis.

If you want the index of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

**Parameters**

axis \{index (0), columns (1)\} Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**See also:**

*Series.sum* Return the sum.

*Series.min* Return the minimum.

*Series.max* Return the maximum.

*Series.idxmin* Return the index of the minimum.

*Series.idxmax* Return the index of the maximum.

*DataFrame.sum* Return the sum over the requested axis.

*DataFrame.min* Return the minimum over the requested axis.

*DataFrame.max* Return the maximum over the requested axis.

*DataFrame.idxmin* Return the index of the minimum over the requested axis.

*DataFrame.idxmax* Return the index of the maximum over the requested axis.
Examples

```python
>>> idx = pd.MultiIndex.from_arrays([
    ... ['warm', 'warm', 'cold', 'cold'],
    ... ['dog', 'falcon', 'fish', 'spider'],
    ... names=["blooded", "animal"]
    ...
]

>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)

>>> s
blooded animal
warm  dog  4
    falcon  2
cold  fish  0
    spider  8
Name: legs, dtype: int64

>>> s.min()
0

Min using level names, as well as indices.

>>> s.min(level='blooded')
blooded
    warm  2
    cold  0
Name: legs, dtype: int64

>>> s.min(level=0)
blooded
    warm  2
    cold  0
Name: legs, dtype: int64
```

**pandas.DataFrame.mod**

Dataframe.mod (other, axis='columns', level=None, fill_value=None)  
Get Modulo of dataframe and other, element-wise (binary operator mod).  
Equivalent to dataframe % other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.
Returns

**DataFrame**  Result of the arithmetic operation.

See also:

- **DataFrame.add**  Add DataFrames.
- **DataFrame.sub**  Subtract DataFrames.
- **DataFrame.mul**  Multiply DataFrames.
- **DataFrame.div**  Divide DataFrames (float division).
- **DataFrame.truediv**  Divide DataFrames (float division).
- **DataFrame.floordiv**  Divide DataFrames (integer division).
- **DataFrame.mod**  Calculate modulo (remainder after division).
- **DataFrame.pow**  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
<td>360</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
<td>180</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
<td>360</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
<td>361</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
<td>181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
<td>361</td>
</tr>
</tbody>
</table>

```python
>>> df.add(1)
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
<td>361</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
<td>181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
<td>361</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
>>> df.div(10)
```

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
<td>36.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
<td>18.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
<td>36.0</td>
</tr>
</tbody>
</table>
Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
    circle     -1    358
     triangle     2    178
    rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
    circle     -1    358
     triangle     2    178
    rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
axis='index')
      angles  degrees
    circle     -1    359
     triangle     2    179
    rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4],
    ...
index=['circle', 'triangle', 'rectangle']})
```

```
>>> df * other
      angles  degrees
    circle      0     NaN
     triangle     9     NaN
    rectangle    16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
    circle      0     0.0
     triangle     9     0.0
    rectangle    16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...
'degrees': [360, 180, 360, 360, 540, 720]},
...
index=['A', 'A', 'A', 'B', 'B', 'B'],
...
['circle', 'triangle', 'rectangle',
...
'square', 'pentagon', 'hexagon'])
```
pandas.DataFrame.mode

DataFrame.m\texttt{ode}(axis=0, numeric\_only=False, dropna=True)

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

Parameters

\begin{itemize}
\item \texttt{axis} [[0 or \texttt{`index'}, 1 or \texttt{`columns'}, default 0] The axis to iterate over while searching for the mode:
\begin{itemize}
\item 0 or \texttt{`index'} : get mode of each column
\item 1 or \texttt{`columns'} : get mode of each row.
\end{itemize}
\item \texttt{numeric\_only} [bool, default False] If True, only apply to numeric columns.
\item \texttt{dropna} [bool, default True] Don’t consider counts of NaN/NaT.
\end{itemize}

New in version 0.24.0.

Returns

\texttt{DataFrame} The modes of each column or row.

See also:

Series.mode Return the highest frequency value in a Series.
Series.value\_counts Return the counts of values in a Series.
Examples

```python
>>> df = pd.DataFrame([('bird', 2, 2),
...                    ('mammal', 4, np.nan),
...                    ('arthropod', 8, 0),
...                    ('bird', 2, np.nan),
...                   index=('falcon', 'horse', 'spider', 'ostrich'),
...                   columns=('species', 'legs', 'wings'))
```

```python
>>> df
species legs wings
falcon  bird  2   2.0
horse  mammal 4  NaN
spider arthropod 8  0.0
ostrich bird  2  NaN
```

By default, missing values are not considered, and the mode of wings are both 0 and 2. Because the resulting DataFrame has two rows, the second row of `species` and `legs` contains NaN.

```python
>>> df.mode()
    species  legs  wings
0     bird    2.0    0.0
1   NaN  NaN    2.0
```

Setting `dropna=False` NaN values are considered and they can be the mode (like for wings).

```python
>>> df.mode(dropna=False)
    species  legs  wings
0     bird    2.0  NaN
```

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```python
>>> df.mode(numeric_only=True)
    legs  wings
0   2.0  0.0
1  NaN  2.0
```

To compute the mode over columns and not rows, use the `axis` parameter:

```python
>>> df.mode(axis='columns', numeric_only=True)
   0  1
falcon  2.0 NaN
horse   4.0 NaN
spider  0.0  8.0
ostrich 2.0 NaN
```

### pandas.DataFrame.mul

DataFrame `mul` (other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator `mul`).

Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rmul`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters
other  [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis  [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level  [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value  [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame  Result of the arithmetic operation.

See also:

DataFrame.add  Add DataFrames.

DataFrame.sub  Subtract DataFrames.

DataFrame.mul  Multiply DataFrames.

DataFrame.div  Divide DataFrames (float division).

DataFrame.truediv  Divide DataFrames (float division).

DataFrame.floordiv  Divide DataFrames (integer division).

DataFrame.mod  Calculate modulo (remainder after division).

DataFrame.pow  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     index=['circle', 'triangle', 'rectangle'])

>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360

Add a scalar with operator version which return the same results.

>>> df + 1

   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle  0.00  36.00
triangle 0.30   18.0
rectangle 0.40  36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle  -1.0  358.0
triangle   2.0  178.0
rectangle   3.0  358.0
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle  -1.0  358.0
triangle   2.0  178.0
rectangle   3.0  358.0
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
   angles  degrees
circle  -1.0  359.0
triangle   2.0  179.0
rectangle   3.0  359.0
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])
>>> df * other
   angles  degrees
circle   0.0   NaN
triangle   9.0   NaN
rectangle 16.0   NaN
```
Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720]},
                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
                                     ['circle', 'triangle', 'rectangle',
                                      'square', 'pentagon', 'hexagon']])
```

```
angles degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```

**pandas.DataFrame.multiply**

DataFrame.multiply(other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator mul).

Equivalent to dataframe * other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**
DataFrame  Result of the arithmetic operation.

See also:

- **DataFrame.add**  Add DataFrames.
- **DataFrame.sub**  Subtract DataFrames.
- **DataFrame.mul**  Multiply DataFrames.
- **DataFrame.div**  Divide DataFrames (float division).
- **DataFrame.truediv**  Divide DataFrames (float division).
- **DataFrame.floordiv**  Divide DataFrames (integer division).
- **DataFrame.mod**  Calculate modulo (remainder after division).
- **DataFrame.pow**  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0
```
>>> df.rdiv(10)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf 0.027778</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333 0.055556</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.500000 0.027778</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 358</td>
</tr>
<tr>
<td>triangle</td>
<td>2 178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 358</td>
</tr>
</tbody>
</table>

>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 358</td>
</tr>
<tr>
<td>triangle</td>
<td>2 178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 358</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

>>> df_multindex
 angles  degrees
 A  circle  0     360
      triangle  3     180
      rectangle  4     360
 B  square  4     360
      pentagon  5     540
      hexagon  6     720

>>> df.div(df_multindex, level=1, fill_value=0)
 angles  degrees
 A  circle  NaN  1.0
      triangle  1.0  1.0
      rectangle  1.0  1.0
 B  square  0.0  0.0
      pentagon  0.0  0.0
      hexagon  0.0  0.0

pandas.DataFrame.ne

DataFrame.ne(other, axis='columns', level=None)
Get Not equal to of dataframe and other, element-wise (binary operator ne).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters
other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns
DataFrame of bool  Result of the comparison.

See also:
DataFrame.eq  Compare DataFrames for equality elementwise.
DataFrame.ne  Compare DataFrames for inequality elementwise.
DataFrame.le  Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt  Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge  Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt  Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. \textit{NaN} values are considered different (i.e. \texttt{NaN} \texttt{!= NaN}).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                     index=['A', 'B', 'C'])
>>> df
       cost  revenue
     A      250     100
     B      150     250
     C      100     300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
       cost  revenue
     A     False     True
     B     False    False
     C      True    False
```

```python
>>> df.eq(100)
       cost  revenue
     A     False     True
     B     False    False
     C      True    False
```

When \textit{other} is a \texttt{Series}, the columns of a DataFrame are aligned with the index of \textit{other} and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
       cost  revenue
     A     True     True
     B     True    False
     C    False     True

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
       cost  revenue
     A     True    False
     B     True     True
     C    False     True
     D     True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in \textit{other}:

```python
>>> df == [250, 100]
       cost  revenue
     A     True     True
     B    False    False
     C    False    False
```

Use the method to control the axis:
Compare to a DataFrame of different shape.

```python
cost revenue
A True False
B False True
C True False
```

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])

>>> other

revenue
A    300
B    250
C    100
D    150
```

```python
>>> df.gt(other)

cost revenue
A  False  False
B  False  False
C   False   True
D  False  False
```

Compare to a MultiIndex by level.

```python
cost revenue
Q1 A 250 100
   B 150 250
   C 100 300
Q2 A 150 200
   B 300 175
   C 220 225
```

```python
>>> df_multindex

cost revenue
Q1 A 250 100
   B 150 250
   C 100 300
Q2 A 150 200
   B 300 175
   C 220 225
```

```python
>>> df.le(df_multindex, level=1)

cost   revenue
Q1 A   True   True
   B   True   True
   C   True   True
Q2 A  False  True
   B   True  False
   C   True  False
```
DataFrame.nlargest

DataFrame.nlargest(n, columns, keep='first')

Return the first n rows ordered by columns in descending order.

Return the first n rows with the largest values in columns, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to df.sort_values(columns, ascending=False).head(n), but more performant.

Parameters

n [int] Number of rows to return.

columns [label or list of labels] Column label(s) to order by.

keep [{‘first’, ‘last’, ‘all’}, default ‘first’] Where there are duplicate values:

• first : prioritize the first occurrence(s)
• last : prioritize the last occurrence(s)
• all [do not drop any duplicates, even it means] selecting more than n items.

New in version 0.24.0.

Returns

DataFrame The first n rows ordered by the given columns in descending order.

See also:

DataFrame.nsmallest Return the first n rows ordered by columns in ascending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first n rows without re-ordering.

Notes

This function cannot be used with all column types. For example, when specifying columns with object or category dtypes, TypeError is raised.

Examples

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 4340000, 
... 434000, 4340000, 337000, 11300, 
... 11300, 11300], 
... 'GDP': [1937894, 2583560, 12011, 4520, 12128, 
... 17036, 182, 38, 311], 
... 'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN', 
... 'IS', 'NR', 'TV', 'AI'], 
... index=['Italy', 'France', 'Malta', 
... 'Maldives', 'Brunei', 'Iceland', 
... 'Nauru', 'Tuvalu', 'Anguilla']}

>>> df
          population     GDP alpha-2
Italy  590000000.0  1937894     IT
France  650000000.0  2583560     FR
```
In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```python
>>> df.nlargest(3, 'population')
   population   GDP   alpha-2
    France  65000000  2583560   FR
     Italy  59000000  1937894   IT
    Malta   4340000   12011    MT
```

When using `keep='last'`, ties are resolved in reverse order:

```python
>>> df.nlargest(3, 'population', keep='last')
   population   GDP   alpha-2
    France  65000000  2583560   FR
     Italy  59000000  1937894   IT
    Brunei   4340000   12128    BN
```

When using `keep='all'`, all duplicate items are maintained:

```python
>>> df.nlargest(3, 'population', keep='all')
   population   GDP   alpha-2
    France  65000000  2583560   FR
     Italy  59000000  1937894   IT
    Malta   4340000   12011    MT
    Maldives  4340000   4520    MV
    Brunei   4340000   12128    BN
```

To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```python
>>> df.nlargest(3, ['population', 'GDP'])
   population   GDP   alpha-2
    France  65000000  2583560   FR
     Italy  59000000  1937894   IT
    Brunei   4340000   12128    BN
```

### pandas.DataFrame.notna

`DataFrame.notna()` detects existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings ‘ ’ or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.

**Returns**
DataFrame  Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull  Alias of notna.
DataFrame.isna  Boolean inverse of notna.
DataFrame.dropna  Omit axes labels with missing values.
notna  Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
                            pd.Timestamp('1940-04-25')],
                      name=['Alfred', 'Batman', ''],
                      toy=[None, 'Batmobile', 'Joker']))
>>> df
   age   born       name    toy
0    5.0 NaT  Alfred     None
1    6.0 1939-05-27  Batman  Batmobile
2   NaN 1940-04-25     Joker

>>> df.notna()
   age  born  name  toy
0  True  False  True  False
1  True   True  True   True
2 False   True  True   True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0  5.0
1  6.0
2 NaN
dtype: float64

>>> ser.notna()
0  True
1  True
2 False
dtype: bool
```
**pandas.DataFrame.notnull**

**DataFrame.notnull()**

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na` = True). NA values, such as None or `numpy.NaN`, get mapped to False values.

**Returns**

- **DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

- **DataFrame.notnull** Alias of notna.
- **DataFrame.isna** Boolean inverse of notna.
- **DataFrame.dropna** Omit axes labels with missing values.
- **notna** Top-level notna.

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age':[5, 6, np.NaN],
...                     'born':[pd.NaT, pd.Timestamp('1939-05-27'),
...                            pd.Timestamp('1940-04-25')],
...                     'name':['Alfred', 'Batman', ''],
...                     'toy':[None, 'Batmobile', 'Joker']})

>>> df
    age   born     name  toy
0    5.0  NaT     Alfred  None
1    6.0 1939-05-27    Batman  Batmobile
2     NaN 1940-04-25     Joker

>>> df.notna()
    age   born     name  toy
0  True  False  True  False
1  True   True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])

>>> ser
0    5.0
1    6.0
2   NaN
dtype: float64

>>> ser.notna()
0  True
```

(continues on next page)
pandas.DataFrame.nsmallest

DataFrame.nsmallest(n, columns, keep='first')

Return the first n rows ordered by columns in ascending order.

Return the first n rows with the smallest values in columns, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to df.sort_values(columns, ascending=True).head(n), but more performant.

Parameters

- **n** [int] Number of items to retrieve.
- **columns** [list or str] Column name or names to order by.
- **keep** [{'first', 'last', 'all'}, default 'first'] Where there are duplicate values:
  - first: take the first occurrence.
  - last: take the last occurrence.
  - all: do not drop any duplicates, even it means selecting more than n items.

New in version 0.24.0.

Returns

DataFrame

See also:

DataFrame.nlargest Return the first n rows ordered by columns in descending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first n rows without re-ordering.

Examples

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
... 434000, 434000, 337000, 337000,
... 11300, 11300],
... 'GDP': [1937894, 2583560, 12011, 4520, 12128,
... 17036, 182, 38, 311],
... 'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN',
... 'IS', 'NR', 'TV', 'AI']},
... index=['Italy', 'France', 'Malta',
... 'Maldives', 'Brunei', 'Iceland',
... 'Nauru', 'Tuvalu', 'Anguilla'])
```

```python
>>> df
   population     GDP alpha-2
Italy       59000000    1937894   IT
```
In the following example, we will use `nsmallest` to select the three rows having the smallest values in column “population”.

```python
>>> df.nsmallest(3, 'population')
   population  GDP  alpha-2
Tuvalu       11300  38   TV
Anguilla     11300  311  AI
Iceland     337000 17036 IS
```

When using `keep='last'`, ties are resolved in reverse order:

```python
>>> df.nsmallest(3, 'population', keep='last')
   population  GDP  alpha-2
   Anguilla   11300  311  AI
   Tuvalu    11300  38   TV
   Nauru      337000 182  NR
```

When using `keep='all'`, all duplicate items are maintained:

```python
>>> df.nsmallest(3, 'population', keep='all')
   population  GDP  alpha-2
   Tuvalu    11300  38   TV
   Anguilla  11300  311  AI
   Iceland  337000 17036 IS
   Nauru       337000 182  NR
```

To order by the smallest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```python
>>> df.nsmallest(3, ['population', 'GDP'])
   population  GDP  alpha-2
   Tuvalu    11300  38   TV
   Anguilla  11300  311  AI
   Nauru       337000 182  NR
```

### pandas.DataFrame.nunique

DataFrame.nunique(axis=0, dropna=True)

Count distinct observations over requested axis.

Return Series with number of distinct observations. Can ignore NaN values.

**Parameters**

- **axis** ([0 or ‘index’, 1 or ‘columns’], default 0) The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- **dropna** [bool, default True] Don’t include NaN in the counts.
Returns

Series

See also:

- **Series.nunique** Method nunique for Series.
- **DataFrame.count** Count non-NA cells for each column or row.

### Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 1, 1]})
>>> df.nunique()
A    3
B    1
dtype: int64
```

```python
>>> df.nunique(axis=1)
0    1
1    2
2    2
dtype: int64
```

### pandas.DataFrame.pad

DataFrame.pad(*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for *DataFrame.fillna()* with method='ffill'.

Returns

{klass} or None Object with missing values filled or None if inplace=True.

### pandas.DataFrame.pct_change

DataFrame.pct_change(*periods=1, fill_method='pad', limit=None, freq=None, **kwargs*)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

- **periods** [int, default 1] Periods to shift for forming percent change.
- **fill_method** [str, default ‘pad’] How to handle NAs before computing percent changes.
- **limit** [int, default None] The number of consecutive NAs to fill before stopping.
- **freq** [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).

**kwargs Additional keyword arguments are passed into DataFrame.shift or Series.shift.

Returns

- **chg** [Series or DataFrame] The same type as the calling object.
See also:

**Series.diff**  Compute the difference of two elements in a Series.

**DataFrame.diff**  Compute the difference of two elements in a DataFrame.

**Series.shift**  Shift the index by some number of periods.

**DataFrame.shift**  Shift the index by some number of periods.

### Examples

#### Series

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64

>>> s.pct_change()
0  NaN
1  0.011111
2 -0.065934
dtype: float64

>>> s.pct_change(periods=2)
0  NaN
1  NaN
2 -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0  90.0
1  91.0
2  NaN
3  85.0
dtype: float64

>>> s.pct_change(fill_method='ffill')
0  NaN
1  0.011111
2  -0.065934
dtype: float64
```

#### DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame({'FR': [4.0405, 4.0963, 4.3149], 'GR': [1.7246, 1.7482, 1.8519],
                    'IT': [4.949, 5.0398, 5.3666],
                    'CH': [4.7775, 4.8361, 5.0443],
                    'UK': [4.5, 4.55, 4.65],
                    'IE': [4.56, 4.61, 4.71],
                    'BE': [2.38, 2.44, 2.54],
                    'NL': [2.23, 2.29, 2.39],
                    'IE': [2.89, 2.95, 3.05]
                   })
```

(continues on next page)
... 'IT': [804.74, 810.01, 860.13]}
...

```python
df
FR   GR   IT
1980-01-01 4.0405 1.7246 804.74
1980-02-01 4.0963 1.7482 810.01
1980-03-01 4.3149 1.8519 860.13
```

```python
df.pct_change()
FR   GR   IT
1980-01-01 NaN NaN NaN
1980-02-01 0.013810 0.013684 0.006549
1980-03-01 0.053365 0.059318 0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```python
df = pd.DataFrame({
    ... '2016': [1769950, 30586265],
    ... '2015': [1500923, 40912316],
    ... '2014': [1371819, 41403351],
    ... index=['GOOG', 'APPL'])
```

```python
df.pct_change(axis='columns')
2016   2015   2014
GOOG   NaN   -0.151997 -0.086016
APPL   NaN   0.151997  0.086016
```

**pandas.DataFrame.pipe**

`DataFrame.pipe(func, *args, **kwargs)`  Apply func(self, *args, **kwargs).

- **Parameters**
  - `func` [function] Function to apply to the Series/DataFrame. `args`, and `kwargs` are passed into `func`. Alternatively a `(callable, data_keyword)` tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the Series/DataFrame.
  - `args` [iterable, optional] Positional arguments passed into `func`.
  - `kwargs` [mapping, optional] A dictionary of keyword arguments passed into `func`.

- **Returns**
  - `object` [the return type of `func`]

**See also:**
- `DataFrame.apply` Apply a function along input axis of DataFrame.
- `DataFrame.applymap` Apply a function elementwise on a whole DataFrame.
**Series.map**  Apply a mapping correspondence on a Series.

**Notes**

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> func(g(h(df), arg1=a, arg2=b, arg3=c))
```

You can write

```python
>>> (df.pipe(h)
...    .pipe(g, arg1=a)
...    .pipe(func, arg2=b, arg3=c)
...)
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```python
>>> (df.pipe(h)
...    .pipe(g, arg1=a)
...    .pipe((func, 'arg2'), arg1=a, arg3=c)
...)
```

**pandas.DataFrame.pivot**

DataFrame.**pivot** *(index=None, columns=None, values=None)*

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified `index` / `columns` to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the User Guide for more on reshaping.

**Parameters**

- **index** [str or object or a list of str, optional] Column to use to make new frame’s index. If None, uses existing index. Changed in version 1.1.0: Also accept list of index names.
- **columns** [str or object or a list of str] Column to use to make new frame’s columns. Changed in version 1.1.0: Also accept list of columns names.
- **values** [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

**Returns**

- DataFrame Returns reshaped DataFrame.

**Raises**

- ValueError: When there are any `index`, `columns` combinations with multiple values. DataFrame.pivot_table when you need to aggregate.

**See also:**
**DataFrame.pivot_table** Generalization of pivot that can handle duplicate values for one index/column pair.

**DataFrame.unstack** Pivot based on the index values instead of a column.

**wide_to_long** Wide panel to long format. Less flexible but more user-friendly than melt.

**Notes**

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

**Examples**

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', 'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})

>>> df
foo  bar  baz  zoo
0    one  A    1    x
1    one  B    2    y
2    one  C    3    z
3    two  A    4    q
4    two  B    5    w
5    two  C    6    t

>>> df.pivot(index='foo', columns='bar', values='baz')
   baz
bar     A  B  C
foo
one    1  2  3
two    4  5  6

>>> df.pivot(index='foo', columns='bar').reset_index()['baz']
   baz
bar     A  B  C
foo
one    1  2  3
two    4  5  6

>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
   baz    zoo
bar     A  B  C  A  B  C
foo
one    1  2  3    x  y  z
two    4  5  6    q  w  t

You could also assign a list of column names or a list of index names.

```python
>>>
```
```python
>>> df
lev1  lev2  lev3  lev4  values
0    1    1    1    1    0
1    1    1    2    2    1
2    1    2    1    3    2
3    2    1    2    4    3
4    2    1    1    5    4
5    2    2    2    6    5
```

```python
>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")
lev2  lev3
lev1
1    0.0  1.0  2.0  NaN
2    4.0  3.0  NaN  5.0
```

```python
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"], values="values")
lev3  lev1  lev2
1    1    0.0  1.0
2    4.0  NaN
2    1    4.0  3.0
2    NaN  5.0
```

A ValueError is raised if there are any duplicates.

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'two', 'two'], ...
                      'bar': ['A', 'A', 'B', 'C'], ...
                      'baz': [1, 2, 3, 4]})
```

Notice that the first two rows are the same for our `index` and `columns` arguments.

```python
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
  ... ValueError: Index contains duplicate entries, cannot reshape
```

### `pandas.DataFrame.pivot_table`

DataFrame.pivot_table(values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

**Parameters**

- `values` [column to aggregate, optional]
**index**  [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

**columns**  [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

**aggfunc**  [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

**fill_value**  [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

**margins**  [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

**dropna**  [bool, default True] Do not include columns whose entries are all NaN.

**margins_name**  [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.

**observed**  [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

**Returns**

DataFrame  An Excel style pivot table.

See also:

*DataFrame.pivot*  Pivot without aggregation that can handle non-numeric data.

*DataFrame.melt*  Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

*wide_to_long*  Wide panel to long format. Less flexible but more user-friendly than melt.

**Examples**

```python
>>> df = pd.DataFrame({
    "A": ["foo", "foo", "foo", "foo", "foo", "bar", "bar", "bar", "bar"],
    "B": ["one", "one", "one", "two", "two", "one", "one", "two", "two"],
    "C": ["small", "large", "large", "small", "small", "large", "small", "large"],
    "D": [1, 2, 3, 4, 5, 6, 7],
    "E": [2, 4, 5, 6, 8, 9, 9]})

>>> df
   A     B     C     D     E
0  foo   one  small  1  2
1  foo   one  large  2  4
2  foo   one  large  2  5
3  foo   two  small  3  5
```

(continues on next page)
This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum)
>>> table
    C     large  small
  A   B
bar  one  4.0   5.0
      two  7.0   6.0
foo  one  4.0   1.0
      two   NaN   6.0
```

We can also fill missing values using the `fill_value` parameter.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
    C     large  small
  A   B
bar  one  4   5
      two  7   6
foo  one  4   1
      two   0   6
```

The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                        aggfunc={'D': np.mean,  
                                 'E': np.mean})
>>> table
         D     E
  A   C
bar large  5.500000  7.500000
     small  5.500000  8.500000
foo large  2.000000  4.500000
     small  2.333333  4.333333
```

We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                        aggfunc={'D': np.mean,  
                                 'E': [np.min, np.max, np.mean]})
>>> table
         D   E  mean  max  mean  min
  A   C
bar large  5.500000  9.0  7.500000  6.0
     small  5.500000  9.0  8.500000  8.0
foo large  2.000000  5.0  4.500000  4.0
     small  2.333333  6.0  4.333333  2.0
```
DataFrame.plot

DataFrame.plot(*args, **kwargs)

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

**Parameters**

- `data` [Series or DataFrame] The object for which the method is called.
- `x` [label or position, default None] Only used if data is a DataFrame.
- `y` [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.
- `kind` [str] The kind of plot to produce:
  - ‘line’: line plot (default)
  - ‘bar’: vertical bar plot
  - ‘barh’: horizontal bar plot
  - ‘hist’: histogram
  - ‘box’: boxplot
  - ‘kde’: Kernel Density Estimation plot
  - ‘density’: same as ‘kde’
  - ‘area’: area plot
  - ‘pie’: pie plot
  - ‘scatter’: scatter plot
  - ‘hexbin’: hexbin plot.
- `ax` [matplotlib axes object, default None] An axes of the current figure.
- `subplots` [bool, default False] Make separate subplots for each column.
- `sharex` [bool, default True if ax is None else False] In case `subplots=True`, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and `sharex=True` will alter all x axis labels for all axis in a figure.
- `sharey` [bool, default False] In case `subplots=True`, share y axis and set some y axis labels to invisible.
- `layout` [tuple, optional] (rows, columns) for the layout of subplots.
- `figsize` [a tuple (width, height) in inches] Size of a figure object.
- `use_index` [bool, default True] Use index as ticks for x axis.
- `title` [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and `subplots` is True, print each item in the list above the corresponding subplot.
- `grid` [bool, default None (matlab style default)] Axis grid lines.
- `legend` [bool or {‘reverse’}] Place legend on axis subplots.
- `style` [list or dict] The matplotlib line style per column.
logx [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. ..
versionchanged:: 0.25.0
logy [bool or ‘sym’, default False] Use log scaling or symlog scaling on y axis. ..
versionchanged:: 0.25.0
loglog [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and
y axes. .. versionchanged:: 0.25.0
xticks [sequence] Values to use for the xticks.
yticks [sequence] Values to use for the yticks.
xlim [2-tuple/list] Set the x limits of the current axes.
ylim [2-tuple/list] Set the y limits of the current axes.
xlabel [label, optional] Name to use for the xlabel on x-axis. Default uses index name
as xlabel, or the x-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).
ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no
ylabel, or the y-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).
rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).
fontsize [int, default None] Font size for xticks and yticks.
colormap [str or matplotlib colormap object, default None] Colormap to select colors
from. If string, load colormap with that name from matplotlib.
colorbar [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’
plots).
position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end)
to 1 (right/top-end). Default is 0.5 (center).
table [bool, Series or DataFrame, default False] If True, draw a table using the data in
the DataFrame and the data will be transposed to meet matplotlib’s default layout.
If a Series or DataFrame is passed, use passed data to draw a table.
yerr [DataFrame, Series, array-like, dict and str] See Plotting with Error Bars for de-
tail.
xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.
stacked [bool, default False in line and bar plots, and True in area plot] If True, create
stacked plot.
sort_columns [bool, default False] Sort column names to determine plot ordering.
secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis
if a list/tuple, which columns to plot on secondary y-axis.
mark_right [bool, default True] When using a secondary_y axis, automatically mark
the column labels with “(right)” in the legend.
include_bool [bool, default is False] If True, boolean values can be plotted.
backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

**kwargs Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

- See matplotlib documentation online for more on this subject
- If kind = 'bar' or 'barh', you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

 pandas.DataFrame.pop

DataFrame.pop(item)

Return item and drop from frame. Raise KeyError if not found.

Parameters

item [label] Label of column to be popped.

Returns

Series

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                        ('parrot', 'bird', 24.0),
...                        ('lion', 'mammal', 80.5),
...                        ('monkey', 'mammal', np.nan)],
...                        columns=('name', 'class', 'max_speed'))
>>> df
   name class  max_speed
0  falcon  bird    389.0
1   parrot  bird     24.0
2     lion  mammal   80.5
3   monkey  mammal      NaN

>>> df.pop('class')
 0  bird
 1  bird
 2  mammal
 3  mammal
Name: class, dtype: object
```
pandas.DataFrame.pow

DataFrame.pow(other, axis='columns', level=None, fill_value=None)

Get Exponential power of dataframes and other, element-wise (binary operator pow).

Equivalent to dataframe ** other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rpow.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

- other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame  Result of the arithmetic operation.

See also:

DataFrame.add  Add DataFrames.
DataFrame.sub  Subtract DataFrames.
DataFrame.mul  Multiply DataFrames.
DataFrame.div  Divide DataFrames (float division).
DataFrame.truediv  Divide DataFrames (float division).
DataFrame.floordiv  Divide DataFrames (integer division).
DataFrame.mod  Calculate modulo (remainder after division).
DataFrame.pow  Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df

   angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1

   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)

   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)

   angles  degrees
circle   0.0      36.0
triangle 0.3       18.0
rectangle 0.4      36.0
```

```python
>>> df.rdiv(10)

   angles  degrees
circle   inf      0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]

   angles  degrees
circle    -1      358
triangle    2      178
rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')

   angles  degrees
circle    -1      358
triangle    2      178
rectangle   3      358
```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

   angles  degrees
circle  -1.0   359.0
triangle  2.0   179.0
rectangle  3.0   359.0

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])

>>> df + other

   angles  degrees
circle  0.0    NaN
triangle  9.0    NaN
rectangle 16.0    NaN

>>> df.mul(other, fill_value=0)

   angles  degrees
circle  0.0    0.0
triangle  9.0    0.0
rectangle 16.0    0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6], 'degrees': [360, 180, 360, 360, 540, 720]}, index=['A', 'A', 'A', 'B', 'B', 'B'], ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])

>>> df_multindex

   angles  degrees
A circle  0.0  360.0
triangle  3.0  180.0
rectangle 4.0  360.0
B square  4.0  360.0
pentagon  5.0  540.0
hexagon  6.0  720.0

>>> df.div(df_multindex, level=1, fill_value=0)

   angles  degrees
A circle  NaN   1.0
triangle  1.0   1.0
rectangle 1.0   1.0
B square  0.0   0.0
pentagon  0.0   0.0
hexagon  0.0   0.0
DataFrame.prod

DataFrame.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values over the requested axis.

Parameters

- **axis** [[index (0), columns (1)]] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

- Series.sum Return the sum.
- Series.min Return the minimum.
- Series.max Return the maximum.
- Series.idxmin Return the index of the minimum.
- Series.idxmax Return the index of the maximum.
- DataFrame.sum Return the sum over the requested axis.
- DataFrame.min Return the minimum over the requested axis.
- DataFrame.max Return the maximum over the requested axis.
- DataFrame.idxmin Return the index of the minimum over the requested axis.
- DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the min_count parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```
Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

### pandas.DataFrame.product

DataFrame.product

DataFrame.product (axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values over the requested axis.

**Parameters**

- `axis` [{`index (0)`, columns (1)}] Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `min_count` [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**See also:**

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

### pandas.DataFrame.quantile

DataFrame.quantile(q=0.5, axis=0, numeric_only=True, interpolation='linear')

Return values at the given quantile over requested axis.

**Parameters**

- `q` [float or array-like, default 0.5 (50% quantile)] Value between 0 <= q <= 1, the quantile(s) to compute.
- `axis` [[0, 1, ‘index’, ‘columns’], default 0] Equals 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- `numeric_only` [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.
- `interpolation` [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points \( i \) and \( j \):
  - linear: \( i + (j - i) \times \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
  - lower: \( i \).
  - higher: \( j \).
  - nearest: \( i \) or \( j \) whichever is nearest.
  - midpoint: \( (i + j) / 2 \).

**Returns**

Series or DataFrame

- If `q` is an array, a DataFrame will be returned where the index is \( q \), the columns are the columns of self, and the values are the quantiles.
- If `q` is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.
See also:

- `core.window.Rolling.quantile` Rolling quantile.
- `numpy.percentile` Numpy function to compute the percentile.

**Examples**

```python
def = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]), columns=['a', 'b'])
def.quantile(.1)
a 1.3
b 3.7
Name: 0.1, dtype: float64
def.quantile([.1, .5])
a 1.3 3.7
b 2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```python
def = pd.DataFrame({'A': [1, 2],
                   'B': [pd.Timestamp('2010'),
                        pd.Timestamp('2011')],
                   'C': [pd.Timedelta('1 days'),
                         pd.Timedelta('2 days')])
def.quantile(0.5, numeric_only=False)
A 1.5
B 2010-07-02 12:00:00
C 1 days 12:00:00
Name: 0.5, dtype: object
```

**pandas.DataFrame.query**

`DataFrame.query(expr, inplace=False, **kwargs)`

Query the columns of a DataFrame with a boolean expression.

**Parameters**

- `expr` [str] The query string to evaluate.

  You can refer to variables in the environment by prefixing them with an ‘@’ character like `@a + b`.

  You can refer to column names that are not valid Python variable names by surrounding them in backticks. Thus, column names containing spaces or punctuations (besides underscores) or starting with digits must be surrounded by backticks. (For example, a column named “Area (cm^2) would be referenced as `Area (cm^2)`). Column names which are Python keywords (like “list”, “for”, “import”, etc) cannot be used.

  For example, if one of your columns is called `a` `a` and you want to sum it with `b`, your query should be `a a` + `b`.

New in version 0.25.0: Backtick quoting introduced.
New in version 1.0.0: Expanding functionality of backtick quoting for more than only spaces.

inplace [bool] Whether the query should modify the data in place or return a modified copy.

**kwargs See the documentation for eval() for complete details on the keyword arguments accepted by DataFrame.query().

Returns

DataFrame or None DataFrame resulting from the provided query expression or None if inplace=True.

See also:

eval Evaluate a string describing operations on DataFrame columns.
DataFrame.eval Evaluate a string describing operations on DataFrame columns.

Notes

The result of the evaluation of this expression is first passed to DataFrame.loc and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to DataFrame.__getitem__().

This method uses the top-level eval() function to evaluate the passed query.

The query() method uses a slightly modified Python syntax by default. For example, the & and | (bitwise) operators have the precedence of their boolean cousins, and and or. This is syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument parser='python'. This enforces the same semantics as evaluation in Python space. Likewise, you can pass engine='python' to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using numexpr as the engine.

The DataFrame.index and DataFrame.columns attributes of the DataFrame instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier index is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the query documentation in indexing.

Backtick quoted variables

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings that are allowed as a Python identifier. These characters include all operators in Python, the space character, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the query parser will raise an error. This excludes whitespace different than the space character, but also the hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, `it's` > `that's` will raise an error, as it forms a quoted string ("s > "that") with a backtick inside.
See also the Python documentation about lexical analysis (https://docs.python.org/3/reference/lexical-analysis.html) in combination with the source code in pandas.core.computation.parsing.

Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6),
... 'B': range(10, 0, -2),
... 'C C': range(10, 5, -1))

>>> df
   A  B   C   C
0  1 10 10
1  2  8  9
2  3  6  8
3  4  4  7
4  5  2  6

>>> df.query('A > B')
   A  B  C   C
4  5  2  6
```

The previous expression is equivalent to

```python
>>> df[df.A > df.B]
   A  B  C   C
4  5  2  6
```

For columns with spaces in their name, you can use backtick quoting.

```python
>>> df.query('B == `C C``')
   A  B  C   C
0  1 10 10
```

The previous expression is equivalent to

```python
>>> df[df.B == df['C C']]  # df['C C'] is used instead of df['C C']
   A  B  C   C
0  1 10 10
```

### pandas.DataFrame.radd

Dataframe. **radd**(other, axis='columns', level=None, fill_value=None)

Get Addition of dataframe and other, element-wise (binary operator radd).

Equivalent to `other + dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `add`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360],
...                   'index': ['circle', 'triangle', 'rectangle']})

>>> df
       angles  degrees
    circle      0      360
   triangle     3      180
  rectangle     4      360

Add a scalar with operator version which return the same results.

>>> df + 1
       angles  degrees
    circle      1      361
   triangle     4      181
  rectangle     5      361

>>> df.add(1)
       angles  degrees
    circle      1      361
   triangle     4      181
  rectangle     5      361

Divide by constant with reverse version.
>>> df.div(10)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>

>>> df.rdiv(10)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>0.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4],
index=['circle', 'triangle', 'rectangle'])

>>> df * other

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.0</td>
</tr>
</tbody>
</table>

>>> df.mul(other, fill_value=0)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
... 'degrees': [360, 180, 360, 360, 540, 720]},
... index=['A', 'A', 'A', 'B', 'B', 'B'],
... ['circle', 'triangle', 'rectangle',
... 'square', 'pentagon', 'hexagon'])
```

```python
>>> df_multindex
    angles  degrees
   A  circle    0     360
     triangle  3     180
       rectangle  4    360
   B  square  4.0     540
       pentagon  5     720
      hexagon  6.0     720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
    angles  degrees
   A  circle    NaN      1.0
     triangle  1.0      1.0
       rectangle  1.0      1.0
   B  square  0.0      0.0
       pentagon  0.0      0.0
      hexagon  0.0      0.0
```

```
pandas.DataFrame.rank

DataFrame.rank(\texttt{axis=0, method='average', numeric_only=\text{None}, na_option='\text{keep}', ascending=True, pct=False})
```

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

**Parameters**

- **axis** \([0 \text{ or } \text{‘index’, 1 or ‘columns’}], \text{default } 0\] Index to direct ranking.
- **method** \([\text{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, \text{default ‘average’}]\] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups.
- **numeric_only** \([\text{bool, optional}]\] For DataFrame objects, rank only numeric columns if set to True.
- **na_option** \([\text{‘keep’, ‘top’, ‘bottom’}, \text{default ‘keep’}]\] How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign smallest rank to NaN values if ascending
  - bottom: assign highest rank to NaN values if ascending.
- **ascending** \([\text{bool, default True}]\] Whether or not the elements should be ranked in ascending order.
pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

core.groupby.GroupBy.rank Rank of values within each group.

Examples

```python
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
... 'spider', 'snake'],
... 'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
Animal     Number_legs
0      cat          4.0
1   penguin          2.0
2       dog          4.0
3    spider          8.0
4     snake         NaN

The following example shows how the method behaves with the above parameters:

• default_rank: this is the default behaviour obtained without using any parameter.

• max_rank: setting method = 'max' the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)

• NA_bottom: choosing na_option = 'bottom', if there are records with NaN values they are placed at the bottom of the ranking.

• pct_rank: when setting pct = True, the ranking is expressed as percentile rank.

```python
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
Animal    Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0      cat          4.0           2.5       3.0     2.5              0.625
1   penguin          2.0           1.0       1.0     1.0              0.250
2       dog          4.0           2.5       3.0     2.5              0.625
3    spider          8.0           4.0       4.0     4.0              1.000
4     snake         NaN           NaN       NaN     NaN              NaN
```
DataFrame.rdiv

DataFrame.rdiv(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator rtruediv).

Equivalent to other / dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, truediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
     angles  degrees
  circle      0      360
  triangle    3     180
  rectangle   4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
     angles  degrees
  circle     1      361
  triangle    4     181
  rectangle   5      361
``` python

>>> df.add(1)
     angles  degrees
  circle     1      361
  triangle    4     181
  rectangle   5      361

Divide by constant with reverse version.

```python
>>> df.div(10)
     angles  degrees
  circle    0.0     36.0
  triangle  0.3     18.0
  rectangle 0.4     36.0
``` python

```python
>>> df.rdiv(10)
     angles  degrees
  circle   inf     0.027778
  triangle  3.333333  0.055556
  rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
     angles  degrees
  circle    -1     358
  triangle     2     178
  rectangle    3     358

```

```python
>>> df.sub([1, 2], axis='columns')
     angles  degrees
  circle    -1     358
  triangle     2     178
  rectangle    3     358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
     angles  degrees
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                   index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle 0
triangle 3
rectangle 4
```

```python
>>> df * other
angles  degrees
circle  0  NaN
triangle  9  NaN
rectangle 16  NaN
```

```python
>>> df.mul(other, fill_value=0)
angles  degrees
circle  0.0
triangle 0.0
rectangle 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                   'degrees': [360, 180, 360, 360, 540, 720],
                   index=[['A', 'A', 'A', 'B', 'B', 'B'],
                          ['circle', 'triangle', 'rectangle',
                           'square', 'pentagon', 'hexagon']])
>>> df_multindex
angles  degrees
A circle 0  360
triangle 3  180
rectangle 4  360
B square 4  360
pentagon 5  540
hexagon 6  720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle NaN  1.0
triangle 1.0  1.0
rectangle 1.0  1.0
B square 0.0  0.0
pentagon 0.0  0.0
hexagon 0.0  0.0
```
pandas.DataFrame.reindex

DataFrame.reindex(labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill_value=np.nan, limit=None, tolerance=None)

Conform Series/DataFrame to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

Parameters

keywords for axes [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

method \{[None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’]\} Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

• None (default): don’t fill gaps
• pad / ffill: Propagate last valid observation forward to next valid.
• backfill / bfill: Use next valid observation to fill gap.
• nearest: Use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs} \left( \text{index}[\text{indexer}] - \text{target} \right) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

Series/DataFrame with changed index.

See also:

DataFrame.set_index Set row labels.
DataFrame.reset_index Remove row labels or move them to new columns.
DataFrame.reindex_like Change to same indices as other DataFrame.
Examples

`DataFrame.reindex` supports two calling conventions

- `(index=index_labels, columns=column_labels, ...)`
- `(labels, axis={'index', 'columns'}, ...)`

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                   'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                   index=index)
>>> df
   http_status  response_time
Firefox       200       0.04
Chrome        200       0.02
Safari        404       0.07
IE10          404       0.08
Konqueror     301       1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10', 'Chrome']
>>> df.reindex(new_index)
   http_status  response_time
Safari       404.0       0.07
Iceweasel    NaN          NaN
Comodo Dragon NaN          NaN
IE10          404.0       0.08
Chrome        200.0       0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
   http_status  response_time
Safari       404       0.07
Iceweasel    0         0.00
Comodo Dragon 0         0.00
IE10          404       0.08
Chrome        200       0.02
```

We can also reindex the columns.
Or we can use “axis-style” keyword arguments

To further illustrate the filling functionality in reindex, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

Suppose we decide to expand the dataframe to cover a wider date range.

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass bfill as an argument to the method keyword.
<table>
<thead>
<tr>
<th>Date</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-12-29</td>
<td>100.0</td>
</tr>
<tr>
<td>2009-12-30</td>
<td>100.0</td>
</tr>
<tr>
<td>2009-12-31</td>
<td>100.0</td>
</tr>
<tr>
<td>2010-01-01</td>
<td>100.0</td>
</tr>
<tr>
<td>2010-01-02</td>
<td>101.0</td>
</tr>
<tr>
<td>2010-01-03</td>
<td>NaN</td>
</tr>
<tr>
<td>2010-01-04</td>
<td>100.0</td>
</tr>
<tr>
<td>2010-01-05</td>
<td>89.0</td>
</tr>
<tr>
<td>2010-01-06</td>
<td>88.0</td>
</tr>
<tr>
<td>2010-01-07</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the [user guide](#) for more.

### pandas.DataFrame.reindex_like

DataFrame.reindex_like(other=None, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.
- **method** [None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**
Series or DataFrame  Same type as caller, but with changed indices on each axis.

See also:

Dataframe.set_index  Set row labels.
Dataframe.reset_index  Remove row labels or move them to new columns.
Dataframe.reindex  Change to new indices or expand indices.

Notes

Same as calling .reindex(index=other.index, columns=other.columns,...).

Examples

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
... [31.0, 87.8, 'high'],
... [22.0, 71.6, 'medium'],
... [35.0, 95.0, 'medium']],
... columns=['temp_celsius', 'temp_fahrenheit',
... 'windspeed'],
... index=pd.date_range(start='2014-02-12',
... end='2014-02-15', freq='D'))
```

```python
>>> df1
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12       24.3            75.7      high
2014-02-13       31.0            87.8      high
2014-02-14       22.0            71.6     medium
2014-02-15       35.0            95.0     medium
```

```python
>>> df2 = pd.DataFrame([[28, 'low'],
... [30, 'low'],
... [35.1, 'medium']],
... columns=['temp_celsius', 'windspeed'],
... index=pd.DatetimeIndex(['2014-02-12', '2014-02-13', '2014-02-15']))
```

```python
>>> df2
   temp_celsius windspeed
2014-02-12       28.0       low
2014-02-13       30.0       low
2014-02-15      35.1       medium
```

```python
>>> df2.reindex_like(df1)
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12       28.0            NaN       low
2014-02-13       30.0            NaN       low
2014-02-14        NaN            NaN            NaN
2014-02-15       35.1            NaN       medium
```
**pandas.DataFrame.rename**

`DataFrame.rename(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False, level=None, errors='ignore')`

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

See the [user guide](#) for more.

**Parameters**

- **mapper** [dict-like or function] Dict-like or function transformations to apply to that axis’ values. Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and `columns`.

- **index** [dict-like or function] Alternative to specifying axis (`mapper, axis=0` is equivalent to `index=mapper`).

- **columns** [dict-like or function] Alternative to specifying axis (`mapper, axis=1` is equivalent to `columns=mapper`).

- **axis** [0 or ‘index’, 1 or ‘columns’], default 0] Axis to target with `mapper`. Can be either the axis name (‘index’, ‘columns’) or number (0, 1). The default is ‘index’.

- **copy** [bool, default True] Also copy underlying data.

- **inplace** [bool, default False] Whether to return a new DataFrame. If True then value of `copy` is ignored.

- **level** [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

- **errors** [{‘ignore’, ‘raise’}, default ‘ignore’] If ‘raise’, raise a `KeyError` when a dict-like `mapper, index, or columns` contains labels that are not present in the Index being transformed. If ‘ignore’, existing keys will be renamed and extra keys will be ignored.

**Returns**

- **DataFrame or None** DataFrame with the renamed axis labels or None if `inplace=True`.

**Raises**

- **KeyError** If any of the labels is not found in the selected axis and “errors=’raise’”.

**See also:**

- `DataFrame.rename_axis` Set the name of the axis.
Examples

DataFrame.rename supports two calling conventions

• (index=index_mapper, columns=columns_mapper, ...)
• (mapper, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```python
def = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
def.rename(columns={"A": "a", "B": "c"})
a  c
0 1 4
1 2 5
2 3 6
```

Rename index using a mapping:

```python
def.rename(index={0: "x", 1: "y", 2: "z"})
A  B
x 1 4
y 2 5
z 3 6
```

Cast index labels to a different type:

```python
def.index
RangeIndex(start=0, stop=3, step=1)
def.rename(index=str).index
Index(['0', '1', '2'], dtype='object')
def.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
Traceback (most recent call last):
  File "<ipython-input-1-5e7b9c4389b4>", line 1
    def.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
KeyError: ['C'] not found in axis
```

Using axis-style parameters:

```python
def.rename(str.lower, axis='columns')
a  b
0 1 4
1 2 5
2 3 6
```

```python
def.rename({1: 2, 2: 4}, axis='index')
A  B
0 1 4
2 2 5
4 3 6
```
pandas.DataFrame.rename_axis

DataFrame.rename_axis(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis’ values. Note that the columns parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.

Use either mapper and axis to specify the axis to target with mapper, or
index and/or columns.

Changed in version 0.24.0.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if inplace=True.

See also:

Series.rename Alter Series index labels or name.

DataFrame.rename Alter DataFrame index labels or name.

Index.rename Set new names on index.

Notes

DataFrame.rename_axis supports two calling conventions

• (index=index_mapper, columns=columns_mapper, ...)

• (mapper, axis=('index', 'columns'), ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter copy is ignored.

The second calling convention will modify the names of the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis labels.

We highly recommend using keyword arguments to clarify your intent.
Examples

Series

```python
>>> s = pd.Series(['dog', 'cat', 'monkey'])
>>> s
0  dog
1  cat
2  monkey
dtype: object
>>> s.rename_axis('animal')
animal
0  dog
1  cat
2  monkey
dtype: object
```

DataFrame

```python
>>> df = pd.DataFrame({
...     'num_legs': [4, 4, 2],
...     'num_arms': [0, 0, 2],
...     'dog', 'cat', 'monkey'"
... })
>>> df
   num_legs  num_arms
dog     4       0
cat     4       0
monkey  2       2
```

```python
>>> df.rename_axis('animal')
   num_legs  num_arms
animal
dog     4       0
cat     4       0
monkey  2       2
```

```python
>>> df.rename_axis('limbs', axis='columns')
   limbs  num_legs  num_arms
animal
dog     4       0
cat     4       0
monkey  2       2
```

MultiIndex

```python
>>> df.index = pd.MultiIndex.from_product([['mammal'],
...                                         ['dog', 'cat', 'monkey']],
...                                        names=['type', 'name'])
>>> df
   limbs  num_legs  num_arms
    type name
mammal dog     4       0
cat     4       0
monkey  2       2
```

```python
>>> df.rename_axis(index={'type': 'class'})
   limbs  num_legs  num_arms
class name
(continues on next page)```

**pandas.DataFrame.reorder_levels**

DataFrame.**reorder_levels**(order, axis=0)

Rearrange index levels using input order. May not drop or duplicate levels.

**Parameters**

- **order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Where to reorder levels.

**Returns**

DataFrame

**pandas.DataFrame.replace**

DataFrame.**replace**(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')

Replace values given in to_replace with value.

Values of the DataFrame are replaced with other values dynamically. This differs from updating with .loc or .iloc, which require you to specify a location to update with some value.

**Parameters**

- **to_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
  - numeric, str or regex:
    - numeric: numeric values equal to to_replace will be replaced with value
    - str: string exactly matching to_replace will be replaced with value
    - regex: regexes matching to_replace will be replaced with value
  - list of str, regex, or numeric:
    - First, if to_replace and value are both lists, they must be the same length.
    - Second, if regex=True then all of the strings in both lists will be interpreted as regexes otherwise they will match directly. This doesn’t matter much for value since there are only a few possible substitution regexes you can use.
    - str, regex and numeric rules apply as above.
• dict:
  – Dicts can be used to specify different replacement values for different existing values. For example, {"a": 'b', 'y': 'z'} replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the value parameter should be None.
  – For a DataFrame a dict can specify that different values should be replaced in different columns. For example, {"a": 1, 'b': 'z'} looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in value. The value parameter should not be None in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
  – For a DataFrame nested dictionaries, e.g., {"a": {'b': np.nan}}, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The value parameter should be None to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) cannot be regular expressions.

• None:
  – This means that the regex argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If value is also None then this must be a nested dictionary or Series. See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching to_replace with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit [int or None, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as to_replace, default False] Whether to interpret to_replace and/or value as regular expressions. If this is True then to_replace must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case to_replace must be None.

method [{‘pad’, ‘ffill’, ‘bfill’, None}] The method to use when for replacement, when to_replace is a scalar, list or tuple and value is None.

Returns

DataFrame or None Object after replacement or None if inplace=True.

Raises

AssertionError
  • If regex is not a bool and to_replace is not None.

TypeError
  • If to_replace is not a scalar, array-like, dict, or None
  • If to_replace is a dict and value is not a list, dict, ndarray, or Series
If `to_replace` is `None` and `regex` is not compilable into a regular expression or is a list, dict, ndarray, or Series.

When replacing multiple `bool` or `datetime64` objects and the arguments to `to_replace` does not match the type of the value being replaced

**ValueError**

- If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

See also:

- `DataFrame.fillna` Fill NA values.
- `DataFrame.where` Replace values based on boolean condition.
- `Series.str.replace` Simple string replacement.

**Notes**

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

- This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

- When dict is used as the `to_replace` value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

**Examples**

**Scalar `to_replace` and `value`**

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0   5
1   1
2   2
3   3
4   4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
                      'B': [5, 6, 7, 8, 9],
                      'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
    A  B   C
0   5  5   a
1   1  6   b
2   2  7   c
3   3  8   d
4   4  9   e
```

3.4. DataFrame 1659
List-like `to_replace`

```python
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```python
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```python
>>> s.replace([1, 2], method='bfill')
0  0
1  3
2  3
3  3
4  4
dtype: int64
```

dict-like `to_replace`

```python
>>> df.replace({0: 10, 1: 100})
   A  B  C
0 10  5  a
1 100  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100  100  a
1   1  6  b
2   2  7  c
3   3  8  d
4   4  9  e
```

```python
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4  400  9  e
```

Regular expression `to_replace`

```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
```

(continues on next page)
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz

>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz

>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz

>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1  xyz new
2  bait xyz

>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1  new new
2  bait xyz

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0  10
1  None
2  None
3  b
4  None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```python
>>> s.replace('a', None)
0  10
1  None
2  None
3  b
4  None
```

(continues on next page)
pandas.DataFrame.resample

DataFrame.resample(rule, axis=0, closed=None, label=None, convention='start', kind=None, loffset=None, base=None, on=None, level=None, origin='start_day', offset=None)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a
datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or pass datetime-like values to the
on or level keyword.

Parameters

- **rule**: [DateOffset, Timedelta or str] The offset string or object representing target conversion.
- **axis**: [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-
sampling. For Series this will default to 0, i.e. along the rows. Must be DatetimeIndex, TimedeltaIndex or PeriodIndex.
- **closed**: [{'right', 'left'}, default None] Which side of bin interval is closed. The default is
‘W’ which all have a default of ‘right’.
- **label**: [{'right', 'left'}, default None] Which bin edge label to label bucket with. The
and ‘W’ which all have a default of ‘right’.
- **convention**: [{'start', 'end', 's', 'e'}, default 'start'] For PeriodIndex only, controls
whether to use the start or end of rule.
- **kind**: [{'timestamp', 'period'}, optional, default None] Pass ‘timestamp’ to convert the
resulting index to a DateTimeIndex or ‘period’ to convert it to a PeriodIndex. By
default the input representation is retained.
- **loffset**: [timedelta, default None] Adjust the resampled time labels.
  Deprecated since version 1.1.0: You should add the loffset to the df.index after the
  resample. See below.
- **base**: [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the
  aggregated intervals. For example, for ‘5min’ frequency, base could range from 0
  through 4. Defaults to 0.
  Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’
or ‘origin’.
- **on**: [str, optional] For a DataFrame, column to use instead of index for resampling.
  Column must be datetime-like.
- **level**: [str or int, optional] For a MultiIndex, level (name or number) to use for resam-
  pling. level must be datetime-like.
origin  [{‘epoch’, ‘start’, ‘start_day’}, Timestamp or str, default ‘start_day’] The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: origin is 1970-01-01
- ‘start’: origin is the first value of the timeseries
- ‘start_day’: origin is the first day at midnight of the timeseries

New in version 1.1.0.

offset  [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns

Resampler object

See also:

groupby  Group by mapping, function, label, or list of labels.
Series.resample  Resample a Series.
DataFrame.resample  Resample a DataFrame.

Notes

See the user guide for more.

To learn more about the offset strings, please see this link.

Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```
Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00 3
2000-01-01 00:06:00 12
2000-01-01 00:09:00 21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00 0
2000-01-01 00:03:00 6
2000-01-01 00:06:00 15
2000-01-01 00:09:00 15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00 0.0
2000-01-01 00:00:30 NaN
2000-01-01 00:01:00 1.0
2000-01-01 00:01:30 NaN
2000-01-01 00:02:00 2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 0
2000-01-01 00:01:00 1
2000-01-01 00:01:30 1
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```python
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 1
2000-01-01 00:01:00 1
2000-01-01 00:01:30 2
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```python
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...```
For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of rule.

Resample a year by quarter using ‘start’ `convention`. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01', freq='A', periods=2))
>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1 1.0
2012Q2 NaN
2012Q3 NaN
2012Q4 NaN
2013Q1 2.0
2013Q2 NaN
2013Q3 NaN
2013Q4 NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using ‘end’ `convention`. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01', freq='Q', periods=4))
>>> q
2018Q1 1
2018Q2 2
2018Q3 3
2018Q4 4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03 1.0
2018-04 NaN
2018-05 NaN
2018-06 2.0
2018-07 NaN
2018-08 NaN
2018-09 3.0
2018-10 NaN
2018-11 NaN
2018-12 4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.
```python
>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
      'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
                                       periods=8,
                                       freq='W')
>>> df
   price  volume    week_starting
0     10      50 2018-01-07
1     11      60 2018-01-14
2     9       40 2018-01-21
3    13     100 2018-01-28
4    14       50 2018-02-04
5    18     100 2018-02-11
6    17       40 2018-02-18
7    19       50 2018-02-25

>>> df.resample('M', on='week_starting').mean()
   price  volume
2018-01-31  10.75   62.5
2018-02-28  17.00   60.0
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
       'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(d2,
                     index=pd.MultiIndex.from_product([days,
                                                    ['morning',
                                                     'afternoon']]))
>>> df2
   price  volume
2000-01-01 morning    10    50
      afternoon    11    60
2000-01-02 morning     9    40
      afternoon   13   100
2000-01-03 morning    14    50
      afternoon   18   100
2000-01-04 morning    17    40
      afternoon   19    50

>>> df2.resample('D', level=0).sum()
   price  volume
2000-01-01      21    110
2000-01-02      22    140
2000-01-03      32    150
2000-01-04      36    90
```

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00    0
```

(continues on next page)
If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00  9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00  9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated base argument, you can now use offset, in this example it is equivalent to have base=2:

```python
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00  0
2000-10-01 23:33:00  9
```

(continues on next page)
To replace the use of the deprecated `loffset` argument:

```python
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
2000-10-01 23:33:00     0
2000-10-01 23:50:00     9
2000-10-02 00:07:00    21
2000-10-02 00:24:00    54
2000-10-02 00:41:00    24
Freq: 17T, dtype: int64
```

`pandas.DataFrame.reset_index`

`DataFrame.reset_index(level=None, drop=False, inplace=False, col_level=0, col_fill='')` reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

**Parameters**

- **level** [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.
- **drop** [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.
- **inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).
- **col_level** [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.
- **col_fill** [object, default ‘’] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

**Returns**

- **DataFrame or None** DataFrame with the new index or None if `inplace=True`.

**See also:**

- `DataFrame.set_index` Opposite of `reset_index`.
- `DataFrame.reindex` Change to new indices or expand indices.
- `DataFrame.reindex_like` Change to same indices as other DataFrame.
Examples

```python
>>> df = pd.DataFrame({
    ('bird', 'falcon'): 389.0,
    ('bird', 'parrot'): 24.0,
    ('mammal', 'lion'): 80.5,
    ('mammal', 'monkey'): np.nan,
},
    index=['falcon', 'parrot', 'lion', 'monkey'],
    columns=('class', 'max_speed'))
>>> df
     class max_speed
   falcon  bird     389.0
   parrot  bird     24.0
   lion    mammal   80.5
   monkey  mammal   NaN

When we reset the index, the old index is added as a column, and a new sequential index is used:

```python
>>> df.reset_index()

     index class max_speed
 0  falcon  bird     389.0
 1  parrot  bird     24.0
 2  lion    mammal   80.5
 3  monkey  mammal   NaN
```

We can use the `drop` parameter to avoid the old index being added as a column:

```python
>>> df.reset_index(drop=True)

     class max_speed
   0  bird     389.0
   1  bird     24.0
   2  mammal   80.5
   3  mammal   NaN
```

You can also use `reset_index` with `MultiIndex`.

```python
>>> index = pd.MultiIndex.from_tuples(
    [('bird', 'falcon'),
     ('bird', 'parrot'),
     ('mammal', 'lion'),
     ('mammal', 'monkey')],
    names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples(
    [('speed', 'max'),
     ('species', 'type')])
>>> df = pd.DataFrame({
    389.0: 'fly',
    24.0: 'fly',
    80.5: 'run',
    np.nan: 'jump',
},
    index=index,
    columns=columns)
>>> df
   speed species  
   max  type  
   class name
   bird  falcon 389.0  fly
   parrot 24.0  fly
   mammal lion 80.5  run
   monkey  NaN  jump
```

If the index has multiple levels, we can reset a subset of them:
If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```python
>>> df.reset_index(level='class', col_level=1)

       speed  species
    class     max   type
name  
  falcon  bird  389.0    fly
   parrot  bird   24.0    fly
     lion  mamal  80.5     run
  monkey  mamal    NaN    jump
```

When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='species')

       speed  species
    class     max   type
name  
  falcon  bird  389.0    fly
   parrot  bird   24.0    fly
     lion  mamal  80.5     run
  monkey  mamal    NaN    jump
```

If we specify a nonexistent level for `col_fill`, it is created:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='genus')

       genus  speed  species
    class     max   type
name  
  falcon  bird  389.0    fly
   parrot  bird   24.0    fly
     lion  mamal  80.5     run
  monkey  mamal    NaN    jump
```

**pandas.DataFrame.rfloordiv**

DataFrame.rfloordiv (other, axis='columns', level=None, fill_value=None)  
Get integer division of dataframe and other, element-wise (binary operator rfloordiv).  
Equivalent to other // dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, floordiv.  
Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis  [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame  Result of the arithmetic operation.

See also:

DataFrame.add  Add DataFrames.
DataFrame.sub  Subtract DataFrames.
DataFrame.mul  Multiply DataFrames.
DataFrame.div  Divide DataFrames (float division).
DataFrame.truediv  Divide DataFrames (float division).
DataFrame.floordiv  Divide DataFrames (integer division).
DataFrame.mod  Calculate modulo (remainder after division).
DataFrame.pow  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

>>> df = pd.DataFrame({'angles': [0, 3, 4],
                    'degrees': [360, 180, 360]},
                    index=['circle', 'triangle', 'rectangle'])
>>> df
     angles  degrees
   circle    0      360
   triangle   3      180
  rectangle   4      360

Add a scalar with operator version which return the same results.

>>> df + 1
     angles  degrees
   circle    1      361
   triangle   4      181
  rectangle   5      361
Divide by constant with reverse version.

```
>>> df.div(10)
   angles  degrees
circle    0.0     36.0
triangle   0.3     18.0
rectangle  0.4     36.0
```

```
>>> df.rdiv(10)
   angles       degrees
circle       inf      0.027778
triangle    3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
   angles  degrees
circle   -1     358
triangle   2     178
rectangle  3     358
```

```
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1     358
triangle   2     178
rectangle  3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
... axis='index')
   angles  degrees
circle   -1     359
triangle   2     179
rectangle  3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
... index=['circle', 'triangle', 'rectangle'])
```

```
>>> df * other
   angles  degrees
circle   0       NaN
triangle   9       NaN
rectangle 16       NaN
```
Divide by a MultiIndex by level.

```python
>>> df_div = df / df_multindex
```

```
      angles  degrees
    A circle       0  360
       triangle    9  0.0
     rectangle   16  0.0
      square      4  360
     pentagon      5  540
   hexagon      6  720
```

```
>>> df_div
      angles  degrees
    A circle NaN  1.0
       triangle 1.0  1.0
     rectangle 1.0  1.0
      square   0.0  0.0
     pentagon  0.0  0.0
   hexagon   0.0  0.0
```

**pandas.DataFrame.rmod**

Dataframe .rmod (other, axis='columns', level=None, fill_value=None)

Get Modulo of dataframe and other, element-wise (binary operator rmod).

Equivalent to other % dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [(0 or ‘index’, 1 or ‘columns’)] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**
DataFrame  Result of the arithmetic operation.

See also:

DataFrame.add  Add DataFrames.
DataFrame.sub  Subtract DataFrames.
DataFrame.mul  Multiply DataFrames.
DataFrame.div  Divide DataFrames (float division).
DataFrame.truediv  Divide DataFrames (float division).
DataFrame.floordiv  Divide DataFrames (integer division).
DataFrame.mod  Calculate modulo (remainder after division).
DataFrame.pow  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle   0      360
triangle 3      180
rectangle 4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle   1      361
triangle 4      181
rectangle 5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle  0.0    36.0
triangle 0.3    18.0
rectangle 0.4   36.0
```
## DataFrame

### Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
  angles  degrees
 circle      2  358
triangle     3  358
rectangle   -1  358
```

```python
>>> df.sub([1, 2], axis='columns')
  angles  degrees
 circle      2  358
triangle     3  358
rectangle   -1  358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
  angles  degrees
 circle      2  358
triangle     3  358
rectangle   -1  358
```

### Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({
    'angles': [0, 3, 4],
    'degrees': [360, 180, 360, 360, 540, 720],
}, index=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
```

```python
df * other
  angles  degrees
 circle   0   NaN
triangle  9   NaN
rectangle 16   NaN
```

```python
df.mul(other, fill_value=0)
  angles  degrees
 circle   0   0.0
triangle  9   0.0
rectangle 16   0.0
```

### Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({
    'angles': [0, 3, 4, 4, 5, 6],
    'degrees': [360, 180, 360, 360, 540, 720],
}, index=['A', 'A', 'A', 'B', 'B', 'B'],
```

```python
df_multindex = pd.DataFrame({
    'angles': [0, 3, 4, 4, 5, 6],
    'degrees': [360, 180, 360, 360, 540, 720],
}, index=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
```

```python
```
```
```python
>>> df_multindex
angles  degrees
    A circle  0   360
      triangle  3   180
     rectangle  4   360
    B square  4   360
      pentagon  5   540
     hexagon  6   720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
    A circle  NaN 1.0
      triangle  1.0 1.0
     rectangle  1.0 1.0
    B square  0.0 0.0
      pentagon  0.0 0.0
     hexagon  0.0 0.0
```

**pandas.DataFrame.rmul**

DataFrame.rmul (other, axis='columns', level=None, fill_value=None) Get Multiplication of dataframe and other, element-wise (binary operator rmul).

Equivalent to other * dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
**DataFrame.floordiv**  Divide DataFrames (integer division).

**DataFrame.mod**  Calculate modulo (remainder after division).

**DataFrame.pow**  Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                      'degrees': [360, 180, 360],
                      index=['circle', 'triangle', 'rectangle'])
>>> df
          angles  degrees
    circle    0       360
    triangle   3       180
    rectangle   4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
          angles  degrees
    circle     1       361
    triangle    4       181
    rectangle    5       361
```

```python
>>> df.add(1)
          angles  degrees
    circle     1       361
    triangle    4       181
    rectangle    5       361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
          angles  degrees
    circle   0.0     36.0
    triangle 0.3     18.0
    rectangle 0.4     36.0
```

```python
>>> df.rdiv(10)
          angles  degrees
    circle     inf   0.027778
    triangle   3.333333  0.055556
    rectangle   2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
          angles  degrees
    circle    -1       358
    triangle     2       178
    rectangle     3       358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                       index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle    0
triangle   3
rectangle  4
```

```python
>>> df * other
angles  degrees
circle   0 NaN
triangle 9 NaN
rectangle 16 NaN
```

```python
>>> df.mul(other, fill_value=0)
angles  degrees
circle   0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B',
                                      'circle', 'triangle', 'rectangle',
                                      'square', 'pentagon', 'hexagon'])
>>> df_multindex
angles  degrees
A circle    0 360
triangle    3 180
rectangle   4 360
B square    4 360
pentagon    5 540
hexagon     6 720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle    NaN 1.0
triangle    1.0 1.0
rectangle   1.0 1.0
```

B square  0.0  0.0
pentagon  0.0  0.0
hexagon   0.0  0.0

pandas.DataFrame.rolling

DataFrame.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)
Provide rolling window calculations.

Parameters

window  [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined get_window_bounds method. Additional rolling keyword arguments, namely min_periods, center, and closed will be passed to get_window_bounds.

min_periods [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, min_periods will default to 1. Otherwise, min_periods will default to the size of the window.

center  [bool, default False] Set the labels at the center of the window.

win_type  [str, default None] Provide a window type. If None, all points are evenly weighted. See the notes below for further information.

on  [str, optional] For a DataFrame, a datetime-like column or MultiIndex level on which to calculate the rolling window, rather than the DataFrame’s index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis  [int or str, default 0]

closed  [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. Defaults to ‘right’.

Changed in version 1.2.0: The closed parameter with fixed windows is now supported.

Returns

a Window or Rolling sub-classed for the particular operation

See also:

expanding Provides expanding transformations.

ewm Provides exponential weighted functions.

3.4. DataFrame 1679
Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

To learn more about the offsets & frequency strings, please see this link.

If win_type=None, all points are evenly weighted; otherwise, win_type can accept a string of any scipy.signal window function.

Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature. Please see the third example below on how to add the additional parameters.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```python
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, using the 'gaussian' window type (note how we need to specify std).

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
   B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
```

Rolling sum with a window length of 2, min_periods defaults to the window length.

```python
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min_periods

```python
>>> df.rolling(2).sum(min_periods=1)
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```
>>> df.rolling(2, min_periods=1).sum()
    B
   0  0.0
   1  1.0
   2  3.0
   3  2.0
   4  4.0

Same as above, but with forward-looking windows

>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
    B
   0  1.0
   1  3.0
   2  2.0
   3  4.0
   4  4.0

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                   index = [pd.Timestamp('20130101 09:00:00'),
                             pd.Timestamp('20130101 09:00:02'),
                             pd.Timestamp('20130101 09:00:03'),
                             pd.Timestamp('20130101 09:00:05'),
                             pd.Timestamp('20130101 09:00:06')])

>>> df
     B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

>>> df.rolling('2s').sum()
     B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
pandas.DataFrame.round

DataFrame.round(decimals=0, *args, **kwargs)
Round a DataFrame to a variable number of decimal places.

Parameters

decimals [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if decimals is a dict-like, or in the index if decimals is a Series. Any columns not included in decimals will be left as is. Elements of decimals which are not columns of the input will be ignored.

*args Additional keywords have no effect but might be accepted for compatibility with numpy.

**kwargs Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

DataFrame A DataFrame with the affected columns rounded to the specified number of decimal places.

See also:

numpy.around Round a numpy array to the given number of decimals.

Series.round Round a Series to the given number of decimals.

Examples

```python
>>> df = pd.DataFrame([(0.21, 0.32), (0.01, 0.67), (0.66, 0.03), (0.21, 0.18)],
                    columns=['dogs', 'cats'])
>>> df
   dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18

By providing an integer each column is rounded to the same number of decimal places

``` python
>>> df.round(1)
   dogs  cats
0  0.2  0.3
1  0.0  0.7
2  0.7  0.0
3  0.2  0.2
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```python
>>> df.round({'dogs': 1, 'cats': 0})
   dogs  cats
0  0.2   0.0
1  0.0   1.0
```

(continues on next page)
Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value.

```python
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
   dogs  cats
0    0.2  0.0
1    0.0  1.0
2    0.7  0.0
3    0.2  0.0
```

**pandas.DataFrame.rpow**

DataFrame (other, axis='columns', level=None, fill_value=None)

Get Exponential power of dataframe and other, element-wise (binary operator rpow).

Equivalent to other ** dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, pow.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0       360
triangle   3       180
rectangle  4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df += 1
   angles  degrees
circle     1       361
triangle   4       181
rectangle  5       361
```

```python
>>> df.add(1)
   angles  degrees
circle     1       361
triangle   4       181
rectangle  5       361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf     0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1      358
triangle   2      178
rectangle  3      358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1      358
triangle   2      178
rectangle  3      358
```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), 
        axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]}, 
                        index=['circle', 'triangle', 'rectangle'])

>>> df + other

</table>
pandas.DataFrame.rsub

DataFrame.rsub(other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator rsub).

Equivalent to other - dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, sub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
  ...                   'degrees': [360, 180, 360]},
  ...                   index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

```python
>>> df.add(1)
    angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
circle   0.0    36.0
triangle 0.3    18.0
rectangle 0.4   36.0
```

```python
>>> df.rdiv(10)
    angles  degrees
circle    inf   0.027778
triangle  3.33333 0.055556
rectangle 2.50000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
    angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```

```python
>>> df.sub([1, 2], axis='columns')
    angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
  ...       axis='index')
    angles  degrees
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
In [3]: other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

In [4]: other
Out[4]:
   angles
circle    0
triangle   3
rectangle  4

In [5]: df * other
   angles  degrees
   circle       NaN
   triangle     9.0
   rectangle    16.0

In [6]: df.mul(other, fill_value=0)
   angles  degrees
   circle    0.0
   triangle  0.0
   rectangle 0.0
```

Divide by a MultiIndex by level.

```python
In [7]: df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720]},
                              index=['A', 'A', 'A', 'B', 'B', 'B'],
                              columns=['circle', 'triangle', 'rectangle',
                                       'square', 'pentagon', 'hexagon'])

In [8]: df_multindex
Out[8]:
   angles  degrees
  A circle    0  360
  triangle   3  180
  rectangle  4  360
  B square   4  360
  pentagon   5  540
  hexagon    6  720

In [9]: df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
  A circle  NaN  1.0
  triangle  1.0  1.0
  rectangle 1.0  1.0
  B square  0.0  0.0
  pentagon  0.0  0.0
  hexagon  0.0  0.0
```
pandas.DataFrame.rtruediv

DataFrame.rtruediv(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator rtruediv).

Equivalent to other / dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, truediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %. **.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [0 or 'index', 1 or 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360],
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0    36.0
triangle 0.3    18.0
rectangle 0.4   36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf    0.027778
triangle 3.33333 0.055556
rectangle 2.50000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
   angles  degrees
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                         index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle 0
triangle 3
rectangle 4
```

```python
>>> df * other
         angles  degrees
    circle  0      NaN
    triangle 9      NaN
    rectangle 16     NaN
```

```python
>>> df.mul(other, fill_value=0)
         angles  degrees
    circle   0      0.0
    triangle  9      0.0
    rectangle 16      0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': [['A', 'A', 'A', 'B', 'B', 'B'],
                                         ['circle', 'triangle', 'rectangle',
                                          'square', 'pentagon', 'hexagon']])
>>> df_multindex
     angles  degrees
    A circle  0        360
    triangle 3        180
    rectangle 4        360
    B square 4        360
      pentagon 5      540
     hexagon 6        720
```

```python
>>> df_multindex['angles']
    circle    0
   triangle   3
rectangle   4
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
         angles  degrees
    A circle NaN       1.0
    triangle 1.0       1.0
    rectangle 1.0      1.0
    B square 0.0       0.0
      pentagon 0.0     0.0
     hexagon 0.0       0.0
```
pandas.DataFrame.sample

DataFrame.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

Parameters

- **n** [int, optional] Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.
- **frac** [float, optional] Fraction of axis items to return. Cannot be used with n.
- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights** [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.
- **random_state** [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.
  Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to np.random.RandomState() as seed
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

Returns

- **Series or DataFrame** A new object of same type as caller containing n items randomly sampled from the caller object.

See also:

- DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.
- SeriesGroupBy.sample Generates random samples from each group of a Series object.
- numpy.random.choice Generates a random sample from a given 1-D numpy array.
Notes

If $\frac{\text{frac}}{1}$, replacement should be set to True.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                     'num_wings': [2, 0, 0, 0],
...                     'num_specimen_seen': [10, 2, 1, 8],
...                     index=['falcon', 'dog', 'spider', 'fish'])
```

```text
num_legs num_wings num_specimen_seen
falcon  2       2       10
dog     4       0       2
spider  8       0       1
fish    0       0       8
```

Extract 3 random elements from the Series df['num_legs']: Note that we use random_state to ensure the reproducibility of the examples.

```python
>>> df['num_legs'].sample(n=3, random_state=1)
fish    0
spider  8
falcon  2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
num_legs num_wings num_specimen_seen
dog     4       0       2
fish    0       0       8
```

An upsample sample of the DataFrame with replacement: Note that replace parameter has to be True for frac parameter > 1.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
num_legs num_wings num_specimen_seen
dog     4       0       2
fish    0       0       8
falcon  2       2       10
falcon  2       2       10
fish    0       0       8
dog     4       0       2
fish    0       0       8
dog     4       0       2
```

Using a DataFrame column as weights. Rows with larger value in the num_specimen_seen column are more likely to be sampled.

```python
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
num_legs num_wings num_specimen_seen
falcon  2       2       10
fish    0       0       8
```
pandas.DataFrame.select_dtypes

DataFrame.select_dtypes(include=None, exclude=None)
Return a subset of the DataFrame’s columns based on the column dtypes.

Parameters

include, exclude [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

Returns

DataFrame The subset of the frame including the dtypes in include and excluding the dtypes in exclude.

Raises

ValueError
• If both of include and exclude are empty
• If include and exclude have overlapping elements
• If any kind of string dtype is passed in.

See also:

DataFrame.dtypes Return Series with the data type of each column.

Notes

• To select all numeric types, use np.number or 'number'
• To select strings you must use the object dtype, but note that this will return all object dtype columns
• See the numpy dtype hierarchy
• To select datetimes, use np.datetime64,'datetime' or 'datetime64'
• To select timedeltas, use np.timedelta64,'timedelta' or 'timedelta64'
• To select Pandas categorical dtypes, use 'category'
• To select Pandas datetimetz dtypes, use 'datetimetz' (new in 0.20.0) or 'datetime64[ns, tz]'

Examples

```python
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
   a   b   c
0  1  True  1.0
1  2   False  2.0
2  1  True  1.0
3  2   False  2.0
4  1  True  1.0
5  2   False  2.0
```
```python
>>> df.select_dtypes(include='bool')
   b
0  True
1  False
2  True
3  False
4  True
5  False

>>> df.select_dtypes(include=['float64'])
   c
0   1.0
1   2.0
2   1.0
3   2.0
4   1.0
5   2.0

>>> df.select_dtypes(exclude=['int64'])
   b     c
0  True  1.0
1  False 2.0
2   True 1.0
3  False 2.0
4   True 1.0
5  False 2.0
```

**pandas.DataFrame.sem**

**DataFrame.sem** *(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)*

Return unbiased standard error of the mean over requested axis. Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- **axis** *(index (0), columns (1))*
- **skipna** *(bool, default True)* Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** *(int or level name, default None)* If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** *(int, default 1)* Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** *(bool, default None)* Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

Series or DataFrame (if level specified)
Notes

To have the same behaviour as `numpy.std`, use `ddof=0` (instead of the default `ddof=1`)

**pandas.DataFrame.set_axis**

`DataFrame.set_axis(labels, axis=0, inplace=False)`

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

**Parameters**

- `labels` [list-like, Index] The values for the new index.
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.
- `inplace` [bool, default False] Whether to return a new DataFrame instance.

**Returns**

- `renamed` [DataFrame or None] An object of type DataFrame or None if `inplace=True`.

**See also:**

`DataFrame.rename_axis` Alter the name of the index or columns.

**Examples**

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```python
>>> df.set_axis(['a', 'b', 'c'], axis='index')
   A  B
a 1  4
b 2  5
c 3  6
```

Change the column labels.

```python
>>> df.set_axis(['I', 'II'], axis='columns')
      I  II
0   1   4
1   2   5
2   3   6
```

Now, update the labels inplace.

```python
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
      i  ii
0   1   4
1   2   5
2   3   6
```
pandas.DataFrame.set_flags

DataFrame.set_flags(*, copy=False, allows_duplicate_labels=None)
Return a new object with updated flags.

Parameters

allows_duplicate_labels [bool, optional] Whether the returned object allows duplicate labels.

Returns

Series or DataFrame The same type as the caller.

See also:

DataFrame.attrs Global metadata applying to this dataset.
DataFrame.flags Global flags applying to this object.

Notes

This method returns a new object that’s a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in DataFrame.attrs.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags.allows_duplicate_labels
True
>>> df2 = df.set_flags(allows_duplicate_labels=False)
>>> df2.flags.allows_duplicate_labels
False
```

pandas.DataFrame.set_index

DataFrame.set_index(keys, drop=True, append=False, inplace=False, verify_integrity=False)
Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

Parameters

keys [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses Series, Index, np.ndarray, and instances of Iterator.

drop [bool, default True] Delete columns to be used as the new index.

append [bool, default False] Whether to append columns to existing index.
**inplace** [bool, default False] If True, modifies the DataFrame in place (do not create a new object).

**verify_integrity** [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

**Returns**

DataFrame or None  Changed row labels or None if `inplace=True`.

**See also:**

`DataFrame.reset_index` Opposite of `set_index`.

`DataFrame.reindex` Change to new indices or expand indices.

`DataFrame.reindex_like` Change to same indices as other DataFrame.

**Examples**

```python
>>> df = pd.DataFrame({
    'month': [1, 4, 7, 10],
    'sale': [55, 40, 84, 31]
})
```

Set the index to become the ‘month’ column:

```python
>>> df.set_index('month')
   year sale
month
  1  2012  55
  4  2014  40
  7  2013  84
 10  2014  31
```

Create a MultiIndex using columns ‘year’ and ‘month’:

```python
>>> df.set_index(['year', 'month'])
   sale
year month
2012 1 55
2014 4 40
2013 7 84
2014 10 31
```

Create a MultiIndex using an Index and a column:

```python
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
   month sale
year
  1  2012  55
  2  2014  40
```

(continues on next page)
Create a MultiIndex using two Series:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
    month  year  sale
1      1  1 2012   55
2      4  4 2014   40
3      9  7 2013   84
4     16 10 2014   31
```

**pandas.DataFrame.shift**

```python
DataFrame.shift(periods=1, freq=None, axis=0, fill_value=<object object>)
```

Shift index by desired number of periods with an optional time freq.

When `freq` is not passed, shift the index without realigning the data. If `freq` is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the `freq`. `freq` can be inferred when specified as “infer” as long as either freq or inferred_freq attribute is set in the index.

**Parameters**

- **periods** [int] Number of periods to shift. Can be positive or negative.
- **freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If `freq` is specified then the index values are shifted but the data is not realigned. That is, use `freq` if you would like to extend the index when shifting and preserve the original data. If `freq` is specified as “infer” then it will be inferred from the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.
- **fill_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of `self`. For numeric data, np.nan is used. For datetime, timedelta, or period data, etc. NaT is used. For extension dtypes, `self.dtype.na_value` is used.

**Returns**

`DataFrame` Copy of input object, shifted.

**See also:**

- `Index.shift` Shift values of Index.
- `DatetimeIndex.shift` Shift values of DatetimeIndex.
- `PeriodIndex.shift` Shift values of PeriodIndex.
- `tshift` Shift the time index, using the index’s frequency if available.
Examples

```python
>>> df = pd.DataFrame({
    "Col1": [10, 20, 15, 30, 45],
    "Col2": [13, 23, 18, 33, 48],
    "Col3": [17, 27, 22, 37, 52],
},
index=pd.date_range("2020-01-01", "2020-01-05")
)

>>> df
       Col1  Col2  Col3
2020-01-01   10    13   17
2020-01-02   20    23   27

```
**pandas.DataFrame.skew**

DataFrame.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased skew over requested axis.

Normalized by N-1.

**Parameters**

- **axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**pandas.DataFrame.slice_shift**

DataFrame.slice_shift(periods=1, axis=0)

Equivalent to shift without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: slice_shift is deprecated, use DataFrame/Series.shift instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.

**Returns**

shifted [same type as caller]

**Notes**

While the slice_shift is faster than shift, you may pay for it later during alignment.

**pandas.DataFrame.sort_index**

DataFrame.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)

Sort object by labels (along an axis).

Returns a new DataFrame sorted by label if inplace argument is False, otherwise updates the original DataFrame and returns None.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.
level [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).

ascending [bool or list of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.

inplace [bool, default False] If True, perform operation in-place.

kind [{‘quicksort’, ‘mergesort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See also ndarray.np.sort for more information. mergesort is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if first; last puts NaNs at the end. Not implemented for MultiIndex.

sort_remaining [bool, default True] If True and sorting by level and index is multi-level, sort by other levels too (in order) after sorting by specified level.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape. For MultiIndex inputs, the key is applied per level.

New in version 1.1.0.

Returns

DataFrame or None The original DataFrame sorted by the labels or None if inplace=True.

See also:

Series.sort_index Sort Series by the index.

DataFrame.sort_values Sort DataFrame by the value.

Series.sort_values Sort Series by the value.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3, 4], [5, 6, 7, 8]], columns=['A', 'B'])
>>> df.sort_index()
A
1  4
29  2
100  1
150  5
234  3
```

By default, it sorts in ascending order, to sort in descending order, use ascending=False
A key function can be specified which is applied to the index before sorting. For a MultiIndex this is applied to each level separately.

```python
def = pd.DataFrame({"a": [1, 2, 3, 4]}, index=["A", "B", "C", "D"])
def.sort_index(key=lambda x: x.str.lower())
```

### pandas.DataFrame.sort_values

DataFrame.sort_values(by, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False, key=None)

Sort by the values along either axis.

**Parameters**

- **by** [str or list of str] Name or list of names to sort by.
  - if `axis` is 0 or ‘index’ then `by` may contain index levels and/or column labels.
  - if `axis` is 1 or ‘columns’ then `by` may contain column levels and/or index labels.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to be sorted.
- **ascending** [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the by.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See also ndarray.np.sort for more information. mergesort is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if first; last puts NaNs at the end.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
  - New in version 1.0.0.
- **key** [callable, optional] Apply the key function to the values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect a Series and return a Series with the same shape as the input. It will be applied to each column in `by` independently.
New in version 1.1.0.

Returns

DataFrame or None  DataFrame with sorted values or None if inplace=True.

See also:

DataFrame.sort_index  Sort a DataFrame by the index.
Series.sort_values  Similar method for a Series.

Examples

```python
>>> df = pd.DataFrame({
  ... 'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
  ... 'col2': [2, 1, 9, 8, 7, 4],
  ... 'col3': [0, 1, 9, 4, 2, 3],
  ... 'col4': ['a', 'B', 'c', 'D', 'e', 'F']
  ... })
>>> df
   col1  col2  col3  col4
0    A     2     0   a
1    A     1     1   B
2    B     9     9   c
3  NaN     8     4   D
4    D     7     2   e
5    C     4     3   F

Sort by col1
```

```python
>>> df.sort_values(by=['col1'])
   col1  col2  col3  col4
0    A     2     0   a
1    A     1     1   B
2    B     9     9   c
3  NaN     8     4   D
4    D     7     2   e
5    C     4     3   F
```

Sort by multiple columns

```python
>>> df.sort_values(by=['col1', 'col2'])
   col1  col2  col3  col4
1    A     1     1   B
0    A     2     0   a
2    B     9     9   c
5    C     4     3   F
4    D     7     2   e
3  NaN     8     4   D
```

Sort Descending

```python
>>> df.sort_values(by='col1', ascending=False)
   col1  col2  col3  col4
4    D     7     2   e
5    C     4     3   F
2    B     9     9   c
```

(continues on next page)
Putting NAs first

```python
>>> df.sort_values(by='col1', ascending=False, na_position='first')
col1  col2  col3  col4
3  NaN  8  4  D
4   D  7  2  e
5   C  4  3  F
2   B  9  9  c
0   A  2  0  a
1   A  1  1  B
```

Sorting with a key function

```python
>>> df.sort_values(by='col4', key=lambda col: col.str.lower())
col1  col2  col3  col4
0   A   2  0   a
1   A  1  1  B
2   B  9  9  c
3  NaN  8  4  D
4   D  7  2  e
5   C  4  3  F
```

Natural sort with the key argument, using the natsort <https://github.com/SethMMorton/natsort> package.

```python
>>> df = pd.DataFrame({
...     "time": ['0hr', '128hr', '72hr', '48hr', '96hr'],
...     "value": [10, 20, 30, 40, 50]
... })
>>> from natsort import index_natsorted
>>> df.sort_values(
...     by="time",
...     key=lambda x: np.argsort(index_natsorted(df["time"]))
... )
time  value
0  0hr   10
1  128hr  20
2  72hr   30
3  48hr   40
4  96hr   50
```
**pandas.DataFrame.sparse**

DataFrame.sparse()

DataFrame accessor for sparse data.

New in version 0.25.0.

**pandas.DataFrame.squeeze**

DataFrame.squeeze(axis=None)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call `squeeze` to ensure you have a Series.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] A specific axis to squeeze.
  By default, all length-1 axes are squeezed.

**Returns**

DataFrame, Series, or scalar The projection after squeezing axis or all the axes.

**See also:**

Series.iloc Integer-location based indexing for selecting scalars.

DataFrame.iloc Integer-location based indexing for selecting Series.

Series.to_frame Inverse of DataFrame.squeeze for a single-column DataFrame.

**Examples**

```python
>>> primes = pd.Series([2, 3, 5, 7])

Slicing might produce a Series with a single value:

```python
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0 2
```

dtype: int64

```python
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```python
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1 3
2 5
3 7
```

dtype: int64
Squeezing is even more effective when used with DataFrames.

```python
def = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
def
  a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
def_a = df[['a']]
def_a
  a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```python
def_a.squeeze('columns')
  0  1
  1  3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```python
def_0a = df.loc[df.index < 1, ['a']]
def_0a
  a
0  1
```

Squeezing the rows produces a single scalar Series:

```python
def_0a.squeeze('rows')
a  1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```python
def_0a.squeeze()
1
```
pandas.DataFrame.stack

DataFrame.stack(level=-1, dropna=True)

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

Parameters

- level [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.
- dropna [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

Returns

- DataFrame or Series Stacked dataframe or series.

See also:

- DataFrame.unstack Unstack prescribed level(s) from index axis onto column axis.
- DataFrame.pivot Reshape dataframe from long format to wide format.
- DataFrame.pivot_table Create a spreadsheet-style pivot table as a DataFrame.

Notes

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

Examples

Single level columns

```python
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
...                                    index=['cat', 'dog'],
...                                    columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```python
>>> df_single_level_cols
weight  height
  cat: 0  1
  dog: 2  3
```

```python
>>> df_single_level_cols.stack()
```

(continues on next page)
cat     weight  0
         height  1
dog     weight  2
         height  3
dtype: int64

Multi level columns: simple case

```python
>>> multicoll = pd.MultiIndex.from_tuples([
    ('weight', 'kg'),
    ('weight', 'pounds')
])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
                                       index=['cat', 'dog'],
                                       columns=multicoll)
```

Stacking a dataframe with a multi-level column axis:

```python
>>> df_multi_level_cols1
weight
kg  pounds
cat  1  2
dog  2  4
```

```python
>>> df_multi_level_cols1.stack()
height weight
kg    NaN  1.0
      NaN  2.0
pounds    2    NaN
```

Missing values

```python
>>> multicol2 = pd.MultiIndex.from_tuples([
    ('weight', 'kg'),
    ('height', 'm')
])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
                                       index=['cat', 'dog'],
                                       columns=multicol2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```python
>>> df_multi_level_cols2
weight height
kg     m
cat  1.0  2.0
dog  3.0  4.0
```

```python
>>> df_multi_level_cols2.stack()
height weight
kg   NaN  1.0
     NaN  2.0
m   2.0   NaN
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```python
>>> df_multi_level_cols2.stack(0)
kg     m
  cat  NaN
  NaN  1.0
```

(continues on next page)
cat height NaN 2.0
    weight 1.0 NaN
dog height NaN 4.0
    weight 3.0 NaN

>>> df_multi_level_cols2.stack([0, 1])
cat height m 2.0
    weight kg 1.0
dog height m 4.0
    weight kg 3.0
dtype: float64

Dropping missing values

>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
           index=['cat', 'dog'],
           columns=multicol2)

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the dropna keyword parameter:

>>> df_multi_level_cols3
weight height
    kg m
cat NaN 1.0
dog 2.0 3.0

>>> df_multi_level_cols3.stack(dropna=False)
height weight
    cat kg NaN NaN
         m 1.0 NaN
    dog kg NaN 2.0
         m 3.0 NaN

>>> df_multi_level_cols3.stack(dropna=True)
height weight
    cat m 1.0 NaN
dog kg NaN 2.0
         m 3.0 NaN

pandas.DataFrame.std

DataFrame.std (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [[index (0), columns (1)]]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

Notes

To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)

pandas.DataFrame.sub

DataFrame.sub (other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator sub).

Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rsub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    'index': ['circle', 'triangle', 'rectangle']})
>>> df
   angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361

```python
>>> df.add(1)
   angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle  0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0

```python
>>> df.rdiv(10)
   angles  degrees
circle  inf     0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1      358
triangle    2      178
rectangle   3      358

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1      358
triangle    2      178
rectangle   3      358
```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 359</td>
</tr>
<tr>
<td>triangle</td>
<td>2 179</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 359</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])

<table>
<thead>
<tr>
<th>angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
</tr>
<tr>
<td>triangle</td>
</tr>
<tr>
<td>rectangle</td>
</tr>
</tbody>
</table>

>>> df + other

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>NaN</td>
</tr>
<tr>
<td>rectangle</td>
<td>NaN</td>
</tr>
</tbody>
</table>

>>> df.mul(other, fill_value=0)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.0</td>
</tr>

pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DataFrame.subtract

DataFrame.subtract(other, axis='columns', level=None, fill_value=None)
Get Subtraction of dataframe and other, element-wise (binary operator sub).

Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rsub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360],
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
      angles  degrees
    circle     0      360
    triangle    3      180
   rectangle    4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
      angles  degrees
    circle     1      361
    triangle    4      181
   rectangle    5      361
```

```python
>>> df.add(1)
      angles  degrees
    circle     1      361
    triangle    4      181
   rectangle    5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
      angles  degrees
    circle    0.0      36.0
    triangle  0.3      18.0
   rectangle  0.4      36.0
```

```python
>>> df.rdiv(10)
      angles    degrees
    circle      inf  0.027778
    triangle  3.333333  0.055556
   rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
      angles  degrees
    circle    -1      358
    triangle     2      178
   rectangle     3      358
```

```python
>>> df.sub([1, 2], axis='columns')
      angles  degrees
    circle    -1      358
    triangle     2      178
   rectangle     3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
      angles  degrees
    circle    -1      358
    triangle     2      178
   rectangle     3      358
```

(continues on next page)

3.4. DataFrame
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
... index=['circle', 'triangle', 'rectangle'])
>>> other
   angles
circle  0
triangle 3
rectangle 4
```

```python
>>> df * other
   angles  degrees
circle  0   NaN
triangle 9   NaN
rectangle 16  NaN
```

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
circle  0    0.0
triangle 9    0.0
rectangle 16   0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
... 'degrees': [360, 180, 360, 360, 540, 720],
... index=['A', 'A', 'A', 'B', 'B', 'B'],
... ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
>>> df_multindex
   angles  degrees
A circle  0    360
   triangle 3    180
   rectangle 4    360
B square  4    360
   pentagon  5    540
   hexagon  6    720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A circle  NaN    1.0
   triangle 1.0    1.0
   rectangle 1.0    1.0
B square  0.0    0.0
   pentagon  0.0    0.0
   hexagon  0.0    0.0
```
pandas.DataFrame.sum

DataFrame.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the sum of the values over the requested axis.

This is equivalent to the method numpy.sum.

Parameters

axis [(index (0), columns (1))] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```python
>>> idx = pd.MultiIndex.from_arrays(
...     [['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded   animal
warm      dog      4
```

(continues on next page)
Sum using level names, as well as indices.

>>> s.sum(level='blooded')
blooded
<table>
<thead>
<tr>
<th>warm</th>
<th>cold</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>8</td>
</tr>
</tbody>
</table>
Name: legs, dtype: int64

>>> s.sum(level=0)
blooded
<table>
<thead>
<tr>
<th>warm</th>
<th>cold</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>8</td>
</tr>
</tbody>
</table>
Name: legs, dtype: int64

By default, the sum of an empty or all-NA Series is 0.

>>> pd.Series([]).sum()  # min_count=0 is the default
0.0

This can be controlled with the `min_count` parameter. For example, if you’d like the sum of an empty series to be NaN, pass `min_count=1`.

>>> pd.Series([]).sum(min_count=1)
nan

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

>>> pd.Series([np.nan]).sum()
0.0

>>> pd.Series([np.nan]).sum(min_count=1)
nan

**pandas.DataFrame.swapaxes**

`DataFrame.swapaxes(axis1, axis2, copy=True)`

Interchange axes and swap values axes appropriately.

**Returns**

- `y` [same as input]
**pandas.DataFrame.swaplevel**

`DataFrame.swaplevel(i=-2, j=-1, axis=0)`  
Swap levels i and j in a MultiIndex on a particular axis.

**Parameters**

- `i, j` [int or str] Levels of the indices to be swapped. Can pass level name as string.
- `axis` [(0 or ‘index’, 1 or ‘columns’), default 0] The axis to swap levels on. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

**Returns**

- `DataFrame`

---

**pandas.DataFrame.tail**

`DataFrame.tail(n=5)`  
Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of n, this function returns all rows except the first n rows, equivalent to `df[n:]`.

**Parameters**

- `n` [int, default 5] Number of rows to select.

**Returns**

- `DataFrame` The last n rows of the caller object.

**See also:**

*DataFrame.head* The first n rows of the caller object.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
                             'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0   alligator
1     bee
2   falcon
3     lion
4   monkey
5  parrot
6    shark
7   whale
8   zebra
```

Viewing the last 5 lines
>>> df.tail()
    animal
   4  monkey
   5  parrot
   6  shark
   7  whale
   8  zebra

Viewing the last $n$ lines (three in this case)

```python
>>> df.tail(3)
    animal
   6  shark
   7  whale
   8  zebra
```

For negative values of $n$

```python
>>> df.tail(-3)
    animal
   3  lion
   4  monkey
   5  parrot
   6  shark
   7  whale
   8  zebra
```

**pandas.DataFrame.take**

`DataFrame.take(indices, axis=0, is_copy=None, **kwargs)`

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- `indices` [array-like] An array of ints indicating which positions to take.
- `axis` [[0 or ‘index’, 1 or ‘columns’, None], default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- `is_copy` [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.
  
  Deprecated since version 1.0.0.
- `**kwargs` For compatibility with `numpy.take()`. Has no effect on the output.

**Returns**

- `taken` [same type as caller] An array-like containing the elements taken from the object.

**See also:**

- `DataFrame.loc` Select a subset of a DataFrame by labels.
- `DataFrame.iloc` Select a subset of a DataFrame by positions.
**numpy.take** Take elements from an array along an axis.

### Examples

```python
def = pd.DataFrame({'name': ['falcon', 'parrot', 'lion', 'monkey'], 'class': ['bird', 'bird', 'mammal', 'mammal'], 'max_speed': [389.0, 24.0, 80.5, np.nan]})
def
```

<table>
<thead>
<tr>
<th>name</th>
<th>class</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>24.0</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
def.take([0, 3])
```

<table>
<thead>
<tr>
<th>name</th>
<th>class</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
def.take([1, 2], axis=1)
```

<table>
<thead>
<tr>
<th>class</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
<td>389.0</td>
</tr>
<tr>
<td>bird</td>
<td>24.0</td>
</tr>
<tr>
<td>mammal</td>
<td>80.5</td>
</tr>
<tr>
<td>mammal</td>
<td>NaN</td>
</tr>
</tbody>
</table>

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
def.take([-1, -2])
```

<table>
<thead>
<tr>
<th>name</th>
<th>class</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.to_clipboard**

`DataFrame.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
• False, write a string representation of the object to the clipboard.

    **kwargs These parameters will be passed to DataFrame.to_csv.

See also:

**DataFrame.to_csv**  Write a DataFrame to a comma-separated values (csv) file.

**read_clipboard**  Read text from clipboard and pass to read_table.

Notes

Requirements for your platform.

• Linux : `xclip`, or `xsel` (with PyQt4 modules)
• Windows : none
• OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])

>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

path_or_buf [str or file handle, default None] File path or object, if None is provided
the result is returned as a string. If a non-binary file object is passed, it should
be opened with newlines=", disabling universal newlines. If a binary file object is
passed, mode might need to contain a ‘b’.

Changed in version 0.24.0: Was previously named “path” for Series.

Changed in version 1.2.0: Support for binary file objects was introduced.

sep [str, default ‘ ‘] String of length 1. Field delimiter for the output file.

na_rep [str, default ‘ ‘] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings
is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s)
if desired. If None is given, and header and index are True, then the index names
are used. A sequence should be given if the object uses MultiIndex. If False do not
print fields for index names. Use index_label=False for easier importing in R.

mode [str] Python write mode, default ‘w’.

encoding [str, optional] A string representing the encoding to use in the output file,
defaults to ‘utf-8’. encoding is not supported if path_or_buf is a non-binary file
object.

compression [str or dict, default ‘infer’] If str, represents compression mode. If dict,
value at ‘method’ is the compression mode. Compression mode may be any of the
following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compres-
sion mode is ‘infer’ and path_or_buf is path-like, then detect compression mode
from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compres-
sion). If dict given and mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of
the above, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key ‘method’ as compression
mode and other entries as additional compression options if compression mode is
‘zip’.

Changed in version 1.1.0: Passing compression options as keys in dict is supported
for compression modes ‘gzip’ and ‘bz2’ as well as ‘zip’.

Changed in version 1.2.0: Compression is supported for binary file objects.

Changed in version 1.2.0: Previous versions forwarded dict entries for ‘gzip’ to
gzip.open instead of gzip.GzipFile which prevented setting mtime.

quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL.
If you have set a float_format then floats are converted to strings and thus
csv.QUOTE_NONNUMERIC will treat them as non-numeric.

quotechar [str, default ‘ ‘] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in
the output file. Defaults to os.linesep, which depends on the OS in which this
method is called (‘n’ for linux, ‘rn’ for Windows, i.e.).
Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.
date_format [str, default None] Format string for datetime objects.
doublequote [bool, default True] Control quoting of quotechar inside a field.
escapechar [str, default None] String of length 1. Character used to escape sep and quotechar when appropriate.
decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.
errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.
to_excel Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
... 'mask': ['red', 'purple'],
... 'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff
'
Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
... archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
... compression=compression_opts)
```
DataFrame.to_dict

DataFrame.to_dict(orient='dict', into=<class 'dict'>)
Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

Parameters

orient [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.

- 'dict' (default) : dict like {column -> {index -> value}}
- 'list' : dict like {column -> [values]}
- 'series' : dict like {column -> Series(values)}
- 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}

Abbreviations are allowed. s indicates series and sp indicates split.

into [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

dict, list or collections.abc.Mapping Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the orient parameter.

See also:

DataFrame.from_dict Create a DataFrame from a dictionary.
DataFrame.to_json Convert a DataFrame to JSON format.

Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2],
...                     'col2': [0.5, 0.75]},
...                    index=['row1', 'row2'])
>>> df
coll  col2
row1   1 0.50
row2   2 0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}
```

You can specify the return orientation.

```python
>>> df.to_dict('series')
{'col1': row1 1
 row2 2
Name: coll, dtype: int64,
```
You can also specify the mapping type.

```python
>>> from collections import OrderedDict, defaultdict
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```

### pandas.DataFrame.to_excel

`DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None, storage_options=None)`

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique `sheet_name`. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

**Parameters**

- `excel_writer` [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- `sheet_name` [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- `na_rep` [str, default ‘’] Missing data representation.
- `float_format` [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

Deprecation since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.
Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([["a", "b"], ["c", "d"]],
    index=["row 1", "row 2"],
    columns=["col 1", "col 2"])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
    sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet_name_1')
    df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx',
    mode='a') as writer:
    df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.DataFrame.to_feather

DataFrame.to_feather(path, **kwargs)

Write a DataFrame to the binary Feather format.

Parameters

- `path` [str or file-like object] If a string, it will be used as Root Directory path.
- `**kwargs` Additional keywords passed to pyarrow.feather.write_feather(). Starting with pyarrow 0.17, this includes the `compression`, `compression_level`, `chunksize` and `version` keywords.

New in version 1.1.0.
### pandas.DataFrame.to_gbq

```python
DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None)
```

Write a DataFrame to a Google BigQuery table.

This function requires the pandas-gbq package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

#### Parameters

- **destination_table** [str] Name of table to be written, in the form `dataset.tablename`.
- **project_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.
- **chunksize** [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to `None` to load the whole dataframe at once.
- **reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.
- **if_exists** [str, default 'fail'] Behavior when the destination table exists. Value can be one of:
  - `'fail'` If table exists raise `pandas_gbq.gbq.TableCreationError`.
  - `'replace'` If table exists, drop it, recreate it, and insert data.
  - `'append'` If table exists, insert data. Create if does not exist.
- **auth_local_webserver** [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.
  
  *New in version 0.2.0 of pandas-gbq.*

- **table_schema** [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. `[{‘name’: ‘col1’, ‘type’: ‘STRING’},...]`. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.
  
  *New in version 0.3.1 of pandas-gbq.*

- **location** [str, optional] Location where the load job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of the target dataset.
  
  *New in version 0.5.0 of pandas-gbq.*

- **progress_bar** [bool, default True] Use the library `tqdm` to show the progress bar for the upload, chunk by chunk.
  
  *New in version 0.5.0 of pandas-gbq.*

- **credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.
  
  *New in version 0.5.0 of pandas-gbq.*
New in version 0.8.0 of pandas-gbq.

New in version 0.24.0.

See also:

pandas_gbq.to_gbq This function in the pandas-gbq library.
read_gbq Read a DataFrame from Google BigQuery.

pandas.DataFrame.to_hdf

DataFrame.to_hdf(path_or_buf, key, mode='a', complib=None, complevel=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, data_columns=None, errors='strict', encoding='UTF-8')

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.

For more information see the user guide.

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.
key [str] Identifier for the group in the store.
mode [{‘a’, ‘w’, ‘r+’}, default ‘a’] Mode to open file:

• ‘w’: write, a new file is created (an existing file with the same name would be deleted).
• ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
• ‘r+’: similar to ‘a’, but the file must already exist.
complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.
append [bool, default False] For Table formats, append the input data to the existing.
format [{‘fixed’, ‘table’, None}, default ‘fixed’] Possible values:

• ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
• If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”
**errors** [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

**encoding** [str, default “UTF-8”]

**min_itemsize** [dict or int, optional] Map column names to minimum string sizes for columns.

**nan_rep** [Any, optional] How to represent null values as str. Not allowed with append=True.

**data_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via data columns*. Applicable only to format='table'.

See also:

*DataFrame.read_hdf* Read from HDF file.

*DataFrame.to_parquet* Write a DataFrame to the binary parquet format.

*DataFrame.to_sql* Write to a sql table.

*DataFrame.to_feather* Write out feather-format for DataFrames.

*DataFrame.to_csv* Write out to a csv file.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A  B
a 1 4
b 2 5
c 3 6
>>> pd.read_hdf('data.h5', 's')
0 1
1 2
2 3
3 4
```

Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```
pandas.DataFrame.to_html

```
pandas.DataFrame.to_html(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, max_cols=None, show_dimensions=False, decimal='.', bold_rows=True, classes=None, render_links=False, encoding=None)
```

Render a DataFrame as an HTML table.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.
- **col_space** [str or int, list or dict of int or str, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.
  New in version 0.25.0: Ability to use str.
- **header** [bool, optional] Whether to print column labels, default True.
- **index** [bool, optional, default True] Whether to print index (row) labels.
- **na_rep** [str, optional, default ‘NaN’] String representation of NaN to use.
- **formatters** [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.
- **float_format** [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by na_rep.
  Changed in version 1.2.0.
- **sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.
- **index_names** [bool, optional, default True] Prints the names of the indexes.
- **justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are
  - left
  - right
  - center
  - justify
  - justify-all
  - start
  - end
  - inherit
• match-parent
• initial
• unset.

**max_rows** [int, optional] Maximum number of rows to display in the console.

**min_rows** [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above **max_rows**).

**max_cols** [int, optional] Maximum number of columns to display in the console.

**show_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal** [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

**bold_rows** [bool, default True] Make the row labels bold in the output.

**classes** [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

**escape** [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

**notebook** [{True, False}, default False] Whether the generated HTML is for IPython Notebook.

**border** [int] A border=border attribute is included in the opening <table> tag. Default `pd.options.display.html.border`.

**encoding** [str, default “utf-8”] Set character encoding.

New in version 1.0.

**table_id** [str, optional] A css id is included in the opening <table> tag if specified.

**render_links** [bool, default False] Convert URLs to HTML links.

New in version 0.24.0.

**Returns**

*str* or *None* If buf is None, returns the result as a string. Otherwise returns None.

**See also:**

to_string Convert DataFrame to a string.

pandas.DataFrame.to_json

DataFrame.to_json(*path_or_buf=None*, *orient=None*, *date_format=None*, *double_precision=10*, *force_ascii=True*, *date_unit='ms'*, *default_handler=None*, *lines=False*, *compression='infer'*, *index=True*, *indent=None*, *storage_options=None*)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

**Parameters**

*path_or_buf* [str or file handle, optional] File path or object. If not specified, the result is returned as a string.
**orient** [str] Indication of expected JSON string format.

- Series:
  - default is ‘index’
  - allowed values are: {'split', 'records', 'index', 'table'}.
- DataFrame:
  - default is ‘columns’
  - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.
- The format of the JSON string:
  - ‘split’: dict like {'index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
  - ‘records’: list like [{column -> value}, . . . , {column -> value}]
  - ‘index’: dict like {index -> {column -> value}}
  - ‘columns’: dict like {column -> {index -> value}}
  - ‘values’: just the values array
  - ‘table’: dict like {‘schema’: {schema}, ‘data’: {data}}

Describing the data, where data component is like orient='records'.

**date_format** [[None, ‘epoch’, ‘iso’]] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.

**double_precision** [int, default 10] The number of decimal places to use when encoding floating point values.

**force_ascii** [bool, default True] Force encoded string to be ASCII.

**date_unit** [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

**default_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

**compression** [{'infer', 'gzip', 'bz2', 'zip', ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

Changed in version 0.24.0: ‘infer’ option added and set to default

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

**indent** [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.
**storage_options**  [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

**Returns**

None or str  If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

**See also:**

**read_json**  Convert a JSON string to pandas object.

**Notes**

The behavior of indent=0 varies from the stdlib, which does not indent the output but does insert newlines. Currently, indent=0 and the default indent=None are equivalent in pandas, though this may change in a future release.

orient='table' contains a ‘pandas_version’ field under ‘schema’. This stores the version of pandas used in the latest revision of the schema.

**Examples**

```python
>>> import json
>>> df = pd.DataFrame(
...   [["a", "b"], ["c", "d"],
...    index=["row 1", "row 2"],
...    columns=["col 1", "col 2"],
...  )

>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "columns": [
    "col 1",
    "col 2"
  ],
  "index": [
    "row 1",
    "row 2"
  ],
  "data": [
    ["a", "b"],
    ["c", "d"],
  ]
}
```

(continues on next page)
Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
  {
    "col 1": "a",
    "col 2": "b"
  },
  {
    "col 1": "c",
    "col 2": "d"
  }
]
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "row 1": {
    "col 1": "a",
    "col 2": "b"
  },
  "row 2": {
    "col 1": "c",
    "col 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "col 1": {
    "row 1": "a",
    "row 2": "c"
  },
  "col 2": {
    "row 1": "b",
    "row 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
```
>>> json.dumps(parsed, indent=4)
[
  ["a",
   "b"],
  ["c",
   "d"]
]

Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "schema": {
    "fields": [
      {
        "name": "index",
        "type": "string"
      },
      {
        "name": "col 1",
        "type": "string"
      },
      {
        "name": "col 2",
        "type": "string"
      }
    ],
    "primaryKey": ["index"],
    "pandas_version": "0.20.0"
  },
  "data": [
    {
      "index": "row 1",
      "col 1": "a",
      "col 2": "b"
    },
    {
      "index": "row 2",
      "col 1": "c",
      "col 2": "d"
    }
  ]
}
```
pandas.DataFrame.to_latex

DataFrame.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None)

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires \usepackage{booktabs}. The output can be copy/pasted into a main LaTeX document or read from an external file with \input{table.tex}.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

Parameters

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- **col_space** [int, optional] The minimum width of each column.
- **header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **na_rep** [str, default ‘NaN’] Missing data representation.
- **formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.
- **float_format** [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example float_format="%.2f" and float_format="{:0.2f}".format will both result in 0.1234 being formatted as 0.12.
- **sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.
- **index_names** [bool, default True] Prints the names of the indexes.
- **bold_rows** [bool, default False] Make the row labels bold in the output.
- **column_format** [str, optional] The columns format as specified in LaTeX table format e.g. ’crl’ for 3 columns. By default, ’l’ will be used for all columns except columns of numbers, which default to ’r’.
- **longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.
- **escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.
encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to column_format The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str or tuple, optional] Tuple (full_caption, short_caption), which results in \caption[short_caption]{full_caption}; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

label [str, optional] The LaTeX label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

New in version 1.0.0.

position [str, optional] The LaTeX positional argument for tables, to be placed after \begin{} in the output.

New in version 1.2.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

DataFrame.to_html Render a DataFrame as an HTML table.

Examples

```python
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
                        mask=['red', 'purple'],
                        weapon=['sai', 'bo staff']))
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DataFrame.to_markdown

`DataFrame.to_markdown(buf=None, mode='wt', index=True, storage_options=None, **kwargs)`

Print DataFrame in Markdown-friendly format.

New in version 1.0.0.

**Parameters**

- `buf` [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- `mode` [str, optional] Mode in which file is opened, “wt” by default.
- `index` [bool, optional, default True] Add index (row) labels.
  
  New in version 1.1.0.
- `storage_options` [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by `fsspec`, e.g., starting “s3://”, “gs://”. An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values.
  
  New in version 1.2.0.
- `**kwargs` These parameters will be passed to `tabulate`.

**Returns**

- `str` DataFrame in Markdown-friendly format.

**Notes**

Requires the `tabulate` package.

**Examples**

```python
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
</tr>
<tr>
<td>1</td>
<td>pig</td>
</tr>
<tr>
<td>2</td>
<td>dog</td>
</tr>
<tr>
<td>3</td>
<td>quetzal</td>
</tr>
</tbody>
</table>
```

Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt="grid"))
+--------+----------+
|       | animal   |
+--------+----------+
| 0      | elk      |
+--------+----------+
| 1      | pig      |
+--------+----------+
| 2      | dog      |
+--------+----------+
```

(continues on next page)
pandas.DataFrame.to_numpy

DataFrame.to_numpy (dtype=None, copy=False, na_value=None)
Convert the DataFrame to a NumPy array.

New in version 0.24.0.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are float16 and float32, the results dtype will be float32. This may require copying data and coercing values, which may be expensive.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.
na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the dtypes of the DataFrame columns.

New in version 1.1.0.

Returns

numpy.ndarray

See also:

Series.to_numpy Similar method for Series.

Examples

```python
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```
With heterogeneous data, the lowest common type will have to be used.

```python
>>> df = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
>>> df.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```
For a mix of numeric and non-numeric types, the output array will have object dtype.

```python
>>> df['C'] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```
pandas.DataFrame.to_parquet

DataFrame.to_parquet(path=None, engine='auto', compression='snappy', index=None, partition_cols=None, storage_options=None, **kwargs)

Write a DataFrame to the binary parquet format.

This function writes the dataframe as a parquet file. You can choose different parquet backends, and have the option of compression. See the user guide for more details.

Parameters

- **path** [str or file-like object, default None] If a string, it will be used as Root Directory path when writing a partitioned dataset. By file-like object, we refer to objects with a write() method, such as a file handle (e.g. via builtin open function) or io.BytesIO. The engine fastparquet does not accept file-like objects. If path is None, a bytes object is returned.
  
  Changed in version 1.2.0.
  
  Previously this was “fname”

- **engine** [{'auto', 'pyarrow', 'fastparquet'}, default 'auto'] Parquet library to use. If ‘auto’, then the option io.parquet.engine is used. The default io.parquet.engine behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

- **compression** [{'snappy', 'gzip', 'brotli', None}, default 'snappy'] Name of the compression to use. Use None for no compression.

- **index** [bool, default None] If True, include the dataframe’s index(es) in the file output. If False, they will not be written to the file. If None, similar to True the dataframe’s index(es) will be saved. However, instead of being saved as values, the RangeIndex will be stored as a range in the metadata so it doesn’t require much space and is faster. Other indexes will be included as columns in the file output.

  New in version 0.24.0.

- **partition_cols** [list, optional, default None] Column names by which to partition the dataset. Columns are partitioned in the order they are given. Must be None if path is not a string.

  New in version 0.24.0.

- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting "s3://", "gcs://". An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

  New in version 1.2.0.

- ****kwargs Additional arguments passed to the parquet library. See pandas io for more details.

Returns

bytes if no path argument is provided else None

See also:

- read_parquet Read a parquet file.
- DataFrame.to_csv Write a csv file.
**DataFrame.to_sql**  Write to a sql table.

**DataFrame.to_hdf**  Write to hdf.

**Notes**

This function requires either the fastparquet or pyarrow library.

**Examples**

```python
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip',
...    compression='gzip')
>>> pd.read_parquet('df.parquet.gzip')
   col1  col2
0     1     3
1     2     4
```

If you want to get a buffer to the parquet content you can use a io.BytesIO object, as long as you don’t use partition_cols, which creates multiple files.

```python
>>> import io
>>> f = io.BytesIO()
>>> df.to_parquet(f)
>>> f.seek(0)
0
>>> content = f.read()
```

**pandas.DataFrame.to_period**

DataFrame.to_period(freq=None, axis=0, copy=True)

Convert DataFrame from DatetimeIndex to PeriodIndex.

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

**Parameters**

- freq [str, default] Frequency of the PeriodIndex.
- axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to convert (the index by default).
- copy [bool, default True] If False then underlying input data is not copied.

**Returns**

DataFrame with PeriodIndex
pandas.DataFrame.to_pickle

DataFrame.to_pickle (path, compression='infer', protocol=5, storage_options=None)
Pickle (serialize) object to file.

Parameters

- **path** [str] File path where the pickled object will be stored.
- **compression** [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and path_or_buf is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’ (otherwise no compression). If dict given and mode is ‘zip’ or inferred as ‘zip’, other entries passed as additional compression options.
- **protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values. New in version 1.2.0.

See also:

- **read_pickle** Load pickled pandas object (or any object) from file.
- **DataFrame.to_hdf** Write DataFrame to an HDF5 file.
- **DataFrame.to_sql** Write DataFrame to a SQL database.
- **DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

Examples

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
```

(continues on next page)
>>> import os
>>> os.remove("./dummy.pkl")

pandas.DataFrame.to_records

DataFrame.to_records(index=True, column_dtypes=None, index_dtypes=None)
Convert DataFrame to a NumPy record array.
Index will be included as the first field of the record array if requested.

Parameters

index [bool, default True] Include index in resulting record array, stored in ‘index’ field
or using the index label, if set.

column_dtypes [str, type, dict, default None] New in version 0.24.0.
If a string or type, the data type to store all columns. If a dictionary, a mapping of
column names and indices (zero-indexed) to specific data types.

index_dtypes [str, type, dict, default None] New in version 0.24.0.
If a string or type, the data type to store all index levels. If a dictionary, a mapping
of index level names and indices (zero-indexed) to specific data types.
This mapping is applied only if index=True.

Returns

numpy.recarray NumPy ndarray with the DataFrame labels as fields and each row of
the DataFrame as entries.

See also:

DataFrame.from_records Convert structured or record ndarray to DataFrame.
numpy.recarray An ndarray that allows field access using attributes, analogous to typed columns in
a spreadsheet.

Examples

>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
                   index=['a', 'b'])
>>> df
   A  B
a  1 0.5
b  2 0.75
>>> df.to_records()
rec.array([(a', 1, 0.5 ), ('b', 2, 0.75)],
dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])

If the DataFrame index has no label then the recarray field name is set to ‘index’. If the index has a label
then this is used as the field name:
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8')])

The index can be excluded from the record array:

>>> df.to_records(index=False)
rec.array([(1, 0.5 ), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])

Data types can be specified for the columns:

>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8')])

As well as for the index:

>>> df.to_records(index_dtypes="<S2")
rec.array([(b'b\'a', 1, 0.5 ), (b'b\'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])

>>> index_dtypes = f"<S/df.index.str.len().max()"
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'b\'a', 1, 0.5 ), (b'b\'b', 2, 0.75)],
          dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])

pandas.DataFrame.to_sql

DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [str] Name of SQL table.

con [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable. See here.

schema [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.

if_exists [[‘fail’, ‘replace’, ‘append’], default ‘fail’] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.
index [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.

index_label [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

cunksize [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

dtype [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

method [{None, ‘multi’, callable}, optional] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- ‘multi’: Pass multiple values in a single INSERT clause.
- callable with signature (pd_table, conn, keys, data_iter).

Details and a sample callable implementation can be found in the section insert method.

New in version 0.24.0.

Raises

ValueError When the table already exists and if_exists is ‘fail’ (the default).

See also:

read_sql Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as Timestamp with timezone type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite:///\', echo=False)
```

Create a table from scratch with 3 rows.
An `sqlalchemy.engine.Connection` can also be passed to `con`:

```python
>>> with engine.begin() as connection:
...    df1 = pd.DataFrame({'name': ['User 4', 'User 5']})
...    df1.to_sql('users', con=connection, if_exists='append')
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```python
>>> df2 = pd.DataFrame({'name': ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5'), (0, 'User 6'),
 (1, 'User 7')]
```

**Overwrite the table with just df2.**

```python
>>> df2.to_sql('users', con=engine, if_exists='replace',
...            index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(1,), (None,), (2,)]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({'A': [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```python
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...           dtype={'A': Integer()})
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1), (None), (2)]
```
pandas.DataFrame.to_stata

DataFrame.to_stata(path, convert_dates=None, write_index=True, byteorder=None, time_stamp=None, data_label=None, variable_labels=None, version=114, convert_strl=None, compression='infer', storage_options=None)

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

Parameters

path [str, buffer or path object] String, path object (pathlib.Path or py._path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.

Changed in version 1.0.0.

Previously this was “fname”

convert_dates [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises NotImplementedError if a datetime column has timezone information.

write_index [bool] Write the index to Stata dataset.

byteorder [str] Can be “>”, “<”, “little”, or “big”. default is sys.byteorder.

time_stamp [datetime] A datetime to use as file creation date. Default is the current time.

data_label [str, optional] A label for the data set. Must be 80 characters or smaller.

variable_labels [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

version [{114, 117, 118, 119, None}, default 114] Version to use in the output dta file. Set to None to let pandas decide between 118 or 119 formats depending on the number of columns in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata 15 and later. Version 114 limits string variables to 244 characters or fewer while versions 117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119 support Unicode characters, and version 119 supports more than 32,767 variables.

Version 119 should usually only be used when the number of variables exceeds the capacity of dta format 118. Exporting smaller datasets in format 119 may have unintended consequences, and, as of November 2020, Stata SE cannot read version 119 files.

Changed in version 1.0.0: Added support for formats 118 and 119.

convert_strl [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

compression [str or dict, default ‘infer’] For on-the-fly compression of the output dta. If string, specifies compression mode. If dict, value at key ‘method’ specifies compression mode. Compression mode must be one of {'infer', 'gzip', 'bz2', 'zip',

3.4. DataFrame
‘xz’, None). If compression mode is ‘infer’ and `fname` is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression). If dict and compression mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of the above, other entries passed as additional compression options.

New in version 1.1.0.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

**Raises**

**NotImplementedError**

- If datetimes contain timezone information
- Column dtype is not representable in Stata

**ValueError**

- Columns listed in `convert_dates` are neither datetime64[ns] or datetime
- Column listed in `convert_dates` is not in DataFrame
- Categorical label contains more than 32,000 characters

**See also:**

**read_stata** Import Stata data files.

**io.stata.StataWriter** Low-level writer for Stata data files.

**io.stata.StataWriter117** Low-level writer for version 117 files.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',
...                           'parrot'],
...                    'speed': [350, 18, 361, 15]})
>>> df.to_stata('animals.dta')
```

**pandas.DataFrame.to_string**

DataFrame.to_string (**buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, min_rows=None, max_cols=None, show_dimensions=False, decimal='.', line_width=None, max_colwidth=None, encoding=None)**

Render a DataFrame to a console-friendly tabular output.

**Parameters**
buf  [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns  [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

col_space  [int, list or dict of int, optional] The minimum width of each column.

header  [bool or sequence, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index  [bool, optional, default True] Whether to print index (row) labels.

na_rep  [str, optional, default ‘NaN’] String representation of NaN to use.

formatters  [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format  [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by na_rep.

Changed in version 1.2.0.

sparsify  [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names  [bool, optional, default True] Prints the names of the indexes.

justify  [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are

  • left
  • right
  • center
  • justify
  • justify-all
  • start
  • end
  • inherit
  • match-parent
  • initial
  • unset.

max_rows  [int, optional] Maximum number of rows to display in the console.

min_rows  [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above max_rows).

max_cols  [int, optional] Maximum number of columns to display in the console.

show_dimensions  [bool, default False] Display DataFrame dimensions (number of rows by number of columns).
**decimal**  [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

**line_width**  [int, optional] Width to wrap a line in characters.

**max_colwidth**  [int, optional] Max width to truncate each column in characters. By default, no limit.

New in version 1.0.0.

**encoding**  [str, default “utf-8”] Set character encoding.

New in version 1.0.

**Returns**

- str or None  If buf is None, returns the result as a string. Otherwise returns None.

**See also:**

- **to_html**  Convert DataFrame to HTML.

**Examples**

```python
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
coll  col2
0 1 4
1 2 5
2 3 6
```

**pandas.DataFrame.to_timestamp**

DataFrame.to_timestamp( *freq=None, how='start', axis=0, copy=True*)  
Cast to DatetimeIndex of timestamps, at beginning of period.

**Parameters**

- **freq**  [str, default frequency of PeriodIndex] Desired frequency.

- **how**  [{‘s’, ‘e’, ‘start’, ‘end’}] Convention for converting period to timestamp; start of period vs. end.

- **axis**  [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to convert (the index by default).

- **copy**  [bool, default True] If False then underlying input data is not copied.

**Returns**

DataFrame with DatetimeIndex
pandas.DataFrame.to_xarray

DataFrame.to_xarray()
Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to
Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

DataFrame.to_hdf Write DataFrame to an HDF5 file.
DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Notes

See the xarray docs

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...   ('parrot', 'bird', 24.0, 2),
...   ('lion', 'mammal', 80.5, 4),
...   ('monkey', 'mammal', np.nan, 4)],
...   columns=['name', 'class', 'max_speed',
...     'num_legs'])
```
```
name   class  max_speed  num_legs
0   falcon  bird       389.0       2
1  parrot   bird        24.0       2
2    lion  mammal      80.5       4
3  monkey  mammal         NaN       4
```
```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (index: 4)
Coordinates:
  * index (index) int64 0 1 2 3
Data variables:
  name (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed (index) float64 389.0 24.0 80.5 NaN
  num_legs (index) int64 2 2 4 4
```
```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389.,  24.,  80.5,  NaN])
Coordinates:
  * index (index) int64 0 1 2 3
```
```
```
```
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'falcon': ['falcon', 'falcon', np.nan, np.nan]})
```
```
... 'animal': ['falcon', 'parrot'],
... 'falcon', 'parrot'],
... 'speed': [350, 18, 361, 15])

>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])

>>> df_multiindex

speed
date  animal
2018-01-01  falcon  350
       parrot  18
2018-01-02  falcon  361
       parrot  15

>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
* date (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal (animal) object 'falcon' 'parrot'
Data variables:
  speed (date, animal) int64 350 18 361 15

pandas.DataFrame.transform

DataFrame.transform(func, axis=0, *args, **kwargs)

Call func on self producing a DataFrame with transformed values.
Produced DataFrame will have same axis length as self.

Parameters

    func [function, str, list-like or dict-like] Function to use for transforming the data.
    If a function, must either work when passed a DataFrame or when passed to
    DataFrame.apply. If func is both list-like and dict-like, dict-like behavior takes
    precedence.

    axis [{0 or ‘index’, 1 or ‘columns’}, default 0] If 0 or ‘index’: apply function to each
    column. If 1 or ‘columns’: apply function to each row.

    *args Positional arguments to pass to func.

    **kwargs Keyword arguments to pass to func.

Returns

    DataFrame A DataFrame that must have the same length as self.

Raises

    ValueError [If the returned DataFrame has a different length than self.]
See also:

**DataFrame.agg** Only perform aggregating type operations.

**DataFrame.apply** Invoke function on a DataFrame.

### Examples

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0  0
1  1
2  2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
    sqrt         exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

You can call transform on a GroupBy object:

```python
>>> df = pd.DataFrame(
...     "Date": ["2015-05-08", "2015-05-07", "2015-05-06", "2015-05-05"],
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120],
... )
>>> df
     Date  Data
0 2015-05-08    5
1 2015-05-07    8
2 2015-05-06    6
3 2015-05-05    1
4 2015-05-08   50
5 2015-05-07  100
6 2015-05-06   60
7 2015-05-05  120
>>> df.groupby('Date')['Data'].transform('sum')
0   55
1  108
2   66
```

pandas.DataFrame.transpose

DataFrame.transpose(*args, copy=False)

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property $T$ is an accessor to the method transpose().

**Parameters**

*args [tuple, optional] Accepted for compatibility with NumPy.

**copy** [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtypes.

Note that a copy is always required for mixed dtypes DataFrames, or for DataFrames with any extension types.

**Returns**

DataFrame The transposed DataFrame.

**See also:**

numpy.transpose Permute the dimensions of a given array.
Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the object dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```python
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
       col1  col2
0       1    3
1       2    4

>>> df1_transposed = df1.T  # or df1.transpose()
>>> df1_transposed
       0  1
    col1  1  2
    col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```python
>>> df1.dtypes
col1  int64
col2  int64
dtype: object

>>> df1_transposed.dtypes
0  int64
1  int64
dtype: object
```

Non-square DataFrame with mixed dtypes

```python
>>> d2 = {'name': ['Alice', 'Bob'], ... 'score': [9.5, 8], ... 'employed': [False, True], ... 'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score employed kids
0  Alice   9.5      False   0
1    Bob   8.0       True   0

>>> df2_transposed = df2.T  # or df2.transpose()
>>> df2_transposed
       0  1
    name  Alice Bob
    score  9.5  8.0
    employed False True
    kids    0   0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the object dtype:
```python
>>> df2.dtypes
name    object
score  float64
employed  bool
kids  int64
dtype: object
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

### pandas.DataFrame.truediv

DataFrame.truediv(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

```python
>>> df.add(1)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
>>> df.div(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>

```python
>>> df.rdiv(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.5</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

```python
>>> df.sub([1, 2], axis='columns')
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

>>> df * other
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN
```

```
>>> df.mul(other, fill_value=0)
angles degrees
circle 0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720]},
                              index=['A', 'A', 'A', 'B', 'B', 'B'],
                              ['circle', 'triangle', 'rectangle',
                               'square', 'pentagon', 'hexagon'])

>>> df_multindex
angles degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
DataFrame.truncate

Truncate a Series or DataFrame before and after some index value. This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True] Return a copy of the truncated section.

Returns

type of caller  The truncated Series or DataFrame.

See also:

- **DataFrame.loc** Select a subset of a DataFrame by label.
- **DataFrame.iloc** Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, **before** and **after** may be specified as strings instead of Timestamps.

Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
                    'B': ['f', 'g', 'h', 'i', 'j'],
                    'C': ['k', 'l', 'm', 'n', 'o'],
                    index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1 a  f  k
2 b  g  l
3 c  h  m
4 d  i  n
5 e  j  o

>>> df.truncate(before=2, after=4)
   A  B  C
2 b  g  l
3 c  h  m
4 d  i  n
```

The columns of a DataFrame can be truncated.
For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                 A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```python
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
... after=pd.Timestamp('2016-01-10')).tail()
                 A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```
Because the index is a DatetimeIndex containing only dates, we can specify `before` and `after` as strings. They will be coerced to Timestamps before truncation.

```python
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                 A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```
Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```python
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                 A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
```
pandas.DataFrame.tshift

DataFrame.tshift \( (\text{periods}=1, \text{freq}=\text{None}, \text{axis}=0) \)
Shift the time index, using the index’s frequency if available.
Deprecated since version 1.1.0: Use shift instead.

**Parameters**

- **periods** \( \text{[int]} \) Number of periods to move, can be positive or negative.
- **freq** \( \text{[DateOffset, timedelta, or str, default None]} \) Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** \( \{0 \text{ or ‘index’, } 1 \text{ or ‘columns’, None}, \text{default 0}\} \) Corresponds to the axis that contains the Index.

**Returns**

- **shifted** \( \text{[Series/DataFrame]} \)

**Notes**

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.DataFrame.tz_convert

DataFrame.tz_convert \( (\text{tz, axis}=0, \text{level}=\text{None}, \text{copy}=\text{True}) \)
Convert tz-aware axis to target time zone.

**Parameters**

- **tz** \( \text{[str or tzinfo object]} \)
- **axis** \( \text{[the axis to convert]} \)
- **level** \( \text{[int, str, default None]} \) If axis is a MultiIndex, convert a specific level. Otherwise must be None.
- **copy** \( \text{[bool, default True]} \) Also make a copy of the underlying data.

**Returns**

- **{klass}** Object with time zone converted axis.

**Raises**

- **TypeError** If the axis is tz-naive.
Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

**Parameters**

- `tz` [str or tzinfo]
- `axis` [the axis to localize]
- `level` [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None.
- `copy` [bool, default True] Also make a copy of the underlying data.
- `ambiguous` ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - 'infer' will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - 'NaT' will return NaT where there are ambiguous times
  - 'raise' will raise an AmbiguousTimeError if there are ambiguous times.
- `nonexistent` [str, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:
  - 'shift_forward' will shift the nonexistent time forward to the closest existing time
  - 'shift_backward' will shift the nonexistent time backward to the closest existing time
  - 'NaT' will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

- **Series or DataFrame** Same type as the input.

**Raises**

- **TypeError** If the TimeSeries is tz-aware and tz is not None.
Examples

Localize local times:

```python
>>> s = pd.Series([1],
...     index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.Series(range(7),
...     index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...         '2018-10-28 02:00:00',
...         '2018-10-28 02:30:00',
...         '2018-10-28 02:00:00',
...         '2018-10-28 02:30:00',
...         '2018-10-28 03:00:00',
...         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00 0
2018-10-28 02:00:00+02:00 1
2018-10-28 02:30:00+02:00 2
2018-10-28 02:00:00+01:00 3
2018-10-28 02:30:00+01:00 4
2018-10-28 03:00:00+01:00 5
2018-10-28 03:30:00+01:00 6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```python
>>> s = pd.Series(range(3),
...     index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...         '2018-10-28 02:36:00',
...         '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00 0
2018-10-28 02:36:00+02:00 1
2018-10-28 03:46:00+01:00 2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or `shift_forward` or `shift_backward`.

```python
>>> s = pd.Series(range(2),
...     index=pd.DatetimeIndex(['2015-03-29 02:30:00',
...         '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
```

(continues on next page)
pandas.DataFrame.unstack

DataFrame.unstack(level=-1, fill_value=None)
Pivot a level of the (necessarily hierarchical) index labels.

Returns a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex).

Parameters

- **level** [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.
- **fill_value** [int, str or dict] Replace NaN with this value if the unstack produces missing values.

Returns

Series or DataFrame

See also:

DataFrame.pivot  Pivot a table based on column values.

DataFrame.stack  Pivot a level of the column labels (inverse operation from unstack).

Examples

```python
>>> index = pd.MultiIndex.from_tuples([('one', 'a'), ('one', 'b'), ...
   ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one a  1.0
   b  2.0
two a  3.0
   b  4.0
dtype: float64
```

```python
>>> s.unstack(level=-1)
a  b
one 1.0  2.0
two 3.0  4.0
```

```python
>>> s.unstack(level=0)
one two
   a  1.0  3.0
   b  2.0  4.0
```
```python
>>> df = s.unstack(level=0)
>>> df.unstack()
  one  a  1.0  
    b  2.0  
  two  a  3.0  
    b  4.0  
```

### pandas.DataFrame.update

`DataFrame.update(other, join='left', overwrite=True, filter_func=None, errors='ignore')`  
Modify in place using non-NA values from another DataFrame.  
Aligns on indices. There is no return value.

**Parameters**

- **other** [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

- **join** [{‘left’}, default ‘left’] Only left join is implemented, keeping the index and columns of the original object.

- **overwrite** [bool, default True] How to handle non-NA values for overlapping keys:
  - True: overwrite original DataFrame’s values with values from `other`.
  - False: only update values that are NA in the original DataFrame.

- **filter_func** [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

- **errors** [{‘raise’, ‘ignore’}, default ‘ignore’] If ‘raise’, will raise a ValueError if the DataFrame and `other` both contain non-NA data in the same place.  
  Changed in version 0.24.0: Changed from `raise_conflict=False|True` to `errors='ignore'|'raise'`.

**Returns**

None [method directly changes calling object]

**Raises**

- ValueError  
  - When `errors='raise'` and there’s overlapping non-NA data.
  - When `errors` is not either ‘ignore’ or ‘raise’

- NotImplementedError  
  - If `join != 'left'`

**See also:**

- `dict.update`  
  Similar method for dictionaries.

- `DataFrame.merge` For column(s)-on-column(s) operations.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                   'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...                        'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame’s length does not increase as a result of the update, only values at matching index/column labels are updated.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B
0  a  d
1  b  e
2  c  f
```

For Series, its name attribute must be set.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A  B
0  a  d
1  b  y
2  c  e
```

If other contains NaNs the corresponding values are not updated in the original dataframe.

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4.0
1  2  500.0
2  3  6.0
```
DataFrame.value_counts

DataFrame.value_counts (subset=None, normalize=False, sort=True, ascending=False)
Return a Series containing counts of unique rows in the DataFrame.
New in version 1.1.0.

Parameters

- subset [list-like, optional] Columns to use when counting unique combinations.
- normalize [bool, default False] Return proportions rather than frequencies.
- sort [bool, default True] Sort by frequencies.
- ascending [bool, default False] Sort in ascending order.

Returns

Series

See also:

Series.value_counts Equivalent method on Series.

Notes

The returned Series will have a MultiIndex with one level per input column. By default, rows that contain any NA values are omitted from the result. By default, the resulting Series will be in descending order so that the first element is the most frequently-occurring row.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 4, 6],
... 'num_wings': [2, 0, 0, 0]},
... index=['falcon', 'dog', 'cat', 'ant'])
>>> df
       num_legs num_wings
falcon      2        2
dog         4        0
cat         4        0
ant         6        0

>>> df.value_counts()
num_legs  num_wings
4        0          2
2        2          1
6        0          1
dtype: int64

>>> df.value_counts(sort=False)
num_legs  num_wings
2        2          1
4        0          2
6        0          1
dtype: int64
```
```python
>>> df.value_counts(ascending=True)
num_legs  num_wings
2        2        1
6        0        1
4        0        2
dtype: int64

>>> df.value_counts(normalize=True)
num_legs  num_wings
4        0        0.50
2        2        0.25
6        0        0.25
dtype: float64
```

**pandas.DataFrame.var**

DataFrame.var (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- **axis** [{index (0), columns (1)}]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

Series or DataFrame (if level specified)

**Notes**

To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)
### pandas.DataFrame.where

**DataFrame.where** *(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)*

Replace values where the condition is False.

#### Parameters

- **cond** *(bool Series/DataFrame, array-like, or callable)* Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **other** *(scalar, Series/DataFrame, or callable)* Entries where *cond* is False are replaced with corresponding value from *other*. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **inplace** *(bool, default False)* Whether to perform the operation in place on the data.

- **axis** *(int, default None)* Alignment axis if needed.

- **level** *(int, default None)* Alignment level if needed.

- **errors** *(str, {'raise', 'ignore'}, default 'raise')* Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.
  - ‘raise’: allow exceptions to be raised.
  - ‘ignore’: suppress exceptions. On error return original object.

- **try_cast** *(bool, default False)* Try to cast the result back to the input type (if possible).

#### Returns

Same type as caller or None if *inplace=True*.

#### See also:

**DataFrame.mask()** Return an object of same shape as self.

#### Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is True the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for **DataFrame.where()** differs from **numpy.where()**. Roughly *df1.where(m, df2)* is equivalent to *np.where(m, df1, df2)*.

For further details and examples see the where documentation in indexing.
Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```python
>>> s.where(s > 1, 10)
0   10
1   10
2    2
3    3
4    4
dtype: int64
>>> s.mask(s > 1, 10)
0    0
1    1
2   10
3   10
4   10
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

(continues on next page)
pandas.DataFrame.xs

DataFrame.xs(key, axis=0, level=None, drop_level=True)

Return cross-section from the Series/DataFrame.

This method takes a key argument to select data at a particular level of a MultiIndex.

Parameters

- key [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- axis [[0 or ‘index’, 1 or ‘columns’], default 0] Axis to retrieve cross-section on.
- level [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- drop_level [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

- DataFrame.loc Access a group of rows and columns by label(s) or a boolean array.
- DataFrame.iloc Purely integer-location based indexing for selection by position.

Notes

xs can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of xs functionality, see MultiIndex Slicers.

Examples

```python
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
       num_legs  num_wings
animal  class
bat     mammal    2     2
cat     mammal    4     0
dog     mammal    4     0
penguin mammal    2     2
>>> df.loc[['walks', 'walks', 'flies', 'walks']]  
```

(continues on next page)
### class animal locomotion

<table>
<thead>
<tr>
<th>animal</th>
<th>locomotion</th>
<th>num_legs</th>
<th>num_wings</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>walks</td>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>dog</td>
<td>walks</td>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>bat</td>
<td>flies</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>bird</td>
<td>penguin walks</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

#### Get values at specified index

```python
>>> df.xs('mammal')
animal locomotion num_legs num_wings
    cat    walks  4   0
    dog    walks  4   0
    bat    flies  2   2
```

#### Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
locomotion num_legs num_wings
walks    4 0
```

#### Get values at specified index and level

```python
>>> df.xs('cat', level=1)
class locomotion num_legs num_wings
    mammal walks 4 0
```

#### Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'),
        level=[0, 'locomotion'])
animal num_legs num_wings
    penguin 2 2
```

#### Get values at specified column and axis

```python
>>> df.xs('num_wings', axis=1)
class animal locomotion num_wings
    mammal cat walks 0
    dog    walks 0
    bat    flies 2
    bird   penguin walks 2
Name: num_wings, dtype: int64
## 3.4.2 Attributes and underlying data

### Axes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.index</code></td>
<td>The index (row labels) of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.columns</code></td>
<td>The column labels of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.dtypes</code></td>
<td>Return the dtypes in the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.info</code></td>
<td>Print a concise summary of a DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.select_dtypes(include=...)</code></td>
<td>Return a subset of the DataFrame's columns based on the column dtypes.</td>
</tr>
<tr>
<td><code>DataFrame.values</code></td>
<td>Return a Numpy representation of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.axes</code></td>
<td>Return a list representing the axes of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.ndim</code></td>
<td>Return an int representing the number of axes / array dimensions.</td>
</tr>
<tr>
<td><code>DataFrame.size</code></td>
<td>Return an int representing the number of elements in this object.</td>
</tr>
<tr>
<td><code>DataFrame.shape</code></td>
<td>Return a tuple representing the dimensionality of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.memory_usage(index=..., deep=...)</code></td>
<td>Return the memory usage of each column in bytes.</td>
</tr>
<tr>
<td><code>DataFrame.empty</code></td>
<td>Indicator whether DataFrame is empty.</td>
</tr>
<tr>
<td><code>DataFrame.set_flags(*[copy,...])</code></td>
<td>Return a new object with updated flags.</td>
</tr>
</tbody>
</table>

## 3.4.3 Conversion

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.astype(...)</code></td>
<td>Cast a pandas object to a specified dtype <code>dtype</code>.</td>
</tr>
<tr>
<td><code>DataFrame.convert_dtypes(...)</code></td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
<tr>
<td><code>DataFrame.infer_objects()</code></td>
<td>Attempt to infer better dtypes for object columns.</td>
</tr>
<tr>
<td><code>DataFrame.copy(...)</code></td>
<td>Make a copy of this object's indices and data.</td>
</tr>
<tr>
<td><code>DataFrame.bool()</code></td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
</tbody>
</table>

## 3.4.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.head(...)</code></td>
<td>Return the first $n$ rows.</td>
</tr>
<tr>
<td><code>DataFrame.at</code></td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td><code>DataFrame.iat</code></td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td><code>DataFrame.loc</code></td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td><code>DataFrame.iloc</code></td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td><code>DataFrame.insert(...)</code></td>
<td>Insert column into DataFrame at specified location.</td>
</tr>
<tr>
<td><code>DataFrame.__iter__()</code></td>
<td>Iterate over info axis.</td>
</tr>
<tr>
<td><code>DataFrame.items()</code></td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
<tr>
<td><code>DataFrame.iteritems()</code></td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.keys()</code></td>
<td>Get the ‘info axis’ (see Indexing for more).</td>
</tr>
<tr>
<td><code>DataFrame.iterrows()</code></td>
<td>Iterate over DataFrame rows as (index, Series) pairs.</td>
</tr>
<tr>
<td><code>DataFrame.itertuples([index, name])</code></td>
<td>Iterate over DataFrame rows as namedtuples.</td>
</tr>
<tr>
<td><code>DataFrame.lookup(row_labels, col_labels)</code></td>
<td>(DEPRECATED) Label-based “fancy indexing” function for DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.pop(item)</code></td>
<td>Return item and drop from frame.</td>
</tr>
<tr>
<td><code>DataFrame.tail(n)</code></td>
<td>Return the last n rows.</td>
</tr>
<tr>
<td><code>DataFrame.xs(key[, axis, level, drop_level])</code></td>
<td>Return cross-section from the Series/DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.get(key[, default])</code></td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>
<tr>
<td><code>DataFrame.isin(values)</code></td>
<td>Whether each element in the DataFrame is contained in values.</td>
</tr>
<tr>
<td><code>DataFrame.where(cond[, other, inplace, ...])</code></td>
<td>Replace values where the condition is False.</td>
</tr>
<tr>
<td><code>DataFrame.mask(cond[, other, inplace, axis, ...])</code></td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td><code>DataFrame.query(expr[, inplace])</code></td>
<td>Query the columns of a DataFrame with a boolean expression.</td>
</tr>
</tbody>
</table>

### pandas.DataFrame.__iter__

DataFrame.__iter__()  
Iterate over info axis.  

Returns

**iterator**  
Info axis as iterator.

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

#### 3.4.5 Binary operator functions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.add(other[, axis, level, fill_value])</code></td>
<td>Get Addition of dataframe and other, element-wise (binary operator <code>add</code>).</td>
</tr>
<tr>
<td><code>DataFrame.sub(other[, axis, level, fill_value])</code></td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator <code>sub</code>).</td>
</tr>
<tr>
<td><code>DataFrame.mul(other[, axis, level, fill_value])</code></td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator <code>mul</code>).</td>
</tr>
<tr>
<td><code>DataFrame.div(other[, axis, level, fill_value])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.truediv(other[, axis, level, ...])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.floordiv(other[, axis, level, ...])</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.mod(other[, axis, level, fill_value])</code></td>
<td>Get Modulo of dataframe and other, element-wise (binary operator <code>mod</code>).</td>
</tr>
<tr>
<td><code>DataFrame.pow(other[, axis, level, fill_value])</code></td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator <code>pow</code>).</td>
</tr>
<tr>
<td><code>DataFrame.dot(other)</code></td>
<td>Compute the matrix multiplication between the DataFrame and other.</td>
</tr>
<tr>
<td><code>DataFrame.radd(other[, axis, level, fill_value])</code></td>
<td>Get Addition of dataframe and other, element-wise (binary operator <code>radd</code>).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.rsub</td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator rsub).</td>
</tr>
<tr>
<td>DataFrame.rmul</td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator rmul).</td>
</tr>
<tr>
<td>DataFrame.rdiv</td>
<td>Get Floating division of dataframe and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td>DataFrame.rtruediv</td>
<td>Get Floating division of dataframe and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td>DataFrame.rfloordiv</td>
<td>Get Integer division of dataframe and other, element-wise (binary operator rfloordiv).</td>
</tr>
<tr>
<td>DataFrame.rmod</td>
<td>Get Modulo of dataframe and other, element-wise (binary operator rmod).</td>
</tr>
<tr>
<td>DataFrame.rpow</td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator rpow).</td>
</tr>
<tr>
<td>DataFrame.lt</td>
<td>Get Less than of dataframe and other, element-wise (binary operator lt).</td>
</tr>
<tr>
<td>DataFrame.gt</td>
<td>Get Greater than of dataframe and other, element-wise (binary operator gt).</td>
</tr>
<tr>
<td>DataFrame.le</td>
<td>Get Less than or equal to of dataframe and other, element-wise (binary operator le).</td>
</tr>
<tr>
<td>DataFrame.ge</td>
<td>Get Greater than or equal to of dataframe and other, element-wise (binary operator ge).</td>
</tr>
<tr>
<td>DataFrame.ne</td>
<td>Get Not equal to of dataframe and other, element-wise (binary operator ne).</td>
</tr>
<tr>
<td>DataFrame.eq</td>
<td>Get Equal to of dataframe and other, element-wise (binary operator eq).</td>
</tr>
<tr>
<td>DataFrame.combine</td>
<td>Perform column-wise combine with another DataFrame.</td>
</tr>
<tr>
<td>DataFrame.combine_first</td>
<td>Update null elements with value in the same location in other.</td>
</tr>
</tbody>
</table>

3.4.6 Function application, GroupBy & window

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.apply</td>
<td>Apply a function along an axis of the DataFrame.</td>
</tr>
<tr>
<td>DataFrame.applymap</td>
<td>Apply a function to a DataFrame elementwise.</td>
</tr>
<tr>
<td>DataFrame.pipe</td>
<td>Apply func(self, *args, **kwargs).</td>
</tr>
<tr>
<td>DataFrame.agg</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>DataFrame.aggregate</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>DataFrame.transform</td>
<td>Call func on self producing a DataFrame with transformed values.</td>
</tr>
<tr>
<td>DataFrame.groupby</td>
<td>Group DataFrame using a mapper or by a Series of columns.</td>
</tr>
<tr>
<td>DataFrame.rolling</td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td>DataFrame.expanding</td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td>DataFrame.ewm</td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
</tbody>
</table>
3.4.7 Computations / descriptive stats

- `DataFrame.abs()` Return a Series/DataFrame with absolute numeric value of each element.
- `DataFrame.all([axis, bool_only, skipna, level])` Return whether all elements are True, potentially over an axis.
- `DataFrame.any([axis, bool_only, skipna, level])` Return whether any element is True, potentially over an axis.
- `DataFrame.clip([lower, upper, axis, inplace])` Trim values at input threshold(s).
- `DataFrame.corr([method, min_periods])` Compute pairwise correlation of columns, excluding NA/null values.
- `DataFrame.corrwith(other[, axis, drop, method])` Compute pairwise correlation.
- `DataFrame.count([axis, level, numeric_only])` Count non-NA cells for each column or row.
- `DataFrame.cov([min_periods, ddof])` Compute pairwise covariance of columns, excluding NA/null values.
- `DataFrame.cummax([axis, skipna])` Return cumulative maximum over a DataFrame or Series axis.
- `DataFrame.cummin([axis, skipna])` Return cumulative minimum over a DataFrame or Series axis.
- `DataFrame.cumprod([axis, skipna])` Return cumulative product over a DataFrame or Series axis.
- `DataFrame.cumsum([axis, skipna])` Return cumulative sum over a DataFrame or Series axis.
- `DataFrame.describe([percentiles, include, ...])` Generate descriptive statistics.
- `DataFrame.diff([periods, axis])` First discrete difference of element.
- `DataFrame.eval(expr[, inplace])` Evaluate a string describing operations on DataFrame columns.
- `DataFrame.kurt([axis, skipna, level, ...])` Return unbiased kurtosis over requested axis.
- `DataFrame.kurtosis([axis, skipna, level, ...])` Return unbiased kurtosis over requested axis.
- `DataFrame.mad([axis, skipna, level])` Return the mean absolute deviation of the values over the requested axis.
- `DataFrame.max([axis, skipna, level, ...])` Return the maximum of the values over the requested axis.
- `DataFrame.mean([axis, skipna, level, ...])` Return the mean of the values over the requested axis.
- `DataFrame.median([axis, skipna, level, ...])` Return the median of the values over the requested axis.
- `DataFrame.min([axis, skipna, level, ...])` Return the minimum of the values over the requested axis.
- `DataFrame.mode([axis, numeric_only, dropna])` Get the mode(s) of each element along the selected axis.
- `DataFrame.pct_change([periods, fill_method, ...])` Percentage change between the current and a prior element.
- `DataFrame.prod([axis, skipna, level, ...])` Return the product of the values over the requested axis.
- `DataFrame.product([axis, skipna, level, ...])` Return the product of the values over the requested axis.
- `DataFrame.quantile([q, axis, numeric_only, ...])` Return values at the given quantile over requested axis.
- `DataFrame.rank([axis, method, numeric_only, ...])` Compute numerical data ranks (1 through n) along axis.
- `DataFrame.round([decimals])` Round a DataFrame to a variable number of decimal places.
- `DataFrame.sem([axis, skipna, level, ddof, ...])` Return unbiased standard error of the mean over requested axis.
- `DataFrame.skew([axis, skipna, level, ...])` Return unbiased skew over requested axis.
- `DataFrame.sum([axis, skipna, level, ...])` Return the sum of the values over the requested axis.
Table 67 – continued from previous page

- **DataFrame.std**
  - ([axis, skipna, level, ddof, ...])
  - Return sample standard deviation over requested axis.

- **DataFrame.var**
  - ([axis, skipna, level, ddof, ...])
  - Return unbiased variance over requested axis.

- **DataFrame.nunique**
  - ([axis, dropna])
  - Count distinct observations over requested axis.

- **DataFrame.value_counts**
  - ([subset, normalize, ...])
  - Return a Series containing counts of unique rows in the DataFrame.

### 3.4.8 Reindexing / selection / label manipulation

- **DataFrame.add_prefix**
  - (prefix)
  - Prefix labels with string prefix.

- **DataFrame.add_suffix**
  - (suffix)
  - Suffix labels with string suffix.

- **DataFrame.align**
  - (other[, join, axis, level, ...])
  - Align two objects on their axes with the specified join method.

- **DataFrame.at_time**
  - (time[, asof, axis])
  - Select values at particular time of day (e.g., 9:30AM).

- **DataFrame.between_time**
  - (start_time, end_time)
  - Select values between particular times of the day (e.g., 9:00-9:30 AM).

- **DataFrame.drop**
  - ([labels, axis, index, ...])
  - Drop specified labels from rows or columns.

- **DataFrame.drop_duplicates**
  - ([subset, keep, ...])
  - Return DataFrame with duplicate rows removed.

- **DataFrame.duplicated**
  - ([subset, keep])
  - Return boolean Series denoting duplicate rows.

- **DataFrame.equals**
  - (other)
  - Test whether two objects contain the same elements.

- **DataFrame.filter**
  - ([items, like, regex, axis])
  - Subset the dataframe rows or columns according to the specified index labels.

- **DataFrame.first**
  - (offset)
  - Select initial periods of time series data based on a date offset.

- **DataFrame.head**
  - ([n])
  - Return the first n rows.

- **DataFrame.idxmax**
  - ([axis, skipna])
  - Return index of first occurrence of maximum over requested axis.

- **DataFrame.idxmin**
  - ([axis, skipna])
  - Return index of first occurrence of minimum over requested axis.

- **DataFrame.last**
  - (offset)
  - Select final periods of time series data based on a date offset.

- **DataFrame.reindex**
  - ([labels, index, columns, ...])
  - Conform Series/DataFrame to new index with optional filling logic.

- **DataFrame.reindex_like**
  - (other[, method, ...])
  - Return an object with matching indices as other object.

- **DataFrame.rename**
  - ([mapper, index, columns, ...])
  - Alter axes labels.

- **DataFrame.rename_axis**
  - ([mapper, index, ...])
  - Set the name of the axis for the index or columns.

- **DataFrame.reset_index**
  - ([mapper, index, ...])
  - Reset the index, or a level of it.

- **DataFrame.sample**
  - ([n, frac, replace, ...])
  - Return a random sample of items from an axis of object.

- **DataFrame.set_axis**
  - (labels[, axis, inplace])
  - Assign desired index to given axis.

- **DataFrame.set_index**
  - (keys[, drop, append, ...])
  - Set the DataFrame index using existing columns.

- **DataFrame.tail**
  - ([n])
  - Return the last n rows.

- **DataFrame.take**
  - (indices[, axis, is_copy])
  - Return the elements in the given positional indices along an axis.

- **DataFrame.truncate**
  - ([before, after, axis, copy])
  - Truncate a Series or DataFrame before and after some index value.
### 3.4.9 Missing data handling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.backfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>DataFrame.bfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>DataFrame.dropna()</code></td>
<td>Remove missing values.</td>
</tr>
<tr>
<td><code>DataFrame.ffill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>DataFrame.fillna()</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>

<tr>
<td><code>DataFrame.T</code></td>
<td>Transpose index and columns.</td>
</tr>
</tbody>
</table>
3.4.11 Combining / comparing / joining / merging

DataFrame.append(other[, ignore_index, ...])  Append rows of other to the end of caller, returning a new object.

DataFrame.assign(**kwargs)  Assign new columns to a DataFrame.

DataFrame.compare(other[, align_axis, ...])  Compare to another DataFrame and show the differences.

DataFrame.join(other[, on, how, lsuffix, ...])  Join columns of another DataFrame.

DataFrame.merge(right[, how, on, left_on, ...])  Merge DataFrame or named Series objects with a database-style join.

DataFrame.update(other[, join, overwrite, ...])  Modify in place using non-NA values from another DataFrame.

3.4.12 Time Series-related

DataFrame.asfreq(freq[, method, how, ...])  Convert TimeSeries to specified frequency.

DataFrame.asof(where[, subset])  Return the last row(s) without any NaNs before where.

DataFrame.shift([periods, freq, axis, ...])  Shift index by desired number of periods with an optional time freq.

DataFrame.slice_shift([periods, axis])  (DEPRECATED) Equivalent to shift without copying data.

DataFrame.tshift([periods, freq, axis])  (DEPRECATED) Shift the time index, using the index’s frequency if available.

DataFrame.first_valid_index()  Return index for first non-NA/null value.

DataFrame.last_valid_index()  Return index for last non-NA/null value.

DataFrame.resample(rule[, axis, closed, ...])  Resample time-series data.

DataFrame.to_period([freq, axis, copy])  Convert DataFrame from DatetimeIndex to PeriodIndex.

DataFrame.to_timestamp([freq, how, axis, copy])  Cast to DatetimeIndex of timestamps, at beginning of period.

DataFrame.tz_convert(tz[, axis, level, copy])  Convert tz-aware axis to target time zone.

DataFrame.tz_localize(tz[, axis, level, ...])  Localize tz-naive index of a Series or DataFrame to target time zone.

3.4.13 Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in DataFrame.attrs.

Flags(obj, *, allows_duplicate_labels)  Flags that apply to pandas objects.
3.4.14 Metadata

_DataFrame.attrs_ is a dictionary for storing global metadata for this DataFrame.

**Warning:** _DataFrame.attrs_ is considered experimental and may change without warning.

_DataFrame.attrs_ Dictionary of global attributes of this dataset.

3.4.15 Plotting

_DataFrame.plot_ is both a callable method and a namespace attribute for specific plotting methods of the form _DataFrame.plot.<kind>_.

**DataFrame.plot([x, y, kind, ax, . . . .])** DataFrame plotting accessor and method

<table>

</tbody>
</table>

**pandas.DataFrame.plot.area**

_DataFrame.plot.area_(x=None, y=None, **kwargs)_

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

**Parameters**

- **x** [label or position, optional] Coordinates for the X axis. By default uses the index.
- **y** [label or position, optional] Column to plot. By default uses all columns.
- **stacked** [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- **kwargs** Additional keyword arguments are documented in _DataFrame.plot()._

**Returns**

- **matplotlib.axes.Axes or numpy.ndarray** Area plot, or array of area plots if subplots is True.
See also:

*Dataframe.plot* Make plots of DataFrame using matplotlib / pylab.

**Examples**

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                        freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different `x`:
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> df = pd.DataFrame(
...     {'sales': [3, 2, 3],
...      'visits': [20, 42, 28],
...      'day': [1, 2, 3],
...     })
>>> ax = df.plot.area(x='day')
```

---

**pandas.DataFrame.plot.bar**

`DataFrame.plot.bar(x=None, y=None, **kwargs)`

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

- **color** [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
• A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a9d19’.

• A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively.

• A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.barh Horizontal bar plot.
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.bar Make a bar plot with matplotlib.

Examples

Basic plot.

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed, 'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Plot stacked bar charts for the DataFrame

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with subplots=True. In this case, a numpy.ndarray of matplotlib.axes.Axes are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don’t like the default colours, you can specify how you’d like each column to be colored.
3.4. DataFrame
Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

**pandas.DataFrame.plot.barh**

DataFrame.plot.barh(x=None, y=None, **kwargs)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**
x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively.
- A dict of the form {column name [color], so that each column will be colored accordingly. For example, if your columns are called \textit{a} and \textit{b}, then passing \{`a': 'green', `b': 'red'} will color bars for column \textit{a} in green and bars for column \textit{b} in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in \texttt{DataFrame.plot()}.  

Returns

matrixlib.axes.Axes or np.ndarray of them An ndarray is returned with one matrixlib.axes.Axes per column when subplots=True.

See also:

\texttt{DataFrame.plot.bar} Vertical bar plot.  
\texttt{DataFrame.plot} Make plots of DataFrame using matplotlib.  
\texttt{matplotlib.axes.Axes.bar} Plot a vertical bar plot using matplotlib.

Examples

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ... 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed, ... 'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```python
>>> ax = df.plot.barh(color={'speed': "red", "lifespan": "green"})
```
Plot a column of the DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...    'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...    'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
pandas.DataFrame.plot.box

DataFrame.plot.box(by=None, **kwargs)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

**kwargs Additional keywords are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
generate_boxplot_example()
```

pandas.DataFrame.plot.density

DataFrame.plot.density(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().
3.4. DataFrame
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)

>>> ax = s.plot.kde(bw_method=3)
```

Finally, the ind parameter determines the evaluation points for the plot of the estimated PDF:
3.4. DataFrame
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

```python
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```
pandas.DataFrame.plot.hexbin

DataFrame.plot.hexbin(x, y, C=None, reduce_C_function=None, gridsize=None, **kwargs)
Generate a hexagonal binning plot.

Generate a hexagonal binning plot of x versus y. If C is None (the default), this is a histogram of the number of occurrences of the observations at (x[i], y[i]).

If C is specified, specifies values at given coordinates (x[i], y[i]). These values are accumulated for each hexagonal bin and then reduced according to reduce_C_function, having as default the NumPy’s mean function (numpy.mean()). (If C is specified, it must also be a 1-D sequence of the same length as x and y, or a column label.)

Parameters

x [int or str] The column label or position for x points.
y [int or str] The column label or position for y points.
C [int or str, optional] The column label or position for the value of (x, y) point.
reduce_C_function [callable, default np.mean] Function of one argument that reduces all the values in a bin to a single number (e.g. np.mean, np.max, np.sum, np.std).
gridsize [int or tuple of (int, int), default 100] The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.
**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.AxesSubplot The matplotlib Axes on which the hexbin is plotted.

See also:

DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.hexbin Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```python
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                     'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses C and np.sum as reduce_C_function. Note that ‘observations’ values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the reduce_C_function.

```python
>>> n = 500
>>> df = pd.DataFrame({
...                     'coord_x': np.random.uniform(-3, 3, size=n),
...                     'coord_y': np.random.uniform(30, 50, size=n),
...                     'observations': np.random.randint(1,5, size=n)
...                     })
>>> ax = df.plot.hexbin(x='coord_x',
...                       y='coord_y',
...                       C='observations',
...                       reduce_C_function=np.sum,
...                       gridsize=20)
```
pandas.DataFrame.plot.hist

DataFrame.plot.hist(by=None, bins=10, **kwargs)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame's Series are in a similar scale.

**Parameters**

- **by** [str or sequence, optional] Column in the DataFrame to group by.
- **bins** [int, default 10] Number of histogram bins to be used.
- **kwargs** Additional keyword arguments are documented in DataFrame.plot().

**Returns**

- **class**:matplotlib.AxesSubplot Return a histogram plot.
See also:

DataFrame.hist Draw histograms per DataFrame’s Series.
Series.hist Draw a histogram with Series’ data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```
**pandas.DataFrame.plot.kde**

DataFrame.plot.kde (bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.
- **ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.
- **kwargs** Additional keyword arguments are documented in pandas.

**Returns**

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**Examples**

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the **ind** parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```
3.4. DataFrame
pandas: powerful Python data analysis toolkit, Release 1.2.2

Chapter 3. API reference
A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### pandas.DataFrame.plot.line

`DataFrame.plot.line(x=None, y=None, **kwargs)`

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- `x` [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- `y` [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
color  [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s line will be filled in green or yellow, alternatively.
- A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color lines for column a in green and lines for column b in red.

New in version 1.1.0.

**kwargs  Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them  An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

matplotlib.pyplot.plot  Plot y versus x as lines and/or markers.

Examples

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame(
...     {'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900],
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).

```python
>>> axes = df.plot.line(
...     subplots=True, color={'pig': 'pink', 'horse': '#742802'})
... )
```

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```
pandas.DataFrame.plot.pie

DataFrame.plot.pie(**kwargs)
    Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps
matplotlib.pyplot.pie() for the specified column. If no column reference is passed and
subplots=True a pie plot is drawn for each numerical column independently.

Parameters

    y [int or label, optional] Label or position of the column to plot. If not provided,
        subplots=True argument must be passed.

**kwargs  Keyword arguments to pass on to DataFrame.plot().

Returns

    matplotlib.axes.Axes or np.ndarray of them  A NumPy array is returned when subplots is
        True.

See also:

    Series.plot.pie  Generate a pie plot for a Series.
    DataFrame.plot  Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the
‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```python
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

pandas.DataFrame.plot.scatter

DataFrame.plot.scatter(x, y, s=None, c=None, **kwargs)
    Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each
point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance
natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted
against each other.

Parameters

    x [int or str] The column name or column position to be used as horizontal coordinates for
        each point.

    y [int or str] The column name or column position to be used as vertical coordinates for each
        point.

    s [str, scalar or array_like, optional] The size of each point. Possible values are:
        • A string with the name of the column to be used for marker’s size.
        • A single scalar so all points have the same size.
• A sequence of scalars, which will be used for each point’s size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

    Changed in version 1.1.0.

c  [str, int or array_like, optional] The color of each point. Possible values are:

    • A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

    • A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point’s color recursively. For instance ['green','yellow'] all points will be filled in green or yellow, alternatively.

    • A column name or position whose values will be used to color the marker points according to a colormap.

    **kwargs  Keyword arguments to pass on to DataFrame.plot().

    Returns

    matplotlib.axes.Axes or numpy.ndarray of them

    See also:

    matplotlib.pyplot.scatter  Scatter plot using multiple input data formats.

    Examples

    Let’s see how to draw a scatter plot using coordinates from the values in a DataFrame’s columns.

    >>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
    ...                     [6.4, 3.2, 1], [5.9, 3.0, 2]],
    ...                     columns=['length', 'width', 'species'])

    >>> ax1 = df.plot.scatter(x='length',
    ...                        y='width',
    ...                        c='DarkBlue')

    And now with the color determined by a column as well.

    >>> ax2 = df.plot.scatter(x='length',
    ...                        y='width',
    ...                        c='species',
    ...                        colormap='viridis')

    DataFrame.boxplot([column, by, ax, . . . ])  Make a box plot from DataFrame columns.

    DataFrame.hist([column, by, grid, . . . ])  Make a histogram of the DataFrame’s.

3.4.16 Sparse accessor

    Sparse-dtype specific methods and attributes are provided under the DataFrame.sparse accessor.

    DataFrame.sparse.density  Ratio of non-sparse points to total (dense) data points.
3.4. DataFrame
DataFrame.sparse.density

DataFrame.sparse.density
Ratio of non-sparse points to total (dense) data points.

DataFrame.sparse.from_spmatrix(data[, index, columns])
Create a new DataFrame from a scipy sparse matrix.

DataFrame.sparse.to_coo()
Return the contents of the frame as a sparse SciPy COO matrix.

DataFrame.sparse.to_dense()
Convert a DataFrame with sparse values to dense.

DataFrame.sparse.from_spmatrix

classmethod DataFrame.sparse.from_spmatrix(data[, index=None, columns=None])
Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

Parameters

data [scipy.sparse.spmatrix] Must be convertible to csc format.

index, columns [Index, optional] Row and column labels to use for the resulting DataFrame. Defaults to a RangeIndex.

Returns

DataFrame Each column of the DataFrame is stored as a \textit{arrays.SparseArray}.

Examples

```python
>>> import scipy.sparse
>>> mat = scipy.sparse.eye(3)
>>> pd.DataFrame.sparse.from_spmatrix(mat)
    0   1   2
0  1.0 0.0 0.0
1  0.0 1.0 0.0
2  0.0 0.0 1.0
```

DataFrame.sparse.to_coo

DataFrame.sparse.to_coo()
Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

Returns

coo_matrix [scipy.sparse.spmatrix] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.
Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find_common_type convention, mixing int64 and uint64 will result in a float64 dtype.

pandas.DataFrame.sparse.to_dense

DataFrame.sparse.to_dense()
Convert a DataFrame with sparse values to dense.
New in version 0.25.0.

Returns
   DataFrame A DataFrame with the same values stored as dense arrays.

Examples

```python
df = pd.DataFrame({'A': pd.arrays.SparseArray([0, 1, 0])})
df.sparse.to_dense()
```

```
   A
0   0
1   1
2   0
```

### 3.5 pandas arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a `Index`, `Series`, or `DataFrame`.

For some data types, pandas extends NumPy's type system. String aliases for these types can be found at `dtypes`.

<table>
<thead>
<tr>
<th>Kind of Data</th>
<th>pandas Data Type</th>
<th>Scalar</th>
<th>Array</th>
</tr>
</thead>
<tbody>
<tr>
<td>TZ-aware datetime</td>

</tr>
<tr>
<td>Boolean (with NA)</td>
<td><code>BooleanDtype</code></td>
<td><code>bool</code></td>
<td><code>Boolean data with missing values</code></td>
</tr>
</tbody>
</table>

Pandas and third-party libraries can extend NumPy's type system (see `Extension types`). The top-level `array()` method can be used to create a new array, which may be stored in a `Series`, `Index`, or as a column in a `DataFrame`.

```python
array(data[, dtype, copy])
```

Create an array.

New in version 0.24.0.

**Parameters**

- **data** [Sequence of objects] The scalars inside `data` should be instances of the scalar type for `dtype`. It's expected that `data` represents a 1-dimensional array of data.

  When `data` is an Index or Series, the underlying array will be extracted from `data`.

- **dtype** [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

  If not specified, there are two possibilities:

  1. When `data` is a `Series`, `Index`, or `ExtensionArray`, the `dtype` will be taken from the data.

3.5.1 pandas.array

`pandas.array(data, dtype=None, copy=True)`

Create an array.

New in version 0.24.0.

**Parameters**

- **data** [Sequence of objects] The scalars inside `data` should be instances of the scalar type for `dtype`. It's expected that `data` represents a 1-dimensional array of data.

  When `data` is an Index or Series, the underlying array will be extracted from `data`.

- **dtype** [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

  If not specified, there are two possibilities:

  1. When `data` is a `Series`, `Index`, or `ExtensionArray`, the `dtype` will be taken from the data.
2. Otherwise, pandas will attempt to infer the `dtype` from the data.

Note that when `data` is a NumPy array, `data.dtype` is **not** used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

<table>
<thead>
<tr>
<th>Scalar Type</th>
<th>Array Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pandas.Interval</code></td>
<td><code>pandas.arrays.IntervalArray</code></td>
</tr>
<tr>
<td><code>pandas.Period</code></td>
<td><code>pandas.arrays.PeriodArray</code></td>
</tr>
<tr>
<td><code>datetime.datetime</code></td>
<td><code>pandas.arrays.DatetimeArray</code></td>
</tr>
<tr>
<td><code>datetime.timedelta</code></td>
<td><code>pandas.arrays.TimedeltaArray</code></td>
</tr>
<tr>
<td><code>int</code></td>
<td><code>pandas.arrays.IntegerArray</code></td>
</tr>
<tr>
<td><code>float</code></td>
<td><code>pandas.arrays.FloatingArray</code></td>
</tr>
<tr>
<td><code>str</code></td>
<td><code>pandas.arrays.StringArray</code></td>
</tr>
<tr>
<td><code>bool</code></td>
<td><code>pandas.arrays.BooleanArray</code></td>
</tr>
</tbody>
</table>

For all other cases, NumPy’s usual inference rules will be used.

Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

Changed in version 1.2.0: Pandas now also infers nullable-floating dtype for float-like input data

```python
copy [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of `data`, creating the new array may require copying data, even if `copy=False`.
```

Returns

**ExtensionArray** The newly created array.

Raises

**ValueError** When `data` is not 1-dimensional.

See also:

- `numpy.array` Construct a NumPy array.
- `Series` Construct a pandas Series.
- `Index` Construct a pandas Index.
- `arrays.PandasArray` ExtensionArray wrapping a NumPy array.
- `Series.array` Extract the array stored within a Series.

Notes

Omitting the `dtype` argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying `dtype` to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn’t change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the `dtype` as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.
This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the dtype.

```python
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- `arrays.DatetimeArray`
- `arrays.TimedeltaArray`

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```python
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```python
>>> pd.array(['1H', '2H'], dtype='timedelta64[ns]')
<TimedeltaArray>
['0 days 01:00:00', '0 days 02:00:00']
Length: 2, dtype: timedelta64[ns]
```

**Examples**

If a dtype is not specified, pandas will infer the best dtype from the values. See the description of `dtype` for the types pandas infers for.

```python
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

```python
>>> pd.array([1, 2, np.nan])
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

```python
>>> pd.array([1.1, 2.2])
<FloatArray>
[1.1, 2.2]
Length: 2, dtype: Float64
```

```python
>>> pd.array(['a', None, 'c'])
<StringArray>
['a', <NA>, 'c']
Length: 3, dtype: string
```
You can use the string alias for `dtype`

```python
>>> pd.array(['a', 'b', 'a'], dtype='category')
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

Or specify the actual `dtype`

```python
>>> pd.array(['a', 'b', 'a'],
            dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
['a', 'b', 'a']
Categories (3, object): ['a' < 'b' < 'c']
```

If pandas does not infer a dedicated extension type a `arrays.PandasArray` is returned.

```python
>>> pd.array([1 + 1j, 3 + 2j])
<PandasArray>
[(1+1j), (3+2j)]
Length: 2, dtype: complex128
```

As mentioned in the “Notes” section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a `arrays.PandasArray`. Specify the `dtype` as a NumPy dtype if you need to ensure there’s no future change in behavior.

```python
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

`data` must be 1-dimensional. A ValueError is raised when the input has the wrong dimensionality.

```python
>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.
```

### 3.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. pandas supports this with the `arrays. DatetimeArray` extension array, which can hold timezone-naive or timezone-aware values.

`Timestamp`, a subclass of `datetime.datetime`, is pandas’ scalar type for timezone-naive or timezone-aware datetime data.

```
Timestamp([ts_input, freq, tz, unit, year, ...]) Pandas replacement for python datetime.datetime object.
```

3.5. pandas arrays 1841
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.Timestamp

class pandas.Timestamp(ts_input=<object object>, freq=None, tz=None, unit=None, year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=None, *, fold=None)

Pandas replacement for python datetime.datetime object.

Timestamp is the pandas equivalent of python’s Datetime and is interchangeable with it in most cases. It’s the type used for the entries that make up a DatetimeIndex, and other timeseries oriented data structures in pandas.

Parameters

- **ts_input** [datetime-like, str, int, float] Value to be converted to Timestamp.
- **freq** [str, DateOffset] Offset which Timestamp will have.
- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will have.
- **unit** [str] Unit used for conversion if ts_input is of type int or float. The valid values are ‘D’, ‘h’, ‘m’, ‘s’, ‘ms’, ‘us’, and ‘ns’. For example, ‘s’ means seconds and ‘ms’ means milliseconds.
- **year, month, day** [int]
- **hour, minute, second, microsecond** [int, optional, default 0]
- **nanosecond** [int, optional, default 0]
- **tzinfo** [datetime.tzinfo, optional, default None]
- **fold** [{0, 1}, default None, keyword-only] Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time

New in version 1.1.0.

Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from datetime.datetime. They can be passed by either position or keyword, but not both mixed together.

Examples

Using the primary calling convention:

This converts a datetime-like string

```python
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```python
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')

Using the other two forms that mimic the API for `datetime.datetime`:

```python
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```python
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

**pandas.Timestamp.asm8**

```
Timestamp.asm8
Return numpy datetime64 format in nanoseconds.
```

3.5. pandas arrays
pandas.Timestamp.day_of_week

Timestamp.day_of_week
Return day of the week.

pandas.Timestamp.day_of_year

Timestamp.day_of_year
Return the day of the year.

pandas.Timestamp.dayofweek

Timestamp.dayofweek
Return day of the week.

pandas.Timestamp.dayofyear

Timestamp.dayofyear
Return the day of the year.

pandas.Timestamp.days_in_month

Timestamp.days_in_month
Return the number of days in the month.

pandas.Timestamp.daysinmonth

Timestamp.daysinmonth
Return the number of days in the month.

pandas.Timestamp.freqstr

property Timestamp.freqstr
Return the total number of days in the month.

pandas.Timestamp.is_leap_year

Timestamp.is_leap_year
Return True if year is a leap year.
pandas.Timestamp.is_month_end

Timestamp.is_month_end
Return True if date is last day of month.

pandas.Timestamp.is_month_start

Timestamp.is_month_start
Return True if date is first day of month.

pandas.Timestamp.is_quarter_end

Timestamp.is_quarter_end
Return True if date is last day of the quarter.

pandas.Timestamp.is_quarter_start

Timestamp.is_quarter_start
Return True if date is first day of the quarter.

pandas.Timestamp.is_year_end

Timestamp.is_year_end
Return True if date is last day of the year.

pandas.Timestamp.is_year_start

Timestamp.is_year_start
Return True if date is first day of the year.

pandas.Timestamp.quarter

Timestamp.quarter
Return the quarter of the year.

pandas.Timestamp.tz

property Timestamp.tz
Alias for tzinfo.
pandas.Timestamp.week

Timestamp.week
Return the week number of the year.

pandas.Timestamp.weekofyear

Timestamp.weekofyear
Return the week number of the year.

**pandas.Timestamp.astimezone**

`Timestamp.astimezone(tz)`  
Convert tz-aware Timestamp to another time zone.

**Parameters**

- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

**Returns**

- `converted` [Timestamp]

**Raises**

- **TypeError** If Timestamp is tz-naive.
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.Timestamp.ceil

Timestamp.ceil(freq, ambiguous='raise', nonexistent='raise')

Return a new Timestamp ceiled to this resolution.

Parameters

- freq [str] Frequency string indicating the ceiling resolution.
- ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - 'NaT' will return NaT for an ambiguous time.
  - 'raise' will raise an AmbiguousTimeError for an ambiguous time.

New in version 0.24.0.

- nonexistent [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Raises

ValueError if the freq cannot be converted.

pandas.Timestamp.combine

classmethod Timestamp.combine(date, time)

Combine date, time into datetime with same date and time fields.

pandas.Timestamp.ctime

Timestamp.ctime()

Return ctime() style string.
pandas.Timestamp.date

Timestamp.date()
Return date object with same year, month and day.

pandas.Timestamp.day_name

Timestamp.day_name()
Return the day name of the Timestamp with specified locale.

Parameters
locale [str, default None (English locale)] Locale determining the language in which to return the day name.

Returns
str

pandas.Timestamp.dst

Timestamp.dst()
Return self.tzinfo.dst(self).

pandas.Timestamp.floor

Timestamp.floor(freq, ambiguous='raise', nonexistent='raise')
Return a new Timestamp floored to this resolution.

Parameters
freq [str] Frequency string indicating the flooring resolution.
ambiguous [bool or {'raise', 'NaT'}, default ‘raise’] The behavior is as follows:
• bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
• ‘NaT’ will return NaT for an ambiguous time.
• ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
New in version 0.24.0.
nonexistent [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
• ‘NaT’ will return NaT where there are nonexistent times.
timedeltas objects will shift nonexistent times by the timedelta.
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.
New in version 0.24.0.

Raises

`ValueError` if the freq cannot be converted.

**pandas.Timestamp.fromisocalendar**

`Timestamp.fromisocalendar()`  
INT, INT, INT -> Construct a date from the ISO year, week number and weekday.  
This is the inverse of the date.isocalendar() function

**pandas.Timestamp.fromisoformat**

`Timestamp.fromisoformat()`  
STRING -> Datetime from datetime.isoformat() output

**pandas.Timestamp.fromordinal**

`classmethod Timestamp.fromordinal(ordinal, freq=None, tz=None)`  
Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the ordinal itself.

Parameters

- `ordinal` [int] Date corresponding to a proleptic Gregorian ordinal.
- `freq` [str, DateOffset] Offset to apply to the Timestamp.
- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.

**pandas.Timestamp.fromtimestamp**

`classmethod Timestamp.fromtimestamp(ts)`  
Transform timestamp[, tz] to tz’s local time from POSIX timestamp.

**pandas.Timestamp.isocalendar**

`Timestamp.isocalendar()`  
Return a 3-tuple containing ISO year, week number, and weekday.

**pandas.Timestamp.isoformat**

`Timestamp.isoformat()`  
[sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[,mmm[uuu]]]]][±HH:MM]. sep is used to separate the year from the time, and defaults to ‘T’. timespec specifies what components of the time to include (allowed values are ‘auto’, ‘hours’, ‘minutes’, ‘seconds’, ‘milliseconds’, and ‘microseconds’).
**pandas.Timestamp.isoweekday**

`pandas.Timestamp.isoweekday()`  
Return the day of the week represented by the date. Monday == 1 … Sunday == 7

**pandas.Timestamp.month_name**

`pandas.Timestamp.month_name()`  
Return the month name of the Timestamp with specified locale.

**Parameters**

- `locale` [str, default None (English locale)] Locale determining the language in which to return the month name.

**Returns**

- `str`

**pandas.Timestamp.normalize**

`pandas.Timestamp.normalize()`  
Normalize Timestamp to midnight, preserving tz information.

**pandas.Timestamp.now**

classmethod `pandas.Timestamp.now(tz=None)`  
Return new Timestamp object representing current time local to tz.

**Parameters**

- `tz` [str or timezone object, default None] Timezone to localize to.

**pandas.Timestamp.replace**

`pandas.Timestamp.replace(year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=None)`  
Implements datetime.replace, handles nanoseconds.

**Parameters**

- `year` [int, optional]
- `month` [int, optional]
- `day` [int, optional]
- `hour` [int, optional]
- `minute` [int, optional]
- `second` [int, optional]
- `microsecond` [int, optional]
- `nanosecond` [int, optional]
tzinfo [tz-convertible, optional]
fold [int, optional]

Returns
Timestamp with fields replaced

pandas.Timestamp.round

Timestamp.round(freq, ambiguous='raise', nonexistent='raise')
Round the Timestamp to the specified resolution.

Parameters
freq [str] Frequency string indicating the rounding resolution.
ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
• bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
• ‘NaT’ will return NaT for an ambiguous time.
• ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
New in version 0.24.0.
nonexistent [{'raise', 'shift_forward', 'shift_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
• ‘NaT’ will return NaT where there are nonexistent times.
• timedelta objects will shift nonexistent times by the timedelta.
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.
New in version 0.24.0.

Returns
a new Timestamp rounded to the given resolution of freq

Raises
ValueError if the freq cannot be converted
pandas.Timestamp.strftime

 Timestamp.strftime(format)
 Return a string representing the given POSIX timestamp controlled by an explicit format string.

 Parameters

 format [str] Format string to convert Timestamp to string. See strftime documentation for more information on the format string: https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior.

 pandas.Timestamp.strptime

 classmethod Timestamp.strptime(string, format)
 Function is not implemented. Use pd.to_datetime().

 pandas.Timestamp.time

 Timestamp.time()
 Return time object with same time but with tzinfo=None.

 pandas.Timestamp.timestamp

 Timestamp.timestamp()
 Return POSIX timestamp as float.

 pandas.Timestamp.timetuple

 Timestamp.timetuple()
 Return time tuple, compatible with time.localtime().

 pandas.Timestamp.timetz

 Timestamp.timetz()
 Return time object with same time and tzinfo.

 pandas.Timestamp.to_datetime64

 Timestamp.to_datetime64()
 Return a numpy.datetime64 object with ‘ns’ precision.
**pandas.Timestamp.to_julian_date**

```
Timestamp.to_julian_date()
```

Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

**pandas.Timestamp.to_numpy**

```
Timestamp.to_numpy()
```

Convert the Timestamp to a NumPy datetime64.

New in version 0.25.0.

This is an alias method for `Timestamp.to_datetime64()`. The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

**Returns**

```
numpy.datetime64
```

**See also:**

`DatetimeIndex.to_numpy` Similar method for DatetimeIndex.

**pandas.Timestamp.to_period**

```
Timestamp.to_period()
```

Return an period of which this timestamp is an observation.

**pandas.Timestamp.to_pydatetime**

```
Timestamp.to_pydatetime()
```

Convert a Timestamp object to a native Python datetime object.

If warn=True, issue a warning if nanoseconds is nonzero.

**pandas.Timestamp.today**

```
classmethod Timestamp.today(cls, tz=None)
```

Return the current time in the local timezone. This differs from `datetime.today()` in that it can be localized to a passed timezone.

**Parameters**

```
tz [str or timezone object, default None] Timezone to localize to.
```
pandas.Timestamp.toordinal

```
Timestamp.toordinal()
Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.
```

pandas.Timestamp.tz_convert

```
Timestamp.tz_convert(tz)
Convert tz-aware Timestamp to another time zone.

Parameters

- tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

- converted [Timestamp]

Raises

- TypeError If Timestamp is tz-naive.
```

pandas.Timestamp.tz_localize

```
Timestamp.tz_localize(tz, ambiguous='raise', nonexistent='raise')
Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

Parameters

- tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.
- ambiguous [bool, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.

The behavior is as follows:
- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- ‘NaT’ will return NaT for an ambiguous time.
- ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.

- nonexistent [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

The behavior is as follows:
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
- ‘NaT’ will return NaT where there are nonexistent times.
timedelta objects will shift nonexistent times by the timedelta.

‘raise’ will raise a NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

localized [Timestamp]

Raises

TypeError If the Timestamp is tz-aware and tz is not None.

```
pandas.Timestamp.tzname

Timestamp.tzname()  # Return self.tzinfo.tzname(self).
```

```
pandas.Timestamp.utcfromtimestamp

classmethod Timestamp.utcfromtimestamp(ts)  # Construct a naive UTC datetime from a POSIX timestamp.
```

```
pandas.Timestamp.utcnow

classmethod Timestamp.utcnow()  # Return a new Timestamp representing UTC day and time.
```

```
pandas.Timestamp.utcoffset

Timestamp.utcoffset()  # Return self.tzinfo.utcoffset(self).
```

```
pandas.Timestamp.utctimetuple

Timestamp.utctimetuple()  # Return UTC time tuple, compatible with time.localtime().
```

```
pandas.Timestamp.weekday

Timestamp.weekday()  # Return the day of the week represented by the date. Monday == 0 . . . Sunday == 6
```

</tbody>
</table>

**pandas.Timestamp.freq**

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a DatetimeArray is a `DatetimeTZDtype`. For timezone-naive data, np.dtype("datetime64[ns]") is used.

If the data are tz-aware, then every value in the array must have the same timezone.

```
arrays.DatetimeArray(values[, dtype, freq, copy])  # Pandas ExtensionArray for tz-naive or tz-aware date-time data.
```

**pandas.arrays.DatetimeArray**

```
class pandas.arrays.DatetimeArray(values, dtype=dtype('<M8[ns]'), freq=None, copy=False)  # Pandas ExtensionArray for tz-naive or tz-aware datetime data.
```

New in version 0.24.0.

**Warning:** DatetimeArray is currently experimental, and its API may change without warning. In particular, DatetimeArray.dtype is expected to change to always be an instance of an ExtensionDtype
Parameters

- **values** [Series, Index, DatetimeArray, ndarray] The datetime data. For DatetimeArray values (or a Series or Index boxing one), *dtype* and *freq* will be extracted from *values*.

- **dtype** [numpy.dtype or DatetimeTZDtype] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.

- **freq** [str or Offset, optional] The frequency.

- **copy** [bool, default False] Whether to copy the underlying array of values.

Attributes

- **None**

Methods

- **None**

---

**DatetimeTZDtype([unit, tz])** An ExtensionDtype for timezone-aware datetime data.

### pandas.DatetimeTZDtype

class pandas.DatetimeTZDtype(*unit='ns', tz=None*)

An ExtensionDtype for timezone-aware datetime data.

This is not an actual numpy *dtype*, but a duck type.

Parameters

- **unit** [str, default “ns”] The precision of the datetime data. Currently limited to "ns".

- **tz** [str, int, or datetime.tzinfo] The timezone.

Raises

- **pytz.UnknownTimeZoneError** When the requested timezone cannot be found.

Examples

```python
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]

>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]
```
Attributes

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unit</td>
<td>The precision of the datetime data.</td>
</tr>
<tr>
<td>tz</td>
<td>The timezone.</td>
</tr>
</tbody>
</table>

**pandas.DatetimeTZDtype.unit**

*property* `DatetimeTZDtype.unit`

The precision of the datetime data.

**pandas.DatetimeTZDtype.tz**

*property* `DatetimeTZDtype.tz`

The timezone.

Methods

None

3.5.3 Timedelta data

NumPy can natively represent timedeltas. pandas provides `Timedelta` for symmetry with `Timestamp`.

**Timedelta**([value, unit])

Represents a duration, the difference between two dates or times.

**pandas.Timedelta**

*class* `pandas.Timedelta`(value=<object object>, unit=None, **kwargs)

Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python’s `datetime.timedelta` and is interchangeable with it in most cases.

**Parameters**

- **value** [Timedelta, timedelta, np.timedelta64, str, or int]
- **unit** [str, default ‘ns’] Denote the unit of the input, if input is an integer.
  
  Possible values:
  
  - ‘days’ or ‘day’
  - ‘hours’, ‘hour’, ‘hr’, or ‘h’
  - ‘minutes’, ‘minute’, ‘min’, or ‘m’
  - ‘seconds’, ‘second’, or ‘sec’
  - ‘milliseconds’, ‘millisecond’, ‘millis’, or ‘milli’
• ‘microseconds’, ‘microsecond’, ‘micros’, or ‘micro’

**kwargs**
Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with datetime.timedelta. Numpy ints and floats will be coerced to python ints and floats.

**Notes**

The `.value` attribute is always in ns.

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds.

**Attributes**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asm8</td>
<td>Return a numpy timedelta64 array scalar view.</td>
</tr>
<tr>
<td>components</td>
<td>Return a components namedtuple-like.</td>
</tr>
<tr>
<td>days</td>
<td>Number of days.</td>
</tr>
<tr>
<td>delta</td>
<td>Return the timedelta in nanoseconds (ns), for internal compatibility.</td>
</tr>
<tr>
<td>microseconds</td>
<td>Number of microseconds (&gt;= 0 and less than 1 second).</td>
</tr>
<tr>
<td>nanoseconds</td>
<td>Return the number of nanoseconds (n), where 0 &lt;= n &lt; 1 microsecond.</td>
</tr>
<tr>
<td>resolution_string</td>
<td>Return a string representing the lowest timedelta resolution.</td>
</tr>
<tr>
<td>seconds</td>
<td>Number of seconds (&gt;= 0 and less than 1 day).</td>
</tr>
</tbody>
</table>

**pandas.Timedelta.asm8**

Timedelta.asm8
Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the numpy.timedelta64().view(), including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

**Returns**

- **numpy timedelta64 array scalar view** Array scalar view of the timedelta in nanoseconds.
Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042,'ns')
```

```python
>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000,'ns')
```

```python
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000,'ns')
```

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42,'ns')
```

**pandas.Timedelta.components**

Timedelta components

Return a components namedtuple-like.

**pandas.Timedelta.days**

Timedelta.days

Number of days.

**pandas.Timedelta.delta**

Timedelta.delta

Return the timedelta in nanoseconds (ns), for internal compatibility.

Returns

int Timedelta in nanoseconds.

Examples

```python
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
86400000000042
```

```python
>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000
```

```python
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42

pandas.Timedelta.microseconds

Timedelta.microseconds
Number of microseconds (>= 0 and less than 1 second).

pandas.Timedelta.nanoseconds

Timedelta.nanoseconds
Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.

Returns

int Number of nanoseconds.

See also:

Timedelta.components Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

Examples

Using string input

>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')

>>> td.nanoseconds
42

Using integer input

>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42

pandas.Timedelta.resolution_string

Timedelta.resolution_string
Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: ‘D’
- Hours: ‘H’
- Minutes: ‘M’
• Seconds: ‘S’
• Milliseconds: ‘L’
• Microseconds: ‘U’
• Nanoseconds: ‘N’

Returns

str  Timedelta resolution.

Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution_string
'N'

>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution_string
'U'

>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution_string
'S'

>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution_string
'U'
```

pandas.Timedelta.seconds

Timedelta.seconds
Number of seconds (>= 0 and less than 1 day).

<table>
<thead>
<tr>
<th>freq</th>
<th>is_populated</th>
<th>value</th>
</tr>
</thead>
</table>

Methods

```
ceil(freq)  Return a new Timedelta ceiled to this resolution.
floor(freq)  Return a new Timedelta floored to this resolution.
isoformat   Format Timedelta as ISO 8601 Duration like
             [n] s are replaced by the values.
round(freq)  Round the Timedelta to the specified resolution.
to_numpy    Convert the Timedelta to a NumPy timedelta64.
to_pytimedelta  Convert a pandas Timedelta object tdelta64.
```
Table 92 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>to_timedelta64</code></td>
<td>Return a numpy.timedelta64 object with ‘ns’ precision.</td>
</tr>
<tr>
<td><code>total_seconds</code></td>
<td>Total seconds in the duration.</td>
</tr>
<tr>
<td><code>view</code></td>
<td>Array view compatibility.</td>
</tr>
</tbody>
</table>

**pandas.Timedelta.ceil**

`Timedelta.ceil(freq)`

Return a new Timedelta ceiled to this resolution.

**Parameters**

- `freq` [str] Frequency string indicating the ceiling resolution.

**pandas.Timedelta.floor**

`Timedelta.floor(freq)`

Return a new Timedelta floored to this resolution.

**Parameters**

- `freq` [str] Frequency string indicating the flooring resolution.

**pandas.Timedelta.isoformat**

`Timedelta.isoformat()`

**Returns**

- `str`

**See also:**

- `Timestamp.isoformat` Function is used to convert the given Timestamp object into the ISO format.

**Notes**

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0’s are removed from the seconds component after the decimal. We do not 0 pad components, so it’s … T5H…, not … T05H…
Examples

```python
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
    ...                 milliseconds=10, microseconds=10, nanoseconds=12)
```

```python
>>> td.isoformat()
'P6DT0H50M3.010010012S'
```

```python
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
```

```python
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
```

```python
>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0MS'
```

**pandas.Timedelta.round**

Timedelta.round(freq)

Round the Timedelta to the specified resolution.

- **Parameters**
  - `freq` [str] Frequency string indicating the rounding resolution.

- **Returns**
  - a new Timedelta rounded to the given resolution of `freq`

- **Raises**
  - ValueError if the freq cannot be converted

**pandas.Timedelta.to_numpy**

Timedelta.to_numpy()

Convert the Timedelta to a NumPy timedelta64.

- New in version 0.25.0.
  - This is an alias method for Timedelta.to_timedelta64(). The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

- **Returns**
  - numpy.timedelta64

See also:

- *Series.to_numpy* Similar method for Series.
pandas.Timedelta.to_pytimedelta

Timedelta.to_pytimedelta()
Convert a pandas Timedelta object into a python timedelta object.
Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use to_pytimedelta() to convert to object dtype.

Returns

datetime.timedelta or numpy.array of datetime.timedelta

See also:

to_timedelta Convert argument to Timedelta type.

Notes

Any nanosecond resolution will be lost.

pandas.Timedelta.to_timedelta64

Timedelta.to_timedelta64()
Return a numpy.timedelta64 object with ‘ns’ precision.

pandas.Timedelta.total_seconds

Timedelta.total_seconds()
Total seconds in the duration.

pandas.Timedelta.view

Timedelta.view()
Array view compatibility.

A collection of timedeltas may be stored in a TimedeltaArray.
arrays.TimedeltaArray(values[, dtype, freq])  Pandas ExtensionArray for timedelta data.
...

pandas.arrays.TimedeltaArray

class pandas.arrays.TimedeltaArray(values, dtype=dtype('<m8[ns]'), freq=<object object>, copy=False)

Pandas ExtensionArray for timedelta data.
New in version 0.24.0.

Warning: TimedeltaArray is currently experimental, and its API may change without warning. In particular, TimedeltaArray.dtype is expected to change to be an instance of an ExtensionDtype subclass.

Parameters

values [array-like] The timedelta data.
dtype [numpy.dtype] Currently, only numpy.dtype("timedelta64[ns]") is accepted.
freq [Offset, optional]
copy [bool, default False] Whether to copy the underlying array of data.

Attributes

None

Methods

None

3.5.4 Timespan data

pandas represents spans of times as Period objects.

3.5.5 Period

Period([value, freq, ordinal, year, month, ...]) Represents a period of time.
**pandas.Period**

```python
class pandas.Period(value=None, freq=None, ordinal=None, year=None, month=None, quarter=None, day=None, hour=None, minute=None, second=None)
```

Represents a period of time.

**Parameters**

- **value** [Period or str, default None] The time period represented (e.g., ‘4Q2005’).
- **freq** [str, default None] One of pandas period strings or corresponding objects.
- **ordinal** [int, default None] The period offset from the proleptic Gregorian epoch.
- **year** [int, default None] Year value of the period.
- **month** [int, default 1] Month value of the period.
- **quarter** [int, default None] Quarter value of the period.
- **day** [int, default 1] Day value of the period.
- **hour** [int, default 0] Hour value of the period.
- **minute** [int, default 0] Minute value of the period.
- **second** [int, default 0] Second value of the period.

</tbody>
</table>
pandas.Period.day

Period.day
Get day of the month that a Period falls on.

Returns
int

See also:

Period.dayofweek Get the day of the week.
Period.dayofyear Get the day of the year.

Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

pandas.Period.day_of_week

Period.day_of_week
Day of the week the period lies in, with Monday=0 and Sunday=6.
If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.
If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns
int Day of the week.

See also:

Period.day_of_week Day of the week the period lies in.
Period.weekday Alias of Period.day_of_week.
Period.day Day of the month.
Period.dayofyear Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.
```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

**pandas.Period.day_of_year**

Period.day_of_year  
Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

**Returns**

int  The day of year.

**See also:**

*Period.day*  Return the day of the month.

*Period.day_of_week*  Return the day of week.

*PeriodIndex.day_of_year*  Return the day of year of all indexes.

**Examples**

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```
pandas.Period.dayofweek

Period.dayofweek
Day of the week the period lies in, with Monday=0 and Sunday=6.
If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.
If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns
int Day of the week.

See also:

Period.day_of_week Day of the week the period lies in.
Period.weekday Alias of Period.day_of_week.
Period.day Day of the month.
Period.dayofyear Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```
For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```
For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

pandas.Period.dayofyear

Period.dayofyear
Return the day of the year.
This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns
int The day of year.

See also:
Period.day  Return the day of the month.

Period.day_of_week  Return the day of week.

PeriodIndex.day_of_year  Return the day of year of all indexes.

Examples

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```

pandas.Period.days_in_month

Period.days_in_month  Get the total number of days in the month that this period falls on.

Returns

int

See also:

Period.daysinmonth  Gets the number of days in the month.

DatetimeIndex.daysinmonth  Gets the number of days in the month.

calendar.monthrange  Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

Examples

```python
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28

>>> pd.Period('2018-03-01').days_in_month
31

Handles the leap year case as well:

```python
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```
pandas.Period.daysinmonth

**Period.daysinmonth**
Get the total number of days of the month that the Period falls in.

**Returns**

int

**See also:**

*Period.days_in_month* Return the days of the month.

*Period.dayofyear* Return the day of the year.

**Examples**

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

pandas.Period.hour

**Period.hour**
Get the hour of the day component of the Period.

**Returns**

int  The hour as an integer, between 0 and 23.

**See also:**

*Period.second* Get the second component of the Period.

*Period.minute* Get the minute component of the Period.

**Examples**

```python
>>> p.hour
13
```

Period longer than a day

```python
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```
**pandas.Period.minute**

Get minute of the hour component of the Period.

**Returns**

- int The minute as an integer, between 0 and 59.

**See also:**

- Period.hour Get the hour component of the Period.
- Period.second Get the second component of the Period.

**Examples**

```python
g = pd.Period("2018-03-11 13:03:12.050000")
g.minute
3
```

**pandas.Period.qyear**

Fiscal year the Period lies in according to its starting-quarter.

The year and the qyear of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

**Returns**

- int The fiscal year of the period.

**See also:**

- Period.year Return the calendar year of the period.

**Examples**

If the natural and fiscal year are the same, qyear and year will be the same.

```python
g = pd.Period('2018Q1', freq='Q')
g.qyear
g.year
2018
2018
```

If the fiscal year starts in April (Q-MAR), the first quarter of 2018 will start in April 2017. year will then be 2018, but qyear will be the fiscal year, 2017.

```python
g = pd.Period('2018Q1', freq='Q-MAR')
g.start_time
Timestamp('2017-04-01 00:00:00')
g.qyear
g.year
2018
2017
```
>>> per.year
2017

pandas.Period.second

Period.second
Get the second component of the Period.

Returns

int  The second of the Period (ranges from 0 to 59).

See also:

Period.hour  Get the hour component of the Period.
Period.minute  Get the minute component of the Period.

Examples

>>> p.second
12

pandas.Period.start_time

Period.start_time
Get the Timestamp for the start of the period.

Returns

Timestamp

See also:

Period.end_time  Return the end Timestamp.
Period.dayofyear  Return the day of year.
Period.daysinmonth  Return the days in that month.
Period.dayofweek  Return the day of the week.

Examples

>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')

>>> period.start_time
Timestamp('2012-01-01 00:00:00')
pandas: powerful Python data analysis toolkit, Release 1.2.2

```
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

**pandas.Period.week**

**Period.week**

Get the week of the year on the given Period.

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
</tr>
</tbody>
</table>

**See also:**

- **Period.dayofweek**  Get the day component of the Period.
- **Period.weekday**  Get the day component of the Period.

**Examples**

```python
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10

>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5

>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

**pandas.Period.weekday**

**Period.weekday**

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>int Day of the week.</td>
</tr>
</tbody>
</table>

**See also:**

- **Period.dayofweek**  Day of the week the period lies in.
- **Period.weekday**  Alias of Period.dayofweek.
- **Period.day**  Day of the month.
- **Period.dayofyear**  Day of the year.
Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

<table>
<thead>
<tr>
<th>end_time</th>
<th>freq</th>
<th>freqstr</th>
<th>is_leap_year</th>
<th>month</th>
<th>ordinal</th>
<th>quarter</th>
<th>weekofyear</th>
<th>year</th>
</tr>
</thead>
</table>

Methods

- `asfreq` Convert Period to desired frequency, at the start or end of the interval.
- `strftime` Returns the string representation of the Period, depending on the selected fmt.
- `to_timestamp` Return the Timestamp representation of the Period.

```python
pandas.Period.asfreq

Period.asfreq()  
Convert Period to desired frequency, at the start or end of the interval.

Parameters

freq [str] The desired frequency.

how [{'E', 'S', 'end', 'start'}, default 'end'] Start or end of the timespan.

Returns
```
resampled [Period]

pandas.Period.strftime

Period.strftime()  
Returns the string representation of the Period, depending on the selected fmt. fmt must be a string containing one or several directives. The method recognizes the same directives as the time.strftime() function of the standard Python distribution, as well as the specific additional directives %f, %F, %q. (formatting & docs originally from scikits.timeries).

<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Locale’s abbreviated weekday name.</td>
<td></td>
</tr>
<tr>
<td>%A</td>
<td>Locale’s full weekday name.</td>

<td></td>
</tr>
<tr>
<td>%s</td>
<td>Second as a decimal number [00,61].</td>
<td>(4)</td>
</tr>
<tr>
<td>%U</td>
<td>Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%w</td>
<td>Weekday as a decimal number [0(Sunday),6].</td>
<td></td>
</tr>
<tr>
<td>%W</td>
<td>Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%x</td>
<td>Locale’s appropriate date representation.</td>
<td></td>
</tr>
<tr>
<td>%X</td>
<td>Locale’s appropriate time representation.</td>
<td></td>
</tr>
<tr>
<td>%y</td>
<td>Year without century as a decimal number [00,99].</td>
<td></td>
</tr>
<tr>
<td>%Y</td>
<td>Year with century as a decimal number.</td>
<td></td>
</tr>
<tr>
<td>%z</td>
<td>Time zone name (no characters if no time zone exists).</td>
<td></td>
</tr>
<tr>
<td>%%</td>
<td>A literal ‘%’ character.</td>
<td></td>
</tr>
</tbody>
</table>
Notes

(1) The %d directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the quarterly attribute.

(2) The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the quarterly attribute.

(3) The %p directive only affects the output hour field if the %I directive is used to parse the hour.

(4) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.

(5) The %U and %W directives are only used in calculations when the day of the week and the year are specified.

Examples

```python
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-%Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

```
```

pandas.Period.to_timestamp

Period.to_timestamp()

Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by how, which is either Start or Finish.

Parameters

freq [str or DateOffset] Target frequency. Default is ‘D’ if self.freq is week or longer and ‘S’ otherwise.

Returns

Timestamp
**Properties**

pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.Period.now

Period.now()

A collection of timedeltas may be stored in a arrays.PeriodArray. Every period in a PeriodArray must have the same freq.

arrays.PeriodArray(values[, dtype, freq, copy]) Pandas ExtensionArray for storing Period data.

pandas.arrays.PeriodArray

class pandas.arrays.PeriodArray (values, dtype=None, freq=None, copy=False)

Pandas ExtensionArray for storing Period data.

Users should use period_range() to create new instances. Alternatively, array() can be used to create new instances from a sequence of Period scalars.

Parameters

values [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).

dtype [PeriodDtype, optional] A PeriodDtype instance from which to extract a freq. If both freq and dtype are specified, then the frequencies must match.

freq [str or DateOffset] The freq to use for the array. Mostly applicable when values is an ndarray of integers, when freq is required. When values is a PeriodArray (or box around), it’s checked that values.freq matches freq.

copy [bool, default False] Whether to copy the ordinals before storing.

See also:

Period Represents a period of time.
PeriodIndex Immutable Index for period data.
period_range Create a fixed-frequency PeriodArray.
array Construct a pandas array.

Notes

There are two components to a PeriodArray

- ordinals : integer ndarray
- freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The freq indicates the span covered by each element of the array. All elements in the PeriodArray have the same freq.
Attributes

None

Methods

None

PeriodDtype(freq)
An ExtensionDtype for Period data.

pandas.PeriodDtype

class pandas.PeriodDtype(freq=None)
An ExtensionDtype for Period data.

This is not an actual numpy dtype, but a duck type.

Parameters

freq [str or DateOffset] The frequency of this PeriodDtype.

Examples

```text
>>> pd.PeriodDtype(freq='D')
period[D]

>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```

Attributes

freq
The frequency object of this PeriodDtype.

pandas.PeriodDtype.freq

property PeriodDtype.freq
The frequency object of this PeriodDtype.
3.5.6 Interval data

Arbitrary intervals can be represented as *Interval* objects.

<table>
<thead>
<tr>
<th>Interval</th>
</tr>
</thead>
<tbody>
<tr>
<td>Immutable object implementing an Interval, a bounded slice-like interval.</td>
</tr>
</tbody>
</table>

**pandas.Interval**

*class pandas.Interval*  
Immutable object implementing an Interval, a bounded slice-like interval.

**Parameters**

- `left` [orderable scalar] Left bound for the interval.
- `right` [orderable scalar] Right bound for the interval.
- `closed` [{'right', 'left', 'both', 'neither'}, default 'right'] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

**See also:**

- *IntervalIndex* An Index of Interval objects that are all closed on the same side.
- *cut* Convert continuous data into discrete bins (Categorical of Interval objects).
- *qcut* Convert continuous data into bins (Categorical of Interval objects) based on quantiles.
- *Period* Represents a period of time.

**Notes**

The parameters `left` and `right` must be from the same type, you must be able to compare them and they must satisfy `left <= right`.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval `[0, 5]` is characterized by the conditions `0 <= x <= 5`. This is what `closed='both'` stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval `(0, 5)` is characterized by the conditions `0 < x < 5`. This is what `closed='neither'` stands for. Intervals can also be half-open or half-closed, i.e. `[0, 5)` is described by `0 <= x < 5`(`closed='left'`) and `(0, 5]` is described by `0 < x <= 5`(`closed='right'`).
Examples

It is possible to build Intervals of different types, like numeric ones:

```python
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it:

```python
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so \(0 < x \leq 5\)):

```python
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length:

```python
>>> iv.length
5
```

You can operate with `+` and `*` over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements:

```python
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds:

```python
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
                          pd.Timestamp('2018-01-01 00:00:00'),
                          closed='left')
>>> pd.Timestamp('2017-01-01 00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```
Attributes

</tbody>
</table>

pandas.Interval.closed

Interval.closed
Whether the interval is closed on the left-side, right-side, both or neither.

pandas.Interval.closed_left

Interval.closed_left
Check if the interval is closed on the left side.
For the meaning of closed and open see Interval.

Returns

bool  True if the Interval is closed on the left-side.

pandas.Interval.closed_right

Interval.closed_right
Check if the interval is closed on the right side.
For the meaning of closed and open see Interval.

Returns

bool  True if the Interval is closed on the left-side.

pandas.Interval.is_empty

Interval.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.

Returns
bool or ndarray  A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True

>>> pd.Interval(0, 0, closed='left').is_empty
True

>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.Interval.left

Interval.left
Left bound for the interval.

pandas.Interval.length

Interval.length
Return the length of the Interval.
**pandas.Interval.mid**

Interval.mid
Return the midpoint of the Interval.

**pandas.Interval.open_left**

Interval.open_left
Check if the interval is open on the left side.
For the meaning of closed and open see Interval.
Returns

**pandas.Interval.open_right**

Interval.open_right
Check if the interval is open on the right side.
For the meaning of closed and open see Interval.
Returns

**pandas.Interval.right**

Interval.right
Right bound for the interval.

**Methods**

<table>
<thead>
<tr>
<th>overlaps</th>
<th>Check whether two Interval objects overlap.</th>
</tr>
</thead>
</table>

**pandas.Interval.overlaps**

Interval.overlaps()
Check whether two Interval objects overlap.
Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.
New in version 0.24.0.

Parameters

other [Interval] Interval to check against for an overlap.

Returns

bool True if the two intervals overlap.
See also:

**IntervalArray.overlaps** The corresponding method for IntervalArray.

**IntervalIndex.overlaps** The corresponding method for IntervalIndex.

## Examples

```python
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```python
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

## Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Interval.closed</strong></td>
<td>Whether the interval is closed on the left-side, right-side, both or neither.</td>

<tr>
<td><strong>Interval.overlaps</strong></td>
<td>Check whether two Interval objects overlap.</td>
</tr>
<tr>
<td><strong>Interval.right</strong></td>
<td>Right bound for the interval.</td>
</tr>
</tbody>
</table>

A collection of intervals may be stored in an `arrays.IntervalArray`.

```python
arrays.IntervalArray(data[, closed, dtype, ...])
```

Pandas array for interval data that are closed on the same side.

---

**3.5. pandas arrays**

---

**pandas: powerful Python data analysis toolkit, Release 1.2.2**
**pandas: powerful Python data analysis toolkit, Release 1.2.2**

**pandas.arrays.IntervalArray**

```python
class pandas.arrays.IntervalArray(data, closed=None, dtype=None, copy=False, verify_integrity=True)
```

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

**Parameters**

- `data` [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.
- `closed` [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- `dtype` [dtype or None, default None] If None, dtype will be inferred.
- `copy` [bool, default False] Copy the input data.
- `verify_integrity` [bool, default True] Verify that the IntervalArray is valid.

**See also:**

- `Index` The base pandas Index type.
- `Interval` A bounded slice-like interval; the elements of an IntervalArray.
- `interval_range` Function to create a fixed frequency IntervalIndex.
- `cut` Bin values into discrete Intervals.
- `qcut` Bin values into equal-sized Intervals based on rank or sample quantiles.

**Notes**

See the user guide for more.

**Examples**

A new IntervalArray can be constructed directly from an array-like of Interval objects:

```python
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
<IntervalArray>
[(0, 1], (1, 5])
Length: 2, closed: right, dtype: interval[int64]
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

**Attributes**

<table>

</tr>
</tbody>
</table>

`pandas.arrays.IntervalArray.left`

**property** `IntervalArray.left`

Return the left endpoints of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.right`

**property** `IntervalArray.right`

Return the right endpoints of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.closed`

**property** `IntervalArray.closed`

Whether the intervals are closed on the left-side, right-side, both or neither.

`pandas.arrays.IntervalArray.mid`

**property** `IntervalArray.mid`

Return the midpoint of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.length`

**property** `IntervalArray.length`

Return an Index with entries denoting the length of each Interval in the IntervalArray.

`pandas.arrays.IntervalArray.is_empty`

**IntervalArray.is_empty**

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns**

- `bool` or `ndarray` A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.
Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
          pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([True, False])
```

**pandas.arrays.IntervalArray.is_non_overlapping_monotonic**

**property** IntervalArray.is_non_overlapping_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

Methods

**pandas.arrays.IntervalArray.from_arrays**

**classmethod** `IntervalArray.from_arrays` *(left, right, closed='right', copy=False, dtype=None)*

Construct from two arrays defining the left and right bounds.

**Parameters**

- **left** [array-like (1-dimensional)] Left bounds for each interval.
- **right** [array-like (1-dimensional)] Right bounds for each interval.
- **closed** [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] Copy the data.
- **dtype** [dtype, optional] If None, dtype will be inferred.

**Returns**

IntervalArray

**Raises**

ValueError When a value is missing in only one of `left` or `right`. When a value in `left` is greater than the corresponding value in `right`.

**See also:**

- `interval_range` Function to create a fixed frequency IntervalIndex.
- `IntervalArray.from_breaks` Construct an IntervalArray from an array of splits.
- `IntervalArray.from_tuples` Construct an IntervalArray from an array-like of tuples.

**Notes**

Each element of `left` must be less than or equal to the `right` element at the same position. If an element is missing, it must be missing in both `left` and `right`. A TypeError is raised when using an unsupported type for `left` or `right`. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

```python
>>> pd.arrays.IntervalArray.from_arrays([[0, 1, 2], [1, 2, 3]])
<IntervalArray>
[[0, 1], (1, 2), (2, 3)]
Length: 3, closed: right, dtype: interval[int64]
```
pandas.arrays.IntervalArray.from_tuples

classmethod IntervalArray.from_tuples(data, closed='right', copy=False, dtype=None)
Construct an IntervalArray from an array-like of tuples.

Parameters

- **data** [array-like (1-dimensional)] Array of tuples.
- **closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] By-default copy the data, this is compat only and ignored.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalArray

See also:

- **interval_range** Function to create a fixed frequency IntervalIndex.
- **IntervalArray.from_arrays** Construct an IntervalArray from a left and right array.
- **IntervalArray.from_breaks** Construct an IntervalArray from an array of splits.

Examples

```python
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[[0, 1), (1, 2]]
Length: 2, closed: right, dtype: interval[int64]
```

pandas.arrays.IntervalArray.from_breaks

classmethod IntervalArray.from_breaks(breaks, closed='right', copy=False, dtype=None)
Construct an IntervalArray from an array of splits.

Parameters

- **breaks** [array-like (1-dimensional)] Left and right bounds for each interval.
- **closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] Copy the data.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalArray

See also:

- **interval_range** Function to create a fixed frequency IntervalIndex.
- **IntervalArray.from_arrays** Construct from a left and right array.
**IntervalArray.from_tuples** Construct from a sequence of tuples.

**Examples**

```python
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
```

**pandas.arrays.IntervalArray.contains**

**IntervalArray.contains**(other)  
Check elementwise if the Intervals contain the value.  
Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.  
New in version 0.25.0.

**Parameters**

- **other** [scalar] The value to check whether it is contained in the Intervals.

**Returns**

- boolean array

**See also:**

- **Interval.contains** Check whether Interval object contains value.
- **IntervalArray.overlaps** Check if an Interval overlaps the values in the IntervalArray.

**Examples**

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]
Length: 3, closed: right, dtype: interval[int64]
```

```python
>>> intervals.contains(0.5)
array([ True, False, False])
```

**pandas.arrays.IntervalArray.overlaps**

**IntervalArray.overlaps**(other)  
Check elementwise if an Interval overlaps the values in the IntervalArray.  
Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.  
New in version 0.24.0.

**Parameters**

- **other** [IntervalArray] Interval to check against for an overlap.
Returns

ndarray  Boolean array positionally indicating where an overlap occurs.

See also:

Interval.overlaps  Check whether two Interval objects overlap.

Examples

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]
Length: 3, closed: right, dtype: interval[int64]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True,  False])
Intervals that share closed endpoints overlap:

>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
Intervals that only have an open endpoint in common do not overlap:

>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

pandas.arrays.IntervalArray.set_closed

IntervalArray.set_closed(closed)

Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

Parameters

closed  [{‘left’, ‘right’, ‘both’, ‘neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

new_index  [IntervalArray]
Examples

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3]
Length: 3, closed: right, dtype: interval[int64]

>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, closed: both, dtype: interval[int64]
```

**pandas.arrays.IntervalArray.to_tuples**

IntervalArray.to_tuples(na_tuple=True)
Return an ndarray of tuples of the form (left, right).

**Parameters**

- **na_tuple** [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

**Returns**

tuples: ndarray

**IntervalDtype**(subtype) An ExtensionDtype for Interval data.

**pandas.IntervalDtype**

class pandas.IntervalDtype(subtype=None)
An ExtensionDtype for Interval data.

This is not an actual numpy dtype, but a duck type.

**Parameters**

- **subtype** [str, np.dtype] The dtype of the Interval bounds.
Examples

```pandas
>>> pd.IntervalDtype(subtype='int64')
interval[int64]
```

Attributes

```python
 subtype
```

The dtype of the Interval bounds.

```python
pandas.IntervalDtypesubtype
```

`property pandas.IntervalDtypesubtype`

The dtype of the Interval bounds.

Methods

```
None
```

3.5.7 Nullable integer

`numpy.ndarray` cannot natively represent integer-data with missing values. pandas provides this through `arrays.IntegerArray`.

```python
arrays.IntegerArray(values, mask[, copy])
```

Array of integer (optional missing) values.

New in version 0.24.0.

Changed in version 1.0.0: Now uses `pandas.NA` as the missing value rather than `numpy.nan`.

```
Warning: IntegerArray is currently experimental, and its API or internal implementation may change without warning.
```

We represent an IntegerArray with 2 `numpy` arrays:

- data: contains a `numpy` integer array of the appropriate dtype
- mask: a boolean array holding a mask on the data, True is missing

To construct an IntegerArray from generic array-like input, use `pandas.array()` with one of the integer dtypes (see examples).

See `Nullable integer data type` for more.

```
Parameters
```
copy [bool, default False] Whether to copy the values and mask.

Returns

IntegerArray

Examples

Create an IntegerArray with *pandas.array()*.

```python
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```python
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32

>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

    Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.
3.5.8 Categorical data

pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a Categorical can be described by a pandas.api.types.CategoricalDtype.

CategoricalDtype([categories, ordered]) Type for categorical data with the categories and orderedness.

pandas.CategoricalDtype
class pandas.CategoricalDtype(categories=None, ordered=False)
Type for categorical data with the categories and orderedness.

Parameters
- categories [sequence, optional] Must be unique, and must not contain any nulls. The categories are stored in an Index, and if an index is provided the dtype of that index will be used.
- ordered [bool or None, default False] Whether or not this categorical is treated as a ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. astype, and will resolve to False if there is no existing ordered to maintain.

See also:
- Categorical Represent a categorical variable in classic R / S-plus fashion.

Notes

This class is useful for specifying the type of a Categorical independent of the values. See CategoricalDtype for more.

Examples

```python
gt = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
pd.Series(['a', 'b', 'a', 'c'], dtype=t)
```
An empty CategoricalDtype with a specific dtype can be created by providing an empty index. As follows,

```python
>>> pd.CategoricalDtype(pd.DatetimeIndex([])).categories.dtype
dtype('<M8[ns]')
```

### Attributes

<table>
<thead>
<tr>
<th>attribute</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>An Index containing the unique categories allowed.</td>
</tr>
<tr>
<td>ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

```python
pandas.CategoricalDtype.categories
```

**property** CategoricalDtype.categories
An Index containing the unique categories allowed.

```python
pandas.CategoricalDtype.ordered
```

**property** CategoricalDtype.ordered
Whether the categories have an ordered relationship.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CategoricalDtype.categories</td>
<td>An Index containing the unique categories allowed.</td>
</tr>
<tr>
<td>CategoricalDtype.ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

Categorical data can be stored in a `pandas.Categorical`

```python
Categorical(values[, categories, ordered, ...])
```

Represent a categorical variable in classic R / S-plus fashion.

### pandas.Categorical

```python
class pandas.Categorical(values, categories=None, ordered=None, dtype=None, fastpath=False)
```

Represent a categorical variable in classic R / S-plus fashion.

`Categoricals` can only take on only a limited, and usually fixed, number of possible values (`categories`). In contrast to statistical categorical variables, a `Categorical` might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the `Categorical` are either in `categories` or `np.nan`. Assigning values outside of `categories` will raise a `ValueError`. Order is defined by the order of the `categories`, not lexical order of the values.

**Parameters**

- `values` [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.
categories [Index-like (unique), optional] The unique categories for this categorical. If not
given, the categories are assumed to be the unique values of values (sorted, if possible,
otherwise in the order in which they appear).

ordered [bool, default False] Whether or not this categorical is treated as a ordered categor-
ical. If True, the resulting categorical will be ordered. An ordered categorical respects,
when sorted, the order of its categories attribute (which in turn is the categories argu-
ment, if provided).

dtype [CategoricalDtype] An instance of CategoricalDtype to use for this categorical.

Raises

ValueError If the categories do not validate.

TypeError If an explicit ordered=True is given but no categories and the values are not
sortable.

See also:

CategoricalDtype Type for categorical data.
CategoricalIndex An Index with an underlying Categorical.

Notes

See the user guide for more.

Examples

```python
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]

>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Missing values are not included as a category.

```python
>>> c = pd.Categorical([1, 2, 3, 1, 2, 3, np.nan])
>>> c
[1, 2, 3, NaN, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

However, their presence is indicated in the codes attribute by code -1.

```python
>>> c.codes
array([ 0,  1,  2,  0,  1,  2, -1], dtype=int8)
```

Ordered Categoricals can be sorted according to the custom order of the categories and can have a min and max
value.

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
...                     categories=['c', 'b', 'a'])
>>> c
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['c' < 'b' < 'a']
```

(continues on next page)
>>> c.min()
'c'

Attributes

categories
Attributes
The categories of this categorical.
codes
The category codes of this categorical.
ordered
Whether the categories have an ordered relationship.
dtype
The CategoricalDtype for this instance.

pandas.Categorical.categories

property Categorical.categories
The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the
new categories must be the same as the number of items in the old categories.

Assigning to categories is an inplace operation!

Raises

ValueError  If the new categories do not validate as categories or if the number of new
categories is unequal the number of old categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Categorical.codes

property Categorical.codes
The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the
categorical.

Returns

ndarray[int]  A non-writable view of the codes array.
pandas.Categorical.ordered

property Categorical.ordered
Whether the categories have an ordered relationship.

pandas.Categorical.dtype

property Categorical.dtype
The CategoricalDtype for this instance.

Methods

from_codes(codes[, categories, ordered, dtype]) Make a Categorical type from codes and categories or dtype.

__array__([dtype]) The numpy array interface.

pandas.Categorical.from_codes

classmethod Categorical.from_codes(codes, categories=None, ordered=None, dtype=None)
Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

Parameters

codes [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in dtype.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in dtype, the resulting categorical will be unordered.

dtype [CategoricalDtype or “category”, optional] If CategoricalDtype, cannot be used together with categories or ordered.

New in version 0.24.0: When dtype is provided, neither categories nor ordered should be provided.

Returns

Categorical
Examples

```
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

**pandas.Categorical.__array__**

Categorical.__array__(dtype=None)  
The numpy array interface.

Returns

numpy.array  A numpy array of either the specified dtype or, if dtype==None (default),  
the same dtype as categorical.categories.dtype.

The alternative Categorical.from_codes() constructor can be used when you have the categories and integer  
codes already:

```
Categorical.from_codes(codes[, categories, ...])  
Make a Categorical type from codes and categories or dtype.
```

The dtype information is available on the Categorical

<table>
<thead>
<tr>
<th>Categorical.dtype</th>
<th>The CategoricalDtype for this instance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Categorical.categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>Categorical.ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td>Categorical.codes</td>
<td>The category codes of this categorical.</td>
</tr>
</tbody>
</table>

np.asarray(categorical) works by implementing the array interface. Be aware, that this converts the Categorical back to a NumPy array, so categories and order information is not preserved!

```
Categorical.__array__((dtype))  
The numpy array interface.
```

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use cat =  
s.astype(dtype) where dtype is either

- the string 'category'
- an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, Series.cat can be used to change the categorical data. See  
Categorical accessor for more.
3.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a `arrays.SparseArray`.

`arrays.SparseArray(data[, sparse_index, ...])` An ExtensionArray for storing sparse data.

`pandas.arrays.SparseArray`

**class pandas.arrays.SparseArray**(data, sparse_index=None, index=None, fill_value=None, kind='integer', dtype=None, copy=False)

An ExtensionArray for storing sparse data.

Changed in version 0.24.0: Implements the ExtensionArray interface.

**Parameters**

- **data** [array-like] A dense array of values to store in the SparseArray. This may contain `fill_value`.
- **sparse_index** [SparseIndex, optional]
- **index** [Index]
- **fill_value** [scalar, optional] Elements in `data` that are `fill_value` are not stored in the SparseArray. For memory savings, this should be the most common value in `data`. By default, `fill_value` depends on the dtype of `data`:

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The fill value is potentially specified in three ways. In order of precedence, these are

1. The `fill_value` argument
2. `dtype.fill_value` if `fill_value` is None and `dtype` is a SparseDtype
3. `data.dtype.fill_value` if `fill_value` is None and `dtype` is not a SparseDtype and `data` is a SparseArray.

**kind** [‘integer’, ‘block’], default ‘integer’ The type of storage for sparse locations.

- ‘block’: Stores a `block` and `block_length` for each contiguous `span` of sparse values. This is best when sparse data tends to be clumped together, with large regions of `fill_value` values between sparse values.
- ‘integer’: uses an integer to store the location of each sparse value.

**dtype** [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of self.sp_values. For SparseDtype, this determines self.sp_values and self.fill_value.

**copy** [bool, default False] Whether to explicitly copy the incoming `data` array.
Examples

```python
>>> from pandas.arrays import SparseArray
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Attributes

| None |

Methods

| None |

```
SparseDtype(dtype, fill_value)
```

Dtype for data stored in `SparseArray`.

**pandas.SparseDtype**

```python
class pandas.SparseDtype(dtype=<class 'numpy.float64'>, fill_value=None)
```

Dtype for data stored in `SparseArray`.

This dtype implements the pandas ExtensionDtype interface.

New in version 0.24.0.

**Parameters**

- **dtype** [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.

- **fill_value** [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on `dtype`.

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The default value may be overridden by specifying a `fill_value`.
Attributes

None

Methods

None

The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the `Series` contains sparse values. See Sparse accessor for more.

### 3.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using `StringDtype` (with the alias "string").

```python
arrays.StringArray(values[, copy])
```

Extension array for string data.

#### pandas.arrays.StringArray

```python
class pandas.arrays.StringArray(values, copy=False)
```

Extension array for string data.

New in version 1.0.0.

**Warning:** StringArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

- `values [array-like]` The array of data.

  **Warning:** Currently, this expects an object-dtype ndarray where the elements are Python strings or `pandas.NA`. This may change without warning in the future. Use `pandas.array()` with `dtype="string"` for a stable way of creating a `StringArray` from any sequence.

- `copy [bool, default False]` Whether to copy the array of data.

**See also:**

- `array` The recommended function for creating a StringArray.
- `Series.str` The string methods are available on Series backed by a StringArray.
Notes

StringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.]
Length: 4, dtype: string
```

Unlike arrays instantiated with dtype="object", StringArray will convert the values to strings.

```python
>>> pd.array(['1', 1], dtype="object")
<PandasArray>
['1', 1]
Length: 2, dtype: object
>>> pd.array(['1', 1], dtype="string")
<StringArray>
['1', '1']
Length: 2, dtype: string
```

However, instantiating StringArrays directly with non-strings will raise an error.

For comparison methods, StringArray returns a pandas.BooleanArray:

```python
>>> pd.array(['a', None, 'c'], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

Attributes

- None

Methods

- None

StringDtype()  Extension dtype for string data.
pandas.StringDtype

class pandas.StringDtype
   Extension dtype for string data.

   New in version 1.0.0.

   Warning: StringDtype is considered experimental. The implementation and parts of the API may change without warning.
   In particular, StringDtype.na_value may change to no longer be numpy.nan.

Examples

>>> pd.StringDtype()
StringDtype

Attributes

None

Methods

None

The Series.str accessor is available for Series backed by a arrays.StringArray. See String handling for more.

3.5.11 Boolean data with missing values

The boolean dtypes (with the alias "boolean") provides support for storing boolean data (True, False values) with missing values, which is not possible with a bool numpy.ndarray.

arrays.BooleanArray(values, mask[, copy])   Array of boolean (True/False) data with missing values.

pandas.arrays.BooleanArray

class pandas.arrays.BooleanArray(values, mask, copy=False)
   Array of boolean (True/False) data with missing values.

   This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

   BooleanArray implements Kleene logic (sometimes called three-value logic) for logical operations. See Kleene logical operations for more.

   To construct an BooleanArray from generic array-like input, use pandas.array() specifying dtype="boolean" (see examples below).
New in version 1.0.0.

**Warning:** BooleanArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

- **values** [numpy.ndarray] A 1-d boolean-dtype array with the data.
- **mask** [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).
- **copy** [bool, default False] Whether to copy the values and mask arrays.

**Returns**

BooleanArray

**Examples**

Create an BooleanArray with `pandas.array()`:

```python
>>> pd.array([True, False, None], dtype="boolean"
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

**Attributes**

None

**Methods**

None

`BooleanDtype()` Extension dtype for boolean data.

**pandas.BooleanDtype**

```python
class pandas.BooleanDtype
    Extension dtype for boolean data.

    New in version 1.0.0.
```

**Warning:** BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.
Examples

```python
>>> pd.BooleanDtype()
BooleanDtype
```

Attributes

Methods

None

3.6 Index objects

3.6.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

```python
Index([data, dtype, copy, name, tupleize_cols]) Immutable sequence used for indexing and alignment.
```

*pandas.Index*

```python
class pandas.Index(data=None, dtype=None, copy=False, name=None, tupleize_cols=True, **kwargs)
```

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects.

**Parameters**

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it’s safe. Otherwise, an error will be raised.
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.
- **tupleize_cols** [bool (default: True)] When True, attempt to create a MultiIndex if possible.

**See also:**

- `RangeIndex` Index implementing a monotonic integer range.
- `CategoricalIndex` Index of `Categoricals`.
- `MultiIndex` A multi-level, or hierarchical Index.
- `IntervalIndex` An Index of `Intervals`.
- `DatetimeIndex` Index of datetime64 data.
- `TimedeltaIndex` Index of timedelta64 data.
- `PeriodIndex` Index of Period data.
- `Int64Index` A special case of `Index` with purely integer labels.
**UInt64Index** A special case of `Index` with purely unsigned integer labels.

**Float64Index** A special case of `Index` with purely float labels.

**Notes**

An Index instance can **only** contain hashable objects.

**Examples**

```python
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')

>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

**Attributes**

<tr>
<td><code>values</code></td>
<td>Return an array representing the data in the Index.</td>
</tr>
</tbody>
</table>
pandas.Index.T

**property** Index.T
Return the transpose, which is by definition self.

pandas.Index.array

Index.array
The ExtensionArray of the data backing this Series or Index.
New in version 0.24.0.

**Returns**

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around numpy.ndarray.
.array differs .values which may require converting the data to a different form.

See also:

Index.to_numpy Similar method that always returns a NumPy array.
Series.to_numpy Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use Series.to_numpy() instead.
Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

```{codeblock}
pandas.Index.asi8

**property** `Index.asi8`

Integer representation of the values.

**Returns**

- `ndarray` An ndarray with int64 dtype.
```

```{codeblock}
pandas.Index.dtype

**Index.dtype**

Return the dtype object of the underlying data.
```

```{codeblock}
pandas.Index.has_duplicates

**property** `Index.has_duplicates`

Check if the Index has duplicate values.

**Returns**

- `bool` Whether or not the Index has duplicate values.
```

Examples

```python
>>> idx = pd.Index([1, 5, 7, 7])
>>> idx.has_duplicates
True
```

```python
>>> idx = pd.Index([1, 5, 7])
>>> idx.has_duplicates
False
```

```python
>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ...
... "Watermelon"]).astype("category")
>>> idx.has_duplicates
True
```
```python
>>> idx = pd.Index(["Orange", "Apple", ...
     "Watermelon"]).astype("category")
>>> idx.has_duplicates
False
```

**pandas.Index.hasnans**

`Index.hasnans`
Return if I have any nan; enables various perf speedups.

**pandas.Index.inferred_type**

`Index.inferred_type`
Return a string of the type inferred from the values.

**pandas.Index.is_all_dates**

`Index.is_all_dates`
Whether or not the index values only consist of dates.

**pandas.Index.is_monotonic**

*property* `Index.is_monotonic`
Alias for `is_monotonic_increasing`.

**pandas.Index.is_monotonic_decreasing**

*property* `Index.is_monotonic_decreasing`
Return if the index is monotonic decreasing (only equal or decreasing) values.

**Examples**

```python
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.Index.is_monotonic_increasing**

**property Index.is_monotonic_increasing**  
Return if the index is monotonic increasing (only equal or increasing) values.

**Examples**

```python
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

**pandas.Index.is_unique**

**Index.is_unique**  
Return if the index has unique values.

**pandas.Index.name**

**property Index.name**  
Return Index or MultiIndex name.

**pandas.Index.nbytes**

**property Index.nbytes**  
Return the number of bytes in the underlying data.

**pandas.Index.ndim**

**property Index.ndim**  
Number of dimensions of the underlying data, by definition 1.

**pandas.Index.nlevels**

**property Index.nlevels**  
Number of levels.
pandas.Index.shape

**property Index.shape**
Return a tuple of the shape of the underlying data.

pandas.Index.size

**property Index.size**
Return the number of elements in the underlying data.

pandas.Index.values

**property Index.values**
Return an array representing the data in the Index.

```
Warning: We recommend using Index.array or Index.to_numpy(), depending on whether you need a reference to the underlying data or a NumPy array.
```

**Returns**

array: numpy.ndarray or ExtensionArray

**See also:**

- Index.array Reference to the underlying data.
- Index.to_numpy A NumPy array representing the underlying data.

<tr>
<td><code>where(cond[, other])</code></td>
<td>Replace values where the condition is False.</td>
</tr>
</tbody>
</table>
pandas.Index.all

Index.all()  
Return whether all elements are Truthy.

Parameters

*args  These parameters will be passed to numpy.all.
**kwargs These parameters will be passed to numpy.all.

Returns

all [bool or array_like (if axis is specified)] A single element array_like may be converted to bool.

See also:

Index.any  Return whether any element in an Index is True.
Series.any  Return whether any element in a Series is True.
Series.all  Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all

True, because nonzero integers are considered True.

>>> pd.Index([1, 2, 3]).all()  
True

False, because 0 is considered False.

>>> pd.Index([0, 1, 2]).all()  
False

any

True, because 1 is considered True.

>>> pd.Index([0, 0, 1]).any()  
True

False, because 0 is considered False.

>>> pd.Index([0, 0, 0]).any()  
False
pandas.Index.any

Index.any(*args, **kwargs)
Return whether any element is Truthy.

Parameters

*args  These parameters will be passed to numpy.any.

**kwargs These parameters will be passed to numpy.any.

Returns

any  [bool or array_like (if axis is specified)] A single element array_like may be converted to bool.

See also:

Index.all  Return whether all elements are True.
Series.all  Return whether all elements are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

```python
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True

>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

pandas.Index.append

Index.append(other)
Append a collection of Index options together.

Parameters

other  [Index or list/tuple of indices]

Returns

appended  [Index]
pandas.Index.argmax

Index.argmax (axis=None, skipna=True, *args, **kwargs)
Return int position of the largest value in the Series.
If the maximum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the maximum value.

See also:

Series.argmax Return position of the maximum value.
Series.argmin Return position of the minimum value.
numpy.ndarray.argmax Equivalent method for numpy arrays.
Series.idxmax Return index label of the maximum values.
Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                     'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
... >>> s
Corn Flakes       100.0
Almond Delight    110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff        110.0
dtype: float64
```

```python
>>> s.argmax()
2
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
Index objects

### pandas.Index.argmin

**Index.min**(axis=None, skipna=True, *args, **kwargs)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

**Parameters**

- **axis** [{None}] Dummy argument for consistency with Series.
- **skipna** [bool, default True] Exclude NA/null values when showing the result.
- ***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

**Returns**

- **int** Row position of the minimum value.

**See also:**

- **Series.argmin** Return position of the minimum value.
- **Series.argmax** Return position of the maximum value.
- **numpy.ndarray.argmin** Equivalent method for numpy arrays.
- **Series.idxmax** Return index label of the maximum values.
- **Series.idxmin** Return index label of the minimum values.

### Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                   'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff     110.0
dtype: float64

>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
**pandas.Index.argsort**

`Index.argsort(*args, **kwargs)`

Return the integer indices that would sort the index.

**Parameters**

* *args* Passed to `numpy.ndarray.argsort`.

**kwargs** Passed to `numpy.ndarray.argsort`.

**Returns**

`numpy.ndarray` Integer indices that would sort the index if used as an indexer.

*See also:*

`numpy.argsort` Similar method for NumPy arrays.

`Index.sort_values` Return sorted copy of Index.

**Examples**

```python
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')

>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])

>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

**pandas.Index.asof**

`Index.asof(label)`

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

**Parameters**

* label [object] The label up to which the method returns the latest index label.

**Returns**

* object The passed label if it is in the index. The previous label if the passed label is not in the sorted index or `NaN` if there is no such label.

*See also:*

`Series.asof` Return the latest value in a Series up to the passed index.

`merge_asof` Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).

`Index.get_loc` An `asof` is a thin wrapper around `get_loc` with method=`'pad'`.  

1932 Chapter 3. API reference
Examples

*Index.asof* returns the latest index label up to the passed label.

```python
>>> idx.asof(‘2014-01-01’)
’2013-12-31’
```

If the label is in the index, the method returns the passed label.

```python
>>> idx.asof(‘2014-01-02’)
’2014-01-02’
```

If all of the labels in the index are later than the passed label, NaN is returned.

```python
>>> idx.asof(‘1999-01-02’)
nan
```

If the index is not sorted, an error is raised.

```python
>>> idx_not_sorted = pd.Index([‘2013-12-31’, ‘2015-01-02’, ...
                             ‘2014-01-03’])
>>> idx_not_sorted.asof(‘2013-12-31’)
Traceback (most recent call last):
  File “”, line 1, in <module>
  File “…/pandas/core/index.py”, line 1446, in asof
ValueError: index must be monotonic increasing or decreasing
```

*pandas.Index.asof_locs*

*Index.asof_locs* (*where*, *mask*)

Return the locations (indices) of labels in the index.

As in the *asof* function, if the label (a particular entry in *where*) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in *where*, -1 is returned.

*mask* is used to ignore NA values in the index during calculation.

**Parameters**

*where*  [Index] An Index consisting of an array of timestamps.

*mask*  [array-like] Array of booleans denoting where values in the original data are not NA.

**Returns**

*numpy.ndarray* An array of locations (indices) of the labels from the Index which correspond to the return values of the *asof* function for every element in *where*. 
**pandas.Index.astype**

Index.astype
dtype, copy=True
Create an Index with values cast to dtypes.

The class of a new Index is determined by dtype. When conversion is impossible, a TypeError exception is raised.

**Parameters**

- **dtype** [numpy dtype or pandas type] Note that any signed integer dtype is treated as 'int64', and any unsigned integer dtype is treated as 'uint64', regardless of the size.
- **copy** [bool, default True] By default, astype always returns a newly allocated object. If copy is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.

**Returns**

- Index Index with values cast to specified dtype.

**pandas.Index.copy**

Index.copy
name=None, deep=False, dtype=None, names=None
Make a copy of this object.

Name and dtype sets those attributes on the new object.

**Parameters**

- **name** [Label, optional] Set name for new object.
- **deep** [bool, default False]
- **dtype** [numpy dtype or pandas type, optional] Set dtype for new object.

Deprecated since version 1.2.0: use astype method instead.

- **names** [list-like, optional] Kept for compatibility with MultiIndex. Should not be used.

**Returns**

- Index Index refer to new object which is a copy of this object.

**Notes**

In most cases, there should be no functional difference from using deep, but if deep is passed it will attempt to deepcopy.
pandas.Index.delete

Index.delete(loc)
Make new Index with passed location(-s) deleted.

Parameters
- loc [int or list of int] Location of item(-s) which will be deleted. Use a list of locations to delete more than one value at the same time.

Returns
- Index New Index with passed location(-s) deleted.

See also:
numpy.delete Delete any rows and column from NumPy array (ndarray).

Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete(1)
Index(['a', 'c'], dtype='object')
```

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete([0, 2])
Index(['b'], dtype='object')
```

pandas.Index.difference

Index.difference(other, sort=None)
Return a new Index with elements of index not in other.
This is the set difference of two Index objects.

Parameters
- other [Index or array-like]
- sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.
  - None: Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
  - False: Do not sort the result.

New in version 0.24.0.
Changed in version 0.24.1: Changed the default value from True to None (without change in behaviour).

Returns
- difference [Index]
Examples

```python
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

**pandas.Index.drop**

Index.drop(labels, errors='raise')
Make new Index with passed list of labels deleted.

**Parameters**

- **labels** [array-like]
- **errors** [{‘ignore’, ‘raise’}, default ‘raise’] If ‘ignore’, suppress error and existing labels are dropped.

**Returns**

- **dropped** [Index]

**Raises**

- **KeyError** If not all of the labels are found in the selected axis

**pandas.Index.drop_duplicates**

Index.drop_duplicates(keep='first')
Return Index with duplicate values removed.

**Parameters**

- **keep** [{‘first’, ‘last’, False}, default ‘first’]
  - ‘first’: Drop duplicates except for the first occurrence.
  - ‘last’: Drop duplicates except for the last occurrence.
  - **False**: Drop all duplicates.

**Returns**

- **deduplicated** [Index]

**See also:**

- **Series.drop_duplicates** Equivalent method on Series.
- **DataFrame.drop_duplicates** Equivalent method on DataFrame.
- **Index.duplicated** Related method on Index, indicating duplicate Index values.
### Examples

Generate an pandas.Index with duplicate values.

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The `keep` parameter controls which duplicate values are removed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of `keep` is ‘first’.

```python
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value ‘last’ keeps the last occurrence for each set of duplicated entries.

```python
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```python
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

### pandas.Index.droplevel

`Index.droplevel(level=0)`

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

**Parameters**

- `level` [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

**Returns**

- Index or MultiIndex

### Examples

```python
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
           names=['x', 'y', 'z'])
```

```python
>>> mi.droplevel()
MultiIndex([(3, 5),
            (4, 6)],
           names=['y', 'z'])
```

```python
>>> mi.droplevel(2)
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])
```
>>> mi.droplevel('z')
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])

>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')

pandas.Index.dropna

Index.dropna (how='any')
Return Index without NA/NaN values.

Parameters

how [{'any', 'all'}, default 'any'] If the Index is a MultiIndex, drop the value when
any or all levels are NaN.

Returns
Index

pandas.Index.duplicated

Index.duplicated (keep='first')
Indicate duplicate index values.

Duplicated values are indicated as True values in the resulting array. Either all duplicates, all except the
first, or all except the last occurrence of duplicates can be indicated.

Parameters

keep [{‘first’, ‘last’, False}, default ‘first’] The value or values in a set of duplicates to
mark as missing.

• ‘first’ : Mark duplicates as True except for the first occurrence.
• ‘last’ : Mark duplicates as True except for the last occurrence.
• False: Mark all duplicates as True.

Returns
numpy.ndarray

See also:

Series.duplicated Equivalent method on pandas.Series.
DataFrame.duplicated Equivalent method on pandas.DataFrame.
Index.drop_duplicates Remove duplicate values from Index.
Examples

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False, True, False, True])
```

which is equivalent to

```python
>>> idx.duplicated(keep='first')
array([False, False, True, False, True])
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> idx.duplicated(keep='last')
array([ True, False, True, False, False])
```

By setting keep on False, all duplicates are True:

```python
>>> idx.duplicated(keep=False)
array([ True, False, True, False, True])
```

pandas.Index.equals

`Index.equals(other)`

Determine if two Index object are equal.

The things that are being compared are:

- The elements inside the Index object.
- The order of the elements inside the Index object.

**Parameters**

other [Any] The other object to compare against.

**Returns**

bool True if “other” is an Index and it has the same elements and order as the calling index; False otherwise.

**Examples**

```python
>>> idx1 = pd.Index([1, 2, 3])
>>> idx1
Int64Index([1, 2, 3], dtype='int64')
>>> idx1.equals(pd.Index([1, 2, 3]))
True
```

The elements inside are compared

```python
>>> idx2 = pd.Index(['1', '2', '3'])
>>> idx2
Index(['1', '2', '3'], dtype='object')
```
The order is compared

```python
>>> ascending_idx = pd.Index([1, 2, 3])
>>> ascending_idx
Int64Index([1, 2, 3], dtype='int64')
>>> descending_idx = pd.Index([3, 2, 1])
>>> descending_idx
Int64Index([3, 2, 1], dtype='int64')
>>> ascending_idx.equals(descending_idx)
False
```

The dtype is not compared

```python
>>> int64_idx = pd.Int64Index([1, 2, 3])
>>> int64_idx
Int64Index([1, 2, 3], dtype='int64')
>>> uint64_idx = pd.UInt64Index([1, 2, 3])
>>> uint64_idx
UInt64Index([1, 2, 3], dtype='uint64')
>>> int64_idx.equals(uint64_idx)
True
```

### pandas.Index.factorize

Index.factorize(sort=False, na_sentinel=-1)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. factorize is available as both a top-level function pandas.factorize(), and as a method Series.factorize() and Index.factorize().

**Parameters**

- **sort** [bool, default False] Sort uniques and shuffle codes to maintain the relationship.
- **na_sentinel** [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

  Changed in version 1.1.2.

**Returns**

- **codes** [ndarray] An integer ndarray that’s an indexer into uniques. uniques.take(codes) will have the same values as values.
- **uniques** [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

  **Note:** Even if there’s a missing value in values, uniques will not contain an entry for it.

**See also:**
**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

### Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])...
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])...
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (−1 by default). Note that missing values are never included in `uniques`.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0])...
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])...
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])...
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

---

3.6. Index objects
values = np.array([1, 2, 1, np.nan])

codes, uniques = pd.factorize(values)  # default: na_sentinel=-1

codes
array([ 0, 1, 0, -1])

uniques
array([1., 2.])

codes, uniques = pd.factorize(values, na_sentinel=None)

codes
array([0, 1, 0, 2])

uniques
array([1., 2., nan])

pandas.Index.fillna

Index.fillna(value=None, downcast=None)
Fill NA/NaN values with the specified value.

Parameters

value [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible,
or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g.
float64 to int64 if possible).

Returns

Index

See also:

DataFrame.fillna Fill NaN values of a DataFrame.
Series.fillna Fill NaN Values of a Series.

pandas.Index.format

Index.format(name=False, formatter=None, na_rep='NaN')
Render a string representation of the Index.

pandas.Index.get_indexer

Index.get_indexer(target, method=None, limit=None, tolerance=None)
Compute indexer and mask for new index given the current index. The indexer should be then used as an
input to ndarray.take to align the current data to the new index.

Parameters

target [Index]

method [{None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional]

• default: exact matches only.

• pad / ffill: find the PREVIOUS index value if no exact match.
• backfill / bfill: use NEXT index value if no exact match
• nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in *target* to match for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation \( \text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

**indexer** [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**Examples**

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([1, 2, -1])
```

Notice that the return value is an array of locations in *index* and *x* is marked by -1, as it is not in *index*.

**pandas.Index.get_indexer_for**

Index.get_indexer_for(*target*, **kwargs)

Guaranteed return of an indexer even when non-unique.

This dispatches to get_indexer or get_indexer_non_unique as appropriate.

**Returns**

**numpy.ndarray** List of indices.

**pandas.Index.get_indexer_non_unique**

Index.get_indexer_non_unique(*target*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

**target** [Index]

**Returns**

**indexer** [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.
missing [ndarray of int] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.

pandas.Index.get_level_values

Index.get_level_values(level)

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

Parameters

level [int or str] It is either the integer position or the name of the level.

Returns

Index Calling object, as there is only one level in the Index.

See also:

MultiIndex.get_level_values Get values for a level of a MultiIndex.

Notes

For Index, level should be 0, since there are no multiple levels.

Examples

```python
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')

Get level values by supplying level as integer:
```
```python
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

pandas.Index.get_loc

Index.get_loc(key, method=None, tolerance=None)

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match.
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
tolerance [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location must satisfy the equation \( \text{abs(index[loc] - key)} \leq \text{tolerance} \).

Returns

loc [int if unique index, slice if monotonic index, else mask]

Examples

```python
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```python
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```python
>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False, True, False, True])
```

pandas.Index.get_slice_bound

`Index.get_slice_bound(label, side, kind)`

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if `side`=='right') position of given label.

Parameters

- `label` [object]
- `side` [{'left', 'right'}]
- `kind` [{'loc', 'getitem'} or None]

Returns

- `int` Index of label.

pandas.Index.get_value

`Index.get_value(series, key)`

Fast lookup of value from 1-dimensional ndarray.

Only use this if you know what you’re doing.

Returns

- `scalar` or `Series`
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.Index.groupby**

Index.groupby(values)

Group the index labels by a given array of values.

**Parameters**

values [array] Values used to determine the groups.

**Returns**

dict {group name -> group labels}

**pandas.Index.holds_integer**

Index.holds_integer()

Whether the type is an integer type.

**pandas.Index.identical**

Index.identical(other)

Similar to equals, but checks that object attributes and types are also equal.

**Returns**

bool If two Index objects have equal elements and same type True, otherwise False.

**pandas.Index.insert**

Index.insert(loc, item)

Make new Index inserting new item at location.

Follows Python list.append semantics for negative values.

**Parameters**

loc [int]

item [object]

**Returns**

new_index [Index]

**pandas.Index.intersection**

Index.intersection(other, sort=False)

Form the intersection of two Index objects.

This returns a new Index with elements common to the index and other.

**Parameters**

other [Index or array-like]

sort [False or None, default False] Whether to sort the resulting index.

- False : do not sort the result.
• None : sort the result, except when self and other are equal or when the values
cannot be compared.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default from True to False, to match
the behaviour of 0.23.4 and earlier.

Returns

intersection [Index]

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

pandas.Index.is_

Index.is_(other)
More flexible, faster check like is but that works through views.

Note: this is not the same as Index.identical(), which checks that metadata is also the same.

Parameters

other [object] Other object to compare against.

Returns

bool True if both have same underlying data, False otherwise.

See also:

Index.identical Works like Index.is_ but also checks metadata.

pandas.Index.is_boolean

Index.is_boolean()
Check if the Index only consists of booleans.

Returns

bool Whether or not the Index only consists of booleans.

See also:

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.
**is_mixed**  Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index([True, False, True])
>>> idx.is_boolean()
True

>>> idx = pd.Index(["True", "False", "True"])
>>> idx.is_boolean()
False

>>> idx = pd.Index([True, False, "True"])
>>> idx.is_boolean()
False
```

**pandas.Index.is_categorical**

Index.is_categorical()  
Check if the Index holds categorical data.

**Returns**

- **bool**  True if the Index is categorical.

**See also:**

- **CategoricalIndex**  Index for categorical data.
- **is_boolean**  Check if the Index only consists of booleans.
- **is_integer**  Check if the Index only consists of integers.
- **is_floating**  Check if the Index is a floating type.
- **is_numeric**  Check if the Index only consists of numeric data.
- **is_object**  Check if the Index is of the object dtype.
- **is_interval**  Check if the Index holds Interval objects.
- **is_mixed**  Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ...
... "Watermelon"]).astype("category")
>>> idx.is_categorical()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```
```python
>>> s = pd.Series(
    ["Peter", "Victor", "Elisabeth", "Mar"]
)
>>> s
0  Peter
1  Victor
2  Elisabeth
3   Mar
dtype: object
>>> s.index.is_categorical()
False
```

**pandas.Index.is_floating**

Index.is_floating()

Check if the Index is a floating type.

The Index may consist of only floats, NaNs, or a mix of floats, integers, or NaNs.

Returns

bool Whether or not the Index only consists of only consists of floats, NaNs, or a mix of floats, integers, or NaNs.

See also:

* is_boolean Check if the Index only consists of booleans.
* is_integer Check if the Index only consists of integers.
* is_numeric Check if the Index only consists of numeric data.
* is_object Check if the Index is of the object dtype.
* is_categorical Check if the Index holds categorical data.
* is_interval Check if the Index holds Interval objects.
* is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_floating()
True

>>> idx = pd.Index([1.0, 2.0, np.nan, 4.0])
>>> idx.is_floating()
True

>>> idx = pd.Index([1, 2, 3, 4, np.nan])
>>> idx.is_floating()
True

>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_floating()
False
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.Index.is_integer**

Index.is_integer()
Check if the Index only consists of integers.

Returns

bool Whether or not the Index only consists of integers.

See also:

is_boolean Check if the Index only consists of booleans.
is_floating Check if the Index is a floating type.
is_numeric Check if the Index only consists of numeric data.

Examples

```python
dx = pd.Index([1, 2, 3, 4])
dx.is_integer()
True
```

```python
dx = pd.Index([1.0, 2.0, 3.0, 4.0])
dx.is_integer()
False
```

```python
dx = pd.Index(['Apple', 'Mango', 'Watermelon'])
dx.is_integer()
False
```

**pandas.Index.is_interval**

Index.is_interval()
Check if the Index holds Interval objects.

Returns

bool Whether or not the Index holds Interval objects.

See also:

IntervalIndex Index for Interval objects.
is_boolean Check if the Index only consists of booleans.
is_integer Check if the Index only consists of integers.
is_floating Check if the Index is a floating type.
is_numeric Check if the Index only consists of numeric data.
**is_object**  Check if the Index is of the object dtype.

**is_categorical**  Check if the Index holds categorical data.

**is_mixed**  Check if the Index holds data with mixed data types.

### Examples

```python
>>> idx = pd.Index([pd.Interval(left=0, right=5),
                  ...                   pd.Interval(left=5, right=10)])
>>> idx.is_interval()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_interval()
False
```

### pandas.Index.is_mixed

**Index.is_mixed**

Check if the Index holds data with mixed data types.

**Returns**

- **bool**  Whether or not the Index holds data with mixed data types.

**See also:**

- **is_boolean**  Check if the Index only consists of booleans.
- **is_integer**  Check if the Index only consists of integers.
- **is_floating**  Check if the Index is a floating type.
- **is_numeric**  Check if the Index only consists of numeric data.
- **is_object**  Check if the Index is of the object dtype.
- **is_categorical**  Check if the Index holds categorical data.
- **is_interval**  Check if the Index holds Interval objects.

### Examples

```python
>>> idx = pd.Index(['a', np.nan, 'b'])
>>> idx.is_mixed()
True

>>> idx = pd.Index([1.0, 2.0, 3.0, 5.0])
>>> idx.is_mixed()
False
```
pandas.Index.is_numeric

Index.is_numeric()
Check if the Index only consists of numeric data.

Returns

bool  Whether or not the Index only consists of numeric data.

See also:

is_boolean  Check if the Index only consists of booleans.

is_integer  Check if the Index only consists of integers.

is_floating  Check if the Index is a floating type.

is_object  Check if the Index is of the object dtype.

is_categorical  Check if the Index holds categorical data.

is_interval  Check if the Index holds Interval objects.

is_mixed  Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4.0])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4.0, np.nan])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4.0, np.nan, "Apple"])
>>> idx.is_numeric()
False
```
pandas.Index.is_object

Index.is_object()
Check if the Index is of the object dtype.

Returns

bool Whether or not the Index is of the object dtype.

See also:

is_boolean Check if the Index only consists of booleans.
is_integer Check if the Index only consists of integers.
is_floating Check if the Index is a floating type.
is_numeric Check if the Index only consists of numeric data.
is_categorical Check if the Index holds categorical data.
is_interval Check if the Index holds Interval objects.
is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index(['Apple', 'Mango', 'Watermelon'])
>>> idx.is_object()
True
```

```python
>>> idx = pd.Index(['Apple', 'Mango', 2.0])
>>> idx.is_object()
True
```

```python
>>> idx = pd.Index(['Watermelon', 'Orange', 'Apple',...
... 'Watermelon']).astype('category')
>>> idx.is_object()
False
```

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_object()
False
```

pandas.Index.is_type_compatible

Index.is_type_compatible(kind)
Whether the index type is compatible with the provided type.
**pandas.Index.isin**

Index.isin(values, level=None)

Return a boolean array where the index values are in values.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

**Parameters**

- **values** [set or list-like] Sought values.
- **level** [str or int, optional] Name or position of the index level to use (if the index is a MultiIndex).

**Returns**

- **is_contained** [ndarray] NumPy array of boolean values.

**See also:**

*Series.isin* Same for Series.

*DataFrame.isin* Same method for DataFrames.

**Notes**

In the case of MultiIndex you must either specify values as a list-like object containing tuples that are the same length as the number of levels, or specify level. Otherwise it will raise a ValueError.

If level is specified:

- if it is the name of one and only one index level, use that level;
- otherwise it should be a number indicating level position.

**Examples**

```python
>>> idx = pd.Index([1, 2, 3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')

Check whether each index value in a list of values.

```python
>>> idx.isin([1, 4])
array([ True, False, False])
```  
```python
>>> midx = pd.MultiIndex.from_arrays([[1, 2, 3], ['red', 'blue', 'green']], names=('number', 'color'))
>>> midx
MultiIndex([(1, 'red'),
            (2, 'blue'),
            (3, 'green')],
           names=['number', 'color'])
```

Check whether the strings in the ‘color’ level of the MultiIndex are in a list of colors.
To check across the levels of a MultiIndex, pass a list of tuples:

```python
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a DatetimeIndex, string values in `values` are converted to Timestamps.

```python
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
dtype='datetime64[ns]', freq=None)

>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```

### pandas.Index.isna

`Index.isna()`  
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.Nan` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

`numpy.ndarray`  
A boolean array of whether my values are NA.

**See also:**

- `Index.notna`  
  Boolean inverse of isna.

- `Index.dropna`  
  Omit entries with missing values.

- `isna`  
  Top-level isna.

- `Series.isna`  
  Detect missing values in Series object.

**Examples**

Show which entries in a pandas.Index are NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')

>>> idx.isna()
array([False, False, True])
```

Empty strings are not considered NA values. None is considered an NA value.
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True])

For datetimes, NaT (Not a Time) is considered as an NA value.

>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'), ..., pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False, True, True, True])

pandas.Index.isnull

Index.isnull()
Detect missing values.
Return a boolean same-sized object indicating if the values are NA. NA values, such as None, numpy. NaN or pd.NaT, get mapped to True values. Everything else get mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas. options.mode.use_inf_as_na = True).

Returns

numpy.ndarray A boolean array of whether my values are NA.

See also:

Index.notna Boolean inverse of isna.
Index.dropna Omit entries with missing values.
isna Top-level isna.
Series.isna Detect missing values in Series object.

Examples

Show which entries in a pandas.Index are NA. The result is an array.

>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False, True])

Empty strings are not considered NA values. None is considered an NA value.

>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True])
For datetimes, \textit{NaT} (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                         pd.Timestamp(''),
...                         None, pd.NaT])
```

```python
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
dtype='datetime64[ns]', freq=None)
```

```python
>>> idx.isna()
array([False, True, True, True])
```

\textbf{pandas.Index.item}

\texttt{Index.item}()  
Return the first element of the underlying data as a Python scalar.

\textbf{Returns}

\begin{itemize}
  \item \texttt{scalar} The first element of \texttt{Index}.
\end{itemize}

\textbf{pandas.Index.join}

\texttt{Index.join}(other, how='left', level=None, return_indexers=False, sort=False)
Compute join_index and indexers to conform data structures to the new index.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{other} [Index]
  \item \texttt{how} ['left', 'right', 'inner', 'outer']
  \item \texttt{level} [int or level name, default None]
  \item \texttt{return_indexers} [bool, default False]
  \item \texttt{sort} [bool, default False] Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword).
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{join_index}, (left_indexer, right_indexer)
\end{itemize}

\textbf{pandas.Index.map}

\texttt{Index.map}(mapper, na_action=None)
Map values using input correspondence (a dict, Series, or function).

\textbf{Parameters}

\begin{itemize}
  \item \texttt{mapper} [function, dict, or Series] Mapping correspondence.
  \item \texttt{na_action} [[None, ‘ignore’]] If ‘ignore’, propagate NA values, without passing them to the mapping correspondence.
\end{itemize}

\textbf{Returns}
**applied** [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

**pandas.Index.max**

```python
Index.\texttt{max}(axis=None, skipna=True, *args, **kwargs)
```

Return the maximum value of the Index.

**Parameters**

- **axis** [int, optional] For compatibility with NumPy. Only 0 or None are allowed.
- **skipna** [bool, default True] Exclude NA/null values when showing the result.
- ***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

**Returns**

- **scalar** Maximum value.

**See also:**

- **Index.min** Return the minimum value in an Index.
- **Series.max** Return the maximum value in a Series.
- **DataFrame.max** Return the maximum values in a DataFrame.

**Examples**

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```

**pandas.Index.memory_usage**

```python
Index.\texttt{memory\_usage}(deep=False)
```

Memory usage of the values.

**Parameters**

- **deep** [bool, default False] Introspect the data deeply, interrogate object dtypes for system-level memory consumption.

**Returns**

- **bytes used**
See also:

`numpy.ndarray.nbytes` Total bytes consumed by the elements of the array.

Notes

Memory usage does not include memory consumed by elements that are not components of the array if `deep=False` or if used on PyPy

**pandas.Index.min**

```python
Index.min(axis=None, skipna=True, *args, **kwargs)
```

Return the minimum value of the Index.

**Parameters**

- `axis` [{None}] Dummy argument for consistency with Series.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

**Returns**

- `scalar` Minimum value.

See also:

* `Index.max` Return the maximum value of the object.
* `Series.min` Return the minimum value in a Series.
* `DataFrame.min` Return the minimum values in a DataFrame.

**Examples**

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([['a', 'b'], [2, 1]])
>>> idx.min()
('a', 1)
```
pandas.Index.notna

Index.notna()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of notna.

Index.isna Inverse of notna.

notna Top-level notna.

Examples

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True, True, True, False])
```

pandas.Index.notnull

Index.notnull()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of notna.
Index.isna  Inverse of notna.
notna  Top-level notna.

Examples

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True, True, True, False])
```

pandas.Index.nunique

Index.nunique (dropna=True)  
Return number of unique elements in the object. 
Excludes NA values by default.

**Parameters**

- **dropna**  [bool, default True] Don’t include NaN in the count.

**Returns**

- int 

**See also:**

DataFrame.nunique  Method nunique for DataFrame.
Series.count  Count non-NA/null observations in the Series.

**Examples**

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```
pandas.Index.putmask

Index.putmask(mask, value)
Return a new Index of the values set with the mask.

Returns
Index

See also:
numpy.ndarray.putmask Changes elements of an array based on conditional and input values.

pandas.Index.ravel

Index.ravel(order='C')
Return an ndarray of the flattened values of the underlying data.

Returns
numpy.ndarray Flattened array.

See also:

numpy.ndarray.ravel Return a flattened array.

pandas.Index.reindex

Index.reindex(target, method=None, level=None, limit=None, tolerance=None)
Create index with target’s values.

Parameters
target [an iterable]

Returns
new_index [pd.Index] Resulting index.
indexer [np.ndarray or None] Indices of output values in original index.

pandas.Index.rename

Index.rename(name, inplace=False)
Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match
number of levels in MultiIndex.

Parameters
name [label or list of labels] Name(s) to set.
inplace [bool, default False] Modifies the object directly, instead of creating a new
Index or MultiIndex.

Returns
Index or None The same type as the caller or None if inplace=True.
pandas: powerful Python data analysis toolkit, Release 1.2.2

See also:

**Index.set_names** Able to set new names partially and by level.

**Examples**

```python
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'], [2018, 2019]], names=['kind', 'year'])
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           names=['kind', 'year'])

>>> idx.rename([['species', 'year']])
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           names=['species', 'year'])

>>> idx.rename('species')
Traceback (most recent call last):
  TypeError: Must pass list-like as 'names'.
```

**pandas.Index.repeat**

*Index.repeat*(repeats, axis=None)

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

**Parameters**

- **repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.
- **axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

- **repeated_index** [Index] Newly created Index with repeated elements.

**See also:**

**Series.repeat** Equivalent function for Series.

**numpy.repeat** Similar method for numpy.ndarray.
Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

**pandas.Index.searchsorted**

```python
Index.searchsorted(value, side='left', sorter=None)
```

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index `self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

**Note:** The Index must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

**Parameters**

- **value** [array_like] Values to insert into `self`.
- **side** [{'left', 'right'}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- **sorter** [1-D array_like, optional] Optional array of integer indices that sort `self` into ascending order. They are typically the result of `np.argsort`.

**Returns**

- **int or array of int** A scalar or array of insertion points with the same shape as `value`.

Changed in version 0.24.0: If `value` is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for `Series` and `Categorical`.

**See also:**

- **sort_values** Sort by the values along either axis.
- **numpy.searchsorted** Similar method from NumPy.
Notes

Binary search is used to find the required insertion points.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0 1
1 2
2 3
dtype: int64

>>> ser.searchsorted(4)
3

>>> ser.searchsorted([0, 4])
array([0, 3])

>>> ser.searchsorted([1, 3], side='left')
array([0, 2])

>>> ser.searchsorted([1, 3], side='right')
array([1, 3])

>>> ser
0 2000-03-11
1 2000-03-12
2 2000-03-13
dtype: datetime64[ns]

>>> ser.searchsorted('3/14/2000')
3

>>> ser = pd.Categorical(
...    ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True
...)
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']

>>> ser.searchsorted('bread')
1

>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```python
>>> ser = pd.Series([2, 1, 3])
>>> ser
0 2
```
1 1
2 3
dtype: int64

>>> ser.searchsorted(1)
0  # wrong result, correct would be 1

pandas.Index.set_names

Index.set_names(names, level=None, inplace=False)
Set Index or MultiIndex name.
Able to set new names partially and by level.

Parameters

- names [label or list of label] Name(s) to set.
- level [int, label or list of int or label, optional] If the index is a MultiIndex, level(s) to set (None for all levels). Otherwise level must be None.
- inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

- Index or None The same type as the caller or None if inplace=True.

See also:

- Index.rename Able to set new names without level.

Examples

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')
```

```python
>>> idx = pd.MultiIndex.from_product([['python', 'cobra'], [2018, 2019]])
>>> idx
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)],)
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)], names=['kind', 'year'])
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

>>> idx.set_names('species', level=0)
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           names=['species', 'year'])

pandas.Index.set_value

Index.set_value(arr, key, value)
   Fast lookup of value from 1-dimensional ndarray.
   Deprecated since version 1.0.

Notes

Only use this if you know what you’re doing.

pandas.Index.shift

Index.shift(periods=1, freq=None)
   Shift index by desired number of time frequency increments.
   This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

Parameters

   periods [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.

   freq [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own freq attribute. Offset aliases are valid strings, e.g., ‘D’, ‘W’, ‘M’ etc.

Returns

   pandas.Index  Shifted index.

See also:

   Series.shift  Shift values of Series.

Notes

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

3.6. Index objects
Examples

Put the first 5 month starts of 2011 into an index.

```python
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```python
>>> month_starts.shift(10, freq='D')
dtype='datetime64[ns]', freq=None)
```

The default value of `freq` is the `freq` attribute of the index, which is ‘MS’ (month start) in this example.

```python
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01', '2012-03-01'],
dtype='datetime64[ns]', freq='MS')
```

pandas.Index.slice_indexer

Index.slice_indexer(start=None, end=None, step=None, kind=None)

Compute the slice indexer for input labels and step.

Index needs to be ordered and unique.

Parameters

- **start** [label, default None] If None, defaults to the beginning.
- **end** [label, default None] If None, defaults to the end.
- **step** [int, default None]
- **kind** [str, default None]

Returns

- **indexer** [slice]

Raises

- **KeyError** [If key does not exist, or key is not unique and index is] not ordered.
Notes

This function assumes that the data is sorted, so use at your own peril.

Examples

This is a method on all index types. For example you can do:

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3, None)
```

```python
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3, None)
```

**pandas.Index.slice_locs**

`Index.slice_locs(start=None, end=None, step=None, kind=None)`

Compute slice locations for input labels.

**Parameters**

- **start** [label, default None] If None, defaults to the beginning.
- **end** [label, default None] If None, defaults to the end.
- **step** [int, defaults None] If None, defaults to 1.
- **kind** [{'loc', 'getitem'} or None]

**Returns**

- **start, end** [int]

**See also:**

- `Index.get_loc` Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```
pandas.Index.sort

Index.sort(*args, **kwargs)

Use sort_values instead.

pandas.Index.sort_values

Index.sort_values(return_indexer=False, ascending=True, na_position='last', key=None)

Return a sorted copy of the index.

Parameters

- **return_indexer** [bool, default False] Should the indices that would sort the index be returned.
- **ascending** [bool, default True] Should the index values be sorted in an ascending order.
- **na_position** [{'first' or 'last'}, default 'last'] Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.
  New in version 1.2.0.
- **key** [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.
  New in version 1.1.0.

Returns

- **sorted_index** [pandas.Index] Sorted copy of the index.
- **indexer** [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

- Series.sort_values Sort values of a Series.
- DataFrame.sort_values Sort values in a DataFrame.

Examples

```python
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')

Sort values in ascending order (default behavior).

>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')

Sort values in descending order, and also get the indices idx was sorted by.

>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```
pandas.Index.sortlevel

Index.sortlevel(level=None, ascending=True, sort_remaining=None)

For internal compatibility with the Index API.
Sort the Index. This is for compat with MultiIndex

Parameters

ascending [bool, default True] False to sort in descending order
level, sort_remaining are compat parameters

Returns

Index

pandas.Index.str

Index.str()

Vectorized string functions for Series and Index.

NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

Examples

```python
>>> s = pd.Series(["A_Str_Series"])  
>>> s
0    A_Str_Series
dtype: object

>>> s.str.split("_")
0    [A, Str, Series]
       dtype: object

>>> s.str.replace("_", ")
0    AStrSeries
       dtype: object
```

pandas.Index.symmetric_difference

Index.symmetric_difference(other, result_name=None, sort=None)

Compute the symmetric difference of two Index objects.

Parameters

other [Index or array-like]

result_name [str]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.

3.6. Index objects
• None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
• False : Do not sort the result.

New in version 0.24.0.
Changed in version 0.24.1: Changed the default value from True to None (without change in behaviour).

Returns

symmetric_difference [Index]

Notes

symmetric_difference contains elements that appear in either idx1 or idx2 but not both. Equivalent to the Index created by idx1.difference(idx2) | idx2.difference(idx1) with duplicates dropped.

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

You can also use the ^ operator:

```python
>>> idx1 ^ idx2
Int64Index([1, 5], dtype='int64')
```

pandas.Index.take

Index.take(indices, axis=0, allow_fill=True, fill_value=None, **kwargs)

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

Parameters

- indices [list] Indices to be taken.
- axis [int, optional] The axis over which to select values, always 0.
- allow_fill [bool, default True]
- fill_value [bool, default None] If allow_fill=True and fill_value is not None, indices specified by -1 is regarded as NA. If Index doesn’t hold NA, raise ValueError.

Returns

- numpy.ndarray Elements of given indices.

See also:

- `numpy.ndarray.take` Return an array formed from the elements of a at the given indices.
### pandas.Index.to_flat_index

`Index.to_flat_index()`  
Identity method.  
New in version 0.24.0.  
This is implemented for compatibility with subclass implementations when chaining.  

**Returns**  
`pd.Index` Caller.  

**See also:**  
`MultiIndex.to_flat_index` Subclass implementation.

### pandas.Index.to_frame

`Index.to_frame(index=True, name=None)`  
Create a DataFrame with a column containing the Index.  
New in version 0.24.0.  

**Parameters**  
- `index` [bool, default True] Set the index of the returned DataFrame as the original Index.  
- `name` [object, default None] The passed name should substitute for the index name (if it has one).  

**Returns**  
`DataFrame` DataFrame containing the original Index data.  

**See also:**  
`Index.to_series` Convert an Index to a Series.  
`Series.to_frame` Convert Series to DataFrame.  

**Examples**

```python  
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')  
>>> idx.to_frame()  
  animal  
  Ant    Ant  
  Bear   Bear  
  Cow    Cow  
```

By default, the original Index is reused. To enforce a new Index:

```python  
>>> idx.to_frame(index=False)  
  animal  
  0    Ant  
  1   Bear  
  2   Cow  
```
To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
            zoo
0       Ant
1        Bear
2        Cow
```

**pandas.Index.to_list**

Index.to_list()  
Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**Returns**

list

**See also:**

numpy.ndarray.tolist  
Return the array as an andim-levels deep nested list of Python scalars.

**pandas.Index.to_native_types**

Index.to_native_types(slicer=None, **kwargs)  
Format specified values of self and return them.

Deprecated since version 1.2.0.

**Parameters**

- **slicer** [int, array-like] An indexer into self that specifies which values are used in the formatting process.
- **kwargs** [dict] Options for specifying how the values should be formatted. These options include the following:
  1) **na_rep** [str] The value that serves as a placeholder for NULL values
  2) **quoting** [bool or None] Whether or not there are quoted values in self
  3) **date_format** [str] The format used to represent date-like values.

**Returns**

numpy.ndarray  
Formatted values.
Index.example

Index.example (dtype=object, copy=True, **kwargs)

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
copy [bool, default True] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensures that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the type of the array.

New in version 1.0.0.

**kwargs Additional keywords passed through to the to_numpy method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.
Index.array Get the actual data stored within.

DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in self will be equal in the returned array; likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, Series.array should be used instead.

This table lays out the different dtypes and default return types of to_numpy() for various dtypes within pandas.
Examples

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the `dtype` to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct `tz`.

```python
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
       dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype="datetime64[ns]"
... array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
       dtype='datetime64[ns]')
```

**pandas.Index.to_series**

Index `to_series` *(index=\(\text{None}\), name=\(\text{None}\)*

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

**Parameters**

- `index` [Index, optional] Index of resulting Series. If None, defaults to original index.
- `name` [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

Series The dtype will be based on the type of the Index values.

**See also:**

- **Index.to_frame** Convert an Index to a DataFrame.
- **Series.to_frame** Convert Series to DataFrame.
Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal    Ant
          Bear
          Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to `index`:

```python
>>> idx.to_series(index=[0, 1, 2])
0   Ant
1   Bear
2   Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_series(name='zoo')
animal    Ant
          Bear
          Cow
Name: zoo, dtype: object
```

**pandas.Index.tolist**

`Index.tolist()`  
Return a list of the values.
These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

```
list
```

See also:

- `numpy.ndarray.tolist` Return the array as an a.ndim-levels deep nested list of Python scalars.
pandas.Index.transpose

Index.transpose(*args, **kwargs)
Return the transpose, which is by definition self.

Returns
%(klass)s

pandas.Index.union

Index.union(other, sort=None)
Form the union of two Index objects.
If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.
Changed in version 0.25.0.

Parameters
other [Index or array-like]
sort [bool or None, default None] Whether to sort the resulting Index.
• None : Sort the result, except when
  1. self and other are equal.
  2. self or other has length 0.
  3. Some values in self or other cannot be compared. A RuntimeWarning is issued in this case.
• False : do not sort the result.
New in version 0.24.0.
Changed in version 0.24.1: Changed the default value from True to None (without change in behaviour).

Returns
union [Index]

Examples

Union matching dtypes

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

Union mismatched dtypes

```python
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```
pandas.Index.unique

Index.unique(level=None)

Return unique values in the index.

Unique values are returned in order of appearance, this does NOT sort.

Parameters

- level [int or str, optional, default None] Only return values from specified level (for MultiIndex).

Returns

Index without duplicates

See also:

unique Numpy array of unique values in that column.
Series.unique Return unique values of Series object.

pandas.Index.value_counts

Index.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

- normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- sort [bool, default True] Sort by frequencies.
- ascending [bool, default False] Sort in ascending order.
- bins [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.
- dropna [bool, default True] Don’t include counts of NaN.

Returns

Series

See also:

Series.count Number of non-NA elements in a Series.
DataFrame.count Number of non-NA elements in a DataFrame.
DataFrame.value_counts Equivalent method on DataFrames.
Examples

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0 2
2.0 1
4.0 1
1.0 1
dtype: int64
```

With `normalize` set to `True`, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0 0.4
2.0 0.2
4.0 0.2
1.0 0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apperations of values, divide the index in the specified number of half-open bins.

```python
>>> s.value_counts(bins=3)
(0.996, 2.0] 2
(2.0, 3.0] 2
(3.0, 4.0] 1
dtype: int64
```

**dropna**

With `dropna` set to `False` we can also see NaN index values.

```python
>>> s.value_counts(dropna=False)
3.0 2
2.0 1
NaN 1
4.0 1
1.0 1
dtype: int64
```

**pandas.Index.where**

Index.`where`(cond, other=None)

Replace values where the condition is False.

The replacement is taken from other.

**Parameters**

- `cond` [bool array-like with the same length as self] Condition to select the values on.
- `other` [scalar, or array-like, default None] Replacement if the condition is False.

**Returns**
**pandas.Index**  A copy of self with values replaced from other where the condition is False.

See also:

*Series.where* Same method for Series.

*DataFrame.where* Same method for DataFrame.

**Examples**

```python
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')

>>> idx.where(idx.isin(['car', 'train']), 'other')
Index(['car', 'other', 'train', 'other'], dtype='object')
```

<td>Immutable sequence used for indexing and alignment.</td>
</tr>
<tr>
<td><code>Float64Index([data, dtype, copy, name])</code></td>
<td>Immutable sequence used for indexing and alignment.</td>
</tr>
</tbody>
</table>
class pandas.RangeIndex (start=None, stop=None, step=None, dtype=None, copy=False, name=None)

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

Parameters

- **start** [int (default: 0), or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.
- **stop** [int (default: 0)]
- **step** [int (default: 1)]
- **dtype** [np.int64] Unused, accepted for homogeneity with other index types.
- **copy** [bool, default False] Unused, accepted for homogeneity with other index types.
- **name** [object, optional] Name to be stored in the index.

See also:

- **Index** The base pandas Index type.
- **Int64Index** Index of int64 data.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>start</strong></td>
<td>The value of the start parameter (0 if this was not supplied).</td>
</tr>
<tr>

<td>The value of the stop parameter.</td>
</tr>
<tr>
<td><strong>step</strong></td>
<td>The value of the step parameter (1 if this was not supplied).</td>
</tr>
</tbody>
</table>

pandas.RangeIndex.start

RangeIndex.start

The value of the start parameter (0 if this was not supplied).
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.RangeIndex.stop

```
RangeIndex.stop
    The value of the stop parameter.
```

pandas.RangeIndex.step

```
RangeIndex.step
    The value of the step parameter (1 if this was not supplied).
```

Methods

```
from_range(data[, name, dtype])
    Create RangeIndex from a range object.
```

pandas.RangeIndex.from_range

```
classmethod RangeIndex.from_range(data, name=None, dtype=None)
    Create RangeIndex from a range object.
    Returns
    RangeIndex
```

pandas.Int64Index

```
class pandas.Int64Index(data=None, dtype=None, copy=False, name=None)
    Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Int64Index is a special case of Index with purely integer labels.
    Parameters
    data [array-like (1-dimensional)]
    dtype [NumPy dtype (default: int64)]
    copy [bool] Make a copy of input ndarray.
    name [object] Name to be stored in the index.
    See also:
    Index The base pandas Index type.
    Notes
    An Index instance can only contain hashable objects.
```
Attributes

None

Methods

None

pandas.UInt64Index
class pandas.UInt64Index(data=None, dtype=None, copy=False, name=None)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of Index with purely unsigned integer labels. .

Parameters

data [array-like (1-dimensional)]
dtype [NumPy dtype (default: uint64)]
copy [bool] Make a copy of input ndarray.
name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can only contain hashable objects.

Attributes

None

Methods

None

pandas.Float64Index
class pandas.Float64Index(data=None, dtype=None, copy=False, name=None)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Float64Index is a special case of Index with purely float labels. .

Parameters

data [array-like (1-dimensional)]
dtype [NumPy dtype (default: float64)]
copy [bool] Make a copy of input ndarray.
name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can only contain hashable objects.

3.6.3 CategoricalIndex

CategoricalIndex([data, categories, ...]) Index based on an underlying Categorical.

pandas.CategoricalIndex

class pandas.CategoricalIndex(data=None, categories=None, ordered=None, dtype=None, copy=False, name=None)

Index based on an underlying Categorical.

CategoricalIndex, like Categorical, can only take on a limited, and usually fixed, number of possible values (categories). Also, like Categorical, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

Parameters

- **data** [array-like (1-dimensional)] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.
- **categories** [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here (and also not in dtype), they will be inferred from the data.
- **ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in dtype, the resulting categorical will be unordered.
dtype [CategoricalDtype or “category”, optional] If CategoricalDtype, cannot be used together with categories or ordered.

copy [bool, default False] Make a copy of input ndarray.

name [object, optional] Name to be stored in the index.

Raises

ValueError If the categories do not validate.

TypeError If an explicit ordered=True is given but no categories and the values are not sortable.

See also:

Index The base pandas Index type.
Categorical A categorical array.
CategoricalDtype Type for categorical data.

Notes

See the user guide for more.

Examples

```python
>>> pd.CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

CategoricalIndex can also be instantiated from a Categorical:

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

Ordered CategoricalIndex can have a min and max value.

```python
>>> ci = pd.CategoricalIndex(...
... ["a", "b", "c", "a", "b", "c"], ordered=True, categories=["c", "b", "a"]
... )
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['c', 'b', 'a'], ordered=True, dtype='category')
>>> ci.min()
'c'
```
Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>codes</td>
<td>The category codes of this categorical.</td>
</tr>
<tr>
<td>categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

**pandas.CategoricalIndex.codes**

**property CategoricalIndex.codes**

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

**Returns**

*ndarray[int]* A non-writable view of the `codes` array.

**pandas.CategoricalIndex.categories**

**property CategoricalIndex.categories**

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is a inplace operation!

**Raises**

* ValueError* If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

* rename_categories* Rename categories.

* reorder_categories* Reorder categories.

* add_categories* Add new categories.

* remove_categories* Remove the specified categories.

* remove_unused_categories* Remove categories which are not used.

* set_categories* Set the categories to the specified ones.
pandas.CategoricalIndex.ordered

**property** CategoricalIndex.ordered
Whether the categories have an ordered relationship.

**Methods**

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rename_categories(*args, **kwargs)</td>
<td>Rename categories.</td>
</tr>
<tr>
<td>reorder_categories(*args, **kwargs)</td>
<td>Reorder categories as specified in new_categories.</td>
</tr>
<tr>
<td>add_categories(*args, **kwargs)</td>
<td>Add new categories.</td>
</tr>
<tr>
<td>remove_categories(*args, **kwargs)</td>
<td>Remove the specified categories.</td>
</tr>
<tr>
<td>remove_unused_categories(*args, **kwargs)</td>
<td>Remove categories which are not used.</td>
</tr>
<tr>
<td>set_categories(*args, **kwargs)</td>
<td>Set the categories to the specified new_categories.</td>
</tr>
<tr>
<td>as_ordered(*args, **kwargs)</td>
<td>Set the Categorical to be ordered.</td>
</tr>
<tr>
<td>as_unordered(*args, **kwargs)</td>
<td>Set the Categorical to be unordered.</td>
</tr>
<tr>
<td>map(mapper)</td>
<td>Map values using input correspondence (a dict, Series, or function).</td>
</tr>
</tbody>
</table>

**pandas.CategoricalIndex.rename_categories**

CategoricalIndex.rename_categories(*args, **kwargs)
Rename categories.

**Parameters**

- **new_categories** [list-like, dict-like or callable] New categories which will replace old categories.
  - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
  - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
  - callable: a callable that is called on all items in the old categories and whose return values comprise the new categories.

- **inplace** [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**

- **ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories.

**See also:**

- reorder_categories Reorder categories.
add_categories  Add new categories.

remove_categories  Remove the specified categories.

remove_unused_categories  Remove categories which are not used.

set_categories  Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(["a", "a", "b"])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

pandas.CategoricalIndex.reorder_categories

CategoricalIndex.reorder_categories(*args, **kwargs)

Reorder categories as specified in new_categories.

new_categories need to include all old categories and no new category items.

Parameters

new_categories  [Index-like] The categories in new order.

ordered  [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

inplace  [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

cat  [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError  If the new categories do not contain all old category items or any new ones

See also:

rename_categories  Rename categories.

add_categories  Add new categories.

*remove_categories* Remove the specified categories.

*remove_unused_categories* Remove categories which are not used.

*set_categories* Set the categories to the specified ones.

**pandas.CategoricalIndex.add_categories**

*CategoricalIndex.add_categories(*args, **kwargs)*

Add new categories.

*new_categories* will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- *new_categories* [category or list-like of category] The new categories to be included.
- inplace [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

**Returns**

- cat [Categorical or None] Categorical with new categories added or None if inplace=True.

**Raises**

- ValueError If the new categories include old categories or do not validate as categories.

**See also:**

*rename_categories* Rename categories.

*reorder_categories* Reorder categories.

*remove_categories* Remove the specified categories.

*remove_unused_categories* Remove categories which are not used.

*set_categories* Set the categories to the specified ones.

**pandas.CategoricalIndex.remove_categories**

*CategoricalIndex.remove_categories(*args, **kwargs)*

Remove the specified categories.

*removals* must be included in the old categories. Values which were in the removed categories will be set to NaN

**Parameters**

- *removals* [category or list of categories] The categories which should be removed.
- inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

**Returns**

- cat [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**
ValueError If the removals are not contained in the categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.remove_unused_categories

CategoricalIndex.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Deprecated since version 1.2.0.

Returns

cat [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.set_categories

CategoricalIndex.set_categories(*args, **kwargs)
Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If rename==True, the categories will simple be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.
ordered [bool, default False] Whether or not the categorical is treated as a ordered
categorical. If not given, do not change the ordered information.

rename [bool, default False] Whether or not the new_categories should be considered
as a rename of the old categories or as reordered categories.

inplace [bool, default False] Whether or not to reorder the categories in-place or return
a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If new_categories does not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.

pandas.CategoricalIndex.as_ordered

CategoricalIndex.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or
return a copy of this categorical with ordered set to True.

Returns

Categorical or None Ordered Categorical or None if inplace=True.

pandas.CategoricalIndex.as_unordered

CategoricalIndex.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or
return a copy of this categorical with ordered set to False.

Returns

Categorical or None Unordered Categorical or None if inplace=True.
pandas.CategoricalIndex.map

CategoricalIndex.map(mapper)
Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a CategoricalIndex which has the same order property as the original, otherwise an Index is returned.

If a dict or Series is used any unmapped category is mapped to NaN. Note that if this happens an Index will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.

Returns

pandas.CategoricalIndex or pandas.Index Mapped index.

See also:

Index.map Apply a mapping correspondence on an Index.
Series.map Apply a mapping correspondence on a Series.
Series.apply Apply more complex functions on a Series.

Examples

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                   ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                   ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                                                             'second',
                                                             'third'],
                                                             ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                  ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True,
                  dtype='category')
```

If the mapping is not one-to-one an Index is returned:

```python
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a dict is used, all unmapped categories are mapped to NaN and the result is an Index:
```python
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

### Modifying and computations

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CategoricalIndex.map(mapper)</code></td>
<td>Map values using input correspondence (a dict, Series, or function).</td>
</tr>
<tr>
<td><code>CategoricalIndex.equals(other)</code></td>
<td>Determine if two CategoricalIndex objects contain the same elements.</td>
</tr>
</tbody>
</table>

**pandas.CategoricalIndex.equals**

`CategoricalIndex.equals(other)`

Determine if two CategoricalIndex objects contain the same elements.

**Returns**

`bool` If two CategoricalIndex objects have equal elements True, otherwise False.
3.6.4 IntervalIndex

| IntervalIndex(data[, closed, dtype, copy, ...]) | Immutable index of intervals that are closed on the same side. |

pandas.IntervalIndex

class pandas.IntervalIndex(data, closed=None, dtype=None, copy=False, name=None, verify_integrity=True)

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

Parameters

- **data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.
- **closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.
- **copy** [bool, default False] Copy the input data.
- **name** [object, optional] Name to be stored in the index.
- **verify_integrity** [bool, default True] Verify that the IntervalIndex is valid.

See also:

- **Index** The base pandas Index type.
- **Interval** A bounded slice-like interval; the elements of an IntervalIndex.
- **interval_range** Function to create a fixed frequency IntervalIndex.
- **cut** Bin values into discrete Intervals.
- **qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the user guide for more.

Examples

A new IntervalIndex is typically constructed using `interval_range()`:

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
    closed='right',
    dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

#### pandas.IntervalIndex.closed

`IntervalIndex.closed`

Whether the intervals are closed on the left-side, right-side, both or neither.

#### pandas.IntervalIndex.length

**Property** `IntervalIndex.length`

Return the length of the Interval.

#### pandas.IntervalIndex.is_empty

`IntervalIndex.is_empty`

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns**

- **bool or ndarray** A boolean indicating if a scalar `Interval` is empty, or a boolean `ndarray` positionally indicating if an `Interval` in an `IntervalArray` or `IntervalIndex` is empty.

**Examples**

An `Interval` that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An `Interval` that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
```
An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
         pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

### pandas.IntervalIndex.is_non_overlapping_monotonic

IntervalIndex.is_non_overlapping_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

### pandas.IntervalIndex.is_overlapping

property IntervalIndex.is_overlapping

Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Returns

**bool** Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

- **Interval.overlaps** Check whether two Interval objects overlap.
- **IntervalIndex.overlaps** Check an IntervalIndex elementwise for overlaps.
Examples

```python
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]],
closed='right',
dtype='interval[int64]')
>>> index.is_overlapping
True

Intervals that share closed endpoints overlap:

```python
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([[0, 1], [1, 2], [2, 3]],
closed='both',
dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[0, 1), [1, 2), [2, 3)),
closed='left',
dtype='interval[int64]')
>>> index.is_overlapping
False
```

`pandas.IntervalIndex.values`

IntervalIndex.values

Return the IntervalIndex’s data as an IntervalArray.

<table>

</tr>
</tbody>
</table>

pandas.IntervalIndex.from_arrays

classmethod IntervalIndex.from_arrays(left, right, closed='right', name=None, copy=False, dtype=None)

Construct from two arrays defining the left and right bounds.

Parameters

left [array-like (1-dimensional)] Left bounds for each interval.
right [array-like (1-dimensional)] Right bounds for each interval.
closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
copy [bool, default False] Copy the data.
dtype [dtype, optional] If None, dtype will be inferred.

Returns

IntervalIndex

Raises

ValueError When a value is missing in only one of left or right. When a value in left is greater than the corresponding value in right.

See also:

interval_range Function to create a fixed frequency IntervalIndex.
IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.
IntervalIndex.from_tuples Construct an IntervalIndex from an array-like of tuples.

Notes

Each element of left must be less than or equal to the right element at the same position. If an element is missing, it must be missing in both left and right. A TypeError is raised when using an unsupported type for left or right. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

Examples

```python
>>> pd.IntervalIndex.from_arrays([[0, 1, 2], [1, 2, 3]])
IntervalIndex([[(0, 1], (1, 2], (2, 3)],
               closed='right',
               dtype='interval[int64]')
```
class method IntervalIndex.from_tuples(data, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array-like of tuples.

Parameters

- **data** [array-like (1-dimensional)] Array of tuples.
- **closed** ['left', 'right', 'both', 'neither'], default 'right' Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] By-default copy the data, this is compat only and ignored.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalIndex

See also:

- **interval_range** Function to create a fixed frequency IntervalIndex.
- **IntervalIndex.from_arrays** Construct an IntervalIndex from a left and right array.
- **IntervalIndex.from_breaks** Construct an IntervalIndex from an array of splits.

Examples

```python
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]],
closed='right',
dtype='interval[int64]')
```

class method IntervalIndex.from_breaks(breaks, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array of splits.

Parameters

- **breaks** [array-like (1-dimensional)] Left and right bounds for each interval.
- **closed** ['left', 'right', 'both', 'neither'], default 'right' Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] Copy the data.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalIndex

See also:

- **interval_range** Function to create a fixed frequency IntervalIndex.
*IntervalIndex.from_arrays* Construct from a left and right array.

*IntervalIndex.from_tuples* Construct from a sequence of tuples.

**Examples**

```python
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]), closed='right', dtype='interval[int64]')
```

**pandas.IntervalIndex.contains**

*IntervalIndex.contains* (*args, **kwargs*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

**Parameters**

other [scalar] The value to check whether it is contained in the Intervals.

**Returns**

boolean array

**See also:**

*Interval.contains* Check whether Interval object contains value.

*IntervalArray.overlaps* Check if an Interval overlaps the values in the IntervalArray.

**Examples**

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4)]
Length: 3, closed: right, dtype: interval[int64]

>>> intervals.contains(0.5)
array([ True, False, False])
```
pandas.IntervalIndex.overlaps

IntervalIndex.overlaps(*args, **kwargs)
Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Parameters

other [IntervalArray] Interval to check against for an overlap.

Returns

ndarray Boolean array positionally indicating where an overlap occurs.

See also:

Interval.overlaps Check whether two Interval objects overlap.

Examples

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])

Intervals that share closed endpoints overlap:
```  
```python
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True, True])

Intervals that only have an open endpoint in common do not overlap:
```  
```python
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])

pandas.IntervalIndex.set_closed

IntervalIndex.set_closed(*args, **kwargs)
Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

Parameters

closed [['left', 'right', 'both', 'neither']] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns
new_index [IntervalArray]

Examples

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray
[(0, 1], (1, 2], (2, 3])
Length: 3, closed: right, dtype: interval[int64]
>>> index.set_closed('both')
<IntervalArray
[[0, 1], [1, 2], [2, 3]]
Length: 3, closed: both, dtype: interval[int64]
```

pandas.IntervalIndex.to_tuples

`IntervalIndex.to_tuples(*args, **kwargs)`

Return an ndarray of tuples of the form (left, right).

Parameters

- `na_tuple`: [bool, default True] Returns NA as a tuple if True, `(nan, nan)`, or just as the NA value itself if False, `nan`.

Returns

- `tuples`: ndarray

IntervalIndex components

- `IntervalIndex.from_arrays(left, right[, ...])`: Construct from two arrays defining the left and right bounds.
- `IntervalIndex.from_tuples(data[, closed, ...])`: Construct an IntervalIndex from an array-like of tuples.
- `IntervalIndex.from_breaks(breaks[, closed, ...])`: Construct an IntervalIndex from an array of splits.
- `IntervalIndex.left`: Whether the intervals are closed on the left-side, right-side, both or neither.
- `IntervalIndex.right`: Return the length of the Interval.
- `IntervalIndex.values`: Return the IntervalIndex’s data as an IntervalArray.
- `IntervalIndex.is_empty`: Indicates if an interval is empty, meaning it contains no points.
- `IntervalIndex.is_non_overlapping_monotonic`: Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
- `IntervalIndex.is_overlapping`: Return True if the IntervalIndex has overlapping intervals, else False.

</tbody>
</table>

**pandas.IntervalIndex.left**

IntervalIndex.left

**pandas.IntervalIndex.right**

IntervalIndex.right

**pandas.IntervalIndex.mid**

IntervalIndex.mid

**pandas.IntervalIndex.get_loc**

IntervalIndex.get_loc(key, method=\texttt{\texttildelow}, tolerance=\texttt{\texttildelow})

Get integer location, slice or boolean mask for requested label.

**Parameters**

- **key** [label]
- **method** [{\texttt{\texttildelow}}, optional]
  - default: matches where the label is within an interval only.

**Returns**

int if unique index, slice if monotonic index, else mask

**Examples**

```python
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```python
>>> index.get_loc(1.5)
1
```
If a label is in several intervals, you get the locations of all the relevant intervals.

```python
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False, True])
```

Only exact matches will be returned if an interval is provided.

```python
>>> index.get_loc(pd.Interval(0, 1))
0
```

## pandas.IntervalIndex.get_indexer

The `IntervalIndex.get_indexer` function computes the indexer and mask for a new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

### Parameters

- **target**: `IntervalIndex` or list of intervals
- **method**: `None`, `'pad'/'ffill'`, `'backfill'/'bfill'`, or `'nearest'` (default: exact matches only)
  - `pad` / `ffill`: find the PREVIOUS index value if no exact match.
  - `backfill` / `bfill`: use NEXT index value if no exact match
  - `nearest`: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit**: `int`, optional Maximum number of consecutive labels in `target` to match for inexact matches.
- **tolerance**: `optional` Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

### Returns

- **indexer**: `ndarray of int` Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

### Raises

- **NotImplementedError** If any method argument other than the default of None is specified as these are not yet implemented.
Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by `-1`, as it is not in `index`.

### 3.6.5 MultiIndex

```python
MultiIndex(levels, codes, sortorder, ...) A multi-level, or hierarchical, index object for pandas objects.
```

**pandas.MultiIndex**

**class** `pandas.MultiIndex(levels=None, codes=None, sortorder=None, names=None, dtype=None, copy=False, name=None, verify_integrity=True)`

A multi-level, or hierarchical, index object for pandas objects.

**Parameters**

- **levels** [sequence of arrays] The unique labels for each level.
- **codes** [sequence of arrays] Integers for each level designating which label at each location.
  
  New in version 0.24.0.
- **sortorder** [optional int] Level of sortedness (must be lexicographically sorted by that level).
- **names** [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).
- **copy** [bool, default False] Copy the meta-data.
- **verify_integrity** [bool, default True] Check that the levels/codes are consistent and valid.

**See also:**

- `MultiIndex.from_arrays` Convert list of arrays to MultiIndex.
- `MultiIndex.from_product` Create a MultiIndex from the cartesian product of iterables.
- `MultiIndex.from_tuples` Convert list of tuples to a MultiIndex.
- `MultiIndex.from_frame` Make a MultiIndex from a DataFrame.
- `Index` The base pandas Index type.

**Notes**

See the user guide for more.
Examples

A new MultiIndex is typically constructed using one of the helper methods `MultiIndex.from_arrays()`, `MultiIndex.from_product()` and `MultiIndex.from_tuples()`. For example (using `from_arrays`):

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
  (1, 'blue'),
  (2, 'red'),
  (2, 'blue')],
  names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.

Attributes

<table>
<thead>
<tr>
<th>names</th>
<th>Names of levels in MultiIndex.</th>
</tr>
</thead>
<tbody>
<tr>
<td>nlevels</td>
<td>Integer number of levels in this MultiIndex.</td>
</tr>
<tr>
<td>levshape</td>
<td>A tuple with the length of each level.</td>
</tr>
</tbody>
</table>

**pandas.MultiIndex.names**

*property* `MultiIndex.names`

Names of levels in MultiIndex.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays(
...     [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
  (2, 4, 6)],
  names=['x', 'y', 'z'])
>>> mi.names
FrozenList(['x', 'y', 'z'])
```

**pandas.MultiIndex.nlevels**

*property* `MultiIndex.nlevels`

Integer number of levels in this MultiIndex.
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([('a', 'b', 'c')],
    )
>>> mi.nlevels
3
```

**pandas.MultiIndex.levshape**

**property** `MultiIndex.levshape`

A tuple with the length of each level.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([('a', 'b', 'c')],
    )
>>> mi.levshape
(1, 1, 1)
```

pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.MultiIndex.from_arrays

classmethod MultiIndex.from_arrays(arrays, sortorder=None, names=None)
Convert arrays to MultiIndex.

Parameters
arrays [list / sequence of array-likes] Each array-like gives one level’s value for each
data point. len(arrays) is the number of levels.
sortorder [int or None] Level of sortedness (must be lexicographically sorted by that
level).
names [list / sequence of str, optional] Names for the levels in the index.

Returns
MultiIndex

See also:
MultiIndex.from_tuples Convert list of tuples to MultiIndex.
MultiIndex.from_product Make a MultiIndex from cartesian product of iterables.
MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```python
>>> arrays = [[[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

pandas.MultiIndex.from_tuples

classmethod MultiIndex.from_tuples(tuples, sortorder=None, names=None)
Convert list of tuples to MultiIndex.

Parameters
tuples [list / sequence of tuple-likes] Each tuple is the index of one row/column.
sortorder [int or None] Level of sortedness (must be lexicographically sorted by that
level).
names [list / sequence of str, optional] Names for the levels in the index.

Returns
MultiIndex

See also:
MultiIndex.from_arrays Convert list of arrays to MultiIndex.
MultiIndex.from_product Make a MultiIndex from cartesian product of iterables.
**MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

**Examples**

```python
tuples = [(1, 'red'), (1, 'blue'),
          (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

**pandas.MultiIndex.from_product**

**classmethod** `MultiIndex.from_product` *(iterables, sortorder=None, names=<object object>)*

Make a MultiIndex from the cartesian product of multiple iterables.

**Parameters**

- `iterables` [list / sequence of iterables] Each iterable has unique labels for each level of the index.
- `sortorder` [int or None] Level of sortedness (must be lexicographically sorted by that level).
- `names` [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from the elements of iterables if an element has a name attribute

**Returns**

`MultiIndex`

**See also:**

- **MultiIndex.from_arrays** Convert list of arrays to MultiIndex.
- **MultiIndex.from_tuples** Convert list of tuples to MultiIndex.
- **MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

**Examples**

```python
numbers = [0, 1, 2]
colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
                              names=['number', 'color'])
MultiIndex([(0, 'green'),
            (0, 'purple'),
            (1, 'green'),
            (1, 'purple'),
            (2, 'green'),
            (2, 'purple')],
           names=['number', 'color'])
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.MultiIndex.from_frame**

classmethod MultiIndex.from_frame(df, sortorder=None, names=None)

Make a MultiIndex from a DataFrame.

New in version 0.24.0.

**Parameters**

- **df** [DataFrame] DataFrame to be converted to MultiIndex.
- **sortorder** [int, optional] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

**Returns**

MultiIndex The MultiIndex representation of the given DataFrame.

See also:

- **MultiIndex.from_arrays** Convert list of arrays to MultiIndex.
- **MultiIndex.from_tuples** Convert list of tuples to MultiIndex.
- **MultiIndex.from_product** Make a MultiIndex from cartesian product of iterables.

**Examples**

```python
>>> df = pd.DataFrame([['HI', 'Temp'], ['HI', 'Precip'],
                     ['NJ', 'Temp'], ['NJ', 'Precip']],
                    columns=['a', 'b'])
>>> df
   a  b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip

>>> pd.MultiIndex.from_frame(df)
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['a', 'b'])

Using explicit names, instead of the column names

```python
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['state', 'observation'])
```
pandas.MultiIndex.set_levels

**MultiIndex.set_levels** *(levels, level=None, inplace=None, verify_integrity=True)*

Set new levels on MultiIndex. Defaults to returning new index.

**Parameters**

- **levels** [sequence or list of sequence] New level(s) to apply.
- **level** [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
- **inplace** [bool] If True, mutates in place.
  
  Deprecated since version 1.2.0.
- **verify_integrity** [bool, default True] If True, checks that levels and codes are compatible.

**Returns**

- **new index (of same type and class...etc) or None** The same type as the caller or None if inplace=True.

**Examples**

```python
>>> idx = pd.MultiIndex.from_tuples([1, "one"), (1, "two"), (2, "one"), (2, "two"), (3, "one"), (3, "two")], names=["foo", "bar"])
>>> idx
MultiIndex([(1, 'one'), (1, 'two'), (2, 'one'), (2, 'two'), (3, 'one'), (3, 'two')], names=['foo', 'bar'])
```

```python
>>> idx.set_levels(['a', 'b', 'c'], inplace=True)
MultiIndex([('a', 1), ('a', 2), ('b', 1), ('b', 2), ('c', 1), ('c', 2)], names=['foo', 'bar'])
```

```python
>>> idx.set_levels(['a', 'b', 'c'], level=0)
MultiIndex([('a', 'one'), ('a', 'two'), ('b', 'one'), ('b', 'one')],)
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.2.2

('b', 'two'),
('c', 'one'),
('c', 'two')],
names=['foo', 'bar'])

>>> idx.set_levels(['a', 'b'], level='bar')
MultiIndex([(1, 'a'),
(1, 'b'),
(2, 'a'),
(2, 'b'),
(3, 'a'),
(3, 'b')],
names=['foo', 'bar'])

If any of the levels passed to set_levels() exceeds the existing length, all of the values from that argument will be stored in the MultiIndex levels, though the values will be truncated in the MultiIndex output.

>>> idx.set_levels([('a', 'b', 'c'), [1, 2, 3, 4]], level=[0, 1])
MultiIndex([('a', 1),
('a', 2),
('b', 1),
('b', 2),
('c', 1),
('c', 2)],
names=['foo', 'bar'])

>>> idx.set_levels([('a', 'b', 'c'), [1, 2, 3, 4]], level=[0, 1]).levels
FrozenList([['a', 'b', 'c'], [1, 2, 3, 4]])

pandas.MultiIndex.set_codes

MultiIndex.set_codes (codes, level=None, inplace=None, verify_integrity=True)

Set new codes on MultiIndex. Defaults to returning new index.

New in version 0.24.0: New name for deprecated method set_labels.

Parameters

codes [sequence or list of sequence] New codes to apply.

level [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

inplace [bool] If True, mutates in place.

Deprecated since version 1.2.0.

verify_integrity [bool (default True)] If True, checks that levels and codes are compatible.

Returns

new index (of same type and class...etc) or None The same type as the caller or None if inplace=True.
Examples

>>> idx = pd.MultiIndex.from_tuples(...
    [(1, "one"), (1, "two"), (2, "one"), (2, "two")], names=["foo", "bar"]
...)
>>> idx
MultiIndex([(1, 'one'), (1, 'two'), (2, 'one'), (2, 'two')], names=['foo', 'bar'])

>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(2, 'one'), (1, 'two'), (2, 'one'), (1, 'two')], names=['foo', 'bar'])

>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'), (1, 'two'), (2, 'two'), (2, 'two')], names=['foo', 'bar'])

>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
MultiIndex([(2, 'one'), (1, 'two'), (2, 'one'), (1, 'two')], names=['foo', 'bar'])

pandas.MultiIndex.to_frame

MultiIndex.to_frame(index=True, name=None)
Create a DataFrame with the levels of the MultiIndex as columns.
Column ordering is determined by the DataFrame constructor with data as a dict.
New in version 0.24.0.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.

name [list / sequence of str, optional] The passed names should substitute index level names.

Returns

DataFrame [a DataFrame containing the original MultiIndex data.]
See also:

**Dataframe** Two-dimensional, size-mutable, potentially heterogeneous tabular data.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([['a', 'b'], ['c', 'd']])
>>> mi
MultiIndex([('a', 'c'),
            ('b', 'd')],
           )

>>> df = mi.to_frame()
>>> df
    0 1
0 a c a c
1 b d b d

>>> df = mi.to_frame(index=False)
>>> df
   0 1
0 a c
1 b d

>>> df = mi.to_frame(name=['x', 'y'])
>>> df
     x  y
0 a  c a  c
1 b  d b  d
```

**pandas.MultiIndex.to_flat_index**

```
MultiIndex.to_flat_index()
```

Convert a MultiIndex to an Index of Tuples containing the level values.

New in version 0.24.0.

**Returns**

`pd.Index` Index with the MultiIndex data represented in Tuples.

**Notes**

This method will simply return the caller if called by anything other than a MultiIndex.
Examples

```python
>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([('foo', 'baz'), ('foo', 'qux'),
      ('bar', 'baz'), ('bar', 'qux')],
     dtype='object')
```

### pandas.MultiIndex.is_lexsorted

**MultiIndex.is_lexsorted()**

Return True if the codes are lexicographically sorted.

Returns

bool

**Examples**

In the below examples, the first level of the MultiIndex is sorted because a<b<c, so there is no need to look at the next level.

```python
>>> pd.MultiIndex.from_arrays([['a', 'b', 'c'], ['d', 'e', 'f']]).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([['a', 'b', 'c'], ['d', 'f', 'e']]).is_lexsorted()
True
```

In case there is a tie, the lexicographical sorting looks at the next level of the MultiIndex.

```python
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'b', 'c']]).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'c', 'b']]).is_lexsorted()
False
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'b', 'b']],
...                           ['aa', 'bb', 'aa', 'bb'])).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'b', 'b']],
...                           ['bb', 'aa', 'aa', 'bb'])).is_lexsorted()
False
```

### pandas.MultiIndex.sortlevel

**MultiIndex.sortlevel(level=0, ascending=True, sort_remaining=True)**

Sort MultiIndex at the requested level.

The result will respect the original ordering of the associated factor at that level.

**Parameters**

- **level** [list-like, int or str, default 0] If a string is given, must be a name of the level. If list-like must be names or ints of levels.
ascending [bool, default True] False to sort in descending order. Can also be a list to specify a directed ordering.

sort_remaining [sort by the remaining levels after level]

Returns

sorted_index [pd.MultiIndex] Resulting index.

indexer [np.ndarray] Indices of output values in original index.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([[0, 0], [2, 1]])
>>> mi
MultiIndex([(0, 2),
           (0, 1)],
          )

>>> mi.sortlevel()
(MultiIndex([(0, 1),
             (0, 2)],
            ), array([1, 0]))

>>> mi.sortlevel(sort_remaining=False)
(MultiIndex([(0, 2),
             (0, 1)],
            ), array([0, 1]))

>>> mi.sortlevel(1)
(MultiIndex([(0, 1),
             (0, 2)],
            ), array([1, 0]))

>>> mi.sortlevel(1, ascending=False)
(MultiIndex([(0, 2),
             (0, 1)],
            ), array([0, 1]))
```

pandas.MultiIndex.droplevel

MultiIndex.droplevel(level=0)
Return index with requested level(s) removed.
If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex
Examples

```python
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
           names=['x', 'y', 'z'])
```

```python
>>> mi.droplevel()  
MultiIndex([(3, 5),
            (4, 6)],
           names=['y', 'z'])
```

```python
>>> mi.droplevel(2)  
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])
```

```python
>>> mi.droplevel('z')  
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])
```

```python
>>> mi.droplevel(['x', 'y'])  
Int64Index([5, 6], dtype='int64', name='z')
```

`pandas.MultiIndex.swaplevel`

`MultiIndex.swaplevel(i=-2, j=-1)`

Swap level i with level j.

Calling this method does not change the ordering of the values.

**Parameters**

- `i` [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

- `j` [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

**Returns**

`MultiIndex` A new MultiIndex.

**See also:**

- `Series.swaplevel` Swap levels i and j in a MultiIndex.
- `Dataframe.swaplevel` Swap levels i and j in a MultiIndex on a particular axis.
Examples

```python
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([('a', 'bb'),
            ('a', 'aa'),
            ('b', 'bb'),
            ('b', 'aa')],
           )
>>> mi.swaplevel(0, 1)
MultiIndex([('bb', 'a'),
            ('aa', 'a'),
            ('bb', 'b'),
            ('aa', 'b')],
           )
```

**pandas.MultiIndex.reorder_levels**

`MultiIndex.reorder_levels(order)`

Rearrange levels using input order. May not drop or duplicate levels.

**Parameters**

- **order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

**Returns**

`MultiIndex`

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([[1, 2], [3, 4]], names=['x', 'y'])
>>> mi
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])
>>> mi.reorder_levels(order=[1, 0])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])
>>> mi.reorder_levels(order=['y', 'x'])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])
```
pandas.MultiIndex.remove_unused_levels

```
MultiIndex.remove_unused_levels()
```

Create new MultiIndex from current that removes unused levels.

Unused level(s) means levels that are not expressed in the labels. The resulting MultiIndex will have the same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

Returns

MultiIndex

Examples

```
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')])
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )

>>> mi[2:]
MultiIndex([(1, 'a'),
            (1, 'b')],
           )
```

The 0 from the first level is not represented and can be removed

```
>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[[1]], ['a', 'b']])
```

pandas.MultiIndex.get_locs

```
MultiIndex.get_locs(seq)
```

Get location for a sequence of labels.

Parameters

- **seq** [label, slice, list, mask or a sequence of such] You should use one of the above for each level. If a level should not be used, set it to slice(None).

Returns

- `numpy.ndarray` NumPy array of integers suitable for passing to iloc.

See also:

- `MultiIndex.get_loc` Get location for a label or a tuple of labels.
- `MultiIndex.slice_locs` Get slice location given start label(s) and end label(s).
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_locs('b')
array([1, 2], dtype=int64)

>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)

>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

IndexSlice

Create an object to more easily perform multi-index slicing.

pandas.IndexSlice

```
pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>

Create an object to more easily perform multi-index slicing.

See also:

MultiIndex.remove_unused_levels  New MultiIndex with no unused levels.
```

Notes

See Defined Levels for further info on slicing a MultiIndex.

Examples

```python
>>> midx = pd.MultiIndex.from_product([['A0','A1'], ['B0','B1','B2','B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
...                     index=midx, columns=columns)

Using the default slice command:

```python
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
   foo   bar
A0  0  1
B1  2  3
A1  8  9
B1 10 11
```

Using the IndexSlice class for a more intuitive command:

```python
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
   foo   bar
A0  0  1
B1  2  3
```

(continues on next page)
MultiIndex constructors

- **MultiIndex.from_arrays**
  
  ```python
  MultiIndex.from_arrays(arrays[, sortorder, ...])
  ```
  
  Convert arrays to MultiIndex.

- **MultiIndex.from_tuples**
  
  ```python
  MultiIndex.from_tuples(tuples[, sortorder, ...])
  ```
  
  Convert list of tuples to MultiIndex.

- **MultiIndex.from_product**
  
  ```python
  MultiIndex.from_product(iterables[, ...])
  ```
  
  Make a MultiIndex from the cartesian product of multiple iterables.

- **MultiIndex.from_frame**
  
  ```python
  MultiIndex.from_frame(df[, sortorder, names])
  ```
  
  Make a MultiIndex from a DataFrame.

MultiIndex properties

- **MultiIndex.names**
  
  Names of levels in MultiIndex.

- **MultiIndex.levels**
  
  MultiIndex component.

- **MultiIndex.codes**
  
  MultiIndex component.

- **MultiIndex.nlevels**
  
  Integer number of levels in this MultiIndex.

- **MultiIndex.levshape**
  
  A tuple with the length of each level.

**pandas.MultiIndex.levels**

- **MultiIndex.levels**
  
  MultiIndex component.

**pandas.MultiIndex.codes**

- **property MultiIndex.codes**
  
  MultiIndex component.

MultiIndex components

- **MultiIndex.set_levels**
  
  ```python
  MultiIndex.set_levels(levels[, level, ...])
  ```
  
  Set new levels on MultiIndex.

- **MultiIndex.set_codes**
  
  ```python
  MultiIndex.set_codes(codes[, level, ...])
  ```
  
  Set new codes on MultiIndex.

- **MultiIndex.to_flat_index**
  
  Convert a MultiIndex to an Index of Tuples containing the level values.

- **MultiIndex.to_frame**
  
  Create a DataFrame with the levels of the MultiIndex as columns.

- **MultiIndex.is_lexsorted**
  
  Return True if the codes are lexicographically sorted.

- **MultiIndex.sortlevel**
  
  Sort MultiIndex at the requested level.

- **MultiIndex.drop_level**
  
  Return index with requested level(s) removed.

- **MultiIndex.swaplevel**
  
  Swap level i with level j.

- **MultiIndex.reorder_levels**
  
  Rearrange levels using input order.

- **MultiIndex.remove_unused_levels**
  
  Create new MultiIndex from current that removes unused levels.

pandas.MultiIndex.get_loc

MultiIndex.get_loc(key, method=None)

Get location for a label or a tuple of labels.

The location is returned as an integer/slice or boolean mask.

**Parameters**

- key [label or tuple of labels (one for each level)]
- method [None]

**Returns**

- loc [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

**See also:**

- Index.get_loc The get_loc method for (single-level) index.
- MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
- MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.

**Notes**

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use MultiIndex.get_locs() instead.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_loc('b')
slice(1, 3, None)

>>> mi.get_loc(('b', 'e'))
1
```
pandas.MultiIndex.get_loc_level

MultiIndex.get_loc_level(key, level=0, drop_level=True)

Get location and sliced index for requested label(s)/level(s).

Parameters

- **key** [label or sequence of labels]
- **level** [int/level name or list thereof, optional]
- **drop_level** [bool, default True] If False, the resulting index will not drop any level.

Returns

- **loc** [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be None.

See also:

- MultiIndex.get_loc Get location for a label or a tuple of labels.
- MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')],
...                                names=['A', 'B'])

>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))

>>> mi.get_loc_level('e', level='B')
(array([False, True, False]), Index(['b'], dtype='object', name='A'))

>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

pandas.MultiIndex.get_indexer

MultiIndex.get_indexer(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

- **target** [MultiIndex or list of tuples]
- **method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
limit [int, optional] Maximum number of consecutive labels in target to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.

pandas.MultiIndex.get_level_values

MultiIndex.get_level_values(level)
Return vector of label values for requested level.

Length of returned vector is equal to the length of the index.

Parameters

level [int or str] level is either the integer position of the level in the MultiIndex, or the name of the level.

Returns

values [Index] Values is a level of this MultiIndex converted to a single Index (or subclass thereof).

Examples

Create a MultiIndex:

```python
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```python
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```
3.6.6 DatetimeIndex

```
DatetimeIndex([data, freq, tz, normalize, ...])  Immutable ndarray-like of datetime64 data.
```

**pandas.DatetimeIndex**

```python
class pandas.DatetimeIndex(data=None, freq=<object object>, tz=None, normalize=False,
closed=None, ambiguous='raise', dayfirst=False, yearfirst=False,
dtype=None, copy=False, name=None)
```

Immutable ndarray-like of datetime64 data.

Represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata.

**Parameters**

- **data** [array-like (1-dimensional), optional] Optional datetime-like data to construct index with.
- **freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- **tz** [pytz.timezone or dateutil.tz.tzfile or datetime.tzinfo or str] Set the Timezone of the data.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **closed** [['left', 'right'], optional] Set whether to include start and end that are on the boundary. The default includes boundary points on either end.
- **ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.

  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- **dayfirst** [bool, default False] If True, parse dates in data with the day first order.
- **yearfirst** [bool, default False] If True parse dates in data with the year first order.
- **dtype** [numpy.dtype or DatetimeTZDtype or str, default None] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.
- **copy** [bool, default False] Make a copy of input ndarray.
- **name** [label, default None] Name to be stored in the index.

See also:

- **Index** The base pandas Index type.
- **TimedeltaIndex** Index of timedelta64 data.
- **PeriodIndex** Index of Period data.
- **to_datetime** Convert argument to datetime.
date_range  Create a fixed-frequency DatetimeIndex.

Notes

To learn more about the frequency strings, please see this link.

</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DatetimeIndex.year

**property** DatetimeIndex.year

The year of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ... pd.date_range("2000-01-01", periods=3, freq="Y")
    ... )
    >>> datetime_series
    0 2000-12-31
    1 2001-12-31
    2 2002-12-31
    dtype: datetime64[ns]
    >>> datetime_series.dt.year
    0 2000
    1 2001
    2 2002
    dtype: int64
```

pandas.DatetimeIndex.month

**property** DatetimeIndex.month

The month as January=1, December=12.

**Examples**

```python
>>> datetime_series = pd.Series(
    ... pd.date_range("2000-01-01", periods=3, freq="M")
    ... )
    >>> datetime_series
    0 2000-01-31
    1 2000-02-29
    2 2000-03-31
    dtype: datetime64[ns]
    >>> datetime_series.dt.month
    0 1
    1 2
    2 3
    dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DatetimeIndex.day

**property** DatetimeIndex.day
The day of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...    pd.date_range("2000-01-01", periods=3, freq="D")
    ... )
>>> datetime_series
0  2000-01-01
1  2000-01-02
2  2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0  1
1  2
2  3
dtype: int64
```

pandas.DatetimeIndex.hour

**property** DatetimeIndex.hour
The hours of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...    pd.date_range("2000-01-01", periods=3, freq="h")
    ... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 01:00:00
2  2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0  0
1  1
2  2
dtype: int64
```
pandas.DatetimeIndex.minute

property DatetimeIndex.minute
The minutes of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
datetime
0 2000-01-01 00:00:00
1 2000-01-01 00:01:00
2 2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.second

property DatetimeIndex.second
The seconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
datetime
0 2000-01-01 00:00:00
1 2000-01-01 00:00:01
2 2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0 0
1 1
2 2
dtype: int64
```
pandas.DatetimeIndex.microsecond

property DatetimeIndex.microsecond
The microseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0 2000-01-01 00:00:00.000000
1 2000-01-01 00:00:00.000001
2 2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.nanosecond

property DatetimeIndex.nanosecond
The nanoseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="ns")
... )
>>> datetime_series
0 2000-01-01 00:00:00.000000000
1 2000-01-01 00:00:00.000000001
2 2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0 0
1 1
2 2
dtype: int64
```
pandas.DatetimeIndex.date

**property** DatetimeIndex.date

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.DatetimeIndex.time

**property** DatetimeIndex.time

Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.DatetimeIndex.timetz

**property** DatetimeIndex.timetz

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.DatetimeIndex.dayofyear

**property** DatetimeIndex.dayofyear

The ordinal day of the year.

pandas.DatetimeIndex.day_of_year

**property** DatetimeIndex.day_of_year

The ordinal day of the year.

pandas.DatetimeIndex.weekofyear

**property** DatetimeIndex.weekofyear

The week ordinal of the year.

Deprecated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

pandas.DatetimeIndex.week

**property** DatetimeIndex.week

The week ordinal of the year.

Deprecated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DatetimeIndex.dayofweek

property DatetimeIndex.dayofweek
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index  Containing integers indicating the day number.

See also:

Series.dt.dayofweek  Alias.
Series.dt.weekday  Alias.
Series.dt.day_name  Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.day_of_week

property DatetimeIndex.day_of_week
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index  Containing integers indicating the day number.

See also:

Series.dt.dayofweek  Alias.
Series.dt.weekday  Alias.
Series.dt.day_name  Returns the name of the day of the week.
Examples

```python
generate_code()
```

**pandas.DatetimeIndex.weekday**

*(property)* DatetimeIndex.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the `dt` accessor) or DatetimeIndex.

Returns

* Series or Index  Containing integers indicating the day number.

See also:

* Series.dt.dayofweek  Alias.
* Series.dt.weekday  Alias.
* Series.dt.day_name  Returns the name of the day of the week.

Examples

```python
generate_code()
```
pandas.DatetimeIndex.quarter

**property** DatetimeIndex.quarter

The quarter of the date.

pandas.DatetimeIndex.tz

**property** DatetimeIndex.tz

Return timezone, if any.

Returns

datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None Returns None when the array is tz-naive.

pandas.DatetimeIndex.freq

**property** DatetimeIndex.freq

Return the frequency object if it is set, otherwise None.

pandas.DatetimeIndex.freqstr

**property** DatetimeIndex.freqstr

Return the frequency object as a string if its set, otherwise None.

pandas.DatetimeIndex.is_month_start

**property** DatetimeIndex.is_month_start

Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.

is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]
(continues on next page)
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

(continued from previous page)

```python
>>> s.dt.is_month_start
0   False
1   False
2    True
dtype: bool
>>> s.dt.is_month_end
0   False
1    True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

```
pandas.DatetimeIndex.is_month_end

property DatetimeIndex.is_month_end
Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.

is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0   False
1   False
2    True
dtype: bool
>>> s.dt.is_month_end
0   False
1    True
2   False
dtype: bool
```

3.6. Index objects
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

### pandas.DatetimeIndex.is_quarter_start

**property** `DatetimeIndex.is_quarter_start`

Indicator for whether the date is the first day of a quarter.

**Returns**

- `is_quarter_start` [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- `quarter` Return the quarter of the date.
- `is_quarter_end` Similar property for indicating the quarter start.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
                  dates  quarter  is_quarter_start
0  2017-03-30       1          False
1  2017-03-31       1          False
2  2017-04-01       2          True
3  2017-04-02       2          False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(["2017-03-30", '2017-03-31', '2017-04-01', '2017-04-02'],
dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_start
array([False, False, True, False])
```
pandas.DatetimeIndex.is_quarter_end

**property** DatetimeIndex.is_quarter_end

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", ... periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
... is_quarter_end=df.dates.dt.is_quarter_end)
   dates          quarter  is_quarter_end
0 2017-03-30          1          False
1 2017-03-31          1          True
2 2017-04-01          2          False
3 2017-04-02          2          False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'], dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_end
array([False,  True, False, False])
```

pandas.DatetimeIndex.is_year_start

**property** DatetimeIndex.is_year_start

Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end Similar property indicating the last day of the year.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on Date-
timeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]
```

```python
>>> dates.dt.is_year_start
0 False
1 False
2 True
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
       dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_year_start
array([False, False, True])
```

`pandas.DatetimeIndex.is_year_end`

**property** `DatetimeIndex.is_year_end`

Indicate whether the date is the last day of the year.

**Returns**

Series or DatetimeIndex The same type as the original data with boolean values. Se-
ries will have the same name and index. DatetimeIndex will have the same name.

**See also:**

`is_year_start` Similar property indicating the start of the year.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on Date-
timeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]
```
pandas.DatetimeIndex.is_leap_year

property DatetimeIndex.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary
day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not
by 400.

Returns

Series or ndarray  Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on Date-
timeIndex.
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.DatetimeIndex.inferred_freq

**DatetimeIndex.inferred_freq:** Optional[str]

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can't autodetect the frequency.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>normalize(*args, *<em>kwargs)</em></td>
<td>Convert times to midnight. The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.</td>
</tr>
<tr>
<td>strftime(*args, *<em>kwargs)</em></td>
<td>Convert to Index using specified date_format.</td>
</tr>
<tr>
<td>snap([freq])*</td>
<td>Snap time stamps to nearest occurring frequency.</td>
</tr>
<tr>
<td>tz_convert(tz)*</td>
<td>Convert tz-aware Datetime Array/Index from one time zone to another.</td>
</tr>
<tr>
<td>tz_localize(tz[, ambiguous, nonexistent])*</td>
<td>Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.</td>
</tr>
<tr>
<td>round(*args, *<em>kwargs)</em></td>
<td>Perform round operation on the data to the specified freq.</td>
</tr>
<tr>
<td>floor(*args, *<em>kwargs)</em></td>
<td>Perform floor operation on the data to the specified freq.</td>
</tr>
<tr>
<td>ceil(*args, *<em>kwargs)</em></td>
<td>Perform ceil operation on the data to the specified freq.</td>
</tr>
<tr>
<td>to_period(*args, *<em>kwargs)</em></td>
<td>Cast to PeriodArray/Index at a particular frequency.</td>
</tr>
<tr>
<td>to_perioddelta(freq)*</td>
<td>Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq.</td>
</tr>
<tr>
<td>to_pydatetime(*args, *<em>kwargs)</em></td>
<td>Return Datetime Array/Index as object ndarray of datetime.datetime objects.</td>
</tr>
<tr>
<td>to_series([keep_tz, index, name])*</td>
<td>Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.</td>
</tr>
<tr>
<td>to_frame([index, name])*</td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td>month_name(*args, *<em>kwargs)</em></td>
<td>Return the month names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td>day_name(*args, *<em>kwargs)</em></td>
<td>Return the day names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td>mean(*args, *<em>kwargs)</em></td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

pandas.DatetimeIndex.normalize

**DatetimeIndex.normalize(*args, **kwargs)**

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on Datetime Array/Index.

**Returns**

- DatetimeArray, DatetimeIndex or Series The same type as the original data. Series
will have the same name and index. DatetimeIndex will have the same name.

See also:

*floor*  Floor the datetimes to the specified freq.

*ceil*  Ceil the datetimes to the specified freq.

*round*  Round the datetimes to the specified freq.

**Examples**

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
                      ...       periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

**pandas.DatetimeIndex.strftime**

DatetimeIndex.**strftime**( *args, **kwargs*)

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

**Parameters**

*date_format*  [str] Date format string (e.g. “%Y-%m-%d”).

**Returns**

*ndarray*  NumPy ndarray of formatted strings.

See also:

*to_datetime*  Convert the given argument to_datetime.

*DatetimeIndex.normalize*  Return DatetimeIndex with times to midnight.

*DatetimeIndex.round*  Round the DatetimeIndex to the specified freq.

*DatetimeIndex.floor*  Floor the DatetimeIndex to the specified freq.
Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
...
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.DatetimeIndex.snap

`DatetimeIndex.snap(freq='S')`
Snap time stamps to nearest occurring frequency.

Returns

`DatetimeIndex`

pandas.DatetimeIndex.tz_convert

`DatetimeIndex.tz_convert(tz)`
Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

`tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A `tz` of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

`TypeError` If Datetime Array/Index is tz-naive.

See also:

`DatetimeIndex.tz` A timezone that has a variable offset from UTC.

`DatetimeIndex.tz_localize` Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```
With the tz=None, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
          dtype='datetime64[ns, Europe/Berlin]', freq='H')
```
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns
Same type as self  Array/Index converted to the specified time zone.

Raises
TypeError  If the Datetime Array/Index is tz-aware and tz is not None.

See also:
DatetimeIndex.tz_convert  Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```python
tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
tz_naive
```
```
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```python
tz_aware = tz_naive.tz_localize(tz='US/Eastern')
tz_aware
```
```
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
               dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
tz_aware.tz_localize(None)
tz_aware.tz_localize(None)
```
```
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                              '2018-10-28 02:00:00',
                              '2018-10-28 02:30:00',
                              '2018-10-28 02:00:00',
                              '2018-10-28 02:30:00',
                              '2018-10-28 03:00:00',
                              '2018-10-28 03:30:00']))
s.dt.tz_localize('CET', ambiguous='infer')
```
```
0  2018-10-28 01:30:00+02:00
```
(continues on next page)
In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly.

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
    ... '2018-10-28 02:36:00',
    ... '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0  2018-10-28 01:20:00+02:00
1  2018-10-28 02:36:00+02:00
2  2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `shift_forward` or `shift_backwards`.

```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
    ... '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0  2015-03-29 03:00:00+02:00
1  2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0  2015-03-29 01:59:59.999999999+01:00
1  2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0  2015-03-29 03:30:00+02:00
1  2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

### pandas.DatetimeIndex.round

**DatetimeIndex.round(***args, **kwargs**)

Perform round operation on the data to the specified `freq`.

**Parameters**

- `freq` [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.

- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
               dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.round("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]
```
pandas.DatetimeIndex.floor

```
pandas.DatetimeIndex.floor(*args, **kwargs)
    Perform floor operation on the data to the specified freq.
```

**Parameters**

- `freq` [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

  New in version 0.24.0.

- `nonexistent` ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

  New in version 0.24.0.

**Returns**

 DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

ValueError if the freq cannot be converted.

**Examples**

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
```

(continues on next page)
Series

```python
>>> pd.Series(rng).dt.floor("H")
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.DatetimeIndex.ceil**

The `ceil` method performs the ceiling operation on the data to the specified `freq`. It takes the following parameters:

- `freq` [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.
- `ambiguous` [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- `nonexistent` [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series: Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**
ValueError if the \texttt{freq} cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00', '2018-01-01 13:00:00'],
dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.DatetimeIndex.to_period**

DatetimeIndex\texttt{.to\_period}(*\texttt{args}, **\texttt{kwargs}*)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

**Parameters**

\texttt{freq} [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

**Returns**

PeriodArray/Index

**Raises**

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

**See also:**

\texttt{PeriodIndex} Immutable ndarray holding ordinal values.

\texttt{DatetimeIndex.to\_pydatetime} Return DatetimeIndex as object.
Examples

```python
>>> df = pd.DataFrame("
y": [1, 2, 3],
...
index = pd.to_datetime(['2000-03-31 00:00:00',
...
'2000-05-31 00:00:00',
...
'2000-08-31 00:00:00'])

>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```python
>>> idx = pd.date_range("2017-01-01", periods=2)

>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

**pandas.DatetimeIndex.to_perioddelta**

DatetimeIndex.to_perioddelta(freq)

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets.

**Parameters**

freq [Period frequency]

**Returns**

TimedeltaArray/Index

**pandas.DatetimeIndex.to_pydatetime**

DatetimeIndex.to_pydatetime(*args, **kwargs)

Return Datetime Array/Index as object ndarray of datetime.datetime objects.

**Returns**

datetimes [ndarray]

**pandas.DatetimeIndex.to_series**

DatetimeIndex.to_series(keep_tz=<object object>, index=None, name=None)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

**Parameters**

keep_tz [optional, defaults True] Return the data keeping the timezone.

If keep_tz is True:

If the timezone is not set, the resulting Series will have a datetime64[ns] dtyped.

Otherwise the Series will have an datetime64[ns, tz] dtyple; the tz will be preserved.
If keep_tz is False:

Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

**index** [Index, optional] Index of resulting Series. If None, defaults to original index.

**name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

**Series**

### pandas.DatetimeIndex.to_frame

**DatetimeIndex.to_frame** *(index=True, name=None)*

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

**Parameters**

- **index** [bool, default True] Set the index of the returned DataFrame as the original Index.

- **name** [object, default None] The passed name should substitute for the index name (if it has one).

**Returns**

**DataFrame** DataFrame containing the original Index data.

**See also:**

- **Index.to_series** Convert an Index to a Series.

- **Series.to_frame** Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
     animal
    0   Ant
    1   Bear
    2   Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
     0    1    2
   animal Ant Bear Cow
```

3.6. Index objects
To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
     zoo
  0  Ant
  1  Bear
  2  Cow
```

### pandas.DatetimeIndex.month_name

`DatetimeIndex.month_name(*args, **kwargs)`

Return the month names of the DateTimeIndex with specified locale.

**Parameters**

- `locale` [str, optional] Locale determining the language in which to return the month name. Default is English locale.

**Returns**

- `Index` Index of month names.

**Examples**

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
               dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

### pandas.DatetimeIndex.day_name

`DatetimeIndex.day_name(*args, **kwargs)`

Return the day names of the DateTimeIndex with specified locale.

**Parameters**

- `locale` [str, optional] Locale determining the language in which to return the day name. Default is English locale.

**Returns**

- `Index` Index of day names.
Examples

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
dtype='datetime64[ns]', freq='D')
```

```
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

`pandas.DatetimeIndex.mean`

`datetimeindex.mean(*args, **kwargs)`

Return the mean value of the Array.

New in version 0.25.0.

**Parameters**

- `skipna` [bool, default True] Whether to ignore any NaT elements.
- `axis` [int, optional, default 0]

**Returns**

**scalar** Timestamp or Timedelta.

**See also:**

- `numpy.ndarray.mean` Returns the average of array elements along a given axis.
- `Series.mean` Return the mean value in a Series.

**Notes**

mean is only defined for Datetime and Timedelta dtypes, not for Period.

<td>Return index locations of values between particular times of day (e.g., 9:00-9:30AM).</td>
</tr>
</tbody>
</table>

**pandas.DatetimeIndex.indexer_at_time**

`DatetimeIndex.indexer_at_time(time, asof=False)`

Return index locations of values at particular time of day (e.g. 9:30AM).

**Parameters**

- `time` [datetime.time or str] Time passed in either as object (datetime.time) or as string in appropriate format (“%H:%M”, “%H%M”, “%1:%M%p”, “%I%M%p”, “%H:%M:%S”, “H:%M:%S”, “%1:%M:%S%p”, “%I%M%S%p”).

**Returns**

- `values_at_time` [array of integers]

**See also:**

- `indexer_between_time` Get index locations of values between particular times of day.
- `DataFrame.at_time` Select values at particular time of day.
pandas.DatetimeIndex.indexer_between_time

DatetimeIndex.indexer_between_time(start_time, end_time, include_start=True, include_end=True)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

Parameters

start_time, end_time [datetime.time, str] Time passed either as object (datetime.time) or as string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

include_start [bool, default True]
include_end [bool, default True]

Returns

values_between_time [array of integers]

See also:

indexer_at_time Get index locations of values at particular time of day.
DataFrame.between_time Select values between particular times of day.

### 3.6.7 TimedeltaIndex

- **Pandas.TimedeltaIndex**

  ```python
  class pandas.TimedeltaIndex(data=None, unit=None, freq=<object object>, closed=None, dtype=dtype('<m8[ns]'), copy=False, name=None)
  ```

  Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

  **Parameters**

  - `data` [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with.
  - `unit` [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.
  - `freq` [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.
  - `copy` [bool] Make a copy of input ndarray.
  - `name` [object] Name to be stored in the index.

  **See also:**

  - `Index` The base pandas Index type.
  - `Timedelta` Represents a duration between two dates or times.
  - `DatetimeIndex` Index of datetime64 data.
  - `PeriodIndex` Index of Period data.
  - `timedelta_range` Create a fixed-frequency TimedeltaIndex.
**Notes**

To learn more about the frequency strings, please see [this link](#).

**Attributes**

</tbody>
</table>
| `components`   | Return a dataframe of the components (days, hours, minutes, seconds, milli-
|                | seconds, microseconds, nanoseconds) of the Timedeltas.                      |
| `inferred_freq`| Tries to return a string representing a frequency guess, generated by infer_freq. |

**pandas.TimedeltaIndex.days**

**property** `TimedeltaIndex.days`

Number of days for each element.

**pandas.TimedeltaIndex.seconds**

**property** `TimedeltaIndex.seconds`

Number of seconds (>= 0 and less than 1 day) for each element.

**pandas.TimedeltaIndex.microseconds**

**property** `TimedeltaIndex.microseconds`

Number of microseconds (>= 0 and less than 1 second) for each element.

**pandas.TimedeltaIndex.nanoseconds**

**property** `TimedeltaIndex.nanoseconds`

Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
**pandas.TimedeltaIndex.components**

`property TimedeltaIndex.components`  
Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

**Returns**

- a DataFrame

**pandas.TimedeltaIndex.inferred_freq**

`TimedeltaIndex.inferred_freq`

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

**Methods**

<table>

**pandas.TimedeltaIndex.to_pytimedelta**

`TimedeltaIndex.to_pytimedelta(*args, **kwargs)`  
Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

**Returns**

- datetimes [ndarray]

**pandas.TimedeltaIndex.to_series**

`TimedeltaIndex.to_series(index=None, name=None)`  
Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

**Parameters**

- index [Index, optional] Index of resulting Series. If None, defaults to original index.
**name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

**Series** The dtype will be based on the type of the Index values.

**See also:**

*Index.to_frame* Convert an Index to a DataFrame.

*Series.to_frame* Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
Ant   Ant
Bear  Bear
Cow   Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to *index*:

```python
>>> idx.to_series(index=[0, 1, 2])
0   Ant
1   Bear
2   Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify *name*:

```python
>>> idx.to_series(name='zoo')
animal
Ant   Ant
Bear  Bear
Cow   Cow
Name: zoo, dtype: object
```

**pandas.TimedeltaIndex.round**

*TimedeltaIndex*.round(*args, **kwargs*)

Perform round operation on the data to the specified *freq*.

**Parameters**

- **freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

- **ambiguous** ['infer', boolndarray, ‘NaN’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order

3.6. Index objects
bool-ndarray where True signifies a DST time, False designates a non-DST
time (note that this flag is only applicable for ambiguous times)

- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default ‘raise’] A
nonexistent time does not exist in a particular timezone where clocks moved for-
ward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing
time
- ‘shift_backward’ will shift the nonexistent time backward to the closest exist-
ing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIn-
dex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
'2018-01-01 12:01:00'],
dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
'2018-01-01 12:00:00'],
dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.round("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```
pandas.TimedeltaIndex.floor

TimedeltaIndex.floor(*args, **kwargs)
Perform floor operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
```
(continues on next page)
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
               dtype='datetime64[ns]', freq=None)

Series

```python
>>> pd.Series(rng).dt.floor("H")
0   2018-01-01 11:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.ceil

TimedeltaIndex.ceil(*args, **kwargs)
Perform ceil operation on the data to the specified freq.

**Parameters**

- `freq` [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.
- `ambiguous` ['infer', bool-narray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-narray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
  New in version 0.24.0.
- `nonexistent` ['shift_forward', 'shift_backward', 'NaT', timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.
  New in version 0.24.0.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**
ValueError if the freq cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00', '2018-01-01 13:00:00'], dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.TimedeltaIndex.to_frame**

TimedeltaIndex.to_frame (index=True, name=None)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

**Parameters**

- **index** [bool, default True] Set the index of the returned DataFrame as the original Index.
- **name** [object, default None] The passed name should substitute for the index name (if it has one).

**Returns**

DataFrame DataFrame containing the original Index data.

**See also:**

- **Index.to_series** Convert an Index to a Series.
- **Series.to_frame** Convert Series to DataFrame.
Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
    0 Ant
    1 Bear
    2 Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
    0 Ant
    1 Bear
    2 Cow
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
   zoo
    0 Ant
    1 Bear
    2 Cow
```

**pandas.TimedeltaIndex.mean**

TimedeltaIndex.mean(*args, **kwargs)

Return the mean value of the Array.

New in version 0.25.0.

Parameters

- `skipna` [bool, default True] Whether to ignore any NaT elements.
- `axis` [int, optional, default 0]

Returns

- `scalar` Timestamp or Timedelta.

See also:

- `numpy.ndarray.mean` Returns the average of array elements along a given axis.
- `Series.mean` Return the mean value in a Series.
Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

</tr>
</tbody>
</table>
**pandas.PeriodIndex**

```python
class pandas.PeriodIndex(data=None, ordinal=None, freq=None, tz=None, dtype=None, copy=False, name=None, **fields)
```

Immutable ndarray holding ordinal values indicating regular periods in time. Index keys are boxed to Period objects which carries the metadata (eg. frequency information).

**Parameters**

- **data** [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.
- **copy** [bool] Make a copy of input ndarray.
- **freq** [str or period object, optional] One of pandas period strings or corresponding objects.
- **year** [int, array, or Series, default None]
- **month** [int, array, or Series, default None]
- **quarter** [int, array, or Series, default None]
- **day** [int, array, or Series, default None]
- **hour** [int, array, or Series, default None]
- **minute** [int, array, or Series, default None]
- **second** [int, array, or Series, default None]
- **tz** [object, default None] Timezone for converting datetime64 data to Periods.
- **dtype** [str or PeriodDtype, default None]

**See also:**

- **Index** The base pandas Index type.
- **Period** Represents a period of time.
- **DatetimeIndex** Index with datetime64 data.
- **TimedeltaIndex** Index of timedelta64 data.
- **period_range** Create a fixed-frequency PeriodIndex.

**Examples**

```python
>>> idx = pd.PeriodIndex(year=[2000, 2002], quarter=[1, 3])
>>> idx
PeriodIndex(['2000Q1', '2002Q3'], dtype='period[Q-DEC]', freq='Q-DEC')
```

**Attributes**

- **day** The days of the period.
- **dayofweek** The day of the week with Monday=0, Sunday=6.
- **day_of_week** The day of the week with Monday=0, Sunday=6.
- **dayofyear** The ordinal day of the year.
- **day_of_year** The ordinal day of the year.
- **days_in_month** The number of days in the month.
- **daysinmonth** The number of days in the month.

pandas.PeriodIndex.day

**property** PeriodIndex.day
The days of the period.

pandas.PeriodIndex.dayofweek

**property** PeriodIndex.dayofweek
The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.day_of_week

**property** PeriodIndex.day_of_week
The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.dayofyear

**property** PeriodIndex.dayofyear
The ordinal day of the year.

pandas.PeriodIndex.day_of_year

**property** PeriodIndex.day_of_year
The ordinal day of the year.
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
pandas.PeriodIndex.days_in_month
```

**property** `PeriodIndex.days_in_month`

The number of days in the month.

```python
pandas.PeriodIndex.daysinmonth
```

**property** `PeriodIndex.daysinmonth`

The number of days in the month.

```python
pandas.PeriodIndex.freq
```

**property** `PeriodIndex.freq`

Return the frequency object if it is set, otherwise None.

```python
pandas.PeriodIndex.freqstr
```

**property** `PeriodIndex.freqstr`

Return the frequency object as a string if its set, otherwise None.

```python
pandas.PeriodIndex.hour
```

**property** `PeriodIndex.hour`

The hour of the period.

```python
pandas.PeriodIndex.is_leap_year
```

**property** `PeriodIndex.is_leap_year`

Logical indicating if the date belongs to a leap year.

```python
pandas.PeriodIndex.minute
```

**property** `PeriodIndex.minute`

The minute of the period.

```python
pandas.PeriodIndex.month
```

**property** `PeriodIndex.month`

The month as January=1, December=12.
pandas.PeriodIndex.quarter

property PeriodIndex.quarter
The quarter of the date.

pandas.PeriodIndex.second

property PeriodIndex.second
The second of the period.

pandas.PeriodIndex.week

property PeriodIndex.week
The week ordinal of the year.

pandas.PeriodIndex.weekday

property PeriodIndex.weekday
The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.weekofyear

property PeriodIndex.weekofyear
The week ordinal of the year.

pandas.PeriodIndex.year

property PeriodIndex.year
The year of the period.

<table>
<thead>
<tr>
<th>end_time</th>
<th>qyear</th>
<th>start_time</th>
</tr>
</thead>
</table>

Methods

asfreq(freq, how)
Convert the Period Array/Index to the specified frequency `freq`.

strftime(*args, **kwargs)
Convert to Index using specified date_format.

to_timestamp(freq, how)
Cast to DatetimeArray/Index.
pandas.PeriodIndex.asfreq

PeriodIndex.asfreq(freq=None, how='E')
Convert the Period Array/Index to the specified frequency freq.

Parameters
freq [str] A frequency.
how [str {'E', 'S'}] Whether the elements should be aligned to the end or start within a period.
• ‘E’, ‘END’, or ‘FINISH’ for end,
• ‘S’, ‘START’, or ‘BEGIN’ for start.
January 31st (‘END’) vs. January 1st (‘START’) for example.

Returns
Period Array/Index Constructed with the new frequency.

Examples

```python
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx
dtype=’period[A-DEC]’, freq=’A-DEC’)

>>> pidx.asfreq(‘M’)  
dtype=’period[M]’, freq=’M’)

>>> pidx.asfreq(‘M’, how=’S’)  
dtype=’period[M]’, freq=’M’)  
```

pandas.PeriodIndex.strftime

PeriodIndex.strftime(*args, **kwargs)
Convert to Index using specified date_format.
Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters
date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns
ndarray NumPy ndarray of formatted strings.

See also:
to_datetime Convert the given argument to datetime.
DatetimeIndex.normalize Return DatetimeIndex with times to midnight.
DatetimeIndex.round  Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor  Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                       periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.PeriodIndex.to_timestamp

PeriodIndex.to_timestamp(freq=None, how='start')
Cast to DatetimeArray/Index.

Parameters

- **freq** [str or DateOffset, optional] Target frequency. The default is ‘D’ for week or longer, ‘S’ otherwise.
- **how** [{'s', 'e', 'start', 'end'}] Whether to use the start or end of the time period being converted.

Returns

DatetimeArray/Index

Properties

- **PeriodIndex.day**  The days of the period.
- **PeriodIndex.dayofweek**  The day of the week with Monday=0, Sunday=6.
- **PeriodIndex.day_of_week**  The day of the week with Monday=0, Sunday=6.
- **PeriodIndex.dayofyear**  The ordinal day of the year.
- **PeriodIndex.day_of_year**  The ordinal day of the year.
- **PeriodIndex.days_in_month**  The number of days in the month.
- **PeriodIndex.daysinmonth**  The number of days in the month.
- **PeriodIndex.end_time**  The end_time of the period.
- **PeriodIndex.freq**  Return the frequency object if it is set, otherwise None.
- **PeriodIndex.freqstr**  Return the frequency object as a string if its set, otherwise None.
- **PeriodIndex.hour**  The hour of the period.
- **PeriodIndex.is_leap_year**  Logical indicating if the date belongs to a leap year.
- **PeriodIndex.minute**  The minute of the period.
- **PeriodIndex.month**  The month as January=1, December=12.
- **PeriodIndex.quarter**  The quarter of the date.
- **PeriodIndex.qyear**  The qyear of the period.
- **PeriodIndex.second**  The second of the period.
- **PeriodIndex.start_time**  The start_time of the period.
- **PeriodIndex.week**  The week ordinal of the year.

3.7 Date offsets

3.7.1 DateOffset

DateOffset

Standard kind of date increment used for a date range.

pandas.tseries.offsets.DateOffset

class pandas.tseries.offsets.DateOffset

Standard kind of date increment used for a date range.

Works exactly like relativedelta in terms of the keyword args you pass in, use of the keyword n is discouraged—you would be better off specifying n in the keywords you use, but regardless it is there for you. n is needed for DateOffset subclasses.

DateOffset work as follows. Each offset specify a set of dates that conform to the DateOffset. For example, Bday defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a DateOffset dateOffset we can use the is_on_offset method: dateOffset.is_on_offset(date).

If a date is not on a valid date, the rollback and rollforward methods can be used to roll the date to the nearest valid date before/after the date.

DateOffsets can be created to move dates forward a given number of valid dates. For example, Bday(2) can be
added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

```python
def __add__(date):
    date = rollback(date) # does nothing if date is valid
    return date + <n number of periods>
```

When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

```python
def __add__(date):
    date = rollforward(date) # does nothing is date is valid
    return date + <n number of periods>
```

Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

```python
date + BDay(0) == BDay.rollforward(date)
```

Since 0 is a bit weird, we suggest avoiding its use.

**Parameters**

- **n** [int, default 1] The number of time periods the offset represents.
- **normalize** [bool, default False] Whether to round the result of a DateOffset addition down to the previous midnight.

**kwds** Temporal parameter that add to or replace the offset value.

Parameters that **add** to the offset (like Timedelta):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that **replace** the offset value:

- year
- month
- day
- weekday
- hour
- minute
- second
- microsecond
- nanosecond.

**See also:**

dateutil.relativedelta.relativedelta The relativedelta type is designed to be applied to an existing datetime and can replace specific components of that datetime, or represents an interval of time.
Examples

```python
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')

>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```

</table>

`pandas.tseries.offsets.DateOffset.base`

```
DateOffset .base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

Methods

```
__call__(*args, **kwargs) Call self as a function.
rollback

Roll provided date backward to next offset only if not on offset.

rollforward

Roll provided date forward to next offset only if not on offset.
```
pandas.tseries.offsets.DateOffset.__call__

DateOffset.__call__(*args, **kwargs)
    Call self as a function.

pandas.tseries.offsets.DateOffset.rollback

DateOffset.rollback()
    Roll provided date backward to next offset only if not on offset.

    Returns
    
    TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.DateOffset.rollforward

DateOffset.rollforward()
    Roll provided date forward to next offset only if not on offset.

    Returns
    
    TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.3 BusinessHour

| BusinessHour | DateOffset subclass representing possibly n business hours. |

```
pandas.tseries.offsets.BusinessHour
```

**class pandas.tseries.offsets.BusinessHour**

DateOffset subclass representing possibly n business hours.

**Parameters**

- `n` [int, default 1] The number of months represented.
- `normalize` [bool, default False] Normalize start/end dates to midnight before generating date range.
- `weekmask` [str, Default ‘Mon Tue Wed Thu Fri’] Weekmask of valid business days, passed to `numpy.busdaycalendar`.
- `start` [str, default “09:00”] Start time of your custom business hour in 24h format.
- `end` [str, default: “17:00”] End time of your custom business hour in 24h format.

**Attributes**

- `base` Returns a copy of the calling offset object with n=1 and all other attributes equal.
- `next_bday` Used for moving to next business day.
- `offset` Alias for self._offset.

```
pandas.tseries.offsets.BusinessHour.base
```

**BusinessHour.base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.
pandas.tseries.offsets.BusinessHour.next_bday

BusinessHour.next_bday
Used for moving to next business day.

pandas.tseries.offsets.BusinessHour.offset

BusinessHour.offset
Alias for self._offset.

Methods

__call__(*args, **kwargs) Call self as a function.
rollback(other) Roll provided date backward to next offset only if not on offset.
rollforward(other) Roll provided date forward to next offset only if not on offset.

Methods

**pandas.tseries.offsets.Week.__call__**

*Week.*\_call\_\_\_(*args, **kwargs)*

Call self as a function.

**pandas.tseries.offsets.Week.rollback**

*Week.*\_rollback*\()

Roll provided date backward to next offset only if not on offset.

Returns

*TimeStamp* Rolled timestamp if not on offset, otherwise unchanged timestamp.

**pandas.tseries.offsets.Week.rollforward**

*Week.*\_rollforward*\()

Roll provided date forward to next offset only if not on offset.

Returns

*TimeStamp* Rolled timestamp if not on offset, otherwise unchanged timestamp.
pandas.tseries.offsets.Week.rollforward

**Week.rollforward()**
Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

<table>

### 3.7.15 WeekOfMonth

<table>
<thead>
<tr>
<th>WeekOfMonth</th>
<th>Describes monthly dates like “the Tuesday of the 2nd week of each month”.</th>
</tr>
</thead>
</table>

**pandas.tseries.offsets.WeekOfMonth**

*class pandas.tseries.offsets.WeekOfMonth*

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

*Parameters*

- **n** [int]
- **week** [int {0, 1, 2, 3, ...}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.
- **weekday** [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.
  - 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday
• 6 is Sunday.

Attributes

<table>
<thead>
<tr>
<th>base</th>
<th>Returns a copy of the calling offset object with n=1 and all other attributes equal.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.WeekOfMonth.base

WeekOfMonth.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
pandas.tseries.offsets.WeekOfMonth.__call__

`WeekOfMonth.__call__(*args, **kwargs)`
Call self as a function.

pandas.tseries.offsets.WeekOfMonth.rollback

`WeekOfMonth.rollback()`
Roll provided date backward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.WeekOfMonth.rollforward

`WeekOfMonth.rollforward()`
Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.16 LastWeekOfMonth

| LastWeekOfMonth | Describes monthly dates in last week of month like “the last Tuesday of each month”. |

2142 Chapter 3. API reference
pandas.tseries.offsets.LastWeekOfMonth

class pandas.tseries.offsets.LastWeekOfMonth
Describes monthly dates in last week of month like “the last Tuesday of each month”.

Parameters

n [int, default 1]

weekday [int {0, 1, . . . , 6}, default 0] A specific integer for the day of the week.

• 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday
• 6 is Sunday.

Attributes

base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.LastWeekOfMonth.base

LastWeekOfMonth.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

Methods

__call__(*args, **kwargs) Call self as a function.
rollback
Roll provided date backward to next offset only if not on offset.
rollforward
Roll provided date forward to next offset only if not on offset.
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.tseries.offsets.LastWeekOfMonth.__call__

LastWeekOfMonth.__call__(*args, **kwargs)
- Call self as a function.

pandas.tseries.offsets.LastWeekOfMonth.rollback

LastWeekOfMonth.rollback()
- Roll provided date backward to next offset only if not on offset.
  - Returns
    - **TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.LastWeekOfMonth.rollforward

LastWeekOfMonth.rollforward()
- Roll provided date forward to next offset only if not on offset.
  - Returns
    - **TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

<table>
<thead>

3.7.17 BQuarterEnd

BQuarterEnd

DateOffset increments between the last business day of each Quarter.

pandas.tseries.offsets.BQuarterEnd

class pandas.tseries.offsets.BQuarterEnd

DateOffset increments between the last business day of each Quarter.

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Examples

```python
>>> from pandas.tseries.offset import BQuarterEnd
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterEnd()
Timestamp('2020-06-30 05:01:15')
>>> ts + BQuarterEnd(2)
Timestamp('2020-09-30 05:01:15')
>>> ts + BQuarterEnd(1, startingMonth=2)
Timestamp('2020-05-29 05:01:15')
>>> ts + BQuarterEnd(startingMonth=2)
Timestamp('2020-05-29 05:01:15')
```

Attributes

```
base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

pandas.tseries.offsets.BQuarterEnd.base

BQuarterEnd.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
### Methods

   Call self as a function.

pandas.tseries.offsets.BQuarterBegin.rollback

BQuarterBegin.rollback()
   Roll provided date backward to next offset only if not on offset.

   Returns
      TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BQuarterBegin.rollforward

BQuarterBegin.rollforward()
   Roll provided date forward to next offset only if not on offset.

   Returns
      TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.25 FY5253

FY5253 Describes 52-53 week fiscal year.

pandas.tseries.offsets.FY5253

class pandas.tseries.offsets.FY5253

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:
• end on the last X day of the Y month.
• end on the last X day closest to the last day of the Y month.
X is a specific day of the week. Y is a certain month of the year.

**Parameters**

- `n` [int]  
- `weekday` [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.
  
  - 0 is Monday  
  - 1 is Tuesday  
  - 2 is Wednesday  
  - 3 is Thursday  
  - 4 is Friday  
  - 5 is Saturday  
  - 6 is Sunday.

- `startingMonth` [int {1, 2, ..., 12}, default 1] The month in which the fiscal year ends.

- `variation` [str, default “nearest”] Method of employing 4-4-5 calendar.
  
  There are two options:
  
  - “nearest” means year end is `weekday` closest to last day of month in year.
  - “last” means year end is final `weekday` of the final month in fiscal year.

**3.7.26 FY5253 Quarter**

- DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).
**pandas.tseries.offsets.FY5253Quarter**

**class pandas.tseries.offsets.FY5253Quarter**

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: [https://en.wikipedia.org/wiki/4-4-5_calendar](https://en.wikipedia.org/wiki/4-4-5_calendar)

The year may either:
- end on the last X day of the Y month.
- end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

**Parameters**

- n [int]
  - weekday [int {0, 1, …, 6}, default 0] A specific integer for the day of the week.
    - 0 is Monday
    - 1 is Tuesday
    - 2 is Wednesday
    - 3 is Thursday
    - 4 is Friday
    - 5 is Saturday
    - 6 is Sunday.

- startingMonth [int {1, 2, …, 12}, default 1] The month in which fiscal years end.

- qtr_with_extra_week [int {1, 2, 3, 4}, default 1] The quarter number that has the leap or 14 week when needed.

- variation [str, default “nearest”] Method of employing 4-4-5 calendar.
  
  There are two options:
  
  - “nearest” means year end is **weekday** closest to last day of month in year.
  - “last” means year end is final **weekday** of the final month in fiscal year.

**Attributes**

- **base**
  
  Returns a copy of the calling offset object with n=1 and all other attributes equal.
pandas.tseries.offsets.FY5253Quarter.base

FY5253Quarter.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.8 Frequencies

| to_offset | Return DateOffset object from string or tuple representation or datetime.timedelta object. |

3.8.1 pandas.tseries.frequencies.to_offset

pandas.tseries.frequencies.to_offset()  # Return DateOffset object from string or tuple representation or datetime.timedelta object.

Parameters

freq [str, tuple, datetime.timedelta, DateOffset or None]

Returns

DateOffset or None

Raises
ValueError If freq is an invalid frequency

See also:

DateOffset Standard kind of date increment used for a date range.

Examples

```python
>>> to_offset("5min")
<5 * Minutes>
```

```python
>>> to_offset("1D1H")
<25 * Hours>
```

```python
>>> to_offset("2W")
<2 * Weeks: weekday=6>
```

```python
>>> to_offset("2B")
<2 * BusinessDays>
```

```python
>>> to_offset(pd.Timedelta(days=1))
<Day>
```

```python
>>> to_offset(Hour())
_HOUR>
```

3.9 Window

Rolling objects are returned by .rolling calls: pandas.DataFrame.rolling(), pandas.Series.rolling(), etc. Expanding objects are returned by .expanding calls: pandas.DataFrame.expanding(), pandas.Series.expanding(), etc. ExponentialMovingWindow objects are returned by .ewm calls: pandas.DataFrame.ewm(), pandas.Series.ewm(), etc.

3.9.1 Rolling window functions

<table>

</tr>
</tbody>
</table>

### pandas.core.window.rolling.Rolling.count

**`Rolling.count()`**

The rolling count of any non-NaN observations inside the window.

**Returns**

- **Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

**See also:**

- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrames.
- `pandas.DataFrame.count` Count of the full DataFrame.

**Examples**

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64
```

### pandas.core.window.rolling.Rolling.sum

**`Rolling.sum(*args, **kwargs)`**

Calculate rolling sum of given DataFrame or Series.

**Parameters**

- **`*args`, **kwargs** For compatibility with other rolling methods. Has no effect on the computed value.

**Returns**

- **Series or DataFrame** Same type as the input, with the same index, containing the rolling sum.
pandas: powerful Python data analysis toolkit, Release 1.2.2

See also:
pandas.Series.sum Reducing sum for Series.
pandas.DataFrame.sum Reducing sum for DataFrame.
Examples
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0
1
1
2
2
3
3
4
4
5
dtype: int64
>>> s.rolling(3).sum()
0
NaN
1
NaN
2
6.0
3
9.0
4
12.0
dtype: float64
>>> s.expanding(3).sum()
0
NaN
1
NaN
2
6.0
3
10.0
4
15.0
dtype: float64
>>> s.rolling(3, center=True).sum()
0
NaN
1
6.0
2
9.0
3
12.0
4
NaN
dtype: float64

For DataFrame, each rolling sum is computed column-wise.
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
A
B
0 1
1
1 2
4
2 3
9
3 4 16
4 5 25
>>> df.rolling(3).sum()
A
B
0
NaN
NaN
1
NaN
NaN
(continues on next page)

3.9. Window

2227


2 6.0 14.0
3 9.0 29.0
4 12.0 50.0

pandas.core.window.rolling.Rolling.mean

Rolling.mean(*args, **kwargs)
Calculate the rolling mean of the values.

Parameters
*args Under Review.
**kwargs Under Review.

Returns
Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:
pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.mean Equivalent method for Series.
pandas.DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1     1.5
2     2.5
3     3.5
dtype: float64

>>> s.rolling(3).mean()
0    NaN
1    NaN
2  2.0
3  3.0
dtype: float64
```
pandas.core.window.rolling.Rolling.median

Rolling.median(**kwargs)
Calculate the rolling median.

Parameters

**kwargs For compatibility with other rolling methods. Has no effect on the computed median.

Returns

Series or DataFrame Returned type is the same as the original object.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.median Equivalent method for Series.
pandas.DataFrame.median Equivalent method for DataFrame.

Examples

Compute the rolling median of a series with a window size of 3.

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0  NaN
1  NaN
2  1.0
3  2.0
4  3.0
dtype: float64
```

pandas.core.window.rolling.Rolling.var

Rolling.var(ddof=1, *args, **kwargs)
Calculate unbiased rolling variance.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

*args, **kwargs For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.var Equivalent method for Series.
pandas.DataFrame.var Equivalent method for DataFrame.
numpy.var Equivalent method for Numpy array.
Notes

The default $ddof$ of 1 used in `Series.var()` is different than the default $ddof$ of 0 in `numpy.var()`. A minimum of 1 period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
      0   NaN
      1   NaN
      2  0.333333
      3  1.000000
      4  1.000000
      5  1.333333
      6  0.000000
dtype: float64

>>> s.expanding(3).var()
      0   NaN
      1   NaN
      2  0.333333
      3  0.916667
      4  0.800000
      5  0.700000
      6  0.619048
dtype: float64
```

**pandas.core.window.rolling.Rolling.std**

Rolling.$\text{std}(ddof=1, *\text{args}, **\text{kwargs})$

Calculate rolling standard deviation.

Normalized by N-1 by default. This can be changed using the $ddof$ argument.

**Parameters**

- $ddof$ [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

- $*\text{args}, **\text{kwargs}$ For NumPy compatibility. No additional arguments are used.

**Returns**

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:

- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrames.
- `pandas.Series.std` Equivalent method for Series.
- `pandas.DataFrame.std` Equivalent method for DataFrame.
- `numpy.std` Equivalent method for Numpy array.
Notes

The default \texttt{ddof} of 1 used in \texttt{Series.std} is different than the default \texttt{ddof} of 0 in \texttt{numpy.std}.

A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0    NaN
1    NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```python
>>> s.expanding(3).std()
0    NaN
1    NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

### pandas.core.window.rolling.Rolling.min

Rolling.\texttt{min} (*\texttt{args}, **\texttt{kwargs})

Calculate the rolling minimum.

**Parameters**

**\texttt{kwargs} Under Review.**

**Returns**

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

**See also:**

- \texttt{pandas.Series.rolling} Calling object with a Series.
- \texttt{pandas.DataFrame.rolling} Calling object with a DataFrame.
- \texttt{pandas.Series.min} Similar method for Series.
- \texttt{pandas.DataFrame.min} Similar method for DataFrame.
Examples

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

`pandas.core.window.rolling.Rolling.max`

Rolling.max(*args, **kwargs)
Calculate the rolling maximum.

**Parameters**

- *args, **kwargs
  Arguments and keyword arguments to be passed into func.

**Returns**

- Series or DataFrame
  Return type is determined by the caller.

**See also:**

- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrame data.
- `pandas.Series.max` Similar method for Series.
- `pandas.DataFrame.max` Similar method for DataFrame.

`pandas.core.window.rolling.Rolling.corr`

Rolling.corr(other=None, pairwise=None, **kwargs)
Calculate rolling correlation.

**Parameters**

- other
  [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

- pairwise
  [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If other is not specified, defaults to True, otherwise defaults to False. Not relevant for Series.

- **kwargs
  Unused.

**Returns**

- Series or DataFrame
  Returned object type is determined by the caller of the rolling calculation.

**See also:**

- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrames.
- `pandas.Series.corr` Equivalent method for Series.
- `pandas.DataFrame.corr` Equivalent method for DataFrame.
- `cov` Similar method to calculate covariance.
- `numpy.corrcoef` NumPy Pearson’s correlation calculation.
Notes

This function uses Pearson’s definition of correlation ([https://en.wikipedia.org/wiki/Pearson_correlation_coefficient](https://en.wikipedia.org/wiki/Pearson_correlation_coefficient)).

When `other` is not specified, the output will be self correlation (e.g. all 1’s), except for `DataFrame` inputs with `pairwise` set to `True`.

Function will return `NaN` for correlations of equal valued sequences; this is the result of a 0/0 division error.

When `pairwise` is set to `False`, only matching columns between `self` and `other` will be used.

When `pairwise` is set to `True`, the output will be a MultiIndex DataFrame with the original index on the first level, and the `other` DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```python
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2x2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0    NaN
1    NaN
2 0.333333
3    NaN
4 0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```python
˓→36.]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.  0.6263001
  0.6263001  1. ]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.  0.5553681
  0.5553681  1. ]
>>> df = pd.DataFrame(matrix, columns=["X","Y"])
>>> df
   X   Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
```

(continues on next page)
>>> df.rolling(4).corr(pairwise=True)

<p>| | |</p>

**pandas.core.window.rolling.Rolling.cov**

Rolling.cov(*other=None, pairwise=None, ddof=1, **kwargs*)

Calculate the rolling sample covariance.

**Parameters**

- **other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

- **pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

- ****kwargs** Keyword arguments to be passed into func.

**Returns**

Series or DataFrame Return type is determined by the caller.

**See also:**

- pandas.Series.rolling Calling object with Series data.
- pandas.DataFrame.rolling Calling object with DataFrame data.
- pandas.Series.cov Similar method for Series.
- pandas.DataFrame.cov Similar method for DataFrame.

**pandas.core.window.rolling.Rolling.skew**

Rolling.skew(**kwargs**)

Unbiased rolling skewness.

**Parameters**

- ****kwargs** Keyword arguments to be passed into func.

**Returns**

Series or DataFrame Return type is determined by the caller.

**See also:**

- pandas.Series.rolling Calling object with Series data.
**pandas.DataFrame.rolling** Calling object with DataFrame data.

**pandas.Series.skew** Similar method for Series.

**pandas.DataFrame.skew** Similar method for DataFrame.

**pandas.core.window.rolling.Rolling.kurt**

Rolling.kurt(**kwargs)

Calculate unbiased rolling kurtosis.

This function uses Fisher’s definition of kurtosis without bias.

**Parameters**

**kwargs Under Review.**

**Returns**

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

**pandas.Series.rolling** Calling object with Series data.

**pandas.DataFrame.rolling** Calling object with DataFrames.

**pandas.Series.kurt** Equivalent method for Series.

**pandas.DataFrame.kurt** Equivalent method for DataFrame.

**scipy.stats.skew** Third moment of a probability density.

**Notes**

A minimum of 4 periods is required for the rolling calculation.

**Examples**

The example below will show a rolling calculation with a window size of four matching the equivalent function call using scipy.stats.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"scipy.stats.kurtosis(arr[:-1], bias=False):.6f")
-1.200000
>>> print(f"scipy.stats.kurtosis(arr[1:], bias=False):.6f")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0    NaN
1    NaN
2    NaN
3   -1.200000
4    3.999946
dtype: float64
```

### 3.9. Window
Rolling.apply (func, raw=False, engine=None, engine_kwars=None, args=None, kwargs=None)

Apply an arbitrary function to each rolling window.

Parameters

func [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.

Changed in version 1.0.0.

raw [bool, default None]

- False: passes each row or column as a Series to the function.
- True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

- 'cython': Runs rolling apply through C-extensions from cython.
- 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.0.0.

engine_kwars [dict, default None]

- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into func.

kwargs [dict, default None] Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.
pandas.Series.apply Similar method for Series.
pandas.DataFrame.apply Similar method for DataFrame.
Notes

See Numba engine for extended documentation and performance considerations for the Numba engine.

pandas.core.window.rolling.Rolling.aggregate

Rolling.aggregate(func, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:
• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:
• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:
pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.

Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
```
>>> df.rolling(2).sum()
   A    B    C
0  NaN  NaN  NaN
1  3.0  9.0  15.0
2  5.0  11.0  17.0

>>> df.rolling(2).agg({'A': 'sum', 'B': 'min'})
   A    B
0  NaN  NaN
1  3.0  4.0
2  5.0  5.0

**pandas.core.window.rolling.Rolling.quantile**

Rolling.quantile(quantile, interpolation='linear', **kwargs)

Calculate the rolling quantile.

**Parameters**

- **quantile** [float] Quantile to compute. 0 <= quantile <= 1.
- **interpolation** [{'linear', 'lower', 'higher', 'midpoint', 'nearest']} This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:
  * linear: \( i + (j - i) \times \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
  * lower: \( i \).
  * higher: \( j \).
  * nearest: \( i \) or \( j \) whichever is nearest.
  * midpoint: \( (i + j) / 2 \).

- **kwargs** For compatibility with other rolling methods. Has no effect on the result.

**Returns**

- **Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

**See also:**

- `pandas.Series.quantile` Computes value at the given quantile over all data in Series.
- `pandas.DataFrame.quantile` Computes values at the given quantile over requested axis in DataFrame.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0  NaN
1  1.0
2  2.0
3  3.0
```

dtype: float64
```python
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0   NaN
1   1.5
2   2.5
3   3.5
dtype: float64
```

**pandas.core.window.rolling.Rolling.sem**

Rolling.sem(ddof=1, *args, **kwargs)

Compute rolling standard error of mean.

**Parameters**

- `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.
- `*args, **kwargs` For NumPy compatibility. No additional arguments are used.

**Returns**

- **Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

**See also:**

- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrames.
- `pandas.Series.sem` Equivalent method for Series.
- `pandas.DataFrame.sem` Equivalent method for DataFrame.

**Notes**

A minimum of one period is required for the rolling calculation.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> s.rolling(2, min_periods=1).sem()
0   NaN
1  0.707107
2  0.707107
3  0.707107
dtype: float64
```

```python
>>> s.expanding().sem()
0   NaN
1  0.707107
2  0.707107
3  0.745356
dtype: float64
```
3.9.2 Weighted window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window.mean(*args, **kwargs)</td>
<td>Calculate the window mean of the values.</td>
</tr>
<tr>
<td>Window.sum(*args, **kwargs)</td>
<td>Calculate window sum of given DataFrame or Series.</td>
</tr>
<tr>
<td>Window.var(ddof)</td>
<td>Calculate unbiased window variance.</td>
</tr>
<tr>
<td>Window.std(ddof)</td>
<td>Calculate window standard deviation.</td>
</tr>
</tbody>
</table>

**pandas.core.window.rolling.Window.mean**

Window.mean(*args, **kwargs)

Calculate the window mean of the values.

**Parameters**

*args Under Review.

**kwargs Under Review.

**Returns**

Series or DataFrame Returned object type is determined by the caller of the window calculation.

**See also:**

- pandas.Series.window Calling object with Series data.
- pandas.DataFrame.window Calling object with DataFrames.
- pandas.Series.mean Equivalent method for Series.
- pandas.DataFrame.mean Equivalent method for DataFrame.

**Examples**

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64

>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```
pandas.core.window.rolling.Window.sum

Window.\texttt{sum}(\ast args, **kwargs)

Calculate window sum of given DataFrame or Series.

Parameters

*args, **kwargs For compatibility with other window methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the window sum.

See also:

\texttt{pandas.Series.sum} Reducing sum for Series.
\texttt{pandas.DataFrame.sum} Reducing sum for DataFrame.

Examples

\begin{verbatim}
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0   1
1   2
2   3
3   4
4   5
dtype: int64

>>> s.rolling(3).sum()
0   NaN
1   NaN
2   6.0
3   9.0
4  12.0
dtype: float64

>>> s.expanding(3).sum()
0   NaN
1   NaN
2   6.0
3   10.0
4   15.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0   NaN
1   6.0
2   9.0
3   12.0
4   NaN
dtype: float64
\end{verbatim}

For DataFrame, each window sum is computed column-wise.
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25

>>> df.rolling(3).sum()
     A  B
0  NaN  NaN
1  NaN  NaN
2   6   14
3   9   29
4  12  50

pandas.core.window.rolling.Window.var

Window.var(ddof=1, *args, **kwargs)

Calculate unbiased window variance.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

- ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

- *args, **kwargs For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the window calculation.

See also:

- pandas.Series.window Calling object with Series data.
- pandas.DataFrame.window Calling object with DataFrames.
- pandas.Series.var Equivalent method for Series.
- pandas.DataFrame.var Equivalent method for DataFrame.
- numpy.var Equivalent method for Numpy array.

Notes

The default \( ddof \) of 1 used in Series.var() is different than the default \( ddof \) of 0 in numpy.var().

A minimum of 1 period is required for the rolling calculation.
### Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std(
       ddof=1,
       )
    0     NaN
    1     NaN
    2  0.333333
    3  1.000000
    4  1.000000
    5  1.333333
    6  0.000000
dtype: float64
```

```python
>>> s.expanding(3).std(
       ddof=1,
       )
    0     NaN
    1     NaN
    2  0.333333
    3  0.916667
    4  0.800000
    5  0.700000
    6  0.619048
dtype: float64
```

### pandas.core.window.rolling.Window.std

**Window.std**(*ddof=1, *args, **kwargs*)

Calculate window standard deviation.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

**Parameters**

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N – ddof, where N represents the number of elements.

- ***args, **kwargs** For NumPy compatibility. No additional arguments are used.

**Returns**

- **Series or DataFrame** Returns the same object type as the caller of the window calculation.

See also:

- **pandas.Series.window** Calling object with Series data.
- **pandas.DataFrame.window** Calling object with DataFrames.
- **pandas.Series.std** Equivalent method for Series.
- **pandas.DataFrame.std** Equivalent method for DataFrame.
- **numpy.std** Equivalent method for Numpy array.
Notes

The default $ddof$ of 1 used in Series.std is different than the default $ddof$ of 0 in numpy.std.

A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0    NaN
1    NaN
2  0.577350
3  1.000000
4  1.000000
5  1.154701
6  0.000000
dtype: float64

>>> s.expanding(3).std()
0    NaN
1    NaN
2  0.577350
3  0.957427
4  0.894427
5  0.836660
6  0.786796
dtype: float64
```

pandas.core.window.expanding.Expanding.count

Expanding.count()

The expanding count of any non-NaN observations inside the window.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.DataFrame.count Count of the full DataFrame.

Examples

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0 1.0
1 2.0
2 1.0
3 1.0
dtype: float64
>>> s.rolling(3).count()
0 1.0
1 2.0
2 2.0
3 2.0
dtype: float64
>>> s.rolling(4).count()
0 1.0
1 2.0
2 2.0
3 3.0
dtype: float64
```

pandas.core.window.expanding.Expanding.sum

Expanding.sum(*args, **kwargs)

Calculate expanding sum of given DataFrame or Series.

Parameters

*args, **kwargs For compatibility with other expanding methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the expanding sum.

See also:

pandas.Series.sum Reducing sum for Series.
pandas.DataFrame.sum Reducing sum for DataFrame.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0   1
1   2
2   3
3   4
4   5
dtype: int64

>>> s.rolling(3).sum()
0   NaN
1   NaN
2   6.0
3   9.0
4   12.0
dtype: float64

>>> s.expanding(3).sum()
0   NaN
1   NaN
2   6.0
3   10.0
4   15.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0   NaN
1   6.0
2   9.0
3   12.0
4   NaN
dtype: float64
```

For DataFrame, each expanding sum is computed column-wise.

```python
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25

>>> df.rolling(3).sum()
   A  B
0  NaN NaN
1  NaN NaN
2   6.0  14.0
3   9.0  29.0
4  12.0  50.0
```
pandas.core.window.expanding.Expanding.mean

Expanding.mean(*args, **kwargs)
Calculate the expanding mean of the values.

Parameters

*args Under Review.
**kwargs Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.mean Equivalent method for Series.
pandas.DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0   NaN
1   1.5
2   2.5
3   3.5
dtype: float64
```

```python
>>> s.rolling(3).mean()
0   NaN
1   NaN
2   2.0
3   3.0
dtype: float64
```

pandas.core.window.expanding.Expanding.median

Expanding.median(**kwargs)
Calculate the expanding median.

Parameters

**kwargs For compatibility with other expanding methods. Has no effect on the computed median.

Returns

Series or DataFrame Returned type is the same as the original object.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.mean Equivalent method for Series.
pandas.DataFrame.mean Equivalent method for DataFrame.

3.9. Window
Examples

Compute the rolling median of a series with a window size of 3.

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

**pandas.core.window.expanding.Expanding.var**

`Expanding.var(ddof=1, *args, **kwargs)`

Calculate unbiased expanding variance.

- **Parameters**
  - `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.
  - `*args, **kwargs` For NumPy compatibility. No additional arguments are used.

- **Returns**
  - `Series` or DataFrame Returns the same object type as the caller of the expanding calculation.

**See also:**
- `pandas.Series.expanding` Calling object with Series data.
- `pandas.DataFrame.expanding` Calling object with DataFrames.
- `pandas.Series.var` Equivalent method for Series.
- `pandas.DataFrame.var` Equivalent method for DataFrame.
- `numpy.var` Equivalent method for Numpy array.

**Notes**

The default `ddof` of 1 used in `Series.var()` is different than the default `ddof` of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

**Examples**

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0     NaN
1     NaN
2  0.333333
3  1.000000
4  1.000000
5  1.333333
6    0.000000
dtype: float64
```
>>> s.expanding(3).var()
0   NaN
1   NaN
2  0.333333
3  0.916667
4  0.800000
5  0.700000
6  0.619048
dtype: float64

pandas.core.window.expanding.Expanding.std

Expanding.std(ddof=1, *args, **kwargs)
Calculate expanding standard deviation.
Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

    ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N − ddof, where N represents the number of elements.

    *args, **kwargs For NumPy compatibility. No additional arguments are used.

Returns

    Series or DataFrame Returns the same object type as the caller of the expanding calculation.

See also:

    pandas.Series.expanding Calling object with Series data.
    pandas.DataFrame.expanding Calling object with DataFrames.
    pandas.Series.std Equivalent method for Series.
    pandas.DataFrame.std Equivalent method for DataFrame.
    numpy.std Equivalent method for Numpy array.

Notes

The default ddof of 1 used in Series.std is different than the default ddof of 0 in numpy.std.
A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0    NaN
1    NaN
2  0.577350
3  1.000000
4  1.000000
5  1.154701
6  0.000000
dtype: float64
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

>>> s.expanding(3).std()
0    NaN
1    NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64

pandas.core.window.expanding.Expanding.min

Expanding.min(*args, **kwargs)
Calculate the expanding minimum.

Parameters

**kwargs Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:
pandas.Series.expanding Calling object with a Series.
pandas.DataFrame.expanding Calling object with a DataFrame.
pandas.Series.min Similar method for Series.
pandas.DataFrame.min Similar method for DataFrame.

Examples

Performing a rolling minimum with a window size of 3.

>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64

pandas.core.window.expanding.Expanding.max

Expanding.max(*args, **kwargs)
Calculate the expanding maximum.

Parameters

*args, **kwargs Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.max Similar method for Series.
pandas.DataFrame.max Similar method for DataFrame.

pandas.core.window.expanding.Expanding.corr

Expanding.corr (other=None, pairwise=None, **kwargs)
Calculate expanding correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

pairwise [bool, default None] Calculate pairwise combinations of columns within a
DataFrame. If other is not specified, defaults to True, otherwise defaults to False. Not
relevant for Series.

**kwargs Unused.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding
calculation.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.corr Equivalent method for Series.
pandas.DataFrame.corr Equivalent method for DataFrame.
cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson’s correlation calculation.

Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_
coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with
pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first
level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.
Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```python
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0 NaN
1 NaN
2 NaN
3 0.333333
4 0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```python
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[1. 0.6263001
 0.6263001 1. ]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[1. 0.5553681
 0.5553681 1. ]
>>> df = pd.DataFrame(matrix, columns=['X','Y'])
>>> df
   X   Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
>>> df.rolling(4).corr(pairwise=True)
   X   Y
0 X  NaN  NaN
1 Y  NaN  NaN
2 X  NaN  NaN
3 Y  NaN  NaN
4 3 X 1.000000 0.626300
  1 X 0.626300 1.000000
  1 Y 0.555368 1.000000
  2 X 1.000000 0.555368
  2 Y 0.555368 1.000000
```
pandas.core.window.expanding.Expanding.cov

Expanding.cov(other=None, pairwise=None, ddof=1, **kwargs)
Calculate the expanding sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

**kwargs Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.cov Similar method for Series.
pandas.DataFrame.cov Similar method for DataFrame.

pandas.core.window.expanding.Expanding.skew

Expanding.skew(**kwargs)
Unbiased expanding skewness.

Parameters

**kwargs Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.skew Similar method for Series.
pandas.DataFrame.skew Similar method for DataFrame.

pandas.core.window.expanding.Expanding.kurt

Expanding.kurt(**kwargs)
Calculate unbiased expanding kurtosis.

This function uses Fisher’s definition of kurtosis without bias.

Parameters

**kwargs Under Review.

Returns
Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

- `pandas.Series.expanding` Calling object with Series data.
- `pandas.DataFrame.expanding` Calling object with DataFrames.
- `pandas.Series.kurt` Equivalent method for Series.
- `pandas.DataFrame.kurt` Equivalent method for DataFrame.
- `scipy.stats.skew` Third moment of a probability density.

Notes

A minimum of 4 periods is required for the expanding calculation.

Examples

The example below will show an expanding calculation with a window size of four matching the equivalent function call using `scipy.stats`.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr, bias=False):.6f}")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()  # type: ignore
0       NaN
1       NaN
2       NaN
3     -1.200000
4       4.999874
dtype: float64
```

`pandas.core.window.expanding.Expanding.apply`

Expanding `apply` *(func, raw=False, engine=None, engine_kwargs=None, args=None, kwargs=None)*

Apply an arbitrary function to each expanding window.

Parameters

- **func** [function] Must produce a single value from an ndarray input if `raw=True` or a single value from a Series if `raw=False`. Can also accept a Numba JIT function with `engine='numba'` specified.

  Changed in version 1.0.0.

- **raw** [bool, default None]

  - `False`: passes each row or column as a Series to the function.
  - `True`: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

- **engine** [str, default None]

  - `'cython'`: Runs rolling apply through C-extensions from cython.
• 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
• None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.0.0.

engine_kwargs [dict, default None]

• For 'cython' engine, there are no accepted engine_kwargs
• For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into func.
kwargs [dict, default None] Keyword arguments to be passed into func.

Returns
Series or DataFrame Return type is determined by the caller.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.apply Similar method for Series.
pandas.DataFrame.apply Similar method for DataFrame.

Notes
See Numba engine for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.aggregate

Expanding.aggregate (func, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters
func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:
• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns
scalar, Series or DataFrame The return can be:
• scalar: when Series.agg is called with single function
• Series: when DataFrame.agg is called with a single function
• DataFrame: when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

pandas.DataFrame.aggregate Similar DataFrame method.
pandas.Series.aggregate Similar Series method.

Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> df.ewm(alpha=0.5).mean()
    A      B      C
0  1.0000  4.0000  7.0000
1  1.6667  4.6667  7.6667
2  2.4286  5.4286  8.4286
```

pandas.core.window.expanding.Expanding.quantile

Expanding. quantile (quantile, interpolation='linear', **kwargs)

Calculate the expanding quantile.

Parameters

quantile [float] Quantile to compute. 0 <= quantile <= 1.

interpolation ["linear", "lower", "higher", "midpoint", "nearest"] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:

• linear: i + (j - i) * fraction, where fraction is the fractional part of the index surrounded by i and j.
• lower: i.
• higher: j.
• nearest: i or j whichever is nearest.
• midpoint: (i + j) / 2.

**kwargs For compatibility with other expanding methods. Has no effect on the result.

Returns
Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.quantile Computes value at the given quantile over all data in Series.
pandas.DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64

>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

pandas.core.window.expanding.Expanding.sem

Expanding.sem(ddof=1, *args, **kwargs)

Compute expanding standard error of mean.

Parameters

- ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- *args, **kwargs For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.sem Equivalent method for Series.
pandas.DataFrame.sem Equivalent method for DataFrame.
Notes

A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> s.rolling(2, min_periods=1).sem()
0    NaN
1    0.707107
2    0.707107
3    0.707107
dtype: float64
```

```python
>>> s.expanding().sem()
0    NaN
1    0.707107
2    0.707107
3    0.745356
dtype: float64
```

### 3.9.4 Exponentially-weighted window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ExponentialMovingWindow.mean(*args,**kwargs)</code></td>
<td>Exponential weighted moving average.</td>

<td>Exponential weighted sample covariance.</td>
</tr>
</tbody>
</table>

**pandas.core.window.ewm.ExponentialMovingWindow.mean**

Exponential weighted moving average.

- **Parameters**
  - *args, **kwargs* Arguments and keyword arguments to be passed into func.

- **Returns**
  - Series or DataFrame Return type is determined by the caller.

See also:

- `pandas.Series.ewm` Calling object with Series data.
- `pandas.DataFrame.ewm` Calling object with DataFrame data.
- `pandas.Series.mean` Similar method for Series.
- `pandas.DataFrame.mean` Similar method for DataFrame.
pandas.core.window.ewm.ExponentialMovingWindow.std

ExponentialMovingWindow.std(bias=False, *args, **kwargs)
    Exponential weighted moving stddev.

Parameters

    bias  [bool, default False] Use a standard estimation bias correction.

    *args, **kwargs  Arguments and keyword arguments to be passed into func.

Returns

    Series or DataFrame  Return type is determined by the caller.

See also:

    pandas.Series.ewm  Calling object with Series data.
    pandas.DataFrame.ewm  Calling object with DataFrame data.
    pandas.Series.std  Similar method for Series.
    pandas.DataFrame.std  Similar method for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.var

ExponentialMovingWindow.var(bias=False, *args, **kwargs)
    Exponential weighted moving variance.

Parameters

    bias  [bool, default False] Use a standard estimation bias correction.

    *args, **kwargs  Arguments and keyword arguments to be passed into func.

Returns

    Series or DataFrame  Return type is determined by the caller.

See also:

    pandas.Series.ewm  Calling object with Series data.
    pandas.DataFrame.ewm  Calling object with DataFrame data.
    pandas.Series.var  Similar method for Series.
    pandas.DataFrame.var  Similar method for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.corr

ExponentialMovingWindow.corr(other=None, pairwise=None, **kwargs)
    Exponential weighted sample correlation.

Parameters

    other  [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

    pairwise  [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

    **kwargs  Keyword arguments to be passed into func.

Returns

    Series or DataFrame  Return type is determined by the caller.
See also:

- `pandas.Series.ewm` Calling object with Series data.
- `pandas.DataFrame.ewm` Calling object with DataFrame data.
- `pandas.DataFrame.corr` Similar method for DataFrame.

`pandas.core.window.ewm.ExponentialMovingWindow.cov`

ExponentialMovingWindow.cov (other=None, pairwise=None, bias=False, **kwargs)

Exponential weighted sample covariance.

Parameters

- `other` [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.
- `pairwise` [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- `bias` [bool, default False] Use a standard estimation bias correction.
- `**kwargs` Keyword arguments to be passed into func.

Returns

- Series or DataFrame Return type is determined by the caller.

See also:

- `pandas.Series.ewm` Calling object with Series data.
- `pandas.DataFrame.ewm` Calling object with DataFrame data.
- `pandas.Series.cov` Similar method for Series.
- `pandas.DataFrame.cov` Similar method for DataFrame.

### 3.9.5 Window indexer

Base class for defining custom window boundaries.

- `api.indexers.BaseIndexer` Base class for window bounds calculations.
- `api.indexers.FixedForwardWindowIndexer` Creates window boundaries for fixed-length windows that include the current row.
- `api.indexers.VariableOffsetWindowIndexer` Calculates window boundaries based on a non-fixed offset such as a BusinessDay.
pandas.api.indexers.BaseIndexer

**class** pandas.api.indexers.BaseIndexer(index_array=None, window_size=0, **kwargs)

Base class for window bounds calculations.

**Methods**

**get_window_bounds**([num_values, min_periods,...])

Computes the bounds of a window.

pandas.api.indexers.BaseIndexer.get_window_bounds

BaseIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, 
closed=None)

Computes the bounds of a window.

**Parameters**

- **num_values** [int, default 0] number of values that will be aggregated over
- **window_size** [int, default 0] the number of rows in a window
- **min_periods** [int, default None] min_periods passed from the top level rolling API
- **center** [bool, default None] center passed from the top level rolling API
- **closed** [str, default None] closed passed from the top level rolling API
- **win_type** [str, default None] win_type passed from the top level rolling API

**Returns**

A tuple of ndarray[int64], indicating the boundaries of each window

pandas.api.indexers.FixedForwardWindowIndexer

**class** pandas.api.indexers.FixedForwardWindowIndexer(index_array=None, window_size=0, **kwargs)

Creates window boundaries for fixed-length windows that include the current row.

**Examples**

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

3.9. Window
```python
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

Methods

get_window_bounds([num_values,
min_periods,...]) Computes the bounds of a window.

```python
def pandas.api.indexers.FixedForwardWindowIndexer.get_window_bounds

FixedForwardWindowIndexer.get_window_bounds(num_values=0,
min_periods=None,
center=None, closed=None)

Computes the bounds of a window.

Parameters

num_values [int, default 0] number of values that will be aggregated over
window_size [int, default 0] the number of rows in a window
min_periods [int, default None] min_periods passed from the top level rolling API
center [bool, default None] center passed from the top level rolling API
closed [str, default None] closed passed from the top level rolling API
win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64], indicating the boundaries of each window
```

```python
def pandas.api.indexers.VariableOffsetWindowIndexer

class pandas.api.indexers.VariableOffsetWindowIndexer(index_array=None,
window_size=0, index=None, offset=None, **kwargs)

Calculate window boundaries based on a non-fixed offset such as a BusinessDay
```
Methods

```python
get_window_bounds([num_values, min_periods, …])
```

Computes the bounds of a window.

```python
pandas.api.indexers.VariableOffsetWindowIndexer.get_window_bounds
```

VariableOffsetWindowIndexer.get_window_bounds

Computes the bounds of a window.

**Parameters**

- `num_values` [int, default 0] number of values that will be aggregated over
- `window_size` [int, default 0] the number of rows in a window
- `min_periods` [int, default None] min_periods passed from the top level rolling API
- `center` [bool, default None] center passed from the top level rolling API
- `closed` [str, default None] closed passed from the top level rolling API
- `win_type` [str, default None] win_type passed from the top level rolling API

**Returns**

A tuple of ndarray[int64], indicating the boundaries of each window

### 3.10 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.

#### 3.10.1 Indexing, iteration

```python
GroupBy.__iter__() Groupby iterator.
GroupBy.groups Dict {group name -> group labels}.
GroupBy.indices Dict {group name -> group indices}.
GroupBy.get_group(name[, obj]) Construct DataFrame from group with provided name.
```
pandas.core.groupby.GroupBy.__iter__

GroupBy.__iter__()
Groupby iterator.

Returns
Generator yielding sequence of (name, subsetted object)
for each group

pandas.core.groupby.GroupBy.groups

@property GroupBy.groups
Dict {group name -> group labels}.

pandas.core.groupby.GroupBy.indices

@property GroupBy.indices
Dict {group name -> group indices}.

pandas.core.groupby.GroupBy.get_group

GroupBy.get_group(name, obj=None)
Construct DataFrame from group with provided name.

Parameters
name [object] The name of the group to get as a DataFrame.
obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns
group [same type as obj]

Grouper(*args, **kwargs)
A Grouper allows the user to specify a groupby instruction for an object.

def __init__(self, *args, **kwargs):
    pass

pandas.Grouper

class pandas.Grouper(*args, **kwargs)
A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If axis and/or level are passed as keywords to both Grouper and groupby, the values passed to Grouper take precedence.

Parameters
key [str, defaults to None] Groupby key, which selects the grouping column of the target.
level [name/number, defaults to None] The level for the target index.
freq [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datatime-like object. For full specification of
available frequencies, please see here.

**axis** [str, int, defaults to 0] Number/name of the axis.

**sort** [bool, default to False] Whether to sort the resulting labels.

**closed** [{‘left’ or ‘right’}] Closed end of interval. Only when *freq* parameter is passed.

**label** [{‘left’ or ‘right’}] Interval boundary to use for labeling. Only when *freq* parameter is passed.

**convention** [{‘start’, ‘end’, ‘e’, ‘s’}] If grouper is PeriodIndex and *freq* parameter is passed.

**base** [int, default 0] Only when *freq* parameter is passed. For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

- Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

**loffset** [str, DateOffset, timedelta object] Only when *freq* parameter is passed.

- Deprecated since version 1.1.0: loffset is only working for .resample(...) and not for Grouper (GH28302). However, loffset is also deprecated for .resample(...) See: DataFrame.resample

**origin** [{‘epoch’, ‘start’, ‘start_day’}, Timestamp or str, default ‘start_day’] The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: *origin* is 1970-01-01
- ‘start’: *origin* is the first value of the timeseries
- ‘start_day’: *origin* is the first day at midnight of the timeseries

- New in version 1.1.0.

**offset** [Timedelta or str, default is None] An offset timedelta added to the origin.

- New in version 1.1.0.

**dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

- New in version 1.2.0.

**Returns**

A specification for a groupby instruction

**Examples**

Syntactic sugar for df.groupby(’A’)

```python
>>> df = pd.DataFrame(
...     {
...         "Animal": ["Falcon", "Parrot", "Falcon", "Falcon", "Parrot"],
...         "Speed": [100, 5, 200, 300, 15],
...     }
... )
>>> df
```

(continues on next page)
Animal Speed
0 Falcon 100
1 Parrot 5
2 Falcon 200
3 Falcon 300
4 Parrot 15

```python
>>> df.groupby(pd.Grouper(key="Animal")).mean()
Speed
Animal   Falcon 200  Parrot 10
```

Specify a resample operation on the column ‘Publish date’

```python
>>> df = pd.DataFrame(
... {  
... "Publish date": [
... pd.Timestamp("2000-01-02"),
... pd.Timestamp("2000-01-02"),
... pd.Timestamp("2000-01-09"),
... pd.Timestamp("2000-01-16"),
... ],
... "ID": [0, 1, 2, 3],
... "Price": [10, 20, 30, 40]
... }
... )

>>> df
Publish date ID Price
0 2000-01-02 0 10
1 2000-01-02 1 20
2 2000-01-09 2 30
3 2000-01-16 3 40

>>> df.groupby(pd.Grouper(key="Publish date", freq="1W")).mean()
ID Price
Publish date
2000-01-02 0.5 15.0
2000-01-09 2.0 30.0
2000-01-16 3.0 40.0
```

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
```

```python
>>> ts
2000-10-01 23:30:00 0
2000-10-01 23:37:00 3
2000-10-01 23:44:00 6
2000-10-01 23:51:00 9
2000-10-01 23:58:00 12
2000-10-02 00:05:00 15
2000-10-02 00:12:00 18
2000-10-02 00:19:00 21
2000-10-02 00:26:00 24
Freq: 7T, dtype: int64
```
>>> ts.groupby(pd.Grouper(freq='17min')).sum()
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64

>>> ts.groupby(pd.Grouper(freq='17min', origin='epoch')).sum()
2000-10-01 23:18:00    0
2000-10-01 23:35:00   18
2000-10-01 23:52:00   27
2000-10-02 00:09:00   39
2000-10-02 00:26:00   24
Freq: 17T, dtype: int64

>>> ts.groupby(pd.Grouper(freq='17min', origin='2000-01-01')).sum()
2000-10-01 23:24:00    3
2000-10-01 23:41:00   15
2000-10-01 23:58:00   45
2000-10-02 00:15:00   45
Freq: 17T, dtype: int64

If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

>>> ts.groupby(pd.Grouper(freq='17min', origin='start')).sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

>>> ts.groupby(pd.Grouper(freq='17min', offset='23h30min')).sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

To replace the use of the deprecated base argument, you can now use offset, in this example it is equivalent to have base=2:

>>> ts.groupby(pd.Grouper(freq='17min', offset='2min')).sum()
2000-10-01 23:16:00    0
2000-10-01 23:33:00    9
2000-10-01 23:50:00   36
2000-10-02 00:07:00   39
2000-10-02 00:24:00   24
Freq: 17T, dtype: int64
### Attributes

<table>
<thead>
<tr>
<th>ax</th>
<th>groups</th>
</tr>
</thead>
</table>

#### 3.10.2 Function application

**GroupBy.apply**\(^\text{func, *args, **kwargs}\)  
Apply function `func` group-wise and combine the results together.

**GroupBy.agg**\(^\text{func, *args, **kwargs}\)  
Aggregate using one or more operations over the specified axis.

**SeriesGroupBy.agg**\([\text{func, engine, ...}]\)  
Aggregate using one or more operations over the specified axis.

**DataFrameGroupBy.agg**\([\text{func, engine, ...}]\)  
Aggregate using one or more operations over the specified axis.

**SeriesGroupBy.transform**\(\text{func, *args[, ...]}\)  
Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values.

**DataFrameGroupBy.transform**\(\text{func, *args[, ...]}\)  
Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values.

**GroupBy.pipe**\(\text{func, *args, **kwargs}\)  
Apply a function `func` with arguments to this GroupBy object and return the function’s result.

---

**pandas.core.groupby.GroupBy.apply**

GroupBy.**apply**\(\text{func, *args, **kwargs}\)  
Apply function `func` group-wise and combine the results together.

The function passed to **apply** must take a dataframe as its first argument and return a DataFrame, Series or scalar. **apply** will then take care of combining the results back together into a single dataframe or series. **apply** is therefore a highly flexible grouping method.

While **apply** is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like **agg** or **transform**. Pandas offers a wide range of method that will be much faster than using **apply** for their specific purposes, so try to use them before reaching for **apply**.

**Parameters**

- **func** [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.

- **args, kwargs** [tuple and dict] Optional positional and keyword arguments to pass to **func**.

**Returns**

- **applied** [Series or DataFrame]

**See also:**

- **pipe** Apply function to the full GroupBy object instead of to each group.
- **aggregate** Apply aggregate function to the GroupBy object.
- **transform** Apply function column-by-column to the GroupBy object.
- **Series.apply** Apply a function to a Series.
- **DataFrame.apply** Apply a function to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.agg

GroupBy.**agg**(func, *args, **kwargs)

pandas.core.groupby.SeriesGroupBy.aggregate

SeriesGroupBy.**aggregate**(func=None, *args, engine=None, engine_kwargs=None, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

  Accepted combinations are:

  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

  Can also accept a Numba JIT function with engine='numba' specified. Only passing a single function is supported with this engine.

  If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

- **args** Positional arguments to pass to func.

- **engine** [str, default None]

  - 'cython': Runs the function through C-extensions from cython.
  - 'numba': Runs the function through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting `compute.use_numba`

  New in version 1.1.0.

- **engine_kwargs** [dict, default None]

  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

  New in version 1.1.0.

- **kwargs** Keyword arguments to be passed into func.

**Returns**

Series

See also:

- **Series.groupby.apply** Apply function func group-wise and combine the results together.
**Series.groupby.transform** Aggregate using one or more operations over the specified axis.
**Series.aggregate** Transforms the Series on each group based on the given function.

**Notes**

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])

>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.groupby([1, 1, 2, 2]).min()
1    1
2    3
dtype: int64

>>> s.groupby([1, 1, 2, 2]).agg('min')
1    1
2    3
dtype: int64

>>> s.groupby([1, 1, 2, 2]).agg(['min', 'max'])
   min  max
1    1    2
2    3    4

The output column names can be controlled by passing the desired column names and aggregations as keyword arguments.

```python
>>> s.groupby([1, 1, 2, 2]).agg(
...   minimum='min',
...   maximum='max',
...)
   minimum  maximum
1        1        2
2        3        4
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.core.groupby.DataFrameGroupBy.aggregate

DataFrameGroupBy.aggregate (func=None, *args, engine=None, engine_kwargs=None, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:
• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

Can also accept a Numba JIT function with engine='numba' specified. Only passing a single function is supported with this engine.

If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

*args Positional arguments to pass to func.

engine [str, default None]
• 'cython': Runs the function through C-extensions from cython.
• 'numba': Runs the function through JIT compiled code from numba.
• None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.1.0.

engine_kwargs [dict, default None]
• For 'cython' engine, there are no accepted engine_kwargs
• For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

New in version 1.1.0.

**kwargs Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply Apply function func group-wise and combine the results together.
DataFrame.groupby.transform Aggregate using one or more operations over the specified axis.
DataFrame.aggregate Transforms the Series on each group based on the given function.
Notes

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         "A": [1, 1, 2, 2],
...         "B": [1, 2, 3, 4],
...         "C": [0.362838, 0.227877, 1.267767, -0.562860],
...     }
...)

>>> df
   A    B    C
0  1    1  0.362838
1  1    2  0.227877
2  2    3  1.267767
3  2    4 -0.562860

The aggregation is for each column.

>>> df.groupby('A').agg('min')
   B    C
A
  1    1  0.227877
  2    3 -0.562860

Multiple aggregations

>>> df.groupby('A').agg(['min', 'max'])
   B  C
min max
A
  1  1  2  0.227877  0.362838
  2  3  4 -0.562860  1.267767

Select a column for aggregation

>>> df.groupby('A').B.agg(['min', 'max'])
   min max
A
  1  1  2
  2  3  4

Different aggregations per column

>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})
   B  C
min max
A
  1  1  2  0.590715
  2  3  4  0.704907
```
To control the output names with different aggregations per column, pandas supports “named aggregation”

```python
>>> df.groupby("A").agg(
...     b_min=pd.NamedAgg(column="B", aggfunc="min"),
...     c_sum=pd.NamedAgg(column="C", aggfunc="sum"))
     b_min  c_sum
A
1   1  0.590715
2   3  0.704907
```

- The keywords are the *output* column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields ['column', 'aggfunc'] to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

See *Named aggregation* for more.

### pandas.core.groupby.SeriesGroupBy.transform

SeriesGroupBy.**transform**(func, *args=None, engine=None, engine_kwargs=None, **kwargs)

Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values

**Parameters**

- **f** [function] Function to apply to each group.
  
  Can also accept a Numba JIT function with `engine='numba'` specified.
  
  If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.
  
  Changed in version 1.1.0.

- **args** Positional arguments to pass to func.

- **engine** [str, default None]
  
  - 'cython': Runs the function through C-extensions from cython.
  
  - 'numba': Runs the function through JIT compiled code from numba.
  
  - None: Defaults to 'cython' or globally setting `compute.use_numba`

  New in version 1.1.0.

- **engine_kwargs** [dict, default None]
  
  For 'cython' engine, there are no accepted `engine_kwargs`
  
  For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{ 'nopython': True, 'nogil': False, 'parallel': False }` and will be applied to the function

  New in version 1.1.0.

- **kwargs** Keyword arguments to be passed into func.
pandas: powerful Python data analysis toolkit, Release 1.2.2

Returns

Series

See also:

Series.groupby.apply Apply function func group-wise and combine the results together.
Series.groupby.aggregate Aggregate using one or more operations over the specified axis.
Series.transform Transforms the Series on each group based on the given function.

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

• f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the input subframe.

• if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.

• f must not mutate groups. Mutation is not supported and may produce unexpected results.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```python
>>> df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar', ...
                      'foo', 'bar'],
                   ...
                   'B': ['one', 'one', 'two', 'three', ...
                         'two', 'two'],
                   ...
                   'C': [1, 5, 5, 2, 5, 5],
                   ...
                   'D': [2.0, 5., 8., 1., 2., 9.])
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
   C    D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000

Broadcast result of the transformation

```
DataFrameGroupBy.transform(func, *args, engine=None, engine_kwars=None, **kwargs)

Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same
indexes as the original object filled with the transformed values.

Parameters

f [function] Function to apply to each group.

Can also accept a Numba JIT function with engine='numba' specified.

If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

*args Positional arguments to pass to func.

engine [str, default None]

- 'cython': Runs the function through C-extensions from cython.
- 'numba': Runs the function through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.1.0.

engine_kwars [dict, default None]

- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True,
'nogil': False, 'parallel': False} and will be applied to the function

New in version 1.1.0.

**kwargs Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply Apply function func group-wise and combine the results together.
DataFrame.groupby.aggregate Aggregate using one or more operations over the specified axis.
DataFrame.transform Transforms the Series on each group based on the given function.
Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

• f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the input subframe.
• if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.
• f must not mutate groups. Mutation is not supported and may produce unexpected results.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```python
>>> df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar', 'foo', 'bar'],
...                    'B': ['one', 'one', 'two', 'three', 'two', 'two'],
...                    'C': [1, 5, 5, 2, 5, 5],
...                    'D': [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
     C         D
0 -1.155  -0.577
1  0.577   0.000
2  0.577   1.155
3 -1.155  -1.000
4  0.577  -0.577
5  0.577   1.000
```

Broadcast result of the transformation

```python
>>> grouped.transform(lambda x: x.max() - x.min())
      C   D
0   4.0  6.0
1   3.0  8.0
2   4.0  6.0
3   3.0  8.0
4   4.0  6.0
5   3.0  8.0
```

pandas.core.groupby.GroupBy.pipe

GroupBy.pipe(func, *args, **kwargs)

Apply a function func with arguments to this GroupBy object and return the function’s result.

Use .pipe when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
...    .pipe(f)
...    .pipe(g, arg1=a)
...    .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- **func** [callable or tuple of (callable, str)] Function to apply to this GroupBy object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the GroupBy object.
- **args** [iterable, optional] Positional arguments passed into func.
- **kwargs** [dict, optional] A dictionary of keyword arguments passed into func.

**Returns**

- **object** [the return type of func.]

**See also:**

- `Series.pipe` Apply a function with arguments to a series.
- `DataFrame.pipe` Apply a function with arguments to a dataframe.
- `apply` Apply function to each group instead of to the full GroupBy object.

**Notes**

See more here

**Examples**

```python
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4
```

To get the difference between each groups maximum and minimum value in one pass, you can do

```python
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
   B
A  
 a  2
 b  2
```

**pandas.core.groupby.GroupBy.all**

`GroupBy.all (skipna=True)`

Return True if all values in the group are truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- **Series or DataFrame** DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.any**

`GroupBy.any (skipna=True)`

Return True if any value in the group is truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- **Series or DataFrame** DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.bfill**

`GroupBy.bfill (limit=None)`

Backward fill the values.

**Parameters**

- `limit` [int, optional] Limit of how many values to fill.

**Returns**

- **Series or DataFrame** Object with missing values filled.

**See also:**

- `Series.backfill` Backward fill the missing values in the dataset.
- `DataFrame.backfill` Backward fill the missing values in the dataset.
- `Series.fillna` Fill NaN values of a Series.
- `DataFrame.fillna` Fill NaN values of a DataFrame.
pandas.core.groupby.GroupBy.backfill

GroupBy.backfill(limit=None)
Backward fill the values.

Parameters

limit  [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Seriesfillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.count

GroupBy.count()
Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumcount

GroupBy.cumcount(ascending=True)
Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:

ngroup Number the groups themselves.
Examples

```python
>>> df = pd.DataFrame([['a'], ['a'], ['a'], ['b'], ['b'], ['a']],
...                   columns=['A'])
>>> df
  A
0 a
1 a
2 a
3 b
4 b
5 a
>>> df.groupby('A').cumcount()
0 0
1 1
2 2
3 0
4 1
5 3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0 3
1 2
2 1
3 1
4 0
5 0
dtype: int64
```

**pandas.core.groupby.GroupBy.cummax**

GroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.cummin**

GroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.cumprod

GroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group.

Returns

Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumsum

GroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group.

Returns

Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.ffill

GroupBy.ffill(limit=None)
Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:
Series.pad Returns Series with minimum number of char in object.
DataFrame.pad Object with missing values filled or None if inplace=True.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.first

GroupBy.first(numeric_only=False, min_count=-1)
Compute first of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed first of values within each group.
pandas.core.groupby.GroupBy.head

**GroupBy.head(n=5)**

Return first n rows of each group.

Similar to `.apply(lambda x: x.head(n))`, but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Does not work for negative values of n.

**Returns**

Series or DataFrame

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**Examples**

```python
def df = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
                      columns=['A', 'B'])
def df.groupby('A').head(1)
A  B
0 1 2
2 5 6
def df.groupby('A').head(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

pandas.core.groupby.GroupBy.last

**GroupBy.last(numeric_only=False, min_count=-1)**

Compute last of group values.

**Parameters**

- `numeric_only` [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- `min_count` [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

Series or DataFrame  Computed last of values within each group.

pandas.core.groupby.GroupBy.max

**GroupBy.max(numeric_only=False, min_count=-1)**

Compute max of group values.

**Parameters**

- `numeric_only` [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- `min_count` [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
Returns

Series or DataFrame  Computed max of values within each group.

pandas.core.groupby.GroupBy.mean

GroupBy.mean(numeric_only=True)
Compute mean of groups, excluding missing values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

pandas.Series or pandas.DataFrame

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...   'B': [np.nan, 2, 3, 4, 5],
...   'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])

Groupby one column and return the mean of the remaining columns in each group.

>>> df.groupby('A').mean()

      B    C
A
1  3.0  1.333333
2  4.0  1.500000

Groupby two columns and return the mean of the remaining column.

>>> df.groupby(['A', 'B']).mean()

      C
A B
1 2.0  2
   4.0  1
2 3.0  1
   5.0  2

Groupby one column and return the mean of only particular column in the group.

>>> df.groupby('A')['B'].mean()

     A
1   3.0
2   4.0
Name: B, dtype: float64
```
**pandas.core.groupby.GroupBy.median**

GroupBy.median(numeric_only=True)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Parameters**

- numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- Series or DataFrame Median of values within each group.

**See also:**

- Series.groupby Apply a function groupby to a Series.
- DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.min**

GroupBy.min(numeric_only=False, min_count=-1)

Compute min of group values.

**Parameters**

- numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

- Series or DataFrame Computed min of values within each group.

**pandas.core.groupby.GroupBy.ngroup**

GroupBy.ngroup(ascending=True)

Number each group from 0 to the number of groups - 1.

This is the enumerative complement of cumcount. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

**Parameters**

- ascending [bool, default True] If False, number in reverse, from number of group - 1 to 0.

**Returns**

- Series Unique numbers for each group.

**See also:**

- cumcount Number the rows in each group.
Examples

```python
>>> df = pd.DataFrame({'A': list('aaabba'))
>>> df
   A
0 a
1 a
2 a
3 b
4 b
5 a

>>> df.groupby('A').ngroup()
0 0
1 0
2 0
3 1
4 1
5 0
dtype: int64

>>> df.groupby('A').ngroup(ascending=False)
0 1
1 1
2 1
3 0
4 0
5 1
dtype: int64

>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
0 0
1 0
2 1
3 3
4 2
5 0
dtype: int64
```

```python
class pandas.core.groupby.GroupBy.
th
```

**GroupBy.**nth *(n, dropna=None)*

Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.

If dropna, will take the nth non-null row, dropna is either ‘all’ or ‘any’; this is equivalent to calling
dropna(how=dropna) before the groupby.

**Parameters**

- **n** [int or list of ints] A single nth value for the row or a list of nth values.
- **dropna** [None or str, optional] Apply the specified dropna operation before counting which row is the nth row. Needs to be None, ‘any’ or ‘all’.

**Returns**

- **Series or DataFrame** N-th value within each group.

**See also:**

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
                    'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A
1  NaN
2  3.0
>>> g.nth(1)
   B
A
1  2.0
2  5.0
>>> g.nth(-1)
   B
A
1  4.0
2  5.0
>>> g.nth([0, 1])
   B
A
1  NaN
1  2.0
2  3.0
2  5.0

Specifying dropna allows count ignoring NaN

```python
>>> g.nth(0, dropna='any')
   B
A
1  2.0
2  3.0
```

NaNs denote group exhausted when using dropna

```python
>>> g.nth(3, dropna='any')
   B
A
1  NaN
2  NaN
```

Specifying as_index=False in groupby keeps the original index.

```python
>>> df.groupby('A', as_index=False).nth(1)
   A  B
1  1  2.0
4  2  5.0
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.core.groupby.GroupBy.ohlc**

```python
GroupBy.ohlc()
```

Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Returns**

- **DataFrame**: Open, high, low and close values within each group.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.pad**

```python
GroupBy.pad(limit=None)
```

Forward fill the values.

**Parameters**

- **limit** [int, optional] Limit of how many values to fill.

**Returns**

- **Series or DataFrame**: Object with missing values filled.

**See also:**

- `Series.pad` Returns Series with minimum number of char in object.
- `DataFrame.pad` Object with missing values filled or None if inplace=True.
- `Series.fillna` Fill NaN values of a Series.
- `DataFrame.fillna` Fill NaN values of a DataFrame.

**pandas.core.groupby.GroupBy.prod**

```python
GroupBy.prod(numeric_only=True, min_count=0)
```

Compute prod of group values.

**Parameters**

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame**: Computed prod of values within each group.
pandas.core.groupby.GroupBy.rank

GroupBy.rank (method='average', ascending=True, na_option='keep', pct=False, axis=0)
Provide the rank of values within each group.

Parameters

    • average: average rank of group.
    • min: lowest rank in group.
    • max: highest rank in group.
    • first: ranks assigned in order they appear in the array.
    • dense: like ‘min’, but rank always increases by 1 between groups.

    ascending  [bool, default True] False for ranks by high (1) to low (N).

    na_option  [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]
    • keep: leave NA values where they are.
    • top: smallest rank if ascending.
    • bottom: smallest rank if descending.

    pct  [bool, default False] Compute percentage rank of data within each group.

    axis  [int, default 0] The axis of the object over which to compute the rank.

Returns

    DataFrame with ranking of values within each group

See also:

    Series.groupby Apply a function groupby to a Series.
    DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.pct_change

GroupBy.pct_change (periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calculate pct_change of each value to previous entry in group.

Returns

    Series or DataFrame Percentage changes within each group.

See also:

    Series.groupby Apply a function groupby to a Series.
    DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.core.groupby.GroupBy.size

GroupBy.size()
Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if as_index is True or a
DataFrame if as_index is False.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.sem

GroupBy.sem(ddof=1)
Compute standard error of the mean of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.std

GroupBy.std(ddof=1)
Compute standard deviation of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard deviation of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.sum

GroupBy.sum(numeric_only=True, min_count=0)
Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.groupby.GroupBy.var

GroupBy.var(ddof=1)
Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddf [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Variance of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.tail

GroupBy.tail(n=5)
Return last n rows of each group.

Similar to .apply(lambda x: x.tail(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Does not work for negative values of n.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame([['a', 1], ['a', 2], ['b', 1], ['b', 2]],
...                   columns=['A', 'B'])
>>> df.groupby('A').tail(1)
   A B
1 a 2
3 b 2
>>> df.groupby('A').tail(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

The following methods are available in both `SeriesGroupBy` and `DataFrameGroupBy` objects, but may differ slightly, usually in that the `DataFrameGroupBy` version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

- **DataFrameGroupBy.all**(`[skipna]`) Return True if all values in the group are truthful, else False.
- **DataFrameGroupBy.any**(`[skipna]`) Return True if any value in the group is truthful, else False.
- **DataFrameGroupBy.backfill**(`[limit]`) Backward fill the values.
- **DataFrameGroupBy.bfill**(`[limit]`) Backward fill the values.
- **DataFrameGroupBy.corr** Compute pairwise correlation of columns, excluding NA/null values.
- **DataFrameGroupBy.count()** Compute count of group, excluding missing values.
- **DataFrameGroupBy.cov** Compute pairwise covariance of columns, excluding NA/null values.
- **DataFrameGroupBy.cumcount**(`[ascending]`) Number each item in each group from 0 to the length of that group - 1.
- **DataFrameGroupBy.cummax**(`[axis]`) Cumulative max for each group.
- **DataFrameGroupBy.cummin**(`[axis]`) Cumulative min for each group.
- **DataFrameGroupBy.cumprod**(`[axis]`) Cumulative product for each group.
- **DataFrameGroupBy.cumsum**(`[axis]`) Cumulative sum for each group.
- **DataFrameGroupBy.describe**(`**kwargs`) Generate descriptive statistics.
- **DataFrameGroupBy.diff** First discrete difference of element.
- **DataFrameGroupBy.ffill**(`[limit]`) Forward fill the values.
- **DataFrameGroupBy.fillna** Fill NA/NaN values using the specified method.
- **DataFrameGroupBy.filter**(`func[, dropna]`) Return a copy of a DataFrame excluding filtered elements.
- **DataFrameGroupBy.hist** Make a histogram of the DataFrame’s.
- **DataFrameGroupBy.idxmax**(`[axis, skipna]`) Return index of first occurrence of maximum over requested axis.
- **DataFrameGroupBy.idxmin**(`[axis, skipna]`) Return index of first occurrence of minimum over requested axis.
- **DataFrameGroupBy.mad** Return the mean absolute deviation of the values over the requested axis.
- **DataFrameGroupBy.nunique**(`[dropna]`) Return DataFrame with counts of unique elements in each position.
- **DataFrameGroupBy.pad**(`[limit]`) Forward fill the values.
- **DataFrameGroupBy.pct_change**(`[periods, . . . ]`) Calculate pct_change of each value to previous entry in group.

### pandas.core.groupby.DataFrameGroupBy.all

DataFrameGroupBy.all(\texttt{skipna=\texttt{True}})

Return True if all values in the group are truthful, else False.

**Parameters**

- \texttt{skipna} [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- \texttt{Series} or \texttt{DataFrame} DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**

- \texttt{Series.groupby} Apply a function groupby to a Series.
- \texttt{DataFrame.groupby} Apply a function groupby to each row or column of a DataFrame.

### pandas.core.groupby.DataFrameGroupBy.any

DataFrameGroupBy.any(\texttt{skipna=\texttt{True}})

Return True if any value in the group is truthful, else False.

**Parameters**

- \texttt{skipna} [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- \texttt{Series} or \texttt{DataFrame} DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

**See also:**

- \texttt{Series.groupby} Apply a function groupby to a Series.
- \texttt{DataFrame.groupby} Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.backfill

DataFrameGroupBy.backfill(limit=None)
Backward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.bfill(limit=None)
Backward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.corr

property DataFrameGroupBy.corr
Compute pairwise correlation of columns, excluding NA/null values.

Parameters

- method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

  New in version 0.24.0.

- min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns
DataFrame  Correlation matrix.

See also:

DataFrame.corrwith  Compute pairwise correlation with another DataFrame or Series.

Series.corr  Compute the correlation between two Series.

Examples

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v

>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...             columns=['dogs', 'cats'])

>>> df.corr(method=histogram_intersection)
     dogs   cats
dogs  1.0  0.3
cats  0.3  1.0
```

pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.count()  
Compute count of group, excluding missing values.

Returns

DataFrame  Count of values within each group.

pandas.core.groupby.DataFrameGroupBy.cov

property DataFrameGroupBy.cov

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods  [int, optional] Minimum number of observations required per pair of columns to have a valid result.

ddof  [int, default 1] Delta degrees of freedom. The divisor used in calculations is N - ddof, where N represents the number of elements. New in version 1.1.0.

Returns

DataFrame  The covariance matrix of the series of the DataFrame.

See also:

Series.cov  Compute covariance with another Series.

core.window.ExponentialMovingWindow.cov  Exponential weighted sample covariance.
**core.window.Expanding.cov** Expanding sample covariance.

**core.window.Rolling.cov** Rolling sample covariance.

**Notes**

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

**Examples**

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                    columns=['dogs', 'cats'])
>>> df.cov()
  dogs  cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
   a      b      c      d      e
a 0.998438 -0.020161 0.059277 -0.008943 0.014144
b -0.020161 1.059352 -0.008543 -0.024738 0.009826
c 0.059277 -0.008543 1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486 0.921297 -0.013692
e 0.014144 0.009826 -0.000271 -0.013692 0.977795
```

**Minimum number of periods**

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
   a      b      c
a 0.316741 NaN -0.150812
b NaN 1.248003 0.191417
c -0.150812 0.191417 0.895202
```
DataFrameGroupBy.cumcount (ascending=True)
Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

**Parameters**

- **ascending** [bool, default True] If False, number in reverse, from length of group - 1 to 0.

**Returns**

- **Series** Sequence number of each element within each group.

**See also:**

- ngroup Number the groups themselves.

**Examples**

```python
>>> df = pd.DataFrame([[‘a’], [‘a’], [‘a’], [‘b’], [‘b’], [‘a’],
...                     columns=[‘A’])
>>> df
     A
0   a
1   a
2   a
3   b
4   b
5   a
>>> df.groupby(‘A’).cumcount()
0  0
1  1
2  2
3  0
4  1
5  3
dtype: int64
>>> df.groupby(‘A’).cumcount(ascending=False)
0  3
1  2
2  1
3  1
4  0
5  0
dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.core.groupby.DataFrameGroupBy.cummax

DataFrameGroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cummin

DataFrameGroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.describe

DataFrameGroupBy.describe(**kwargs)
Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

- **percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

- **include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
  - ‘all’ : All columns of the input will be included in the output.
  - A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])).
  - None (default) : The result will include all numeric columns.

- **exclude** [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
  - A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
  - None (default) : The result will exclude nothing.

- **datetime_is_numeric** [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

- DataFrame.count Count number of non-NA/null observations.
- DataFrame.max Maximum of the values in the object.
- DataFrame.min Minimum of the values in the object.
- DataFrame.mean Mean of the values.
- DataFrame.std Standard deviation of the observations.
- DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtypes.
Notes

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the count and top results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count  3.0
mean   2.0
std    1.0
min    1.0
25%    1.5
50%    2.0
75%    2.5
max    3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count  4
unique 3
top    a
freq   2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([...
... np.datetime64("2000-01-01"),
... np.datetime64("2010-01-01"),
... np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count  3
mean  2006-09-01 08:00:00
```

(continues on next page)
Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
                        'numeric': [1, 2, 3],
                        'object': ['a', 'b', 'c']})
```

```python
>>> df.describe()  
```

<table>
<thead>
<tr>

</tbody>
</table>
pandas.core.groupby.DataFrameGroupBy.diff

property DataFrameGroupBy.diff
First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

Parameters

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Take difference over rows (0) or columns (1).

Returns

- **Dataframe** First differences of the Series.

See also:

- **DataFrame.pct_change** Percent change over given number of periods.
- **DataFrame.shift** Shift index by desired number of periods with an optional time freq.
- **Series.diff** First discrete difference of object.

Notes

For boolean dtypes, this uses operator.xor() rather than operator.sub(). The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
                     'b': [1, 1, 2, 3, 5, 8],
                     'c': [1, 4, 9, 16, 25, 36]})
>>> df.diff()
   a    b    c
0   NaN  NaN  NaN
1   1.0  0.0  3.0
2   1.0  1.0  5.0
3   1.0  1.0  7.0
4   1.0  2.0  9.0
5   1.0  3.0 11.0
```

Difference with previous column

```python
>>> df.diff(axis=1)
   a    b    c
0   NaN  NaN  NaN
1   1.0  0.0  3.0
2   1.0  1.0  5.0
3   1.0  1.0  7.0
4   1.0  2.0  9.0
5   1.0  3.0 11.0
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.2.2

(continued from previous page)

1 NaN -1 3
2 NaN -1 7
3 NaN -1 13
4 NaN 0 20
5 NaN 2 28

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
   a   b   c
0  NaN NaN NaN
1  NaN NaN NaN
2  NaN NaN NaN
3  3.0  2.0  15.0
4  3.0  4.0  21.0
5  3.0  6.0  27.0
```

Difference with following row

```python
>>> df.diff(periods=-1)
   a   b   c
0 -1.0  0.0  3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN  NaN
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
   a
0  NaN
1 255.0
```

`pandas.core.groupby.DataFrameGroupBy.ffill`

**DataFrameGroupBy.ffill**(limit=None)

Forward fill the values.

**Parameters**

- `limit` [int, optional] Limit of how many values to fill.

**Returns**

- Series or DataFrame Object with missing values filled.

**See also:**

- `Series.pad` Returns Series with minimum number of char in object.
- `DataFrame.pad` Object with missing values filled or None if inplace=True.
- `Series.fillna` Fill NaN values of a Series.
- `DataFrame.fillna` Fill NaN values of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.fillna

**property DataFrameGroupBy.fillna**

Fill NA/NaN values using the specified method.

**Parameters**

- **value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **axis** [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.

- **inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**

DataFrame or None Object with missing values filled or None if inplace=True.

**See also:**

- **interpolate** Fill NaN values using interpolation.
- **reindex** Conform object to new index.
- **asfreq** Convert TimeSeries to specified frequency.

**Examples**

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                     columns=list('ABCD'))

>>> df
   A  B   C   D
0  NaN 2.0 NaN  0
1  3.0 4.0 NaN  1
2  NaN NaN NaN  5
3  NaN 3.0 NaN  4

Replace all NaN elements with 0s.

>>> df.fillna(0)
   A  B   C   D
0  0  2.0  0.0  0
```

(continues on next page)
We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method='ffill')
  A   B   C   D
0  NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  3.0  4.0 NaN  5
3  3.0  3.0 NaN  4
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
  A   B   C   D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
  A   B   C   D
0  0.0  2.0  2.0  0
1  3.0  4.0 NaN  1
2  NaN  1.0 NaN  5
3  NaN  3.0 NaN  4
```

**pandas.core.groupby.DataFrameGroupBy.filter**

DataFrameGroupBy.filter(func, dropna=True, *args, **kwargs)

Return a copy of a DataFrame excluding filtered elements.

Elements from groups are filtered if they do not satisfy the boolean criterion specified by func.

Parameters

- **func** [function] Function to apply to each subframe. Should return True or False.
- **dropna** [Drop groups that do not pass the filter. True by default;] If False, groups that evaluate False are filled with NaNs.

Returns

- **filtered** [DataFrame]
Notes

Each subframe is endowed the attribute ‘name’ in case you need to know which group you are working on.

Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                      'foo', 'bar'],
...                   'B' : [1, 2, 3, 4, 5, 6],
...                   'C' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
   A  B  C
1  bar 2  5.0
3  bar 4  1.0
5  bar 6  9.0
```

**pandas.core.groupby.DataFrameGroupBy.hist**

**property** DataFrameGroupBy.hist

Make a histogram of the DataFrame’s.

A histogram is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

- **data** [DataFrame] The pandas object holding the data.
- **column** [str or sequence] If passed, will be used to limit data to a subset of columns.
- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- **ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
- **sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- **sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
- **figsize** [tuple] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.
- **layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib.pyplot.hist().

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

matplotlib.pyplot.hist Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1],
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

pandas.core.groupby.DataFrameGroupBy.idxmax

DataFrameGroupBy.idxmax(axis=0, skipna=True)

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises

ValueError

• If the row/column is empty

See also:
3.10. GroupBy
**Series.idxmax** Return index of the maximum element.

**Notes**

This method is the DataFrame version of `ndarray.argmax`.

**Examples**

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
                     'co2_emissions': [37.2, 19.66, 1712]},
                     index=['Pork', 'Wheat Products', 'Beef'])
```

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption  Wheat Products
co2_emissions  Beef
```

To return the index for the maximum value in each row, use `axis="columns"`.

```python
>>> df.idxmax(axis="columns")
Pork  co2_emissions
Wheat Products  consumption
Beef  co2_emissions
```

**pandas.core.groupby.DataFrameGroupBy.idxmin**

`DataFrameGroupBy.idxmin(axis=0, skipna=True)`

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

**Parameters**

- `axis` {{0 or ‘index’, 1 or ‘columns’}, default 0} The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- `Series` Indexes of minima along the specified axis.

**Raises**

- `ValueError`
• If the row/column is empty

See also:

**Series.idxmin** Return index of the minimum element.

**Notes**

This method is the DataFrame version of `ndarray.argmin`.

**Examples**

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                      'co2_emissions': [37.2, 19.66, 1712]},
...                     index=['Pork', 'Wheat Products', 'Beef'])
```

<table>
<thead>
<tr>
<th></th>
<th>consumption</th>
<th>co2_emissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pork</td>
<td>10.51</td>
<td>37.20</td>
</tr>
<tr>
<td>Wheat Products</td>
<td>103.11</td>
<td>19.66</td>
</tr>
<tr>
<td>Beef</td>
<td>55.48</td>
<td>1712.00</td>
</tr>
</tbody>
</table>

By default, it returns the index for the minimum value in each column.

```python
>>> df.idxmin()
```

```
consumption    Pork
co2_emissions  Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```python
>>> df.idxmin(axis="columns")
```

```
Pork    consumption
Wheat Products    co2_emissions
Beef    consumption
dtype: object
```

**pandas.core.groupby.DataFrameGroupBy.mad**

**property** `DataFrameGroupBy.mad`

Return the mean absolute deviation of the values over the requested axis.

**Parameters**

- `axis` [(index (0), columns (1))] Axis for the function to be applied on.
- `skipna` [bool, default None] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**Returns**

- `Series` or `DataFrame` (if level specified)
pandas.core.groupby.DataFrameGroupBy.nunique

DataFrameGroupBy.nunique(dropna=True)

Return DataFrame with counts of unique elements in each position.

Parameters

dropna [bool, default True] Don’t include NaN in the counts.

Returns

nunique: DataFrame

Examples

```python
groupby('id').nunique()
```

```
id value1 value2
id
egg 1 1
ham 1 2
spam 2 1
```

Check for rows with the same id but conflicting values:

```python
groupby('id').filter(lambda g: (g.nunique() > 1).any())
```

```
id value1 value2
id
0 spam 1 a
3 spam 2 a
4 ham 5 x
5 ham 5 y
```

pandas.core.groupby.DataFrameGroupBy.pad

DataFrameGroupBy.pad(limit=None)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad Returns Series with minimum number of char in object.
DataFrame.pad  Object with missing values filled or None if inplace=True.
Series.fillna  Fill NaN values of a Series.
DataFrame.fillna  Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.pct_change

DataFrameGroupBy.pct_change(periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calculate pct_change of each value to previous entry in group.

Returns
Series or DataFrame  Percentage changes within each group.

See also:
Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.plot

property  DataFrameGroupBy.plot
Class implementing the .plot attribute for groupby objects.

pandas.core.groupby.DataFrameGroupBy.quantile

DataFrameGroupBy.quantile(q=0.5, interpolation='linear')
Return group values at the given quantile, a la numpy.percentile.

Parameters
q  [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.
interpolation  [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] Method to use when the desired quantile falls between two points.

Returns
Series or DataFrame  Return type determined by caller of GroupBy object.

See also:
Series.quantile  Similar method for Series.
DataFrame.quantile  Similar method for DataFrame.
numpy.percentile  NumPy method to compute qth percentile.

Examples

```python
>>> df = pd.DataFrame([
...     ['a', 1], ['a', 2], ['a', 3],
...     ['b', 1], ['b', 3], ['b', 5]
... ], columns=['key', 'val'])
>>> df.groupby('key').quantile()
key  
    val
a  2.0
b  3.0
```
pandas.core.groupby.DataFrameGroupBy.rank

DataFrameGroupBy.rank (method='average', ascending=True, na_option='keep', pct=False, axis=0)

Provide the rank of values within each group.

Parameters

  method [{'average', 'min', 'max', 'first', 'dense'}, default 'average']
  • average: average rank of group.
  • min: lowest rank in group.
  • max: highest rank in group.
  • first: ranks assigned in order they appear in the array.
  • dense: like ‘min’, but rank always increases by 1 between groups.

  ascending [bool, default True] False for ranks by high (1) to low (N).

  na_option [{'keep', 'top', 'bottom'}, default 'keep']
  • keep: leave NA values where they are.
  • top: smallest rank if ascending.
  • bottom: smallest rank if descending.

  pct [bool, default False] Compute percentage rank of data within each group.

  axis [int, default 0] The axis of the object over which to compute the rank.

Returns

  DataFrame with ranking of values within each group

See also:

  Series.groupby Apply a function groupby to a Series.

  DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.resample

DataFrameGroupBy.resample (rule, *args, **kwargs)

Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string “string” -> “frequency”.

See the frequency aliases documentation for more details.

Parameters

  rule [str or DateOffset] The offset string or object representing target grouper conversion.

  *args, **kwargs Possible arguments are how, fill_method, limit, kind and on, and other arguments of TimeGrouper.

Returns

  Grouper Return a new grouper with our resampler appended.

See also:

  Grouper Specify a frequency to resample with when grouping by a key.

  DatetimeIndex.resample Frequency conversion and resampling of time series.
Examples

```python
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * range(2),
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
   a    b
2000-01-01 00:00:00 0 1
2000-01-01 00:01:00 0 1
2000-01-01 00:02:00 5 1
2000-01-01 00:03:00 0 1

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> df.groupby('a').resample('3T').sum()
   a    b
a  
0  2000-01-01 00:00:00 0 2
   2000-01-01 00:03:00 0 1
5  2000-01-01 00:00:00 5 1

Upsample the series into 30 second bins.

```python
>>> df.groupby('a').resample('30S').sum()
   a    b
a  
0  2000-01-01 00:00:00 0 1
   2000-01-01 00:00:30 0 0
   2000-01-01 00:01:00 0 1
   2000-01-01 00:01:30 0 0
   2000-01-01 00:02:00 0 0
   2000-01-01 00:02:30 0 0
   2000-01-01 00:03:00 0 1
5  2000-01-01 00:02:00 5 1

Resample by month. Values are assigned to the month of the period.

```python
>>> df.groupby('a').resample('M').sum()
   a    b
a  
0  2000-01-31 0 3
5  2000-01-31 5 1

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> df.groupby('a').resample('3T', closed='right').sum()
   a    b
a  
0  1999-12-31 23:57:00 0 1
   2000-01-01 00:00:00 0 2
5  2000-01-01 00:00:00 5 1

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.

```python
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
   a    b
0 2000-01-01 00:00:00 0 1
  2000-01-01 00:03:00 0 2
  5 2000-01-01 00:03:00 5 1
```

**pandas.core.groupby.DataFrameGroupBy.sample**

`DataFrameGroupBy.sample(n=None, frac=None, replace=False, weights=None, random_state=None)`  
Return a random sample of items from each group.

You can use `random_state` for reproducibility.

New in version 1.1.0.

**Parameters**

- `n` [int, optional] Number of items to return for each group. Cannot be used with `frac` and must be no larger than the smallest group unless `replace` is True. Default is one if `frac` is None.
- `frac` [float, optional] Fraction of items to return. Cannot be used with `n`.
- `replace` [bool, default False] Allow or disallow sampling of the same row more than once.
- `weights` [list-like, optional] Default None results in equal probability weighting. If passed a list-like then values must have the same length as the underlying DataFrame or Series object and will be used as sampling probabilities after normalization within each group. Values must be non-negative with at least one positive element within each group.
- `random_state` [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

**Returns**

- Series or DataFrame A new object of same type as caller containing items randomly sampled within each group from the caller object.

See also:

- `DataFrame.sample` Generate random samples from a DataFrame object.
- `numpy.random.choice` Generate a random sample from a given 1-D numpy array.

**Examples**

```python
>>> df = pd.DataFrame(
...     {...
...         "a": ["red"] * 2 + ["blue"] * 2 + ["black"] * 2,  
...         "b": range(6)
...     },
...     ...
... )
>>> df
      a   b
0  red  0
1  red  1
2  blue  2
3  blue  3
4  black  4
5  black  5
```
Select one row at random for each distinct value in column a. The `random_state` argument can be used to guarantee reproducibility:

```python
>>> df.groupby("a").sample(n=1, random_state=1)
a  b
4 black 4
2 blue 2
1 red 1
```

Set `frac` to sample fixed proportions rather than counts:

```python
>>> df.groupby("a")["b"].sample(frac=0.5, random_state=2)
5 5
2 2
0 0
Name: b, dtype: int64
```

Control sample probabilities within groups by setting weights:

```python
>>> df.groupby("a").sample(
... n=1,
... weights=[1, 1, 1, 0, 0, 1],
... random_state=1,
...)
a  b
5 black 5
2 blue 2
0 red 0
```

**pandas.core.groupby.DataFrameGroupBy.shift**

DataFrameGroupBy `.shift` *(periods=1, freq=None, axis=0, fill_value=None)*

Shift each group by periods observations. If freq is passed, the index will be increased using the periods and the freq.

**Parameters**

- `periods` [int, default 1] Number of periods to shift.
- `freq` [str, optional] Frequency string.
- `axis` [axis to shift, default 0] Shift direction.
- `fill_value` [optional] The scalar value to use for newly introduced missing values.

New in version 0.24.0.

**Returns**

- Series or DataFrame Object shifted within each group.

**See also:**

- `Index.shift` Shift values of Index.
- `tshift` Shift the time index, using the index’s frequency if available.
**pandas.core.groupby.DataFrameGroupBy.size**

`DataFrameGroupBy.size()`  
Compute group sizes.  

**Returns**  

*DataFrame or Series* Number of rows in each group as a Series if `as_index` is True or a DataFrame if `as_index` is False.

**See also:**  

*Series.groupby* Apply a function groupby to a Series.  
*DataFrame.groupby* Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.DataFrameGroupBy.skew**

**property** `DataFrameGroupBy.skew`  
Return unbiased skew over requested axis.  

Normalized by N-1.  

**Parameters**  

*axis* [[index (0), columns (1)]] Axis for the function to be applied on.  
*skipna* [bool, default True] Exclude NA/null values when computing the result.  
*level* [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.  
*numeric_only* [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.  

**kwargs** Additional keyword arguments to be passed to the function.

**Returns**  

Series or DataFrame (if level specified)

**pandas.core.groupby.DataFrameGroupBy.take**

**property** `DataFrameGroupBy.take`  
Return the elements in the given **positional** indices along an axis.  

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.  

**Parameters**  

*indices* [array-like] An array of ints indicating which positions to take.  
*axis* [[0 or ‘index’, 1 or ‘columns’, None], default 0] The axis on which to select elements.  
0 means that we are selecting rows, 1 means that we are selecting columns.  
*is_copy* [bool] Before pandas 1.0, *is_copy=False* can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, *take* always returns a copy, and the keyword is therefore deprecated.  
Deprecation since version 1.0.0.  

**kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

**Returns**
taken [same type as caller] An array-like containing the elements taken from the object.

See also:

- **DataFrame.loc** Select a subset of a DataFrame by labels.
- **DataFrame.iloc** Select a subset of a DataFrame by positions.
- **numpy.take** Take elements from an array along an axis.

### Examples

```python
def = pd.DataFrame([('falcon', 'bird', 389.0),
                   ('parrot', 'bird', 24.0),
                   ('lion', 'mammal', 80.5),
                   ('monkey', 'mammal', np.nan)],
                   columns=['name', 'class', 'max_speed'],
                   index=[0, 2, 3, 1])
def

name    class     max_speed
0       falcon    bird       389.0
2       parrot    bird       24.0
3       lion      mammal     80.5
1       monkey    mammal     NaN

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That’s because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
def.take([0, 3])

name    class     max_speed
0       falcon    bird       389.0
1       monkey    mammal     NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
def.take([1, 2], axis=1)

class     max_speed
0         bird       389.0
2         bird       24.0
3         mammal     80.5
1         mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
def.take([-1, -2])

name    class     max_speed
1       monkey    mammal     NaN
3       lion      mammal     80.5
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

pandas.core.groupby.DataFrameGroupBy.tshift

property DataFrameGroupBy.tshift
Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use shift instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.
freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
axis [(0 or ‘index’, 1 or ‘columns’, None), default 0] Corresponds to the axis that contains the Index.

Returns
shifted [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

The following methods are available only for SeriesGroupBy objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SeriesGroupBy.hist</td>
<td>Draw histogram of the input series using matplotlib.</td>
</tr>
<tr>
<td>SeriesGroupBy.nlargest</td>
<td>Return the largest n elements.</td>
</tr>
<tr>
<td>SeriesGroupBy.nsmallest</td>
<td>Return the smallest n elements.</td>
</tr>
<tr>
<td>SeriesGroupBy.nunique([dropna])</td>
<td>Return number of unique elements in the group.</td>
</tr>
<tr>
<td>SeriesGroupBy.unique</td>
<td>Return unique values of Series object.</td>
</tr>
<tr>
<td>SeriesGroupBy.value_counts([normalize, ...])</td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td>SeriesGroupBy.is_monotonic_increasing</td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
<tr>
<td>SeriesGroupBy.is_monotonic_decreasing</td>
<td></td>
</tr>
</tbody>
</table>

pandas.core.groupby.SeriesGroupBy.hist

property SeriesGroupBy.hist
Draw histogram of the input series using matplotlib.

Parameters

by [object, optional] If passed, then used to form histograms for separate groups.
ax [matplotlib axis object] If not passed, uses gca().
grid [bool, default True] Whether to show axis grid lines.
xlabelsize [int, default None] If specified changes the x-axis label size.
xrot [float, default None] Rotation of x axis labels.
ylabelsize [int, default None] If specified changes the y-axis label size.
yrot [float, default None] Rotation of y axis labels.
figsize [tuple, default None] Figure size in inches by default.
bins  [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend  [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

    New in version 1.0.0.

legend  [bool, default False] Whether to show the legend.

    New in version 1.1.0.

**kwargs  To be passed to the actual plotting function.

Returns

    matplotlib.AxesSubplot  A histogram plot.

See also:

    matplotlib.axes.Axes.hist  Plot a histogram using matplotlib.

** pandas.core.groupby.SeriesGroupBy.nlargest **

**property**  `SeriesGroupBy.nlargest`

Return the largest \( n \) elements.

**Parameters**

    n  [int, default 5] Return this many descending sorted values.

    keep  [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of \( n \) elements:

        • first  [return the first \( n \) occurrences in order] of appearance.

        • last  [return the last \( n \) occurrences in reverse] order of appearance.

        • all  [keep all occurrences. This can result in a Series of] size larger than \( n \).

**Returns**

    Series  The \( n \) largest values in the Series, sorted in decreasing order.

See also:

    Series.nsmallest  Get the \( n \) smallest elements.

    Series.sort_values  Sort Series by values.

    Series.head  Return the first \( n \) rows.
Notes

Faster than `s.sort_values(ascending=False).head(n)` for small $n$ relative to the size of the Series object.

Examples

```python
>>> countries_population = {"Italy": 59000000, "France": 65000000,
... "Malta": 434000, "Maldives": 434000,
... "Brunei": 434000, "Iceland": 337000,
... "Nauru": 11300, "Tuvalu": 11300,
... "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy  59000000
France  65000000
Malta  434000
Maldives  434000
Brunei  434000
Iceland  337000
Nauru  11300
Tuvalu  11300
Anguilla  11300
Montserrat  5200
dtype: int64

The $n$ largest elements where $n=5$ by default.

```python
>>> s.nlargest()
France  65000000
Italy  59000000
Malta  434000
Maldives  434000
Brunei  434000
dtype: int64
```

The $n$ largest elements where $n=3$. Default keep value is ‘first’ so Malta will be kept.

```python
>>> s.nlargest(3)
France  65000000
Italy  59000000
Malta  434000
```

The $n$ largest elements where $n=3$ and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```python
>>> s.nlargest(3, keep='last')
France  65000000
Italy  59000000
Brunei  434000
```

The $n$ largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.
>>> s.nlargest(3, keep='all')
France 65000000
Italy 59000000
Malta 434000
Maldives 434000
Brunei 434000
dtype: int64

pandas.core.groupby.SeriesGroupBy.nsmallest

property SeriesGroupBy.nsmallest
Return the smallest n elements.

Parameters

n [int, default 5] Return this many ascending sorted values.

keep [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of n elements:

• first [return the first n occurrences in order] of appearance.
• last [return the last n occurrences in reverse] order of appearance.
• all [keep all occurrences. This can result in a Series of] size larger than n.

Returns

Series The n smallest values in the Series, sorted in increasing order.

See also:

Series.nlargest Get the n largest elements.
Series.sort_values Sort Series by values.
Series.head Return the first n rows.

Notes

Faster than .sort_values().head(n) for small n relative to the size of the Series object.

Examples

>>> countries_population = {"Italy": 59000000, "France": 65000000, ...
... "Brunei": 434000, "Malta": 434000, ...
... "Maldives": 434000, "Iceland": 337000, ...
... "Nauru": 11300, "Tuvalu": 11300, ...
... "Anguilla": 11300, "Montserrat": 5200}

>>> s = pd.Series(countries_population)

>>> s
Italy 59000000
France 65000000
Brunei 434000
Malta 434000
Maldives 434000
Iceland 337000
Nauru 11300
Tuvalu 11300
Anguilla 11300

(continues on next page)
The \( n \) smallest elements where \( n=5 \) by default.

```python
>>> s.nsmallest()
Montserrat   5200
Nauru        11300
Tuvalu       11300
Anguilla     11300
Iceland      337000
dtype: int64
```

The \( n \) smallest elements where \( n=3 \). Default keep value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)
Montserrat   5200
Nauru        11300
Tuvalu       11300
dtype: int64
```

The \( n \) smallest elements where \( n=3 \) and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')
Montserrat   5200
Anguilla     11300
Tuvalu       11300
dtype: int64
```

The \( n \) smallest elements where \( n=3 \) with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest(3, keep='all')
Montserrat   5200
Nauru        11300
Tuvalu       11300
Anguilla     11300
dtype: int64
```

**pandas.core.groupby.SeriesGroupBy.nunique**

SeriesGroupBy\( . \)\texttt{nunique}(\texttt{dropna=True})

Return number of unique elements in the group.

Returns

Series Number of unique values within each group.
pandas.core.groupby.SeriesGroupBy.unique

**property SeriesGroupBy.unique**

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

**Returns**

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

**See also:**

unique Top-level unique method for any 1-d array-like object.
Index.unique Return Index with unique values from an Index object.

**Notes**

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes:

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

**Examples**

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])

>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
daarray(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
... for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

An unordered Categorical will return categories in the order of appearance.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']
```

An ordered Categorical preserves the category ordering.

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
... ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```
**pandas.core.groupby.SeriesGroupBy.value_counts**

```python
SeriesGroupBy.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)
```

**pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing**

**property** `SeriesGroupBy.is_monotonic_increasing`

Alias for `is_monotonic`.

**pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing**

**property** `SeriesGroupBy.is_monotonic_decreasing`

Return boolean if values in the object are monotonic_decreasing.

```python
bool
```

The following methods are available only for `DataFrameGroupBy` objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrameGroupBy.corrwith</code></td>
<td>Compute pairwise correlation.</td>
</tr>
<tr>
<td><code>DataFrameGroupBy.boxplot</code></td>
<td>Make box plots from <code>DataFrameGroupBy</code> data.</td>
</tr>
</tbody>
</table>

**pandas.core.groupby.DataFrameGroupBy.corrwith**

**property** `DataFrameGroupBy.corrwith`

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters**

- `other` ([DataFrame, Series]) Object with which to compute correlations.
- `axis` ([0 or 'index', 1 or 'columns'], default 0) The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.
- `drop` (bool, default False) Drop missing indices from result.
- `method` ([‘pearson’, ‘kendall’, ‘spearman’] or callable) Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float.

New in version 0.24.0.

**Returns**

- `Series` Pairwise correlations.

**See also:**

- `DataFrame.corr` Compute pairwise correlation of columns.
pandas.core.groupby.DataFrameGroupBy.boxplot

DataFrameGroupBy.boxplot(subplots=True, column=None, fontsize=None, rot=0, grid=True, ax=None, figsize=None, layout=None, sharex=False, sharey=True, backend=None, **kwargs)

Make box plots from DataFrameGroupBy data.

Parameters

grouped [Grouped DataFrame]
subplots [bool]
  • False - no subplots will be used
  • True - create a subplot for each group.
column [column name or list of names, or vector] Can be any valid input to groupby.
fontsize [int or str]
rot [label rotation angle]
grid [Setting this to True will show the grid]
ax [Matplotlib axis object, default None]
figsize [A tuple (width, height) in inches]
layout [tuple (optional)] The layout of the plot: (rows, columns).
sharex [bool, default False] Whether x-axes will be shared among subplots.
sharey [bool, default True] Whether y-axes will be shared among subplots.
backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib's boxplot function.

Returns
dict of key/value = group key/DataFrame.boxplot return value
or DataFrame.boxplot return value in case subplots=figures=False

Examples

You can create boxplots for grouped data and show them as separate subplots:

```python
>>> import itertools
>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])
>>> data = np.random.randn(len(index),4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>> grouped = df.groupby(level='lvl1')
>>> grouped.boxplot(rot=45, fontsize=12, figsize=(8,10))
```

The subplots=False option shows the boxplots in a single figure.
Chapter 3. API reference
3.11 Resampling

Resampler objects are returned by resample calls: \texttt{pandas.DataFrame.resample()}, \texttt{pandas.Series.resample()}.

### 3.11.1 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{Resampler.<strong>iter</strong>()}</td>
<td>Resampler iterator.</td>
</tr>
<tr>
<td>\texttt{Resampler.groups}</td>
<td>Dict {group name -&gt; group labels}.</td>
</tr>
<tr>
<td>\texttt{Resampler.indices}</td>
<td>Dict {group name -&gt; group indices}.</td>
</tr>
<tr>
<td>\texttt{Resampler.get_group(name[, obj])}</td>
<td>Construct DataFrame from group with provided name.</td>
</tr>
</tbody>
</table>
### pandas.core.resample.Resampler.__iter__

**Resampler.__iter__()**

Resampler iterator.

**Returns**

Generator yielding sequence of (name, subsetted object) for each group.

**See also:**

- **GroupBy.__iter__**: Generator yielding sequence for each group.

### pandas.core.resample.Resampler.groups

**property Resampler.groups**

Dict {group name -> group labels}.

### pandas.core.resample.Resampler.indices

**property Resampler.indices**

Dict {group name -> group indices}.

### pandas.core.resample.Resampler.get_group

**Resampler.get_group(name, obj=None)**

Construct DataFrame from group with provided name.

**Parameters**

- **name** [object] The name of the group to get as a DataFrame.
- **obj** [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

**Returns**

- **group** [same type as obj]

### 3.11.2 Function application

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Resampler.apply</strong></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><strong>Resampler.aggregate</strong></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><strong>Resampler.transform</strong></td>
<td>Call function producing a like-indexed Series on each group and return a Series with the transformed values.</td>
</tr>
<tr>
<td><strong>Resampler.pipe</strong></td>
<td>Apply a function <code>func</code> with arguments to this Resampler object and return the function’s result.</td>
</tr>
</tbody>
</table>
pandas.core.resample.Resampler.apply

Resampler.apply(func, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:
- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:
- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

DataFrame.groupby.aggregate Aggregate using callable, string, dict, or list of string/callables.
DataFrame.resample.transform Transforms the Series on each group based on the given function.
DataFrame.aggregate Aggregate using one or more operations over the specified axis.

Notes

agg is an alias for aggregate. Use the alias.
A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1,2,3,4,5],
                 index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left, label=left, convention=start]
```

3.11. Resampling
```python
>>> r.agg(np.sum)
2013-01-01 00:00:00  3
2013-01-01 00:00:02  7
2013-01-01 00:00:04  5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum','mean','max'])
    sum  mean  max
2013-01-01 00:00:00  3   1.5  2
2013-01-01 00:00:02  7   3.5  4
2013-01-01 00:00:04  5   5.0  5
```

```python
>>> r.agg({'result' : lambda x: x.mean() / x.std(), 'total' : np.sum})
     total  result
2013-01-01 00:00:00    3    2.121320
2013-01-01 00:00:02    7    4.949747
2013-01-01 00:00:04    5    NaN
```

#### pandas.core.resample.Resampler.aggregate

**Resampler.aggregate** *(func, *args, **kwargs)*

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. `[np.sum, 'mean']`
  - dict of axis labels -> functions, function names or list of such.

- **args** Positional arguments to pass to `func`.

- **kwargs** Keyword arguments to pass to `func`.

**Returns**

- scalar, Series or DataFrame The return can be:
  
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

  Return scalar, Series or DataFrame.

**See also:**

- DataFrame.groupby.aggregate Aggregate using callable, string, dict, or list of string/callables.
- DataFrame.resample.transform Transforms the Series on each group based on the given function.
- DataFrame.aggregate Aggregate using one or more operations over the specified axis.
Notes

`agg` is an alias for `aggregate`. Use the alias.
A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
g  = pd.Series([1,2,3,4,5],
               index=pd.date_range('20130101', periods=5,freq='s'))
g  2013-01-01 00:00:00 1
2013-01-01 00:00:01 2
2013-01-01 00:00:02 3
2013-01-01 00:00:03 4
2013-01-01 00:00:04 5
Freq: S, dtype: int64
```

```python
r  = g.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
label=left, convention=start]  
```

```python
r.agg(np.sum)
2013-01-01 00:00:00 3
2013-01-01 00:00:02 7
2013-01-01 00:00:04 5
Freq: 2S, dtype: int64
```

```python
r.agg(['sum','mean','max'])
sum  mean  max
2013-01-01 00:00:00   3  1.5  2
2013-01-01 00:00:02   7  3.5  4
2013-01-01 00:00:04   5  5.0  5
```

```python
r.agg({'result' : lambda x: x.mean() / x.std(),
       'total' : np.sum})
total  result
2013-01-01 00:00:00   3  2.121320
2013-01-01 00:00:02   7  4.949747
2013-01-01 00:00:04   5 NaN
```

pandas.core.resample.Resampler.transform

`Resampler.transform(arg, *args, **kwargs)`

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

Parameters

arg [function] To apply to each group. Should return a Series with the same index.

Returns

transformed [Series]
Examples

```python
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

**pandas.core.resample.Resampler.pipe**

Resampler.pipe(func, *args, **kwargs)

Apply a function `func` with arguments to this Resampler object and return the function’s result.

Use `.pipe` when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- `func` [callable or tuple of (callable, str)] Function to apply to this Resampler object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Resampler object.
- `args` [iterable, optional] Positional arguments passed into `func`.

**Returns**

- `object` [the return type of `func`]

**See also:**

- Series.pipe Apply a function with arguments to a series.
- DataFrame.pipe Apply a function with arguments to a dataframe.
- apply Apply function to each group instead of to the full Resampler object.

**Notes**

See more [here](#)

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
...                   index=pd.date_range('2012-08-02', periods=4))
>>> df
          A
2012-08-02  1
2012-08-03  2
2012-08-04  3
2012-08-05  4
```
To get the difference between each 2-day period’s maximum and minimum value in one pass, you can do

```python
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
A
2012-08-02  1
2012-08-04  1
```

### 3.11.3 Upsampling

#### `pandas.core.resample.Resampler.ffill`

**Resampler.ffill** *(limit=\*None\*)

Forward fill the values.

**Parameters**

- **limit** \[int, optional\] Limit of how many values to fill.

**Returns**

- An upsampled Series.

**See also:**

- `Series.fillna` Fill NA/NaN values using the specified method.
- `DataFrame.fillna` Fill NA/NaN values using the specified method.

#### `pandas.core.resample.Resampler.backfill`

**Resampler.backfill** *(limit=\*None\*)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

**Parameters**

- **limit** \[int, optional\] Limit of how many values to fill.

**Returns**

- `Series, DataFrame` An upsampled Series or DataFrame with backward filled NaN values.

**See also:**
**bfill** Alias of backfill.

**fillna** Fill NaN values using the specified method, which can be ‘backfill’.

**nearest** Fill NaN values with nearest neighbor starting from center.

**pad** Forward fill NaN values.

**Series.fillna** Fill NaN values in the Series using the specified method, which can be ‘backfill’.

**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

**Examples**

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00 1
2018-01-01 01:00:00 2
2018-01-01 02:00:00 3
Freq: H, dtype: int64
```

```python
>>> s.resample('30min').backfill()
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 NaN
2018-01-01 00:30:00 2.0
2018-01-01 00:45:00 2.0
2018-01-01 01:00:00 2.0
2018-01-01 01:15:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 01:45:00 3.0
2018-01-01 02:00:00 3.0
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
>>> df
   a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 01:00:00  NaN  3.0
2018-01-01 02:00:00  6.0  5.0
```

```python
>>> df.resample('15min').backfill(limit=2)
   a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  2.0  1.0
2018-01-01 00:30:00  2.0  1.0
2018-01-01 00:45:00  2.0  1.0
2018-01-01 01:00:00  2.0  1.0
2018-01-01 01:15:00  2.0  1.0
2018-01-01 01:30:00  2.0  1.0
2018-01-01 01:45:00  2.0  1.0
2018-01-01 02:00:00  2.0  1.0
Freq: 15T, dtype: float64
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> df.resample('30min').backfill()
   a    b
2018-01-01 00:00:00 2.0 1
2018-01-01 00:30:00 NaN 3
2018-01-01 01:00:00 NaN 3
2018-01-01 01:30:00 6.0 5
2018-01-01 02:00:00 6.0 5

>>> df.resample('15min').backfill(limit=2)
   a    b
2018-01-01 00:00:00 2.0 1.0
2018-01-01 00:15:00 NaN NaN
2018-01-01 00:30:00 NaN 3.0
2018-01-01 00:45:00 NaN 3.0
2018-01-01 01:00:00 NaN 3.0
2018-01-01 01:15:00 NaN NaN
2018-01-01 01:30:00 6.0 5.0
2018-01-01 01:45:00 6.0 5.0
2018-01-01 02:00:00 6.0 5.0
```

pandas.core.resample.Resampler.bfill

Resampler.bfill(limit=None)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series, DataFrame An upsampled Series or DataFrame with backward filled NaN values.

See also:

- bfill Alias of backfill.
- fillna Fill NaN values using the specified method, which can be ‘backfill’.
- nearest Fill NaN values with nearest neighbor starting from center.
- pad Forward fill NaN values.
- Series.fillna Fill NaN values in the Series using the specified method, which can be ‘backfill’.
- DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

Examples

Resampling a Series:

```python
g s = pd.Series([1, 2, 3],
                index=pd.date_range('20180101', periods=3, freq='h'))
g s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64

>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64

>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2
2018-01-01 00:45:00    2
2018-01-01 01:00:00    NaN
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3
2018-01-01 01:45:00    3
2018-01-01 02:00:00    3
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```python
g df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
g df
   a  b
2018-01-01 00:00:00    2 1
2018-01-01 01:00:00  NaN 3
2018-01-01 02:00:00    6 5

>>> df.resample('30min').backfill()
   a  b
2018-01-01 00:00:00    2 1
2018-01-01 00:30:00  NaN 3
2018-01-01 01:00:00  NaN 3
2018-01-01 01:30:00    6 5
2018-01-01 02:00:00    6 5

>>> df.resample('15min').backfill(limit=2)
   a  b
2018-01-01 00:00:00    2 1
2018-01-01 00:15:00    NaN NaN
2018-01-01 00:30:00  NaN 3
2018-01-01 00:45:00    NaN NaN
2018-01-01 01:00:00    NaN NaN
2018-01-01 01:15:00    NaN NaN
2018-01-01 01:30:00    6 5
2018-01-01 01:45:00    6 5
```

(continues on next page)
pandas.core.resample.Resampler.pad

Resampler.pad(limit=None)
Forward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

An upsampled Series.

See also:

Series.fillna Fill NA/NaN values using the specified method.
DataFrame.fillna Fill NA/NaN values using the specified method.

pandas.core.resample.Resampler.nearest

Resampler.nearest(limit=None)
Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The nearest method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If limit is given, fill only this many values in each direction for each of the original values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with NaN values filled with their nearest value.

See also:

backfill Backward fill the new missing values in the resampled data.
pad Forward fill NaN values.
Examples

```python
>>> s = pd.Series([1, 2],
                index=pd.date_range('20180101',
                                    periods=2,
                                    freq='1h'))
>>> s
2018-01-01 00:00:00 1
2018-01-01 01:00:00 2
Freq: H, dtype: int64

>>> s.resample('15min').nearest()
2018-01-01 00:00:00 1
2018-01-01 00:15:00 1
2018-01-01 00:30:00 2
2018-01-01 00:45:00 2
2018-01-01 01:00:00 2
Freq: 15T, dtype: int64

Limit the number of upsampled values imputed by the nearest:

```python
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 00:45:00 2.0
2018-01-01 01:00:00 2.0
Freq: 15T, dtype: float64
```pandas.core.resample.Resampler.fillna

Resampler.fillna(method, limit=None)
Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

**Parameters**

- **method** [{‘pad’, ‘backfill’, ‘ffill’, ‘bfill’, ‘nearest’}] Method to use for filling holes in resampled data
  - ‘pad’ or ‘ffill’: use previous valid observation to fill gap (forward fill).
  - ‘backfill’ or ‘bfill’: use next valid observation to fill gap.
  - ‘nearest’: use nearest valid observation to fill gap.

- **limit** [int, optional] Limit of how many consecutive missing values to fill.

**Returns**

- **Series or DataFrame** An upsampled Series or DataFrame with missing values filled.

**See also:**

- backfill Backward fill NaN values in the resampled data.
- pad Forward fill NaN values in the resampled data.
- nearest Fill NaN values in the resampled data with nearest neighbor starting from center.
interpolate Fill NaN values using interpolation.

Series.fillna Fill NaN values in the Series using the specified method, which can be ‘bfill’ and ‘ffill’.

DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be ‘bfill’ and ‘ffill’.

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00 1
2018-01-01 01:00:00 2
2018-01-01 02:00:00 3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```python
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 2.0
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 NaN
2018-01-01 00:30:00 2.0
2018-01-01 01:00:00 2.0
2018-01-01 01:15:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 15T, dtype: float64
```

```python
>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 1
```

(continues on next page)
2018-01-01 01:00:00 2
2018-01-01 01:30:00 2
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64

```
>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

Missing values present before the upsampling are not affected.

```
>>> sm = pd.Series([1, None, 3],
                   index=pd.date_range('20180101', periods=3, freq='h'))
>>> sm
2018-01-01 00:00:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 02:00:00 3.0
Freq: H, dtype: float64
```

```
>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

Dataframe resampling is done column-wise. All the same options are available.

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
>>> df
   a   b
2018-01-01 00:00:00 2.0 1
```

```

**pandas.core.resample.Resampler.asfreq**

```
Resampler.asfreq(fill_value=None)
```

Return the values at the new freq, essentially a reindex.

**Parameters**

- `fill_value` [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

**Returns**

DataFrame or Series Values at the specified freq.

See also:

- `Series.asfreq` Convert TimeSeries to specified frequency.
- `DataFrame.asfreq` Convert TimeSeries to specified frequency.

**pandas.core.resample.Resampler.interpolate**

```
Resampler.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)
```

Interpolate values according to different methods.

Fill NaN values using an interpolation method.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

**Parameters**

- `method` [str, default ‘linear’] Interpolation technique to use. One of:
  - ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
  - ‘index’, ‘values’: use the actual numerical values of the index.
  - ‘pad’: Fill in NaNs using existing values.
  - ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an `order` (int), e.g. `df.interpolate(method='polynomial', order=5)`.
• ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis `[[0 or ‘index’, 1 or ‘columns’, None]}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction `[[‘forward’, ‘backward’, ‘both’}], Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:
• If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
• If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:
• If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
• else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area `[[None, ‘inside’, ‘outside’]], default None] If limit is specified, consecutive NaNs will be filled with this restriction.

• None: No fill restriction.
• ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**`**kwargs**` [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

See also:

fillna Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline Cubic spline data interpolator.
Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2   NaN
3    3.0
dtype: float64

>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ... "fill_two_more", np.nan, np.nan, np.nan, ... 4.71, np.nan])
>>> s
0       NaN
1    single_one
2       NaN
3  fill_two_more
4       NaN
5       NaN
6       NaN
7    4.71
8       NaN
dtype: object

>>> s.interpolate(method='pad', limit=2)
0   NaN
1  single_one
2  single_one
3  fill_two_more
4  fill_two_more
5  fill_two_more
6   NaN
7    4.71
8    4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).
Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```python
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
```

Using polynomial interpolation.

```python
>>> df['d'].interpolate(method='polynomial', order=2)
```

**pandas.core.resample.Resampler.count**

Resampler.count()

Compute count of group, excluding missing values.

Returns

Series or DataFrame  Count of values within each group.

See also:

Series.groupby  Apply a function groupby to a Series.

DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

**pandas.core.resample.Resampler.nunique**

Resampler.nunique(_method='nunique')

Return number of unique elements in the group.

Returns

Series  Number of unique values within each group.

**pandas.core.resample.Resampler.first**

Resampler.first(_method='first', min_count=0, *args, **kwargs)

Compute first of group values.

Parameters

numeric_only  [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count  [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed first of values within each group.
pandas.core.resample.Resampler.last

Resampler.last(_method='last', min_count=0, *args, **kwargs)
Compute last of group values.

Parameters

numeric_only  [bool, default False] Include only float, int, boolean columns. If None, will
 attempt to use everything, then use only numeric data.

min_count    [int, default -1] The required number of valid values to perform the operation. If
 fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed last of values within each group.

pandas.core.resample.Resampler.max

Resampler.max(_method='max', min_count=0, *args, **kwargs)
Compute max of group values.

Parameters

numeric_only  [bool, default False] Include only float, int, boolean columns. If None, will
 attempt to use everything, then use only numeric data.

min_count    [int, default -1] The required number of valid values to perform the operation. If
 fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed max of values within each group.

pandas.core.resample.Resampler.mean

Resampler.mean(_method='mean', *args, **kwargs)
Compute mean of groups, excluding missing values.

Parameters

numeric_only  [bool, default True] Include only float, int, boolean columns. If None, will
 attempt to use everything, then use only numeric data.

Returns

pandas.Series or pandas.DataFrame

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                   'B': [np.nan, 2, 3, 4, 5],
...                   'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])

Groupby one column and return the mean of the remaining columns in each group.

```python
>>> df.groupby('A').mean()

    B      C
A  
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```python
>>> df.groupby(['A', 'B']).mean()

   C
A B  
1  2.0  2
  4.0  1
2  3.0  1
  5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```python
>>> df.groupby('A')['B'].mean()

A  
1  3.0
2  4.0
Name: B, dtype: float64
```

```python
pandas.core.resample.Resampler.median

Resampler.median(_method='median', *args, **kwargs)
Compute median of groups, excluding missing values.
```

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

- `numeric_only` [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- `Series or DataFrame` Median of values within each group.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
pandas.core.resample.Resampler.min

Resampler.min(_method='min', min_count=0, *args, **kwargs)
Compute min of group values.

Parameters

  numeric_only [bool, default False] Include only float, int, boolean columns. If None, will
  attempt to use everything, then use only numeric data.

  min_count [int, default -1] The required number of valid values to perform the operation. If
  fewer than min_count non-NA values are present the result will be NA.

Returns

  Series or DataFrame  Computed min of values within each group.

pandas.core.resample.Resampler.ohlc

Resampler.ohlc(_method='ohlc', *args, **kwargs)
Compute open, high, low and close values of a group, excluding missing values.
For multiple groupings, the result index will be a MultiIndex

Returns

  DataFrame  Open, high, low and close values within each group.

See also:

  Series.groupby Apply a function groupby to a Series.
  DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.prod

Resampler.prod(_method='prod', min_count=0, *args, **kwargs)
Compute prod of group values.

Parameters

  numeric_only [bool, default True] Include only float, int, boolean columns. If None, will
  attempt to use everything, then use only numeric data.

  min_count [int, default 0] The required number of valid values to perform the operation. If
  fewer than min_count non-NA values are present the result will be NA.

Returns

  Series or DataFrame  Computed prod of values within each group.

pandas.core.resample.Resampler.size

Resampler.size()
Compute group sizes.

Returns

  DataFrame or Series  Number of rows in each group as a Series if as_index is True or a
  DataFrame if as_index is False.

See also:

  Series.groupby Apply a function groupby to a Series.
  DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.resample.Resampler.sem

Resampler.sem(_method='sem', *args, **kwargs)
Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddf [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.std

Resampler.std(ddof=1, *args, **kwargs)
Compute standard deviation of groups, excluding missing values.

Parameters

ddf [int, default 1] Degrees of freedom.

Returns

Dataframe or Series Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

Resampler.sum(_method='sum', min_count=0, *args, **kwargs)
Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.resample.Resampler.var

Resampler.var(ddof=1, *args, **kwargs)
Compute variance of groups, excluding missing values.

Parameters

ddf [int, default 1] Degrees of freedom.

Returns

Dataframe or Series Variance of values within each group.
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.core.resample.Resampler.quantile**

Resampler.quantile(q=0.5, **kwargs)

Return value at the given quantile.

New in version 0.24.0.

**Parameters**

- **q** [float or array-like, default 0.5 (50% quantile)]

**Returns**

- **DataFrame** or **Series** Quantile of values within each group.

**See also:**

Series.quantile Return a series, where the index is q and the values are the quantiles.

DataFrame.quantile Return a DataFrame, where the columns are the columns of self, and the values are the quantiles.

DataFrameGroupBy.quantile Return a DataFrame, where the columns are groupby columns, and the values are its quantiles.

### 3.12 Style

Styler objects are returned by pandas.DataFrame.style.

#### 3.12.1 Styler constructor

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Styler(data[, precision, table_styles, ...])</td>
<td>Helps style a DataFrame or Series according to the data with HTML and CSS.</td>
</tr>
<tr>
<td>Styler.from_custom_template(searchpath, name)</td>
<td>Factory function for creating a subclass of Styler.</td>
</tr>
</tbody>
</table>

**pandas.io.formats.style.Styler**

**class pandas.io.formats.style.Styler(data, precision=None, table_styles=None, uuid=None, caption=None, table_attributes=None, cell_ids=True, na_rep=None, uuid_len=5)**

Helps style a DataFrame or Series according to the data with HTML and CSS.

**Parameters**

- **data** [Series or DataFrame] Data to be styled - either a Series or DataFrame.
- **precision** [int] Precision to round floats to, defaults to pd.options.display.precision.
- **table_styles** [list-like, default None] List of {selector: (attr, value)} dicts; see Notes.
- **uuid** [str, default None] A unique identifier to avoid CSS collisions; generated automatically.
- **caption** [str, default None] Caption to attach to the table.
- **table_attributes** [str, default None] Items that show up in the opening <table> tag in addition to automatic (by default) id.
- **cell_ids** [bool, default True] If True, each cell will have an id attribute in their HTML tag. The id takes the form T_<uuid>_row<num_row>_col<num_col> where
<uuid> is the unique identifier, <num_row> is the row number and <num_col> is the column number.

**na_rep** [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.

New in version 1.0.0.

**uuid_len** [int, default 5] If uuid is not specified, the length of the uuid to randomly generate expressed in hex characters, in range [0, 32].

New in version 1.2.0.

See also:

**DataFrame.style** Return a Styler object containing methods for building a styled HTML representation for the DataFrame.

**Notes**

Most styling will be done by passing style functions into Styler.apply or Styler.applymap. Style functions should return values with strings containing CSS 'attr: value' that will be applied to the indicated cells.

If using in the Jupyter notebook, Styler has defined a _repr_html_ to automatically render itself. Otherwise call Styler.render to get the generated HTML.

CSS classes are attached to the generated HTML:

- Index and Column names include index_name and level<k> where k is its level in a MultiIndex
- Index label cells include
  - row_heading
  - row<n> where n is the numeric position of the row
  - level<k> where k is the level in a MultiIndex
- Column label cells include * col_heading * col<n> where n is the numeric position of the column
  * level<k> where k is the level in a MultiIndex
- Blank cells include blank
- Data cells include data

**Attributes**

<td><code>where(cond, value[, other, subset])</code></td>
<td>Apply a function elementwise.</td>
</tr>
</tbody>
</table>

**pandas.io.formats.style.Styler.apply**

Styler.apply(func, axis=0, subset=None, **kwargs)

Apply a function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

**Parameters**

- **func** [function] func should take a Series or DataFrame (depending on axis), and return an object with the same shape. Must return a DataFrame with identical index and column labels when axis=None.

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Apply to each column (axis=0 or ‘index’), to each row (axis=1 or ‘columns’), or to the entire DataFrame at once with axis=None.

- **subset** [IndexSlice] A valid indexer to limit data to before applying the function. Consider using a pandas.IndexSlice.

- **kwargs** [dict] Pass along to func.

**Returns**

- **self** [Styler]
Notes

The output shape of `func` should match the input, i.e. if `x` is the input row, column, or table (depending on `axis`), then `func(x).shape == x.shape` should be true.

This is similar to `DataFrame.apply`, except that `axis=None` applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

Examples

```python
>>> def highlight_max(x):
...     return ['background-color: yellow' if v == x.max() else '' for v in x]
...
>>> df = pd.DataFrame(np.random.randn(5, 2))
>>> df.style.apply(highlight_max)
```

**pandas.io.formats.style.Styler.applymap**

Styler.applymap (func, subset=None, **kwargs)

Apply a function elementwise.

Parameters

- **func** [function] `func` should take a scalar and return a scalar.
- **subset** [IndexSlice] A valid indexer to limit data to before applying the function.
  Consider using a pandas.IndexSlice.
- **kwargs** [dict] Pass along to `func`.

Returns

- self [Styler]

See also:

- **Styler.where** Updates the HTML representation with a style which is selected in accordance with the return value of a function.

**pandas.io.formats.style.Styler.background_gradient**

Styler.background_gradient (cmap='PuBu', low=0, high=0, axis=0, subset=None, text_color_threshold=0.408, vmin=None, vmax=None)

Color the background in a gradient style.

The background color is determined according to the data in each column (optionally row). Requires matplotlib.

Parameters

- **cmap** [str or colormap] Matplotlib colormap.
- **low** [float] Compress the range by the low.
- **high** [float] Compress the range by the high.
axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

subset [IndexSlice] A valid slice for data to limit the style application to.

text_color_threshold [float or int] Luminance threshold for determining text color. Facilitates text visibility across varying background colors. From 0 to 1. 0 = all text is dark colored, 1 = all text is light colored.

New in version 0.24.0.

vmin [float, optional] Minimum data value that corresponds to colormap minimum value. When None (default): the minimum value of the data will be used.

New in version 1.0.0.

vmax [float, optional] Maximum data value that corresponds to colormap maximum value. When None (default): the maximum value of the data will be used.

New in version 1.0.0.

Returns

self [Styler]

Raises

ValueError If text_color_threshold is not a value from 0 to 1.

Notes

Set text_color_threshold or tune low and high to keep the text legible by not using the entire range of the color map. The range of the data is extended by low * (x.max() - x.min()) and high * (x.max() - x.min()) before normalizing.
- ‘mid’ : the center of the cell is at (max-min)/2, or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

\textbf{vmin} [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to \textit{vmin}. When None (default): the minimum value of the data will be used.
New in version 0.24.0.

\textbf{vmax} [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to \textit{vmax}. When None (default): the maximum value of the data will be used.
New in version 0.24.0.

\textbf{Returns}

\textit{self} [Styler]

\textbf{pandas.io.formats.style.Styler.clear}

\textbf{Styler.clear}()
Reset the styler, removing any previously applied styles.
Returns None.

\textbf{pandas.io.formats.style.Styler.export}

\textbf{Styler.export}()
Export the styles to applied to the current Styler.
Can be applied to a second style with \textbf{Styler.use}.

\textbf{Returns}

\textit{styles} [list]

\textbf{See also:}

\textit{Styler.use} Set the styles on the current Styler.

\textbf{pandas.io.formats.style.Styler.format}

\textbf{Styler.format} (formatter, subset=None, na_rep=None)
Format the text display value of cells.

\textbf{Parameters}

\textit{formatter} [str, callable, dict or None] If \textit{formatter} is None, the default formatter is used.

\textit{subset} [IndexSlice] An argument to \textbf{DataFrame.loc} that restricts which elements \textit{formatter} is applied to.

\textit{na_rep} [str, optional] Representation for missing values. If \textit{na_rep} is None, no special formatting is applied.
New in version 1.0.0.
Returns

self [Styler]

Notes

formatter is either an a or a dict {column name: a} where a is one of

- str: this will be wrapped in: a.format(x)
- callable: called with the value of an individual cell

The default display value for numeric values is the “general” (g) format with pd.options.display.precision.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(4, 2), columns=['a', 'b'])
>>> df.style.format("{:.2%}")
>>> df['c'] = ['a', 'b', 'c', 'd']
>>> df.style.format({'c': str.upper})
```

pandas.io.formats.style.Styler.from_custom_template

classmethod Styler.from_custom_template(searchpath, name)

Factory function for creating a subclass of Styler.

Uses a custom template and Jinja environment.

Parameters

- searchpath [str or list] Path or paths of directories containing the templates.
- name [str] Name of your custom template to use for rendering.

Returns

MyStyler [subclass of Styler] Has the correct env and template class attributes set.

pandas.io.formats.style.Styler.hide_columns

Styler.hide_columns(subset)

Hide columns from rendering.

Parameters

- subset [IndexSlice] An argument to DataFrame.loc that identifies which columns are hidden.

Returns

self [Styler]
pandas.io.formats.style.Styler.hide_index

Styler.hide_index()
Hide any indices from rendering.

Returns
self [Styler]

pandas.io.formats.style.Styler.highlight_max

Styler.highlight_max (subset=None, color='yellow', axis=0)
Highlight the maximum by shading the background.

Parameters

subset [IndexSlice, default None] A valid slice for data to limit the style application to.

color [str, default ‘yellow’]

axis [[0 or ‘index’, 1 or ‘columns’, None], default 0] Apply to each column (axis=0 or ‘index’), to each row (axis=1 or ‘columns’), or to the entire DataFrame at once with axis=None.

Returns
self [Styler]

pandas.io.formats.style.Styler.highlight_min

Styler.highlight_min (subset=None, color='yellow', axis=0)
Highlight the minimum by shading the background.

Parameters

subset [IndexSlice, default None] A valid slice for data to limit the style application to.

color [str, default ‘yellow’]

axis [[0 or ‘index’, 1 or ‘columns’, None], default 0] Apply to each column (axis=0 or ‘index’), to each row (axis=1 or ‘columns’), or to the entire DataFrame at once with axis=None.

Returns
self [Styler]
**pandas.io.formats.style.Styler.highlight_null**

Styler.highlight_null(null_color='red', subset=None)
Shade the background null_color for missing values.

**Parameters**

null_color [str, default 'red']
subset [label or list of labels, default None] A valid slice for data to limit the style application to.

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.pipe**

Styler.pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs), and return the result.

New in version 0.24.0.

**Parameters**

func [function] Function to apply to the Styler. Alternatively, a (callable, keyword) tuple where keyword is a string indicating the keyword of callable that expects the Styler.

*args [optional] Arguments passed to func.

**kwargs [optional] A dictionary of keyword arguments passed into func.

**Returns**

object [] The value returned by func.

See also:

**Dataframe.pipe** Analogous method for DataFrame.

**Styler.apply** Apply a function row-wise, column-wise, or table-wise to modify the dataframe’s styling.

**Notes**

Like Dataframe.pipe(), this method can simplify the application of several user-defined functions to a styler. Instead of writing:

```
f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)
```

users can write:

```
(df.style.set_precision(3)
  .pipe(g, arg1=a)
  .pipe(f, arg2=b, arg3=c))
```
In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling `Styler.apply()` or `Styler.set_properties()`). Using `.pipe`, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.

**Examples**

```python
>>> def format_conversion(styler):
...     return styler.set_properties(**{'text-align': 'right'}).
...     format({'conversion': '{:.1%}'}))
```

The user-defined `format_conversion` function above can be called within a sequence of other style modifications:

```python
>>> df = pd.DataFrame({'trial': list(range(5)),
...                    'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
>>> (df.style
...    .highlight_min(subset=['conversion'], color='yellow')
...    .pipe(format_conversion)
...    .set_caption("Results with minimum conversion highlighted."))
```

**pandas.io.formats.style.Styler.render**

`Styler.render(**kwargs)`

Render the built up styles to HTML.

**Parameters**

**kwargs Any additional keyword arguments are passed through to self.

template.render. This is useful when you need to provide additional variables for a custom template.

**Returns**

rendered [str] The rendered HTML.

**Notes**

Styler objects have defined the `_repr_html_` method which automatically calls `self.render()` when it’s the last item in a Notebook cell. When calling `Styler.render()` directly, wrap the result in `IPython.display.HTML` to view the rendered HTML in the notebook.

Pandas uses the following keys in render. Arguments passed in `**kwargs` take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- precision
- table_styles
- caption

---

3.12. Style 2361
• table_attributes

**pandas.io.formats.style.Styler.set_caption**

Styler.set_caption(caption)

Set the caption on a Styler.

**Parameters**

caption [str]

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.set_na_rep**

Styler.set_na_rep(na_rep)

Set the missing data representation on a Styler.

New in version 1.0.0.

**Parameters**

na_rep [str]

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.set_precision**

Styler.set_precision(precision)

Set the precision used to render.

**Parameters**

precision [int]

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.set_properties**

Styler.set_properties(subset=None, **kwargs)

Method to set one or more non-data dependent properties or each cell.

**Parameters**

subset [IndexSlice] A valid slice for data to limit the style application to.

**kwargs [dict] A dictionary of property, value pairs to be set for each cell.

**Returns**

self [Styler]
Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{'background-color': 'yellow'})
```

**pandas.io.formats.style.Styler.set_table_attributes**

Styler.set_table_attributes(attributes)

Set the table attributes.

These are the items that show up in the opening `<table>` tag in addition to automatic (by default) id.

Parameters

attributes [str]

Returns

self [Styler]

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

**pandas.io.formats.style.Styler.set_table_styles**

Styler.set_table_styles(table_styles, axis=0, overwrite=True)

Set the table styles on a Styler.

These are placed in a `<style>` tag before the generated HTML table.

This function can be used to style the entire table, columns, rows or specific HTML selectors.

Parameters

- table_styles [list or dict] If supplying a list, each individual table_style should be a dictionary with selector and props keys. selector should be a CSS selector that the style will be applied to (automatically prefixed by the table’s UUID) and props should be a list of tuples with (attribute, value). If supplying a dict, the dict keys should correspond to column names or index values, depending upon the specified axis argument. These will be mapped to row or col CSS selectors. MultiIndex values as dict keys should be in their respective tuple form. The dict values should be a list as specified in the form with CSS selectors and props that will be applied to the specified row or column.

  Changed in version 1.2.0.

- axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'). Only used if table_styles is dict.

  New in version 1.2.0.
overwrite [boolean, default True] Styles are replaced if True, or extended if False. CSS rules are preserved so most recent styles set will dominate if selectors intersect.

New in version 1.2.0.

Returns

self [Styler]

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                    columns=['A', 'B', 'C', 'D'])
>>> df.style.set_table_styles(
...    [{'selector': 'tr:hover',
...      'props': [('background-color', 'yellow')]}
...)
```

Adding column styling by name

```python
>>> df.style.set_table_styles(
...    {'A': [{'selector': '',
         'props': [('color', 'red')]},
...           'B': [{'selector': 'td',
               'props': [('color', 'blue')]}]
... }, overwrite=False)
```

Adding row styling

```python
>>> df.style.set_table_styles(
...    {0: [{'selector': 'td:hover',
           'props': [('font-size', '25px')]}
... }, axis=1, overwrite=False)
```

pandas.io.formats.style.Styler.set_td_classes

**Styler.set_td_classes (classes)**

Add string based CSS class names to data cells that will appear within the Styler HTML result. These classes are added within specified `<td>` elements.

**Parameters**

classes [DataFrame] DataFrame containing strings that will be translated to CSS classes, mapped by identical column and index values that must exist on the underlying Styler data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

**Returns**

self [Styler]
pandas: powerful Python data analysis toolkit, Release 1.2.2

Examples
>>>
>>>
...
...
...
>>>

df = pd.DataFrame(data=[[1, 2, 3], [4, 5, 6]], columns=["A", "B", "C"])
classes = pd.DataFrame([
["min-val red", "", "blue"],
["red", None, "blue max-val"]
], index=df.index, columns=df.columns)
df.style.set_td_classes(classes)

Using MultiIndex columns and a classes DataFrame as a subset of the underlying,
>>> df = pd.DataFrame([[1,2],[3,4]], index=["a", "b"],
...
columns=[["level0", "level0"], ["level1a", "level1b"]])
>>> classes = pd.DataFrame(["min-val"], index=["a"],
...
columns=[["level0"],["level1a"]])
>>> df.style.set_td_classes(classes)

Form of the output with new additional css classes,
>>> df = pd.DataFrame([[1]])
>>> css = pd.DataFrame(["other-class"])
>>> s = Styler(df, uuid="_", cell_ids=False).set_td_classes(css)
>>> s.hide_index().render()
'<style type="text/css" ></style>'
'<table id="T__" >'
' <thead>'
'
<tr><th class="col_heading level0 col0" >0</th></tr>'
' </thead>'
' <tbody>'
'
<tr><td class="data row0 col0 other-class" >1</td></tr>'
' </tbody>'
'</table>'

pandas.io.formats.style.Styler.set_uuid
Styler.set_uuid(uuid)
Set the uuid for a Styler.
Parameters
uuid [str]
Returns
self [Styler]
pandas.io.formats.style.Styler.to_excel
Styler.to_excel(excel_writer,
sheet_name='Sheet1',
na_rep='',
float_format=None,
columns=None, header=True, index=True, index_label=None, startrow=0,
startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf',
verbose=True, freeze_panes=None)
Write Styler to an Excel sheet.

3.12. Style

2365


To write a single Styler to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

**Parameters**

- **excel_writer** [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- **sheet_name** [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- **na_rep** [str, default ‘ ’] Missing data representation.
- **float_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- **columns** [sequence or list of str, optional] Columns to write.
- **header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow** [int, default 0] Upper left cell row to dump data frame.
- **startcol** [int, default 0] Upper left cell column to dump data frame.
- **engine** [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xlsm.writer`, and `io.excel.xls.writer`.

Deprecation warning: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.

- **merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- **encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- **inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).
- **verbose** [bool, default True] Display more information in the error logs.
- **freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a non-fsspec URL. See the fsspec and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

**See also:**

---

2366 Chapter 3. API reference
**to_csv** Write DataFrame to a comma-separated values (csv) file.

**ExcelWriter** Class for writing DataFrame objects into excel sheets.

**read_excel** Read an Excel file into a pandas DataFrame.

**read_csv** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

**Examples**

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                    index=['row 1', 'row 2'],
...                    columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
...               sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx',
...                      mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```
pandas.io.formats.style.Styler.use

Styler.use (styles)
Set the styles on the current Styler.
Possibly uses styles from Styler.export.

Parameters

styles [list] List of style functions.

Returns

self [Styler]

See also:

Styler.export Export the styles to applied to the current Styler.

pandas.io.formats.style.Styler.where

Styler.where (cond, value, other=None, subset=None, **kwargs)
Apply a function elementwise.
Updates the HTML representation with a style which is selected in accordance with the return value of a function.

Parameters

cond [callable] cond should take a scalar and return a boolean.
value [str] Applied when cond returns true.
other [str] Applied when cond returns false.
subset [IndexSlice] A valid indexer to limit data to before applying the function.
Consider using a pandas.IndexSlice.

**kwargs [dict] Pass along to cond.

Returns

self [Styler]

See also:

Styler.applymap Updates the HTML representation with the result.

3.12.2 Styler properties

Styler.env
Styler.template
Styler.loader
pandas.io.formats.style.Styler.env

### 3.12.5 Style export and import

- `styler.render(**kwargs)` Render the built up styles to HTML.
- `styler.export()` Export the styles to applied to the current Styler.
- `styler.use(styles)` Set the styles on the current Styler.
- `styler.to_excel(excel_writer[, sheet_name, ...])` Write Styler to an Excel sheet.

### 3.13 Plotting

The following functions are contained in the `pandas.plotting` module.

**Function Documentation**

- `andrews_curves(frame, class_column[, ax, ...])`: Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.
- `autocorrelation_plot(series[, ax])`: Autocorrelation plot for time series.
- `bootstrap_plot(series[, fig, size, samples])`: Bootstrap plot on mean, median and mid-range statistics.
- `boxplot(data[, column, by, ax, fontsize, ...])`: Make a box plot from DataFrame columns.
- `deregister_matplotlib_converters()`: Remove pandas formatters and converters.
- `lag_plot(series[, lag, ax])`: Lag plot for time series.
- `parallel_coordinates(frame, class_column[, ...])`: Parallel coordinates plotting.
- `plot_params`: Stores pandas plotting options.
- `radviz(frame, class_column[, ax, color, ...])`: Plot a multidimensional dataset in 2D.
- `register_matplotlib_converters()`: Register pandas formatters and converters with matplotlib.
- `scatter_matrix(frame[, alpha, figsize, ax, ...])`: Draw a matrix of scatter plots.
- `table(ax, data[, rowLabels, colLabels])`: Helper function to convert DataFrame and Series to matplotlib.table.

### 3.13.1 pandas.plotting.andrews_curves

`pandas.plotting.andrews_curves(frame, class_column, ax=None, samples=200, color=None, colormap=None, **kwargs)`

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

\[ f(t) = \frac{x_1}{\sqrt{2}} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \ldots \]

Where \( x \) coefficients correspond to the values of each dimension and \( t \) is linearly spaced between -\( \pi \) and +\( \pi \). Each row of `frame` then corresponds to a single curve.

**Parameters**

- `frame` [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0).
- `class_column` [Name of the column containing class names]
- `ax` [matplotlib axes object, default None]
- `samples` [Number of points to plot in each curve]
- `color` [list or tuple, optional] Colors to use for the different classes.
- `colormap` [str or matplotlib colormap object, default None] Colormap to select colors from.
  - If string, load colormap with that name from matplotlib.
**kwargs Options to pass to matplotlib plotting method.

Returns

class: `matplotlib.axis.Axes`

Examples

```python
def = pd.read_csv(
    ...  'https://raw.github.com/pandas-dev/
    ...  'pandas/master/pandas/tests/io/data/csv/iris.csv'
    ...  )
>>> pd.plotting.andrews_curves(df, 'Name')
```

![Andrew's Curves Plot](image)
3.13.2 pandas.plotting.autocorrelation_plot

pandas.plotting.autocorrelation_plot(\textit{series}, \textit{ax}=\text{None}, **\textit{kwargs})

Autocorrelation plot for time series.

\textbf{Parameters}

- \texttt{series} [Time series]

- \texttt{ax} [Matplotlib axis object, optional]

**\texttt{kwargs}  Options to pass to matplotlib plotting method.

\textbf{Returns}

\texttt{class:matplotlib.axis.Axes}

\textbf{Examples}

The horizontal lines in the plot correspond to 95\% and 99\% confidence bands.

The dashed line is 99\% confidence band.

```python
>>> spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
>>> s = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
>>> pd.plotting.autocorrelation_plot(s)
```
3.13.3 pandas.plotting.bootstrap_plot

pandas.plotting.bootstrap_plot (series, fig=None, size=50, samples=500, **kwds)
Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relaying on random sampling with replacement [1]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

Parameters

series [pandas.Series] Series from where to get the samplings for the bootstrapping.
fig [matplotlib.figure.Figure, default None] If given, it will use the fig reference for plotting instead of creating a new one with default parameters.
size [int, default 50] Number of data points to consider during each sampling. It must be less than or equal to the length of the series.
samples [int, default 500] Number of times the bootstrap procedure is performed.
**kwds Options to pass to matplotlib plotting method.

Returns

matplotlib.figure.Figure Matplotlib figure.

See also:
Dataframe.plot Basic plotting for DataFrame objects.
Series.plot Basic plotting for Series objects.

Examples

This example draws a basic bootstrap plot for a Series.

```python
>>> s = pd.Series(np.random.uniform(size=100))
>>> pd.plotting.bootstrap_plot(s)
```

3.13.4 pandas.plotting.boxplot

pandas.plotting.boxplot (data, column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, **kwargs)
Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of the box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR = Q3 - Q1) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia’s entry for boxplot.

Parameters

column [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to pandas.DataFrame.groupby().
by [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.groupby(). One box-plot will be done per value of columns in by.
ax [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.
fontsize [float or str] Tick label font size in points or as a string (e.g., `large`).

rot [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

grid [bool, default True] Setting this to True will show the grid.

figsize [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

layout [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

return_type [{'axes', 'dict', 'both'} or None, default 'axes'] The kind of object to return. The default is `axes`.

- `axes` returns the matplotlib axes the boxplot is drawn on.
- `dict` returns a dictionary whose values are the matplotlib Lines of the boxplot.
- `both` returns a namedtuple with the axes and dict.

- when grouping with `by`, a Series mapping columns to `return_type` is returned.

  If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

**kwargs All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

Returns

result See Notes.

See also:

- `Series.plot.hist` Make a histogram.
- `matplotlib.pyplot.boxplot` Matplotlib equivalent plot.

Notes

The return type depends on the `return_type` parameter:

- `axes` : object of class `matplotlib.axes.Axes`
- `dict` : dict of `matplotlib.lines.Line2D` objects
- `both` : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:

- `Series`
- `array` (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                     columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```
Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
    columns=['Col1', 'Col2'])
    ... 'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. `['X', 'Y']`) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
    columns=['Col1', 'Col2', 'Col3'])
    ... 'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
    ... 'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
    ... layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels...
Boxplot grouped by ['X', 'Y']

Col1

Col2

(A, A)  (A, B)  (B, A)  (B, B)

[X, Y]  [X, Y]  [X, Y]  [X, Y]
Boxplot grouped by X

Col1

Col2

A  X  B
in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                          return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                        return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```
3.13.5 pandas.plotting.deregister_matplotlib_converters

pandas.plotting.deregister_matplotlib_converters()

Remove pandas formatters and converters.

Removes the custom converters added by register(). This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas’ own types like Timestamp and Period are removed completely. Converters for types pandas overwrites, like datetime.datetime, are restored to their original value.

See also:

register_matplotlib_converters Register pandas formatters and converters with matplotlib.

3.13.6 pandas.plotting.lag_plot

pandas.plotting.lag_plot(series, lag=1, ax=None, **kwds)

Lag plot for time series.

Parameters

- **series** [Time series]
- **lag** [lag of the scatter plot, default 1]
- **ax** [Matplotlib axis object, optional]
- **kwds** Matplotlib scatter method keyword arguments.

Returns

class:matplotlib.axis.Axes

Examples

Lag plots are most commonly used to look for patterns in time series data.

Given the following time series

```python
>>> np.random.seed(5)
>>> x = np.cumsum(np.random.normal(loc=1, scale=5, size=50))
>>> s = pd.Series(x)
>>> s.plot()
```

A lag plot with lag=1 returns

```python
>>> pd.plotting.lag_plot(s, lag=1)
```

3.13.7 pandas.plotting.parallel_coordinates

pandas.plotting.parallel_coordinates(frame, class_column, cols=None, ax=None, color=None, use_columns=False, xticks=None, colormap=None, axvlines=True, axvlines_kwds=None, sort_labels=False, **kwargs)

Parallel coordinates plotting.

Parameters

- **frame** [DataFrame]
class_column [str] Column name containing class names.

cols [list, optional] A list of column names to use.

color [list or tuple, optional] Colors to use for the different classes.

use_columns [bool, optional] If true, columns will be used as xticks.

xticks [list or tuple, optional] A list of values to use for xticks.

colormap [str or matplotlib colormap, default None] Colormap to use for line colors.

axvlines [bool, optional] If true, vertical lines will be added at each xtick.

axvlines_kwds [keywords, optional] Options to be passed to axvline method for vertical lines.

sort_labels [bool, default False] Sort class_column labels, useful when assigning colors.

**kwargs Options to pass to matplotlib plotting method.

Returns

class:matplotlib.axis.Axes

Examples

```python
def df = pd.read_csv(
...   'https://raw.github.com/pandas-dev/
...     'pandas/master/pandas/tests/io/data/csv/iris.csv'
... )
def pd.plotting.parallel_coordinates(
...   df, 'Name', color=('556270', '#4ECDC4', '#C7F464')
... )
```

3.13.8 pandas.plotting.plot_params

pandas.plotting.plot_params = {'xaxis.compat': False}
Stores pandas plotting options.

Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.

3.13.9 pandas.plotting.radviz

pandas.plotting.radviz (frame, class_column, ax=None, color=None, colormap=None, **kwds)
Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated Series in the DataFrame are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the original article describing RadViz.

Parameters
3.13. Plotting
frame [DataFrame] Object holding the data.

class_column [str] Column name containing the name of the data point category.

ax [matplotlib.axes.Axes, optional] A plot instance to which to add the information.

color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].

colormap [str or matplotlib.colors.Colormap, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**kws Options to pass to matplotlib scatter plotting method.

Returns

class:matplotlib.axes.Axes

See also:

plotting.andrews_curves Plot clustering visualization.

Examples

```python
>>> df = pd.DataFrame(
...     {'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
...      'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
...      'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
...      'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
...      'Category': ['virginica', 'virginica', 'setosa', 'virginica', 'virginica', 'versicolor', 'versicolor', 'setosa', 'virginica', 'setosa']}
...     )
...
>>> pd.plotting.radviz(df, 'Category')
```

3.13.10 pandas.plotting.register_matplotlib_converters

pandas.plotting.register_matplotlib_converters()

Register pandas formatters and converters with matplotlib.

This function modifies the global matplotlib.units.registry dictionary. pandas adds custom converters for

- pd.Timestamp
- pd.Period
- np.datetime64
- datetime.datetime
- datetime.date
- datetime.time
3.13. Plotting
See also:

deregister_matplotlib_converters Remove pandas formatters and converters.

3.13.11 pandas.plotting.scatter_matrix

pandas.plotting.scatter_matrix(frame, alpha=0.5, figsize=None, ax=None, grid=False, diagonal='hist', marker='.', density_kws=None, hist_kws=None, range_padding=0.05, **kwargs)

Draw a matrix of scatter plots.

Parameters

frame [Dataframe] Amount of transparency applied.
alpha [float, optional] A tuple (width, height) in inches.
figsize [(float, float), optional] [Matplotlib axis object, optional]
ax grid [bool, optional] Setting this to True will show the grid.
diagonal ['hist', 'kde'] Pick between 'kde' and 'hist' for either Kernel Density Estimation or Histogram plot in the diagonal.
marker [str, optional] Matplotlib marker type, default '.'.
density_kws [keywords] Keyword arguments to be passed to kernel density estimate plot.
hist_kws [keywords] Keyword arguments to be passed to hist function.
range_padding [float, default 0.05] Relative extension of axis range in x and y with respect to (x_max - x_min) or (y_max - y_min).

Returns

numpy.ndarray A matrix of scatter plots.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A','B','C','D'])
>>> pd.plotting.scatter_matrix(df, alpha=0.2)
```

3.13.12 pandas.plotting.table

pandas.plotting.table(ax, data, rowLabels=None, colLabels=None, **kwargs)

Helper function to convert DataFrame and Series to matplotlib.table.

Parameters

ax [Matplotlib axes object]
data [DataFrame or Series] Data for table contents.

**kwargs Keyword arguments to be passed to matplotlib.table.table. If rowLabels or colLabels is not specified, data index or column name will be used.

Returns

dlinewidth table object
3.13. Plotting
3.14 General utility functions

3.14.1 Working with options

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>describe_option</code></td>
<td>Prints the description for one or more registered options.</td>
</tr>
<tr>
<td><code>reset_option</code></td>
<td>Reset one or more options to their default value.</td>
</tr>
<tr>
<td><code>get_option</code></td>
<td>Retrieves the value of the specified option.</td>
</tr>
<tr>
<td><code>set_option</code></td>
<td>Sets the value of the specified option.</td>
</tr>
<tr>
<td><code>option_context</code></td>
<td>Context manager to temporarily set options in the <code>with</code> statement context.</td>
</tr>
</tbody>
</table>

**pandas.describe_option**

```python
pandas.describe_option(pat[, _print_desc])
```

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

**Parameters**

- `pat` [str] Regexp pattern. All matching keys will have their description displayed.
- `_print_desc` [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

**Returns**
None by default, the description(s) as a unicode string if `_print_desc` is False
Notes

The available options with its descriptions:

**compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
Valid values: False, True [default: True] [currently: True]

**compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False
Valid values: False, True [default: False] [currently: False]

**compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
Valid values: False, True [default: True] [currently: True]

**display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

**display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

**display.column_space** No description available. [default: 12] [currently: 12]

**display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

**display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

**display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf8]

**display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

**display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

**display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

**display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

**display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

**display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

**display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]

**display.latex.longtable** :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: False] [currently: False]

**display.latex multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: False] [currently: False]

**display.latex multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: False] [currently: False]

**display.large_rows** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False, True [default: False] [currently: False]

**display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

**display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

**display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.
In case Python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

`display.max_colwidth` [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

`display.max_info_columns` [int] `max_info_columns` is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

`display.max_info_rows` [int or None] `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

`display.max_rows` [int] If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case Python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

`display.max_seq_items` [int or None] When pretty-printing a long sequence, no more then `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

`display.memory_usage` [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True, False, ‘deep’ [default: True] [currently: True]

`display.min_rows` [int] The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]

`display.multi_sparse` [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

`display.notebook_repr_html` [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

`display.pprint_nest_depth` [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

`display.precision` [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to `precision` in numpy. `set_printoptions()` [default: 6] [currently: 6]

`display.show_dimensions` [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

`display.unicode.ambiguous_as_wide` [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

`display.unicode.east_asian_width` [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

`display.width` [int] Width of the display in characters. In case Python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

fault: auto] [currently: auto]

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas: powerful Python data analysis toolkit, Release 1.2.2

3.14. General utility functions 2393
display.[width]
• io.excel.ods.[reader, writer]
• io.excel.xls.[reader, writer]
• io.excel.xlsb.[reader]
• io.excel.xlsm.[reader, writer]
• io.excel.xlsx.[reader, writer]
• io.parquet.[engine]
• mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
• plotting.[backend]
• plotting.matplotlib.[register_converters]

Parameters

pat [str/regex] If specified only options matching prefix* will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

None

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False, True [default: True] [currently: True]
compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False, True [default: False] [currently: False]
compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False, True [default: True] [currently: True]
display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst [boolean] When True, prints and parses dates with the day first, e.g. 20/01/2005 [default: False] [currently: False]
display.date_yearfirst [boolean] When True, prints and parses dates with the year first, e.g. 2005/01/20 [default: False] [currently: False]
display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf8]
display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple "pages" if its width exceeds display.width. [default: True] [currently: True]
display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
display.html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [current: True]
display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]
display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]
display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True, False, ‘deep’ [default: True] [currently: True]
display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
**display.pprint_nest_depth** [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

**display.precision** [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy.

**display.show_dimensions** [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

**display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

**io.hdf.default_format** [format] default format writing format, if None, then put will default to 'fixed' and append will default to 'table' [default: None] [currently: None]

**io.hdf.dropna_table** [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

**mode.chained_assignment** [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

**mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

**mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

**mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

**plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
plotting.matplotlib.register_converters  [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas.get_option

pandas.get_option (pat) = `<pandas._config.config.CallableDynamicDoc object>`

Retrieves the value of the specified option.

Available options:
• compute.[use_bottleneck, use_numba, use_numexpr]
• display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
• display.html.[border, table_schema, use_mathjax]
• display.[large_repr]
• display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
• display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
• display.unicode.[ambiguous_as_wide, east_asian_width]
• display.[width]
• io.excel.ods.[reader, writer]
• io.excel.xls.[reader, writer]
• io.excel.xlsb.[reader]
• io.excel.xlsm.[reader, writer]
• io.excel.xlsx.[reader, writer]
• io.hdf.[default_format, dropna_table]
• io.parquet.[engine]
• mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
• plotting.[backend]
• plotting.matplotlib.[register_converters]

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

result [the value of the option]

Raises

OptionError [if no such option exists]

Notes

The available options with its descriptions:
compute.use_bottleneck  [bool] Use the bottleneck library to accelerate if it is installed, the default is True
Valid values: False, True [default: True] [currently: True]
compute.use_numba  [bool] Use the numba engine option for select operations if it is installed, the default is False
Valid values: False, True [default: False] [currently: False]
compute.use_numexpr  [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
Valid values: False, True [default: True] [currently: True]
display.chop_threshold  [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify  ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst  [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
display.date_yearfirst  [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
display.encoding  [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf8]
display.expand_frame_repr  [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
display.float_format  [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
display.html.border  [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
display.html.table_schema  [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
display.html.use_mathjax  [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
display.large_repr  ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape  [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
display.latex.multicolumn  [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multicolumn_format  [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multirow  [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
display.latex.repr  [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories  [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_columns  [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_colwidth  [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_info_columns  [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
**display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

**display.max_rows** [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

**display.max_seq_items** [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

**display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

**display.min_rows** [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

**display.multi_sparse** [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

**display.notebook_repr_html** [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

**display.pprint_nest_depth** [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

**display.precision** [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy. set_printoptions(). [default: 6] [currently: 6]

**display.show_dimensions** [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

**display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

**pandas: powerful Python data analysis toolkit, Release 1.2.2**

**io.hdf.default_format** [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

**io.hdf.dropna_table** [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

**mode.chained_assignment** [string] Raise an exception, warn, or no action if trying to use chained assignment. The default is warn [default: warn] [currently: warn]

**mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

**mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

**mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

**plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

**plotting.matplotlib.register_converters** [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

**pandas.set_option**

**pandas.set_option**(pat, value) = <pandas._config.config.CallableDynamicDoc object>

Sets the value of the specified option.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsxm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]
Parameters

- **pat** [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

- **value** [object] New value of option.

Returns

None

Raises

OptionError if no such option exists

Notes

The available options with their descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False. Valid values: False, True [default: False] [currently: False]
- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **display.chop_threshold** [float or None] If set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. Used by DataFrameFormatter. [default: right] [currently: right]
- **display.column_space** No description available. [default: 12] [currently: 12]
- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf8]
- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]
- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
- **display.html.border** [int] A border=value attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. [default: False] [currently: False]
- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. [default: True] [currently: True]
- **display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]

3.14. General utility functions 2401
display.latex.longtable [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: False] [currently: False]
display.latex.mutirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]
display.latex.mutirow_format [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex columns. Valid values: False, True [default: l] [currently: l]
display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a ‘...’ placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]
display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]
display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of ‘...’ to the resulting string.

If set to None, the numbers of items to be printed is unlimited. [default: 100] [currently: 100]
display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True, False, ’deep’ [default: True] [currently: True]
display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]
display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy. set_printoptions(). [default: 6] [currently: 6]
display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)
plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
plotting.matplotlib.register_converters [boolean or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
pandas: powerful Python data analysis toolkit, Release 1.2.2

**pandas.option_context**

class pandas.option_context (*args)

Context manager to temporarily set options in the with statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...]).`

**Examples**

```python
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
... ...
```

**Methods**

___call__(func) Call self as a function.

**pandas.option_context.__call__**

`option_context.__call__(func)` Call self as a function.

### 3.14.2 Testing functions

**testing.assert_frame_equal**

`testing.assert_frame_equal(left, right[, check_dtype=True, check_index_type='equiv', check_column_type='equiv', check_frame_type=True, check_less_precise=<object object>, check_names=True, by_blocks=False, check_exact=False, check_datetimelike_compat=False, check_categorical=True, check_like=False, check_freq=True, check_flags=True, rtol=1e-05, atol=1e-08, obj='DataFrame')`

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. Is is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

**Parameters**

- **left** [DataFrame] First DataFrame to compare.
right  [DataFrame] Second DataFrame to compare.

check_dtype  [bool, default True] Whether to check the DataFrame dtype is identical.

check_index_type  [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_column_type  [bool or {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and inferred_type are identical. Is passed as the exact argument of assert_index_equal().

check_frame_type  [bool, default True] Whether to check the DataFrame class is identical.

check_less_precise  [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().

check_names  [bool, default True] Whether to check that the names attribute for both the index and column attributes of the DataFrame is identical.

by_blocks  [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

check_exact  [bool, default False] Whether to compare number exactly.

check_datetimelike_compat  [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical  [bool, default True] Whether to compare internal Categorical exactly.

check_like  [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.

check_freq  [bool, default True] Whether to check the freq attribute on a DatetimeIndex or TimedeltaIndex.

New in version 1.1.0.

check_flags  [bool, default True] Whether to check the flags attribute.

rtol  [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol  [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj  [str, default ‘DataFrame’] Specify object name being compared, internally used to show appropriate assertion message.

See also:

assert_series_equal  Equivalent method for asserting Series equality.

DataFrame.equals  Check DataFrame equality.
Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```python
>>> from pandas._testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
df1 equals itself.

```python
>>> assert_frame_equal(df1, df1)
``` df1 differs from df2 as column ‘b’ is of a different type.

```python
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
... 
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute “dtype” are different [left]: int64 [right]: float64
Ignore differing dtypes in columns with check_dtype.

```python
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

**pandas.testing.assert_series_equal**

`pandas.testing.assert_series_equal` (left, right, check_dtypes=True, check_index_type='equiv', check_series_type=True, check_less_precise=<object object>, check_names=True, check_exact=False, check_datetimelike_compat=False, check_categorical=True, check_category_order=True, check_freq=True, check_flags=True, rtol=1e-05, atol=1e-08, obj='Series')

Check that left and right Series are equal.

**Parameters**

- `left` [Series]
- `right` [Series]
- `check_dtypes` [bool, default True] Whether to check the Series dtype is identical.
- `check_index_type` [bool or {'equiv'}], default ‘equiv’] Whether to check the Index class, dtype and inferred_type are identical.
- `check_series_type` [bool, default True] Whether to check the Series class is identical.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
check_names  [bool, default True] Whether to check the Series and Index names attribute.

check_exact  [bool, default False] Whether to compare number exactly.

check_datetimelike_compat  [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical  [bool, default True] Whether to compare internal Categorical exactly.

check_category_order  [bool, default True] Whether to compare category order of internal Categoricals.

New in version 1.0.2.

check_freq  [bool, default True] Whether to check the freq attribute on a DatetimeIndex or TimedeltaIndex.

New in version 1.1.0.

check_flags  [bool, default True] Whether to check the flags attribute.

New in version 1.2.0.

rtol  [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol  [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj  [str, default ‘Series’] Specify object name being compared, internally used to show appropriate assertion message.

Examples

```python
>>> from pandas.testing import assert_series_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b = pd.Series([1, 2, 3, 4])
>>> assert_series_equal(a, b)
```

pandas.testing.assert_index_equal

pandas.testing.assert_index_equal(  
left,  
right,  
exact='equiv',  
check_names=True,  
check_less_precise=<object object>,  
check_exact=True,  
check_categorical=True,  
check_order=True,  
rtol=1e-05,  
atol=1e-08,  
obj=’Index’)

Check that left and right Index are equal.

Parameters

left  [Index]

right  [Index]

equal  [bool or {‘equiv’}, default ‘equiv’] Whether to check the Index class, dtype and inferred_type are identical. If ‘equiv’, then RangeIndex can be substituted for Int64Index as well.

check_names  [bool, default True] Whether to check the names attribute.
check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().

check_exact [bool, default True] Whether to compare number exactly.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_order [bool, default True] Whether to compare the order of index entries as well as their values. If True, both indexes must contain the same elements, in the same order. If False, both indexes must contain the same elements, but in any order.

New in version 1.2.0.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default ‘Index’] Specify object name being compared, internally used to show appropriate assertion message.

Examples

>>> from pandas.testing import assert_index_equal
>>> a = pd.Index([1, 2, 3])
>>> b = pd.Index([1, 2, 3])
>>> assert_index_equal(a, b)

pandas.testing.assert_extension_array_equal

pandas.testing.assert_extension_array_equal (left, right, check_dtypes=True, index_values=None, check_less_precise=False, check_exact=False, rtol=1e-05, atol=1e-08)

Check that left and right ExtensionArrays are equal.

Parameters

left, right [ExtensionArray] The two arrays to compare.

check_dtypes [bool, default True] Whether to check if the ExtensionArray dtypes are identical.

index_values [numpy.ndarray, default None] Optional index (shared by both left and right), used in output.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().
**check_exact** [bool, default False] Whether to compare number exactly.

**rtol** [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

**atol** [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

**Notes**

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.

**Examples**

```python
>>> from pandas.testing import assert_extension_array_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b, c = a.array, a.array
>>> assert_extension_array_equal(b, c)
```

### 3.14.3 Exceptions and warnings

<table>

</tr>
</tbody>
</table>

continues on next page
Table 393 – continued from previous page

| errors.UnsupportedFunctionCall | Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. |

**pandas.errors.AccessorRegistrationWarning**

*exception* pandas.errors.AccessorRegistrationWarning
Warning for attribute conflicts in accessor registration.

**pandas.errors.DtypeWarning**

*exception* pandas.errors.DtypeWarning
Warning raised when reading different dtypes in a column from a file.

Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

See also:
- **read_csv** Read CSV (comma-separated) file into a DataFrame.
- **read_table** Read general delimited file into a DataFrame.

**Notes**

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

**Examples**

This example creates and reads a large CSV file with a column that contains `int` and `str`.

```python
>>> df = pd.DataFrame({'a': ([1] * 100000 + [X] * 100000 + ...
...                      [1] * 100000),
...                      'b': [b] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types
Importantly notice that `df2` will contain both `str` and `int` for the same input, `1`.

```python
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
```

One way to solve this issue is using the `dtype` parameter in the `read_csv` and `read_table` functions to explicit the conversion:
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})

No warning was issued.

>>> import os
>>> os.remove('test.csv')

pandas.errors.DuplicateLabelError

exception pandas.errors.DuplicateLabelError
Error raised when an operation would introduce duplicate labels.
New in version 1.2.0.

Examples

>>> s = pd.Series([0, 1, 2], index=['a', 'b', 'c']).set_flags(...
  allows_duplicate_labels=False
...)
>>> s.reindex(['a', 'a', 'b'])
Traceback (most recent call last):
  ...
DuplicateLabelError: Index has duplicates.
    positions
    label
    a       [0, 1]

pandas.errors.EmptyDataError

exception pandas.errors.EmptyDataError
Exception that is thrown in pd.read_csv (by both the C and Python engines) when empty data or header is encountered.

pandas.errors.InvalidIndexError

exception pandas.errors.InvalidIndexError
Exception raised when attempting to use an invalid index key.
New in version 1.1.0.

pandas.errors.MergeError

exception pandas.errors.MergeError
Error raised when problems arise during merging due to problems with input data. Subclass of ValueError.
pandas.errors.NullFrequencyError

exception pandas.errors.NullFrequencyError
Error raised when a null freq attribute is used in an operation that needs a non-null frequency, particularly `DatetimeIndex.shift`, `TimedeltaIndex.shift`, `PeriodIndex.shift`.

pandas.errors.NumbaUtilError

exception pandas.errors.NumbaUtilError
Error raised for unsupported Numba engine routines.

pandas.errorsOutOfBoundsDatetime

exception pandas.errorsOutOfBoundsDatetime
Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

pandas.errorsOutOfBoundsTimedelta

exception pandas.errorsOutOfBoundsTimedelta
Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

pandas.errors.ParserError

exception pandas.errors.ParserError
Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like `read_csv` or `read_html` are parsing contents of a file.

See also:

- `read_csv` Read CSV (comma-separated) file into a DataFrame.
- `read_html` Read HTML table into a DataFrame.

pandas.errors.ParserWarning

exception pandas.errors.ParserWarning
Warning raised when reading a file that doesn’t use the default ‘c’ parser.

Raised by `pd.read_csv` and `pd.read_table` when it is necessary to change parsers, generally from the default ‘c’ parser to ‘python’.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, ‘c’ unsupported options include the following parameters:
1. `sep` other than a single character (e.g. regex separators)
2. `skipfooter` higher than 0
3. `sep=None` with `delim_whitespace=False`

The warning can be avoided by adding `engine='python'` as a parameter in `pd.read_csv` and `pd.read_table` methods.

See also:

- `pd.read_csv` Read CSV (comma-separated) file into DataFrame.
pd.read_table  Read general delimited file into DataFrame.

Examples

Using a sep in pd.read_csv other than a single character:

```python
>>> import io
>>> csv = '''a;b;c
... 1;1,8
... 1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;]')
... # ParserWarning: Falling back to the 'python' engine...
```

Adding engine='python' to pd.read_csv removes the Warning:

```python
>>> df = pd.read_csv(io.StringIO(csv), sep='[;]', engine='python')
```

pandas.errors.PerformanceWarning

exception pandas.errors.PerformanceWarning
Warning raised when there is a possible performance impact.

pandas.errors.UnsortedIndexError

exception pandas.errors.UnsortedIndexError
Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of KeyError.

pandas.errors.UnsupportedFunctionCall

exception pandas.errors.UnsupportedFunctionCall
Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. np.cumsum(groupby_object).

3.14.4 Data types related functionality

<table>
<thead>
<tr>

<td>Efficiently infer the type of a passed val, or list-like array of values.</td>
</tr>
<tr>
<td>api.types.pandas_dtype(dtype)</td>
<td>Convert input into a pandas only dtype object or a numpy dtype object.</td>
</tr>
</tbody>
</table>

3.14. General utility functions 2413
pandas.api.types.union_categoricals

**pandas.api.types.union_categoricals** *(to_union, sort_categories=False, ignore_order=False)*

Combine list-like of Categorical-like, unioning categories.

All categories must have the same dtype.

**Parameters**

- `to_union` [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.
- `sort_categories` [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.
- `ignore_order` [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

**Returns**

Categorical

**Raises**

- **TypeError**
  - all inputs do not have the same dtype
  - all inputs do not have the same ordered property
  - all inputs are ordered and their categories are not identical
  - sort_categories=True and Categoricals are ordered

- **ValueError** Empty list of categoricals passed

**Notes**

To learn more about categories, see link

**Examples**

```python
>>> from pandas.api.types import union_categoricals

If you want to combine categoricals that do not necessarily have the same categories, `union_categoricals` will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python
>>> a = pd.Categorical(['b', 'c'])
>>> b = pd.Categorical(['a', 'b'])
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the categories of the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python
>>> union_categoricals([a, b], sort_categories=True)
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also `append` for).
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)
>>> union_categoricals([a, b])
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']

Raises `TypeError` because the categories are ordered and not identical.

```python
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
Traceback (most recent call last):
  ...
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
>>> a = pd.Categorical(["a", "b", "c"], ordered=True)
>>> b = pd.Categorical(["c", "b", "a"], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`

```python
>>> a = pd.Series(["b", "c"], dtype='category')
>>> b = pd.Series(["a", "b"], dtype='category')
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

### pandas.api.types.infer_dtype

`pandas.api.types.infer_dtype()`

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

**Parameters**

- `value` [scalar, list, ndarray, or pandas type]
- `skipna` [bool, default True] Ignore NaN values when inferring the type.

**Returns**

- `str` Describing the common type of the input data.

**Results can include:**

- string
- bytes
- floating
- integer
- mixed-integer
• mixed-integer-float
• decimal
• complex
• categorical
• boolean
• datetime64
• datetime
• date
• timedelta64
• timedelta
• time
• period
• mixed

Raises

TypeError If ndarray-like but cannot infer the dtype

Notes

• ‘mixed’ is the catchall for anything that is not otherwise specialized
• ‘mixed-integer-float’ are floats and integers
• ‘mixed-integer’ are integers mixed with non-integers

Examples

```python
>>> infer_dtype(['foo', 'bar'])
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=True)
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=False)
'mixed'

>>> infer_dtype([b'foo', b'bar'])
'bytes'

>>> infer_dtype([1, 2, 3])
'integer'

>>> infer_dtype([1, 2, 3.5])
'mixed-integer-float'

>>> infer_dtype([1.0, 2.0, 3.5])
'floating'
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

```python
>>> infer_dtypes(['a', 1])
'mixed-integer'

>>> infer_dtypes([Decimal(1), Decimal(2.0)])
'decimal'

>>> infer_dtypes([True, False])
'boolean'

>>> infer_dtypes([True, False, np.nan])
'mixed'

>>> infer_dtypes([pd.Timestamp('20130101')])
'datetime'

>>> infer_dtypes([datetime.date(2013, 1, 1)])
'date'

>>> infer_dtypes([np.datetime64('2013-01-01')])
'datetime64'

>>> infer_dtypes([datetime.timedelta(0, 1, 1)])
'timedelta'

>>> infer_dtypes(pd.Series(list('aabc')).astype('category'))
'categorical'
```

pandas.api.types.pandas_dtype

**pandas.api.types.pandas_dtype**(dtypes)

Convert input into a pandas only dtypes object or a numpy dtypes object.

**Parameters**

- dtypes [object to be converted]

**Returns**

np.dtypes or a pandas dtype

**Raises**

TypeError if not a dtypes

**Dtype introspection**

</tbody>
</table>

**pandas.api.types.is_bool_dtype**

**pandas.api.types.is_bool_dtype(arr_or_dtype)**
Check whether the provided array or dtype is of a boolean dtype.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of a boolean dtype.
Notes

An ExtensionArray is considered boolean when the \_is\_boolean attribute is set to True.

Examples

```python
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool_)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.arrays.SparseArray([True, False]))
True
```

pandas.api.types.is_categorical_dtype

pandas.api.types.is_categorical_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Categorical dtype.

Parameters

- arr_or_dtype [array-like] The array-like or dtype to check.

Returns

- boolean Whether or not the array-like or dtype is of the Categorical dtype.

Examples

```python
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True
```
pandas.api.types.is_complex_dtype

Check whether the provided array or dtype is of a complex dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a complex dtype.

Examples

```python
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex_)
True
>>> is_complex_dtype(np.array([‘a’, ‘b’]))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

pandas.api.types.is_datetime64_any_dtype

Check whether the provided array or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64 dtype.

Examples

```python
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64)  # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype(“ns”, “US/Eastern”))
True
>>> is_datetime64_any_dtype(np.array([‘a’, ‘b’]))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype=“datetime64[ns]”))
```
pandas: powerful Python data analysis toolkit, Release 1.2.2

>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True

pandas.api.types.is_datetime64_dtype

pandas.api.types.is_datetime64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False

pandas.api.types.is_datetime64_ns_dtype

pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64[ns] dtype.

Examples

>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64) # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array([a', 'b']))
(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.2.2

(continued from previous page)

False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64"))  # no unit
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64[ps]"))  # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True

pandas.api.types.is_datetime64tz_dtype

pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)
Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

Examples

>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3]))  # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True

>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True

pandas.api.types.is_extension_type

pandas.api.types.is_extension_type(arr)
Check whether an array-like is of a pandas extension class instance.

Deprecated since version 1.0.0: Use is_extension_array_dtype instead.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters

arr [array-like] The array-like to check.

Returns
boolean  Whether or not the array-like is of a pandas extension class instance.

Examples

```python
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>> cat = pd.Categorical([1, 2, 3])
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import csr_matrix
>>> is_extension_type(csr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True
```

pandas.api.types.is_extension_array_dtype

pandas.api.types.is_extension_array_dtype(arr_or_dtype)

Check if an object is a pandas extension array type.

See the Use Guide for more.

Parameters

arr_or_dtype  [object] For array-like input, the .dtype attribute will be extracted.

Returns

bool  Whether the arr_or_dtype is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:

• Categorical
• Sparse
• Interval
• Period
• DatetimeArray
• TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.
Examples

```python
>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True

>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False
```

**pandas.api.types.is_float_dtype**

Check whether the provided array or dtype is of a float dtype.

This function is internal and should not be exposed in the public API.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of a float dtype.

Examples

```python
>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True
```

**pandas.api.types.is_int64_dtype**

Check whether the provided array or dtype is of the int64 dtype.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of the int64 dtype.
Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

Examples

```python
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64)  # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.]))  # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

**pandas.api.types.is_integer_dtype**

`pandas.api.types.is_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of an integer dtype.

Unlike in `in_any_int_dtype`, timedelta64 instances will return False.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of an integer dtype and not an instance of timedelta64.
Examples

```python
>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.]))  # float
    False
```

**pandas.api.types.is_interval_dtype**

pandas.api.types.is_interval_dtype(arr_or_dtype)  
Check whether an array-like or dtype is of the Interval dtype.

**Parameters**

arr_or_dtype [array-like] The array-like or dtype to check.

**Returns**

boolean Whether or not the array-like or dtype is of the Interval dtype.

Examples

```python
>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
```
pandas.api.types.is_numeric_dtype

pandas.api.types.is_numeric_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a numeric dtype.

Parameters

- arr_or_dtype  [array-like] The array or dtype to check.

Returns

- boolean  Whether or not the array or dtype is of a numeric dtype.

Examples

```python
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

pandas.api.types.is_object_dtype

pandas.api.types.is_object_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the object dtype.

Parameters

- arr_or_dtype  [array-like] The array-like or dtype to check.

Returns

- boolean  Whether or not the array-like or dtype is of the object dtype.
Examples

```python
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

**pandas.api.types.is_period_dtype**

pandas.api.types.is_period_dtype(arr_or_dtype)

Check whether an array-like or dtype is of the Period dtype.

**Parameters**

- **arr_or_dtype** [array-like] The array-like or dtype to check.

**Returns**

- **boolean** Whether or not the array-like or dtype is of the Period dtype.

Examples

```python
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

**pandas.api.types.is_signed_integer_dtype**

pandas.api.types.is_signed_integer_dtype(arr_or_dtype)

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in in_any_int_dtype, timedelta64 instances will return False.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

**Parameters**

- **arr_or_dtype** [array-like] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of a signed integer dtype and not an instance of timedelta64.
pandas: powerful Python data analysis toolkit, Release 1.2.2

Examples

```python
>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64)  # unsigned
False
>>> is_signed_integer_dtype('int8')
True
>>> is_signed_integer_dtype('Int8')
True
>>> is_signed_integer_dtype(pd.Int8Dtype)
True
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

pandas.api.types.is_string_dtype

pandas.api.types.is_string_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the string dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the string dtype.

Examples

```python
>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>> is_string_dtype(np.array(['a', 'b']))
True
```

(continues on next page)

3.14. General utility functions
>>> is_string_dtype(pd.Series([1, 2]))
False

pandas.api.types.is_timedelta64_dtype

pandas.api.types.is_timedelta64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False

pandas.api.types.is_timedelta64_ns_dtype

pandas.api.types.is_timedelta64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like np.timedelta64 will return False if passed into this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the timedelta64[ns] dtype.

Examples

>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]'))  # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False
pandas.api.types.is_unsigned_integer_dtype

pandas.api.types.is_unsigned_integer_dtype(arr_or_dtype)

Check whether the provided array or dtype is of an unsigned integer dtype.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.UInt64Dtype) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an unsigned integer dtype.

Examples

```python
>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int)  # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2]))  # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True
```

pandas.api.types.is_sparse

pandas.api.types.is_sparse(arr)

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

Parameters

arr [array-like] Array-like to check.

Returns

bool Whether or not the array-like is a pandas sparse array.
Examples

Returns True if the parameter is a 1-D pandas sparse array.

```python
>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True
```

Returns False if the parameter is not sparse.

```python
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns False if the parameter is not a pandas sparse array.

```python
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns False if the parameter has more than one dimension.

**Iterable introspection**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api.types.is_dict_like(obj)</code></td>
<td>Check if the object is dict-like.</td>
</tr>
<tr>
<td><code>api.types.is_file_like(obj)</code></td>
<td>Check if the object is a file-like object.</td>
</tr>
<tr>
<td><code>api.types.is_list_like</code></td>
<td>Check if the object is list-like.</td>
</tr>
<tr>
<td><code>api.types.is_named_tuple(obj)</code></td>
<td>Check if the object is a named tuple.</td>
</tr>
<tr>
<td><code>api.types.is_iterator</code></td>
<td>Check if the object is an iterator.</td>
</tr>
</tbody>
</table>

**pandas.api.types.is_dict_like**

`pandas.api.types.is_dict_like(obj)`

Check if the object is dict-like.

**Parameters**

- **obj** [The object to check]

**Returns**

- **is_dict_like** [bool] Whether `obj` has dict-like properties.
Examples

```python
>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True
```

**pandas.api.types.is_file_like**

**pandas.api.types.is_file_like(obj)**

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a `read` and/or `write` method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

**Parameters**

- obj [The object to check]

**Returns**

- is_file_like [bool] Whether `obj` has file-like properties.

Examples

```python
>>> import io
>>> buffer = io.StringIO("data")
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```

**pandas.api.types.is_list_like**

**pandas.api.types.is_list_like()**

Check if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

**Parameters**

- obj [object] Object to check.
  
  - allow_sets [bool, default True] If this parameter is False, sets will not be considered list-like.
  
  New in version 0.24.0.

**Returns**

- bool Whether `obj` has list-like properties.
Examples

```python
>>> is_list_like([1, 2, 3])
True
>>> is_list_like((1, 2, 3))
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False
```

**pandas.api.types.is_named_tuple**

`pandas.api.types.is_named_tuple(obj)`

Check if the object is a named tuple.

**Parameters**

- `obj` [The object to check]

**Returns**

- `is_named_tuple` [bool] Whether `obj` is a named tuple.

Examples

```python
>>> from collections import namedtuple
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False
```

**pandas.api.types.is_iterator**

`pandas.api.types.is_iterator()`

Check if the object is an iterator.

This is intended for generators, not list-like objects.

**Parameters**

- `obj` [The object to check]

**Returns**

- `is_iter` [bool] Whether `obj` is an iterator.
Examples

```python
>>> is_iterator((x for x in []))
True
>>> is_iterator([1, 2, 3])
False
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False
```

</table>

### pandas.api.types.is_bool

`pandas.api.types.is_bool()`

Return True if given object is boolean.

**Returns**

`bool`

### pandas.api.types.is_categorical

`pandas.api.types.is_categorical(arr)`

Check whether an array-like is a Categorical instance.

**Parameters**

`arr` [array-like] The array-like to check.

**Returns**

`boolean` Whether or not the array-like is of a Categorical instance.
Examples

```python
>>> is_categorical([1, 2, 3])
False

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```python
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

**pandas.api.types.is_complex**

```python
def pandas.api.types.is_complex() -> bool:
    Return True if given object is complex.
Returns
    bool
```

**pandas.api.types.is_float**

```python
def pandas.api.types.is_float() -> bool:
    Return True if given object is float.
Returns
    bool
```

**pandas.api.types.is_hashable**

```python
def pandas.api.types.is_hashable(obj) -> bool:
    Return True if hash(obj) will succeed, False otherwise.
    Some types will pass a test against collections.abc.Hashable but fail when they are actually hashed with hash().
    Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.
Returns
    bool
```

Examples

```python
>>> import collections
>>> a = (1,)
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```
pandas.api.types.is_integer

pandas.api.types.is_integer()

   Return True if given object is integer.

   Returns

   bool

pandas.api.types.is_interval

pandas.api.types.is_interval()

pandas.api.types.is_number

pandas.api.types.is_number(obj)

   Check if the object is a number.

   Returns True when the object is a number, and False if is not.

   Parameters

   obj [any type] The object to check if is a number.

   Returns

   is_number [bool] Whether obj is a number or not.

   See also:

   api.types.is_integer Checks a subgroup of numbers.

Examples

>>> pd.api.types.is_number(1)
True
>>> pd.api.types.is_number(7.15)
True

Booleans are valid because they are int subclass.

>>> pd.api.types.is_number(False)
True

>>> pd.api.types.is_number("foo")
False
>>> pd.api.types.is_number("5")
False

3.14. General utility functions 2437
pandas.api.types.is_re

pandas.api.types.is_re(obj)
   Check if the object is a regex pattern instance.
   Parameters
       obj [The object to check]
   Returns
       is_regex [bool] Whether obj is a regex pattern.

Examples

>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False

pandas.api.types.is_re_compilable

pandas.api.types.is_re_compilable(obj)
   Check if the object can be compiled into a regex pattern instance.
   Parameters
       obj [The object to check]
   Returns
       is_regex_compilable [bool] Whether obj can be compiled as a regex pattern.

Examples

>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False

pandas.api.types.is_scalar

pandas.api.types.is_scalar()
   Return True if given object is scalar.
   Parameters
       val [object] This includes:
       • numpy array scalar (e.g. np.int64)
       • Python builtin numerics
       • Python builtin byte arrays and strings
       • None
       • datetime.datetime
• datetime.timedelta
• Period
• decimal.Decimal
• Interval
• DateOffset
• Fraction
• Number.

Returns

    bool  Return True if given object is scalar.

Examples

```python
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True

>>> pd.api.types.is_scalar([2, 3])
False

>>> pd.api.types.is_scalar({0: 1, 2: 3})
False

>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```python
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

### 3.14.5 Bug report function

`show_versions([as_json])` Provide useful information, important for bug reports.

pandas.show_versions

pandas.show_versions (as_json=False)

Provide useful information, important for bug reports.

It comprises info about hosting operation system, pandas version, and versions of other installed relative packages.

Parameters

    as_json  [str or bool, default False]
        • If False, outputs info in a human readable form to the console.
• If str, it will be considered as a path to a file. Info will be written to that file in JSON format.
• If True, outputs info in JSON format to the console.

3.15 Extensions

These are primarily intended for library authors looking to extend pandas objects.

<table>
<thead>
<tr>
<th>api.extensions.register_extension_dtype</th>
<th>Register an ExtensionType with pandas as class decorator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>api.extensions.register_dataframe_accessor</td>
<td>Register a custom accessor on DataFrame objects.</td>
</tr>
<tr>
<td>api.extensions.register_series_accessor</td>
<td>Register a custom accessor on Series objects.</td>
</tr>
<tr>
<td>api.extensions.register_index_accessor</td>
<td>Register a custom accessor on Index objects.</td>
</tr>
<tr>
<td>api.extensions.ExtensionDtype()</td>
<td>A custom data type, to be paired with an ExtensionArray.</td>
</tr>
</tbody>
</table>

3.15.1 pandas.api.extensions.register_extension_dtype

pandas.api.extensions.register_extension_dtype(cls)
Register an ExtensionType with pandas as class decorator.

New in version 0.24.0.

This enables operations like .astype(name) for the name of the ExtensionDtype.

Returns
callable A class decorator.

Examples

```python
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     name = "myextension"
```

3.15.2 pandas.api.extensions.register_dataframe_accessor

pandas.api.extensions.register_dataframe_accessor(name)
Register a custom accessor on DataFrame objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
**register_index_accessor**  Register a custom accessor on Index objects.

**Notes**

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

**Examples**

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return float(lon.mean()), float(lat.mean())

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```python
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),  
                       "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```
3.15.3 pandas.api.extensions.register_series_accessor

```python
def __init__(self, pandas_object):  # noqa: E999
    ...  
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```bash
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

### Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:
pandas: powerful Python data analysis toolkit, Release 1.2.2

3.15.4 pandas.api.extensions.register_index_accessor

pandas.api.extensions.register_index_accessor(name)

Register a custom accessor on Index objects.

Parameters

- name [str] Name under which the accessor should be registered. A warning is issued if this
  name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

- register_dataframe_accessor Register a custom accessor on DataFrame objects.
- register_series_accessor Register a custom accessor on Series objects.
- register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the
signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...$
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your ac-
cessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
  ...AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        ...$
```

(continues on next page)
lat = self._obj.latitude
lon = self._obj.longitude
return (float(lon.mean()), float(lat.mean()))

def plot(self):
    # plot this array's data on a map, e.g., using Cartopy
    pass

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
    ...:                     "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

### 3.15.5 pandas.api.extensions.ExtensionDtype

**class** pandas.api.extensions.ExtensionDtype

A custom data type, to be paired with an ExtensionArray.

**See also:**

- extensions.register_extension_dtype: Register an ExtensionType with pandas as class decorator.
- extensions.ExtensionArray: Abstract base class for custom 1-D array types.

**Notes**

The interface includes the following abstract methods that must be implemented by subclasses:

- type
- name

The following attributes and methods influence the behavior of the dtype in pandas operations:

- _is_numeric
- _is_boolean
- _get_common_dtype

Optionally one can override construct_array_type for construction with the name of this dtype via the Registry. See `extensions.register_extension_dtype`.

- construct_array_type

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

ExtensionDtypes are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that’s the `freq` attribute.

If you have a parametrized dtype you should set the `` `_metadata`` class property.

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype.__init__` (if any). If any of the attributes in `_metadata` don’t implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

Changed in version 0.24.0: Added `_metadata`, `__hash__`, and changed the default definition of `__eq__`.

For interaction with Apache Arrow (pyarrow), a `__from_arrow__` method can be implemented: this method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas
ExtensionArray for this dtype and the passed values:

```python
class ExtensionDtype:
    def __from_arrow__(
        self, array: Union[pyarrow.Array, pyarrow.ChunkedArray]
    ) -> ExtensionArray:
        ...
```

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>kind</code></td>
<td>A character code (one of ‘biufcmMOSUV’), default ‘O’</td>
</tr>
<tr>
<td><code>na_value</code></td>
<td>Default NA value to use for this type.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>A string identifying the data type.</td>
</tr>
<tr>
<td><code>names</code></td>
<td>Ordered list of field names, or None if there are no fields.</td>
</tr>
<tr>
<td><code>type</code></td>
<td>The scalar type for the array, e.g.</td>
</tr>
</tbody>
</table>

**pandas.api.extensions.ExtensionDtype.kind**

**property** `ExtensionDtype.kind`

A character code (one of ‘biufcmMOSUV’), default ‘O’

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably ‘O’ for object if the extension type cannot be represented as a built-in NumPy type.

**See also:**

`numpy.dtype.kind`
pandas.api.extensions.ExtensionDtype.na_value

**property** ExtensionDtype.na_value
Default NA value to use for this type.

This is used in e.g. ExtensionArray.take. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for JSONArray, this is an empty dictionary.

pandas.api.extensions.ExtensionDtype.name

**property** ExtensionDtype.name
A string identifying the data type.

Will be used for display in, e.g. Series.dtype

pandas.api.extensions.ExtensionDtype.names

**property** ExtensionDtype.names
Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type

**property** ExtensionDtype.type
The scalar type for the array, e.g. int

It’s expected ExtensionArray[item] returns an instance of ExtensionDtype.type for scalar item, assuming that value is valid (not NA). NA values do not need to be instances of type.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>construct_array_type()</td>
<td>Return the array type associated with this dtype.</td>
</tr>
<tr>
<td>construct_from_string(string)</td>
<td>Construct this type from a string.</td>
</tr>
<tr>
<td>is_dtype(dtype)</td>
<td>Check if we match ‘dtype’.</td>
</tr>
</tbody>
</table>

pandas.api.extensions.ExtensionDtype.construct_array_type

**classmethod** ExtensionDtype.construct_array_type()

Return the array type associated with this dtype.

Returns
type
pandas.api.extensions.ExtensionDtype.construct_from_string

classmethod ExtensionDtype.construct_from_string(string)
Construct this type from a string.

This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as period[H] (where H means hourly frequency).

By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

Parameters

string [str] The name of the type, for example category.

Returns

ExtensionDtype Instance of the dtype.

Raises

TypeError If a class cannot be constructed from this `string`.

Examples

For extension dtypes with arguments the following may be an adequate implementation.

```python
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"\bmy_type\[(?P<arg_name>.+)\]\b")
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(f"Cannot construct a '{cls.__name__}' from '{string}'")
```

pandas.api.extensions.ExtensionDtype.is_dtype

classmethod ExtensionDtype.is_dtype(dtype)
Check if we match 'dtype'.

Parameters

dtype [object] The object to check.

Returns

bool
Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`.
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

---

**api.extensions.ExtensionArray()**
Abstract base class for custom 1-D array types.

**arrays.PandasArray(values[, copy])**
A pandas ExtensionArray for NumPy data.

### 3.15.6 pandas.api.extensions.ExtensionArray

**class pandas.api.extensions.ExtensionArray**

Abstract base class for custom 1-D array types.

Pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`.

**Notes**

The interface includes the following abstract methods that must be implemented by subclasses:

- `_from_sequence`
- `_from_factorized`
- `__getitem__`
- `__len__`
- `__eq__`
- `__str__`
- `dtype`
- `nbytes`
- `isna`
- `take`
- `copy`
- `_concat_same_type`

A default repr displaying the type, (truncated) data, length, and `dtype` is provided. It can be customized or replaced by by overriding:

- `__repr__`: A default repr for the `ExtensionArray`.
- `__format__`: Print scalars inside a Series or DataFrame.

Some methods require casting the `ExtensionArray` to an `ndarray` of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- `fillna`
- `dropna`
- `unique`
- `factorize / _values_for_factorize`
- `argsort / _values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `_reduce`
One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError)` and no register method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `.values` to ensure full compatibility with pandas internals. But other names as `.data`, `.data`, `.items`, ... can be freely used.

If implementing NumPy’s `__array_ufunc__` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in inputs. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See NumPy universal functions for more.

By default, ExtensionArrays are not hashable. Immutable subclasses may override this behavior.

## Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dtype</code></td>
<td>An instance of <code>ExtensionDtype</code>.</td>
</tr>
<tr>
<td><code>nbytes</code></td>
<td>The number of bytes needed to store this object in memory.</td>
</tr>
<tr>
<td><code>ndim</code></td>
<td>Extension Arrays are only allowed to be 1-dimensional.</td>
</tr>
<tr>
<td><code>shape</code></td>
<td>Return a tuple of the array dimensions.</td>
</tr>
</tbody>
</table>

```python
pandas.api.extensions.ExtensionArray.dtype
```

**property** `ExtensionArray.dtype`

An instance of `ExtensionDtype`. 

---

3.15. Extensions
pandas.api.extensions.ExtensionArray.nbytes

**property** ExtensionArray.nbytes
The number of bytes needed to store this object in memory.

pandas.api.extensions.ExtensionArray.ndim

**property** ExtensionArray.ndim
Extension Arrays are only allowed to be 1-dimensional.

pandas.api.extensions.ExtensionArray.shape

**property** ExtensionArray.shape
Return a tuple of the array dimensions.

Methods

- `argsort([ascending, kind, na_position])`: Return the indices that would sort this array.
- `astype(dtype, copy)`: Cast to a NumPy array with `dtype`.
- `copy()`: Return a copy of the array.
- `dropna()`: Return ExtensionArray without NA values.
- `factorize([na_sentinel])`: Encode the extension array as an enumerated type.
- `fillna([value, method, limit])`: Fill NA/NaN values using the specified method.
- `equals(other)`: Return if another array is equivalent to this array.
- `isna()`: A 1-D array indicating if each value is missing.
- `ravel([order])`: Return a flattened view on this array.
- `repeat([repeats, axis])`: Repeat elements of a ExtensionArray.
- `searchsorted(value[, side, sorter])`: Find indices where elements should be inserted to maintain order.
- `shift([periods, fill_value])`: Shift values by desired number.
- `take(indices, *[allow_fill, fill_value])`: Take elements from an array.
- `unique()`: Compute the ExtensionArray of unique values.
- `view([dtype])`: Return a view on the array.
- `_concat_same_type(to_concat)`: Concatenate multiple array of this dtype.
- `_formatter([boxed])`: Formatting function for scalar values.
- `_from_factorized(values, original)`: Reconstruct an ExtensionArray after factorization.
- `_from_sequence(scalars, *[dty, copy])`: Construct a new ExtensionArray from a sequence of scalars.
- `_from_sequence_of_strings(strings, *[dty, boxed])`: Construct a new ExtensionArray from a sequence of strings.
- `_reduce(name, *[skipna])`: Return a scalar result of performing the reduction operation.
- `_values_for_argsort()`: Return values for sorting.
- `_values_for_factorize()`: Return an array and missing value suitable for factorization.
pandas.api.extensions.ExtensionArray.argsort

ExtensionArray.argsort(ascending=True, kind='quicksort', na_position='last', *args, **kwargs)

Return the indices that would sort this array.

Parameters

- **ascending** [bool, default True] Whether the indices should result in an ascending or descending sort.
- **kind** ['quicksort', 'mergesort', 'heapsort'], optional] Sorting algorithm.
- *args, **kwargs: Passed through to numpy.argsort().

Returns

- ndarray Array of indices that sort self. If NaN values are contained, NaN values are placed at the end.

See also:

- numpy.argsort Sorting implementation used internally.

pandas.api.extensions.ExtensionArray.astype

ExtensionArray.astype(dtype, copy=True)

Cast to a NumPy array with 'dtype'.

Parameters

- **dtype** [str or dtype] Typecode or data-type to which the array is cast.
- **copy** [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

Returns

- array [ndarray] NumPy ndarray with 'dtype' for its dtype.

pandas.api.extensions.ExtensionArray.copy

ExtensionArray.copy()

Return a copy of the array.

Returns

- ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

ExtensionArray.dropna()

Return ExtensionArray without NA values.

Returns

- valid [ExtensionArray]
pandas.api.extensions.ExtensionArray.factorize

ExtensionArray.factorize(na_sentinel=-1)
Encode the extension array as an enumerated type.

Parameters

na_sentinel [int, default -1] Value to use in the codes array to indicate missing values.

Returns

codes [ndarray] An integer NumPy array that’s an indexer into the original ExtensionArray.

uniques [ExtensionArray] An ExtensionArray containing the unique values of self.

Note: uniques will not contain an entry for the NA value of the ExtensionArray if there are any missing values present in self.

See also:

factorize Top-level factorize method that dispatches here.

Notes

pandas.factorize() offers a sort keyword as well.

pandas.api.extensions.ExtensionArray.fillna

ExtensionArray.fillna(value=None, method=None, limit=None)
Fill NA/NaN values using the specified method.

Parameters

value [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like ‘value’ can be given. It’s expected that the array-like have the same length as ‘self’.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

ExtensionArray With NA/NaN filled.
pandas.api.extensions.ExtensionArray.equals

ExtensionArray.equals(other)
Return if another array is equivalent to this array.
Equivalent means that both arrays have the same shape and dtype, and all values compare equal. Missing values in the same location are considered equal (in contrast with normal equality).

Parameters
- other [ExtensionArray] Array to compare to this Array.

Returns
- boolean Whether the arrays are equivalent.

pandas.api.extensions.ExtensionArray.isna

ExtensionArray.isna()
A 1-D array indicating if each value is missing.

Returns
- na_values [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like SparseArray, where returning an ndarray would be expensive, an ExtensionArray may be returned.

Notes
If returning an ExtensionArray, then
- na_values._is_boolean should be True
- na_values should implement ExtensionArray._reduce()
- na_values.any and na_values.all should be implemented

pandas.api.extensions.ExtensionArray.ravel

ExtensionArray.ravel(order='C')
Return a flattened view on this array.

Parameters

Returns
- ExtensionArray
Notes

- Because ExtensionArrays are 1D-only, this is a no-op.
- The “order” argument is ignored, is for compatibility with NumPy.

**pandas.api.extensions.ExtensionArray.repeat**

ExtensionArray.\texttt{repeat} \((\texttt{repeats}, \texttt{axis=\text{None}})\)

Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecutively a given number of times.

**Parameters**

- \texttt{repeats} [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.
- \texttt{axis} [None] Must be \texttt{None}. Has no effect but is accepted for compatibility with numpy.

**Returns**

- \texttt{repeated\_array} [ExtensionArray] Newly created ExtensionArray with repeated elements.

**See also:**

- \texttt{Series.repeat} Equivalent function for Series.
- \texttt{Index.repeat} Equivalent function for Index.
- \texttt{numpy.repeat} Similar method for \texttt{numpy.ndarray}.
- \texttt{ExtensionArray.take} Take arbitrary positions.

**Examples**

```python
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
>>> cat.repeat(2)
['a', 'a', 'b', 'b', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
>>> cat.repeat([1, 2, 3])
['b', 'b', 'c', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
```
pandas.api.extensions.ExtensionArray.searchsorted

ExtensionArray.searchsorted(value, side='left', sorter=None)

Find indices where elements should be inserted to maintain order.

New in version 0.24.0.

Find the indices into a sorted array self (a) such that, if the corresponding elements in value were inserted before the indices, the order of self would be preserved.

Assuming that self is sorted:

<table>
<thead>
<tr>
<th>side</th>
<th>returned index i satisfies</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>self[i-1] &lt; value &lt;= self[i]</td>
</tr>
<tr>
<td>right</td>
<td>self[i-1] &lt;= value &lt; self[i]</td>
</tr>
</tbody>
</table>

Parameters

- value [array_like] Values to insert into self.
- side [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of self).
- sorter [1-D array_like, optional] Optional array of integer indices that sort array a into ascending order. They are typically the result of argsort.

Returns

- array of ints Array of insertion points with the same shape as value.

See also:

- numpy.searchsorted Similar method from NumPy.

pandas.api.extensions.ExtensionArray.shift

ExtensionArray.shift(periods=1, fill_value=None)

Shift values by desired number.

Newly introduced missing values are filled with self.dtype.na_value.

New in version 0.24.0.

Parameters

- periods [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.
- fill_value [object, optional] The scalar value to use for newly introduced missing values. The default is self.dtype.na_value.

New in version 0.24.0.

Returns

- ExtensionArray Shifted.
Notes

If `self` is empty or `periods` is 0, a copy of `self` is returned.

If `periods > len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

pandas.api.extensions.ExtensionArray.take

`ExtensionArray.take(indices, *, allow_fill=False, fill_value=None)`

Take elements from an array.

Parameters

- `indices` [sequence of int] Indices to be taken.
- `allow_fill` [bool, default False] How to handle negative values in `indices`.
  - False: negative values in `indices` indicate positional indices from the right (the default). This is similar to `numpy.take()`.
  - True: negative values in `indices` indicate missing values. These values are set to `fill_value`. Any other other negative values raise a `ValueError`.
- `fill_value` [any, optional] Fill value to use for NA-indices when `allow_fill` is True. This may be `None`, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many ExtensionArrays, there will be two representations of `fill_value`: a user-facing “boxed” scalar, and a low-level physical NA value. `fill_value` should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

Returns

`ExtensionArray`

Raises

- `IndexError` When the indices are out of bounds for the array.
- `ValueError` When `indices` contains negative values other than `-1` and `allow_fill` is True.

See also:

- `numpy.take` Take elements from an array along an axis.
- `api.extensions.take` Take elements from an array.

Notes

ExtensionArray.take is called by `Series.__getitem__.loc, iloc`, when `indices` is a sequence of values. Additionally, it’s called by `Series.reindex()`, or any other method that causes realignment, with a `fill_value`. 
Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method pandas.api.extensions.take().

```python
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.
    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

pandas.api.extensions.ExtensionArray.unique

ExtensionArray.unique()

Compute the ExtensionArray of unique values.

Returns

uniques [ExtensionArray]

pandas.api.extensions.ExtensionArray.view

ExtensionArray.view(dtype=None)

Return a view on the array.

Parameters

dtype [str, np.dtype, or ExtensionDtype, optional] Default None.

Returns

ExtensionArray or np.ndarray  A view on the ExtensionArray's data.

pandas.api.extensions.ExtensionArray._concat_same_type

classmethod ExtensionArray._concat_same_type(to_concat)

Concatenate multiple array of this dtype.

Parameters

to_concat [sequence of this type]

Returns

ExtensionArray
**pandas.api.extensions.ExtensionArray._formatter**

ExtensionArray._formatter(boxed=False)

Formatting function for scalar values.

This is used in the default `__repr__`. The returned formatting function receives instances of your scalar type.

**Parameters**

- boxed [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

**Returns**

Callable[[Any], str] A callable that gets instances of the scalar type and returns a string. By default, `repr()` is used when boxed=False and `str()` is used when boxed=True.

**pandas.api.extensions.ExtensionArray._from_factorized**

classmethod ExtensionArray._from_factorized(values, original)

Reconstruct an ExtensionArray after factorization.

**Parameters**

- values [ndarray] An integer ndarray with the factorized values.
- original [ExtensionArray] The original ExtensionArray that factorize was called on.

**See also:**

- `factorize` Top-level factorize method that dispatches here.
- `ExtensionArray.factorize` Encode the extension array as an enumerated type.

**pandas.api.extensions.ExtensionArray._from_sequence**

classmethod ExtensionArray._from_sequence(scalars, *, dtype=None, copy=False)

Construct a new ExtensionArray from a sequence of scalars.

**Parameters**

- scalars [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type` or be converted into this type in this method.
- dtype [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.
- copy [bool, default False] If True, copy the underlying data.

**Returns**

ExtensionArray
pandas.api.extensions.ExtensionArray._from_sequence_of_strings

classmethod ExtensionArray._from_sequence_of_strings(strings, *, dtype=None, copy=False)

Construct a new ExtensionArray from a sequence of strings.

New in version 0.24.0.

Parameters

- **strings** [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.
- **dtype** [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.
- **copy** [bool, default False] If True, copy the underlying data.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._reduce

ExtensionArray._reduce(name, *, skipna=True, **kwargs)

Return a scalar result of performing the reduction operation.

Parameters

- **name** [str] Name of the function, supported values are: { any, all, min, max, sum, mean, median, prod, std, var, sem, kurt, skew }.
- **skipna** [bool, default True] If True, skip NaN values.
- **kwargs** Additional keyword arguments passed to the reduction function. Currently, `ddof` is the only supported kwarg.

Returns

scalar

Raises

TypeError [subclass does not define reductions]

pandas.api.extensions.ExtensionArray._values_for_argsort

ExtensionArray._values_for_argsort()

Return values for sorting.

Returns

ndarray The transformed values should maintain the ordering between values within the array.

See also:

ExtensionArray.argsort Return the indices that would sort this array.
pandas.api.extensions.ExtensionArray._values_for_factorize

ExtensionArray._values_for_factorize()
Return an array and missing value suitable for factorization.

Returns

values [ndarray] An array suitable for factorization. This should maintain order and be a supported dtype (Float64, Int64, UInt64, String, Object). By default, the extension array is cast to object dtype.

na_value [object] The value in values to consider missing. This will be treated as NA in the factorization routines, so it will be coded as na_sentinel and not included in uniques. By default, np.nan is used.

Notes

The values returned by this method are also used in pandas.util.hash_pandas_object().

3.15.7 pandas.arrays.PandasArray

class pandas.arrays.PandasArray(values, copy=False)
A pandas ExtensionArray for NumPy data.

New in version 0.24.0.

This is mostly for internal compatibility, and is not especially useful on its own.

Parameters

values [ndarray] The NumPy ndarray to wrap. Must be 1-dimensional.

copy [bool, default False] Whether to copy values.

Attributes

None

Methods

None

Additionally, we have some utility methods for ensuring your object behaves correctly.

api.indexers.check_array_indexer(array, indexer) Check if indexer is a valid array indexer for array.
3.15.8 pandas.api.indexers.check_array_indexer

pandas.api.indexers.check_array_indexer(array, indexer)
Check if indexer is a valid array indexer for array.

For a boolean mask, array and indexer are checked to have the same length. The dtype is validated, and if it is an integer or boolean ExtensionArray, it is checked if there are missing values present, and it is converted to the appropriate numpy array. Other dtypes will raise an error.

Non-array indexers (integer, slice, Ellipsis, tuples, ..) are passed through as is.

New in version 1.0.0.

Parameters

array [array-like] The array that is being indexed (only used for the length).
indexer [array-like or list-like] The array-like that’s used to index. List-like input that is not yet a numpy array or an ExtensionArray is converted to one. Other input types are passed through as is.

Returns

numpy.ndarray The validated indexer as a numpy array that can be used to index.

Raises

IndexError When the lengths don’t match.

ValueError When indexer cannot be converted to a numpy ndarray to index (e.g. presence of missing values).

See also:

api.types.is_bool_dtype Check if key is of boolean dtype.

Examples

When checking a boolean mask, a boolean ndarray is returned when the arguments are all valid.

```python
>>> mask = pd.array([True, False])
>>> arr = pd.array([1, 2])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([[ True, False]])
```

An IndexError is raised when the lengths don’t match.

```python
>>> mask = pd.array([True, False, True])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
  ...
IndexError: Boolean index has wrong length: 3 instead of 2.
```

NA values in a boolean array are treated as False.

```python
>>> mask = pd.array([True, pd.NA])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([[ True, False]])
```

A numpy boolean mask will get passed through (if the length is correct):
```python
>>> mask = np.array([True, False])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])

Similarly for integer indexers, an integer ndarray is returned when it is a valid indexer, otherwise an error is (for
integer indexers, a matching length is not required):

```python
>>> indexer = pd.array([0, 2], dtype="Int64")
>>> arr = pd.array([1, 2, 3])
>>> pd.api.indexers.check_array_indexer(arr, indexer)
array([0, 2])

```python
>>> indexer = pd.array([0, pd.NA], dtype="Int64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
 ...  
ValueError: Cannot index with an integer indexer containing NA values
```

For non-integer/boolean dtypes, an appropriate error is raised:

```python
>>> indexer = np.array([0., 2.], dtype="float64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
 ...  
IndexError: arrays used as indices must be of integer or boolean type
```

The sentinel `pandas.api.extensions.no_default` is used as the default value in some methods. Use an `is`
comparison to check if the user provides a non-default value.

4.1.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the GitHub “issues” tab to find issues that interest you. There are a number of issues listed under Docs and good first issue where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

When you start working on an issue, it’s a good idea to assign the issue to yourself, so nobody else duplicates the work on it. GitHub restricts assigning issues to maintainers of the project only. In most projects, and until recently in pandas, contributors added a comment letting others know they are working on an issue. While this is ok, you need to check each issue individually, and it’s not possible to find the unassigned ones.

For this reason, we implemented a workaround consisting of adding a comment with the exact text take. When you
do it, a GitHub action will automatically assign you the issue (this will take seconds, and may require refreshing the page to see it). By doing this, it’s possible to filter the list of issues and find only the unassigned ones.

So, a good way to find an issue to start contributing to pandas is to check the list of unassigned good first issues and assign yourself one you like by writing a comment with the exact text take.

If for whatever reason you are not able to continue working with the issue, please try to unassign it, so other people know it’s available again. You can check the list of assigned issues, since people may not be working in them anymore. If you want to work on one that is assigned, feel free to kindly ask the current assignee if you can take it (please allow at least a week of inactivity before considering work in the issue discontinued).

Feel free to ask questions on the mailing list or on Gitter.

### 4.1.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See this stackoverflow article and this blogpost for tips on writing a good bug report.

Trying the bug-producing code out on the master branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using GitHub Flavored Markdown:

```python
>>> from pandas import DataFrame
df = DataFrame(...)...```

2. Include the full version string of pandas and its dependencies. You can use the built-in function:

```python
>>> import pandas as pd
>>> pd.show_versions()```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the pandas community and be open to comments/ideas from others.

### 4.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.
Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on GitHub. To contribute you will need to sign up for a free GitHub account. We use Git for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the GitHub help pages.
- the NumPy’s documentation.
- Matthew Brett’s Pydagogue.

Getting started with Git

GitHub has instructions for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

Forking

You will need your own fork to work on the code. Go to the pandas project page and hit the Fork button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
# git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory pandas-yourname and connects your repository to the upstream (main project) pandas repository.

Note that performing a shallow clone (with `--depth==N`, for some N greater or equal to 1) might break some tests and features as `pd.show_versions()` as the version number cannot be computed anymore.

Creating a development environment

To test out code changes, you’ll need to build pandas from source, which requires a C/C++ compiler and Python environment. If you’re making documentation changes, you can skip to Contributing to the documentation but if you skip creating the development environment you won’t be able to build the documentation locally before pushing your changes.

Using a Docker container

Instead of manually setting up a development environment, you can use Docker to automatically create the environment with just several commands. pandas provides a DockerFile in the root directory to build a Docker image with a full pandas development environment.

Docker Commands

Pass your GitHub username in the DockerFile to use your own fork:
Even easier, you can integrate Docker with the following IDEs:

**Visual Studio Code**

You can use the DockerFile to launch a remote session with Visual Studio Code, a popular free IDE, using the .devcontainer.json file. See https://code.visualstudio.com/docs/remote/containers for details.

**PyCharm (Professional)**

Enable Docker support and use the Services tool window to build and manage images as well as run and interact with containers. See https://www.jetbrains.com/help/pycharm/docker.html for details.

Note that you might need to rebuild the C extensions if/when you merge with upstream/master using:

```
python setup.py build_ext -j 4
```

**Installing a C compiler**

pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you’re using.

If you have setup your environment using *conda*, the packages *c-compiler* and *cxx-compiler* will install a fitting compiler for your platform that is compatible with the remaining conda packages. On Windows and macOS, you will also need to install the SDks as they have to be distributed separately. These packages will be automatically installed by using *pandas's environment.yml*.

**Windows**

You will need *Build Tools for Visual Studio 2017*.

**Warning:** You **DO NOT** need to install Visual Studio 2019. You only need “Build Tools for Visual Studio 2019” found by scrolling down to “All downloads” -> “Tools for Visual Studio 2019”. In the installer, select the “C++ build tools” workload.

You can install the necessary components on the commandline using *vs_buildtools.exe*:

```
vs_buildtools.exe --quiet --wait --norestart --nocache ^
--installPath C:\BuildTools ^
--add "Microsoft.VisualStudio.Workload.VCTools;includeRecommended" ^
--add Microsoft.VisualStudio.Component.VC.v141 ^
--add Microsoft.VisualStudio.Component.VC.v141.x86.x64 ^
```

To setup the right paths on the commandline, call "C:\BuildTools\VC\Auxiliary\Build\vcvars64.bat" -vcvars_ver=14.16 10.0.17763.0.

**macOS**

4.1. Contributing to pandas
pandas: powerful Python data analysis toolkit, Release 1.2.2

To use the conda-based compilers, you will need to install the Developer Tools using xcode-select --install. Otherwise information about compiler installation can be found here: https://devguide.python.org/setup/#macos

Linux

For Linux-based conda installations, you won’t have to install any additional components outside of the conda environment. The instructions below are only needed if your setup isn’t based on conda environments.

Some Linux distributions will come with a pre-installed C compiler. To find out which compilers (and versions) are installed on your system:

```
# for Debian/Ubuntu:
dpkg --list | grep compiler
# for Red Hat/RHEL/CentOS/Fedora:
yum list installed | grep -i --color compiler
```

GCC (GNU Compiler Collection), is a widely used compiler, which supports C and a number of other languages. If GCC is listed as an installed compiler nothing more is required. If no C compiler is installed (or you wish to install a newer version) you can install a compiler (GCC in the example code below) with:

```
# for recent Debian/Ubuntu:
sudo apt install build-essential
# for Red Hat/RHEL/CentOS/Fedora
yum groupinstall "Development Tools"
```

For other Linux distributions, consult your favourite search engine for compiler installation instructions.

Let us know if you have any difficulties by opening an issue or reaching out on Gitter.

Creating a Python environment

Now create an isolated pandas development environment:

- Install either Anaconda, miniconda, or miniforge
- Make sure your conda is up to date (conda update conda)
- Make sure that you have cloned the repository
- cd to the pandas source directory

We’ll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
# Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-ppx517
```
At this point you should be able to import pandas from your locally built version:

```
$ python # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs here.

**Creating a Python environment (pip)**

If you aren’t using conda for your development environment, follow these instructions. You’ll need to have at least Python 3.6.1 installed on your system.

**Unix/macOS with virtualenv**

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We’ll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev

# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

**Unix/macOS with pyenv**

Consult the docs for setting up pyenv here.

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We’ll use ~/Users/<yourname>/.pyenv/versions/pandas-dev
pyenv virtualenv <version> <name-to-give-it>

# For instance:
pyenv virtualenv 3.7.6 pandas-dev

# Activate the virtualenv
pyenv activate pandas-dev
```

(continues on next page)
# Now install the build dependencies in the cloned pandas repo
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517

## Windows

Below is a brief overview on how to set-up a virtual environment with Powershell under Windows. For details please refer to the official virtualenv user guide.

Use an ENV_DIR of your choice. We’ll use ~\virtualenv\pandas-dev where ‘~’ is the folder pointed to by either $env:USERPROFILE (Powershell) or %USERPROFILE% (cmd.exe) environment variable. Any parent directories should already exist.

```bash
# Create a virtual environment
python -m venv $env:USERPROFILE\virtualenvs\pandas-dev

# Activate the virtualenv. Use activate.bat for cmd.exe
-\virtualenvs\pandas-dev\Scripts\Activate.ps1

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

### Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```bash
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```bash
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to pandas. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```bash
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on updating a PR.
4.1.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don’t have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn’t make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

Documentation:

- About the pandas documentation
- Updating a pandas docstring
- How to build the pandas documentation
  - Requirements
  - Building the documentation
  - Building master branch documentation

About the pandas documentation

The documentation is written in reStructuredText, which is almost like writing in plain English, and built using Sphinx. The Sphinx Documentation has an excellent introduction to reST. Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder doc/.
  
The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what’s new, installation, etc).

- The docstrings follow a pandas convention, based on the Numpy Docstring Standard. Follow the pandas docstring guide for detailed instructions on how to write a correct docstring.

pandas docstring guide

About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.

The next example gives an idea of what a docstring looks like:

```python
def add(num1, num2):
    """
    Add up two integer numbers.

    This function simply wraps the `+` operator, and does not
    ```
(continues on next page)
do anything interesting, except for illustrating what the docstring of a very simple function looks like.

Parameters
----------
num1 : int
    First number to add.
num2 : int
    Second number to add.

Returns
-------
int
    The sum of `\texttt{num1}` and `\texttt{num2}`.

See Also
--------
subtract : Subtract one integer from another.

Examples
--------
>>> add(2, 2)
4
>>> add(25, 0)
25
>>> add(10, -10)
0
***
    return num1 + num2

Some standards regarding docstrings exist, which make them easier to read, and allow them be easily exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite broad, other more specific standards also exist. In the case of pandas, the NumPy docstring convention is followed. These conventions are explained in this document:

- numpydoc docstring guide (which is based in the original Guide to NumPy/SciPy documentation)
numpydoc is a Sphinx extension to support the NumPy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- Sphinx reStructuredText primer
- Quick reStructuredText reference
- Full reStructuredText specification

pandas has some helpers for sharing docstrings between related classes, see Sharing docstrings.

The rest of this document will summarize all the above guidelines, and will provide additional conventions specific to the pandas project.
Writing a docstring

General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

On rare occasions reST styles like bold text or italics will be used in docstrings, but it is common to have inline code, which is presented between backticks. The following are considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. os, list, numpy.abs, datetime, date, True)
- A pandas class (in the form `class:`pandas.Series`)
- A pandas method (in the form `meth:`pandas.Series.sum`)
- A pandas function (in the form `func:`pandas.to_datetime`)

**Note:** To display only the last component of the linked class, method or function, prefix it with ~. For example, `class:`~pandas.Series` will link to pandas.Series but only display the last part, Series as the link text. See Sphinx cross-referencing syntax for details.

Good:

```python
def add_values(arr):
    ""
    Add the values in `arr`.
    This is equivalent to Python `sum` of `meth:`pandas.Series.sum`.
    Some sections are omitted here for simplicity.
    ""
    return sum(arr)
```

Bad:

```python
def func():
    """Some function.
    With several mistakes in the docstring.
    It has a blank line after the signature `def func():`
    The text 'Some function' should go in the line after the opening quotes of the docstring, not in the same line.
    There is a blank line between the docstring and the first line of code `foo = 1`.
    The closing quotes should be in the next line, not in this one.""
    foo = 1
```

(continues on next page)
bar = 2
return foo + bar

Section 1: short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

Good:

```python
def astype(dtype):
    """
    Cast Series type.
    This section will provide further details.
    """
    pass
```

Bad:

```python
def astype(dtype):
    """
    Casts Series type.
    Verb in third-person of the present simple, should be infinitive.
    """
    pass
```

```python
def astype(dtype):
    """
    Method to cast Series type.
    Does not start with verb.
    """
    pass
```

```python
def astype(dtype):
    """
    Cast Series type
    Missing dot at the end.
    """
    pass
```

```python
def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in
    the parameter dtype.
    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```
**Section 2: extended summary**

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. Every paragraph in the extended summary ends with a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```python
def unstack():
    
    Pivot a row index to columns.

    When using a MultiIndex, a level can be pivoted so each value in
    the index becomes a column. This is especially useful when a subindex
    is repeated for the main index, and data is easier to visualize as a
    pivot table.

    The index level will be automatically removed from the index when added
    as columns.

    
    pass
```

**Section 3: parameters**

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including `*args` and `**kwargs`, but not `self`.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for `*args` and `**kwargs`, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is `None`, meaning that the value will not be used. Instead of "str, default None ", it is preferred to write "str, optional". When None is a value being used, we will keep the form “str, default None”. For example, in `df.to_csv(compression=None)`, None is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use "str, optional". Only in cases like `func(value=None)` and `None` is being used in the same way as 0 or `foo` would be used, then we will specify "str, int or None, default None".

**Good:**

```python
class Series:
    def plot(self, kind, color='blue', **kwargs):
        
        Generate a plot.
```

(continues on next page)
Render the data in the Series as a matplotlib plot of the specified kind.

Parameters
----------
kind : str
    Kind of matplotlib plot.
color : str, default 'blue'
    Color name or rgb code.
**kwargs
    These parameters will be passed to the matplotlib plotting function.

""
pass

Bad:

class Series:
    def plot(self, kind, **kwargs):
        ""
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the specified kind.

        Note the blank line between the parameters title and the first parameter. Also, note that after the name of the parameter `kind` and before the colon, a space is missing.

        Also, note that the parameter descriptions do not start with a capital letter, and do not finish with a dot.

        Finally, the `**kwargs` parameter is missing.

        Parameters
        ----------
        kind: str
            kind of matplotlib plot
        ""
        pass

Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool
For complex types, define the subtypes. For `dict` and `tuple`, as more than one type is present, we use the brackets to help read the type (curly brackets for `dict` and normal brackets for `tuple`):

- list of int
- dict of `{str : int}`
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- `{0, 10, 25}`
- `{‘simple’, ‘advanced’}`
- `{‘low’, ‘medium’, ‘high’}`
- `{‘cat’, ‘dog’, ‘bird’}`

If the type is defined in a Python module, the module must be specified:

- `datetime.date`
- `datetime.datetime`
- `decimal.Decimal`

If the type is in a package, the module must be also specified:

- `numpy.ndarray`
- `scipy.sparse.coo_matrix`

If the type is a pandas type, also specify pandas except for Series and DataFrame:

- `Series`
- `DataFrame`
- `pandas.Index`
- `pandas.Categorical`
- `pandas.arrays.SparseArray`

If the exact type is not relevant, but must be compatible with a NumPy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:

- int or float
- float, decimal.Decimal or None
- str or list of str

If `None` is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:
– axis : {0 or ‘index’, 1 or ‘columns’, None}, default None

Section 4: returns or yields

If the method returns a value, it will be documented in this section. Also if the method yields its output. The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```python
def sample():
    """
    Generate and return a random number.

    The value is sampled from a continuous uniform distribution between
    0 and 1.
    
    Returns
    -------
    float
        Random number generated.
    """
    return np.random.random()
```

With more than one value:

```python
import string

def random_letters():
    """
    Generate and return a sequence of random letters.

    The length of the returned string is also random, and is also
    returned.
    
    Returns
    -------
    length : int
        Length of the returned string.
    letters : str
        String of random letters.
    """
    length = np.random.randint(1, 10)
    letters = ''.join(np.random.choice(string.ascii_lowercase)
                      for i in range(length))
    return length, letters
```

If the method yields its value:

```python
def sample_values():
    """
    (continues on next page)
```
Generate an infinite sequence of random numbers.

The values are sampled from a continuous uniform distribution between 0 and 1.

Yields
------
float
    Random number generated.
    
while True:
    yield np.random.random()

Section 5: see also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the `head()` and `tail()` methods. As `tail()` does the equivalent as `head()` but at the end of the `Series` or `DataFrame` instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `items`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section has a header, “See Also” (note the capital S and A), followed by the line with hyphens and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrates what this method or function does, why is it relevant in this context, and what the key differences are between the documented function and the one being referenced. The description must also end with a dot.

Note that in “Returns” and “Yields”, the description is located on the line after the type. In this section, however, it is located on the same line, with a colon in between. If the description does not fit on the same line, it can continue onto other lines which must be further indented.
For example:

class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.
        """
        Returns
        ------
        Series
            Subset of the original series with the 5 first values.
        See Also
        ------
        Series.tail : Return the last 5 elements of the Series.
        Series.iloc : Return a slice of the elements in the Series,
            which can also be used to return the first or last n.
        """
        return self.iloc[:5]

Section 6: notes

This is an optional section used for notes about the implementation of the algorithm, or to document technical
aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some
counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

Section 7: examples

This is one of the most important sections of a docstring, despite being placed in the last position, as often
people understand concepts better by example than through accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that
returns the given output in a deterministic way, and that can be copied and run by users.

Examples are presented as a session in the Python terminal. >>> is used to present code. ... is used for code
continuing from the previous line. Output is presented immediately after the last line of code generating the
output (no blank lines in between). Comments describing the examples can be added with blank lines before
and after them.

The way to present examples is as follows:

1. Import required libraries (except numpy and pandas)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:
class Series:

def head(self, n=5):
    """
    Return the first elements of the Series.

    This function is mainly useful to preview the values of the Series without displaying all of it.

    Parameters
    --------
    n : int
        Number of values to return.

    Return
    -----
    pandas.Series
        Subset of the original series with the n first values.

    See Also
    --------
    tail : Return the last n elements of the Series.

    Examples
    --------
    >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
    ...                   'Lion', 'Monkey', 'Rabbit', 'Zebra'])
    >>> s.head()
    0    Ant
    1    Bear
    2    Cow
    3    Dog
    4   Falcon
dtype: object

    With the `\n` parameter, we can change the number of returned rows:

    >>> s.head(n=3)
    0    Ant
    1    Bear
    2    Cow
dtype: object
    """
    return self.iloc[:n]

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star ** to make a text bold, like in **this example**.
Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```python
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in PEP 8 imports) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single Series use the name s, and if illustrating with a single DataFrame use the name df. For indices, idx is the preferred name. If a set of homogeneous Series or DataFrame is used, name them s1, s2, s3... or df1, df2, df3... If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example df_main and df_to_join.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the head method, it requires to be higher than 5, to show the example with the default values. If doing the mean, we could use something like [1, 2, 3], so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments head(n=3) are preferred to positional arguments head(3).

Good:

```python
class Series:
    def mean(self):
        """
        Compute the mean of the input.
        Examples
        --------
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

    def fillna(self, value):
        """
        Replace missing values by `value`.
        Examples
        --------
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
```

(continues on next page)
Group by index and return mean.

Examples
---------
>>> s = pd.Series([380., 370., 24., 26],
... name='max_speed',
... index=['falcon', 'falcon', 'parrot', 'parrot'])
>>> s.groupby_mean()
index
falcon  375.0
parrot  25.0
Name: max_speed, dtype: float64

def contains(self, pattern, case_sensitive=True, na=numpy.nan):
    
    Return whether each value contains `pattern`.

    In this case, we are illustrating how to use sections, even
    if the example is simple enough and does not require them.

    Examples
    --------
    >>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
    >>> s.contains(pattern='a')
    0   False
    1   False
    2    True
    3     NaN
    dtype: bool

    **Case sensitivity**

    With `case_sensitive` set to `False` we can match `a` with both
    `a` and `A`:

    >>> s.contains(pattern='a', case_sensitive=False)
    0    True
    1   False
    2    True
    3     NaN
    dtype: bool

    **Missing values**

    We can fill missing values in the output using the `na` parameter:

    >>> s.contains(pattern='a', na=False)
    0   False
    1   False
    2    True
    3    False
    dtype: bool

    pass
Bad:

```python
def method(foo=None, bar=None):
    
    A sample DataFrame method.

    Do not import NumPy and pandas.

    Try to use meaningful data, when it makes the example easier to understand.

    Try to avoid positional arguments like in `df.method(1)` . They can be all right if previously defined with a meaningful name, like in `present_value(interest_rate)` , but avoid them otherwise.

    When presenting the behavior with different parameters, do not place all the calls one next to the other. Instead, add a short sentence explaining what the example shows.

    Examples
    --------
    >>> import numpy as np
    >>> import pandas as pd
    >>> df = pd.DataFrame(np.random.randn(3, 3),
    ... columns=('a', 'b', 'c'))
    >>> df.method(1)
    21
    >>> df.method(bar=14)
    123
    
    pass
```

Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and NumPy, those are already imported as import pandas as pd and import numpy as np) and define all variables you use in the example.

- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

  ```python
  >>> np.random.seed(42)
  >>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
  ```

- If you have a code snippet that wraps multiple lines, you need to use ‘…” on the continued lines:

  ```python
  >>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'], columns=['A', 'B'])
  ```

- If you want to show a case where an exception is raised, you can do:
It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use ... to represent this part.

If you want to show that `s.plot()` returns a `matplotlib.AxesSubplot` object, this will fail the doctest

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

## Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```python
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.
        
        Examples
        -------
        .. plot::
            :context: close-figs
            >>> s = pd.Series([1, 2, 3])
            >>> s.plot()
        """
        pass
```

## Sharing docstrings

pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `{klass}`. The variables filled in later on using the `doc` decorator. Finally, docstrings can also be appended to with the `doc` decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the class names in this docstring.
class Parent:
    @doc(klass="Parent")
    def my_function(self):
        """Apply my function to {klass}."""
        ...

class ChildA(Parent):
    @doc(Parent.my_function, klass="ChildA")
    def my_function(self):
        ...

class ChildB(Parent):
    @doc(Parent.my_function, klass="ChildB")
    def my_function(self):
        ...

The resulting docstrings are

>>> print(Parent.my_function.__doc__)
Apply my function to Parent.

>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.

>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.

Notice:

1. We “append” the parent docstring to the children docstrings, which are initially empty.

Our files will often contain a module-level _shared_doc_kwargs with some common substitution values (things like klass, axes, etc).

You can substitute and append in one shot with something like

@doc(template, **_shared_doc_kwargs)
def my_function(self):
    ...

where template may come from a module-level _shared_docs dictionary mapping function names to docstrings. Wherever possible, we prefer using doc, since the docstring-writing processes is slightly closer to normal.

See pandas.core.generic.NDFrame.fillna for an example template, and pandas.core.series.Series.fillna and pandas.core.generic.frame.fillna for the filled versions.

• The tutorials make heavy use of the IPython directive sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

.. ipython:: python

    x = 2
    x**3

will be rendered as:

In [1]: x = 2

(continues on next page)
Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation files in `doc/source/reference` house the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The Attributes and Methods sections will be automatically added to the class’ rendered documentation by numpydoc. See `DataFrame` for an example.

2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an Attributes and Methods section in the class docstring. See `CategoricalIndex` for an example.

Every method should be included in a toctree in one of the documentation files in `doc/source/reference`, else Sphinx will emit a warning.

**Note:** The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/development/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use `pandoc` with the following command:

```
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in the files in `doc/source/reference` (which is used to generate the API Reference page) and the actual public methods. This will identify methods documented in `doc/source/reference` that are not actually class methods, and existing methods that are not documented in `doc/source/reference`.

**Updating a pandas docstring**

When improving a single function or method’s docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the `DataFrame.mean` method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the `pandas docstring guide` for a detailed guide on how to format the docstring.

The examples in the docstring (‘doctests’) must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the examples section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

**4.1. Contributing to pandas**
How to build the pandas documentation

Requirements

First, you need to have a development environment to be able to build pandas (see the docs on creating a development environment above).

Building the documentation

So how do you build the docs? Navigate to your local doc/ directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder doc/build/html/.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api

# compile the docs with only a single section, relative to the "source" folder.
# For example, compiling only this guide (doc/source/development/contributing.rst)
python make.py clean
python make.py --single development/contributing.rst

# compile the reference docs for a single function
python make.py clean
python make.py --single pandas.DataFrame.join
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you’ll have the satisfaction of seeing your new and improved documentation!
Building master branch documentation

When pull requests are merged into the pandas master branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted here, see also the Continuous Integration section.

4.1.5 Contributing to the code base

Code Base:

- Code standards
- Pre-commit
- Optional dependencies
  - C (cpplint)
  - Python (PEP8 / black)
  - Import formatting
  - Backwards compatibility
- Type hints
  - Style guidelines
  - pandas-specific types
  - Validating type hints
- Testing with continuous integration
- Test-driven development/code writing
  - Writing tests
  - Transitioning to pytest
  - Using pytest
  - Using hypothesis
  - Testing warnings
- Running the test suite
- Running the performance test suite
- Documenting your code
**Code standards**

Writing good code is not just about what you write. It is also about *how* you write it. During *Continuous Integration* testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

```
./ci/code_checks.sh
```

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters *lint, patterns* and *doctests* (e.g. ./ci/code_checks.sh lint).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as *backwards compatible* as possible to avoid mass breakages.

In addition to ./ci/code_checks.sh, some extra checks are run by `pre-commit` - see [here](#) for how to run them.

Additional standards are outlined on the [pandas code style guide](#).

**Pre-commit**

You can run many of these styling checks manually as we have described above. However, we encourage you to use `pre-commit hooks` instead to automatically run `black, flake8, isort` when you make a git commit. This can be done by installing `pre-commit`:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the pandas repository. Now all of the styling checks will be run each time you commit changes without your needing to run each one manually. In addition, using `pre-commit` will also allow you to more easily remain up-to-date with our code checks as they change.

Note that if needed, you can skip these checks with `git commit --no-verify`.

If you don’t want to use `pre-commit` as part of your workflow, you can still use it to run its checks with:

```
pre-commit run --files <files you have modified>
```

without needing to have done `pre-commit install` beforehand.

*Note: If you have conflicting installations of virtualenv, then you may get an error - see [here](#).*

Also, due to a *bug in virtualenv*, you may run into issues if you’re using conda. To solve this, you can downgrade virtualenv to version 20.0.33.
Optional dependencies

Optional dependencies (e.g. matplotlib) should be imported with the private helper pandas.compat._optional.import_optional_dependency. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an ImportError is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in Optional dependencies and the minimum required version should be set in the pandas.compat._optional.VERSIONS dict.

C (cpplint)

pandas uses the Google standard. Google provides an open source style checker called cpplint, but we use a fork of it that can be found here. Here are some of the more common cpplint issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the cpplint tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```bash
$ cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```bash
$ cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the ClangFormat tool, which can be downloaded here. To configure, in your home directory, run the following command:

```bash
$ clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```bash
$ clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```bash
$ clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```bash
$ clang-format modified-c-directory/*.c modified-c-directory/*.h
$ clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct all of them. Thus, it is recommended that you run cpplint to double check and make any other style fixes manually.

4.1. Contributing to pandas
Python (PEP8 / black)

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project. We encourage you to use pre-commit.

Continuous Integration will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
black pandas
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply black as you edit files.

You should use a black version 20.8b1 as previous versions are not compatible with the pandas codebase.

One caveat about git diff upstream/master -u -- "*.py" | flake8 --diff: this command will catch any stylistic errors in your changes specifically, but beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it may take longer:

```
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the -r flag is not available, so you have to omit it and run this slightly modified command:

```
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the xargs command (unless installed for example via the MinGW toolchain), but one can imitate the behaviour as follows:

```
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with .py), and run flake8 on them, one after the other.

Note that these commands can be run analogously with black.

Import formatting

pandas uses isort to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found here.

A summary of our current import sections (in order):

- Future
- Python Standard Library
- Third Party
  - pandas._libs, pandas.compat, pandas.util.*, pandas.errors (largely not dependent on pandas.core)
  - pandas.core.dtypes (largely not dependent on the rest of pandas.core)
- Rest of pandas.core.*
- Non-core pandas.io, pandas.plotting, pandas.tseries
- Local application/library specific imports
Imports are alphabetically sorted within these sections.

As part of Continuous Integration checks we run:

```
isort --check-only pandas
```

to check that imports are correctly formatted as per the `setup.cfg`.

If you see output like the below in Continuous Integration checks:

```
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are incorrectly sorted
The command "ci/code_checks.sh" exited with 1
```

You should run:

```
isort pandas/io/pytables.py
```

to automatically format imports correctly. This will modify your local copy of the files.

Alternatively, you can run a command similar to what was suggested for black and flake8 right above:

```
git diff upstream/master --name-only -- '*.py' | xargs -r isort
```

Where similar caveats apply if you are on OSX or Windows.

You can then verify the changes look ok, then git commit and push.

**Backwards compatibility**

Please try to maintain backward compatibility. pandas has lots of users with lots of existing code, so don’t break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate
deprecate('old_func', 'new_func', '1.1.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
    """Summary of the function.

    .. deprecated:: 1.1.0
        Use new_func instead.
    """
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()
```

(continues on next page)
def new_func():
    pass

You’ll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See Testing warnings for more.

**Type hints**

pandas strongly encourages the use of PEP 484 style type hints. New development should contain type hints and pull requests to annotate existing code are accepted as well!

**Style guidelines**

Types imports should follow the from typing import ... convention. So rather than

```python
import typing
primes: typing.List[int] = []
```

You should write

```python
from typing import List, Optional, Union
primes: List[int] = []
```

`Optional` should be used where applicable, so instead of

```python
maybe_primes: List[Union[int, None]] = []
```

You should write

```python
maybe_primes: List[Optional[int]] = []
```

In some cases in the code base classes may define class variables that shadow builtins. This causes an issue as described in Mypy 1775. The defensive solution here is to create an unambiguous alias of the builtin and use that without your annotation. For example, if you come across a definition like

```python
class SomeClass1:
    str = None
```

The appropriate way to annotate this would be as follows

```python
str_type = str
class SomeClass2:
    str: str_type = None
```

In some cases you may be tempted to use cast from the typing module when you know better than the analyzer. This occurs particularly when using custom inference functions. For example
from typing import cast
from pandas.core.dtypes.common import is_number

def cannot_infer_bad(obj: Union[str, int, float]):
    if is_number(obj):
        ...
    else:  # Reasonably only str objects would reach this but...
        obj = cast(str, obj)  # Mypy complains without this!
        return obj.upper()

The limitation here is that while a human can reasonably understand that is_number would catch the int and float types mypy cannot make that same inference just yet (see mypy #5206. While the above works, the use of cast is strongly discouraged. Where applicable a refactor of the code to appease static analysis is preferable.

def cannot_infer_good(obj: Union[str, int, float]):
    if isinstance(obj, str):
        return obj.upper()
    else:
        ...

With custom types and inference this is not always possible so exceptions are made, but every effort should be exhausted to avoid cast before going down such paths.

pandas-specific types

Commonly used types specific to pandas will appear in pandas._typing and you should use these where applicable. This module is private for now but ultimately this should be exposed to third party libraries who want to implement type checking against pandas.

For example, quite a few functions in pandas accept a dtype argument. This can be expressed as a string like "object", a numpy.dtype like np.int64 or even a pandas ExtensionDtype like pd.CategoricalDtype. Rather than burden the user with having to constantly annotate all of those options, this can simply be imported and reused from the pandas._typing module

from pandas._typing import Dtype

def as_type(dtype: Dtype) -> ...:
    ...

This module will ultimately house types for repeatedly used concepts like “path-like”, “array-like”, “numeric”, etc... and can also hold aliases for commonly appearing parameters like axis. Development of this module is active so be sure to refer to the source for the most up to date list of available types.
Validating type hints

pandas uses mypy to statically analyze the code base and type hints. After making any change you can ensure your type hints are correct by running

```
mypy pandas
```

Testing with continuous integration

The pandas test suite will run automatically on Travis-CI and Azure Pipelines continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for Travis-CI and Azure Pipelines.

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.

```
All checks have passed
2 successful checks

continuous-integration/travis-ci/pr — The Travis CI build passed

pandas-dev.pandas — Successful in 36m — Build #20190109.23 succeeded

This branch has no conflicts with the base branch
Merging can be performed automatically.
```

Note: Each time you push to your fork, a new run of the tests will be triggered on the CI. You can enable the auto-cancel feature, which removes any non-currently-running tests for that same pull-request, for Travis-CI here.

Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace test-driven development (TDD). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses pytest and the convenient extensions in numpy.testing.
Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the testing page of the wiki.

The `pandas._testing` module has many special `assert` functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```python
def test_pivot(self):
    data = {
        'index': ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns': ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values': [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One': {'A': 1., 'B': 2., 'C': 3.},
        'Two': {'A': 1., 'B': 2., 'C': 3.}
    })
    assert_frame_equal(pivoted, expected)
```

Please remember to add the Github Issue Number as a comment to a new test. E.g. “# brief comment, see GH#28907”

Transiting to pytest

pandas existing test structure is mostly class-based, meaning that you will typically find tests wrapped in a class.

```python
class TestReallyCoolFeature:
    pass
```

Going forward, we are moving to a more functional style using the pytest framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```python
def test_really_cool_feature():
    pass
```
Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like test_* and only take arguments that are either fixtures or parameters
- pytest.mark can be used to set metadata on test functions, e.g. skip or xfail.
- using parametrize: allow testing of multiple cases
- to set a mark on a parameter, pytest.param(..., marks=...) syntax should be used
- fixture, code for object construction, on a per-test basis
- using bare assert for scalars and truth-testing
- tm.assert_series_equal (and its counter part tm.assert_frame_equal), for pandas object comparisons.
- the typical pattern of constructing an expected and comparing versus the result

We would name this file test_cool_feature.py and put in an appropriate place in the pandas/tests/ structure.

```python
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize(
    'dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip),
             pytest.param('int32', marks=pytest.mark.xfail(reason='to show how it works'))]
)
def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype

    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)
```

A test run of this yields
Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select only those tests which match `int8`.

Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe all valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See Getting Started with Hypothesis for more of an introduction, then refer to the Hypothesis documentation for details.

```python
import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
    st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
    st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

given(value=any_json_value)
def test_json_roundtrip(value):
    result = json.loads(json.dumps(value))
    assert value == result
```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with
Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

**Testing warnings**

By default, one of pandas CI workers will fail if any unhandled warnings are emitted. If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```
import pandas._testing as tm

def df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
    df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning’s stacklevel is set correctly. The stacklevel is what ensures the user’s file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren’t actually testing the warning itself (say because it’s going to be removed in the future, or because we’re matching a 3rd-party library’s behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
    ...
```

If the test generates a warning of class `category` whose message starts with `msg`, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python’s usual `warnings` module to control whether a warning is ignored / raised at different places within a single test.

```
with warnings.catch_warnings():
    warnings.simplefilter("ignore", FutureWarning)
    # Or use warnings.filterwarnings(...)```

Alternatively, consider breaking up the unit test.

**Running the test suite**

The tests can then be run directly inside your Git clone (without having to install pandas) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:
Using **pytest-xdist**, one can speed up local testing on multicore machines. To use this feature, you will need to install **pytest-xdist** via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the **pytest** documentation.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

### Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. **pandas** is in the process of migrating to **asv benchmarks** to enable easy monitoring of the performance of critical **pandas** operations. These benchmarks are all found in the **pandas/asv_bench** directory, and the test results can be found here.

To use all features of **asv**, you will need either **conda** or **virtualenv**. For more details please check the **asv** installation webpage.

To install **asv**:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to **asv_bench/** and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace **HEAD** with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses **conda** by default for creating the benchmark environments. If you want to use **virtualenv** instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The **-E virtualenv** option should be added to all **asv** commands that run benchmarks. The default value is defined in **asv.conf.json**.

Running the full benchmark suite can be an all-day process, depending on your hardware and its resource utilization. However, usually it is sufficient to paste only a subset of the results into the pull request to show that the
committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run benchmarks from a `pandas/asv_bench/benchmarks/groupby.py` file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of benchmarks from a file, you can do it using `.` as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of `pandas` already installed in your current Python environment. This can be useful if you do not have `virtualenv` or `conda`, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH=$PWD/../`.

```
asv [remaining arguments]
```

This will display stderr from the benchmarks, and use your local `python` that comes from your `$PATH`.

Information on how to write a benchmark and how to use `asv` can be found in the `asv` documentation.

### Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.rst`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `issue:` where `1234` is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation above. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 1.1.0
```

This will put the text `New in version 1.1.0` wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method (example) or a new keyword argument (example).

### 4.1.6 Contributing your changes to pandas

#### Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you’ve made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:
git add path/to/file-to-be-added.py

Doing 'git status' again should give something like:

```bash
# On branch shiny-new-feature
# modified: /relative/path/to/file-you-added.py
```

Finally, commit your changes to your local repository with an explanatory message. pandas uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- **ENH**: Enhancement, new functionality
- **BUG**: Bug fix
- **DOC**: Additions/updates to documentation
- **TST**: Additions/updates to tests
- **BLD**: Updates to the build process/scripts
- **PERF**: Performance improvement
- **TYP**: Type annotations
- **CLN**: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```bash
git commit -m
```

**Pushing your changes**

When you want your changes to appear publicly on your GitHub page, push your forked feature branch’s commits:

```bash
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```bash
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin  git@github.com:yourname/pandas.git (fetch)
origin  git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the pandas project. For that to happen, a pull request needs to be submitted on GitHub.

4.1. Contributing to pandas
Review your code

When you’re ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – https://github.com/your-user-name/pandas
2. Click on Branches
3. Click on the Compare button for your feature branch
4. Select the base and compare branches, if necessary. This will be master and shiny-new-feature, respectively.

Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the Pull Request button
3. You can then click on Commits and Files Changed to make sure everything looks okay one last time
4. Write a description of your changes in the Preview Discussion tab
5. Click Send Pull Request.

This request then goes to the repository maintainers, and they will review the code.

Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the Continuous Integration tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/ for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run git commit to save those fixes.
If you have uncommitted changes at the moment you want to update the branch with master, you will need to stash them prior to updating (see the stash docs). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

### Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won’t warn you if your feature branch has not actually been merged. The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

### 4.1.7 Tips for a successful pull request

If you have made it to the Review your code phase, one of the core contributors may take a look. Please note however that a handful of people are responsible for reviewing all of the contributions, which can often lead to bottlenecks.

To improve the chances of your pull request being reviewed, you should:

- **Reference an open issue** for non-trivial changes to clarify the PR’s purpose
- **Ensure you have appropriate tests.** These should be the first part of any PR
- **Keep your pull requests as simple as possible.** Larger PRs take longer to review
- **Ensure that CI is in a green state.** Reviewers may not even look otherwise
- **Keep Updating your pull request,** either by request or every few days

### 4.2 pandas code style guide

**Table of contents:**

- **Patterns**
  - Using `foo.__class__`
- **String formatting**
pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project. We encourage you to use pre-commit to automatically run black, flake8, isort, and related code checks when you make a git commit.

### 4.2.1 Patterns

**Using `foo.__class__`**

pandas uses `type(foo)` instead of `foo.__class__` as it is making the code more readable. For example:

**Good:**

```python
foo = "bar"
type(foo)
```

**Bad:**

```python
foo = "bar"
foo.__class__
```

### 4.2.2 String formatting

**Concatenated strings**

**Using f-strings**

pandas uses f-strings formatting instead of `%` and `.format()` string formatters.

The convention of using f-strings on a string that is concatenated over several lines, is to prefix only the lines containing values which need to be interpreted.

For example:

**Good:**

```python
foo = "old_function"
bar = "new_function"

my_warning_message = {
    f"Warning, {foo} is deprecated, "
    "please use the new and way better "
    f"{bar}""
}
```
Bad:

```python
foo = "old_function"
bar = "new_function"

my_warning_message = {
    f"Warning, {foo} is deprecated, "
    f"please use the new and way better "
    f"{bar}"}
```

**White spaces**

Only put white space at the end of the previous line, so there is no whitespace at the beginning of the concatenated string.

For example:

**Good:**

```python
example_string = {
    "Some long concatenated string, "
    "with good placement of the "
    "whitespaces"
}
```

**Bad:**

```python
example_string = {
    "Some long concatenated string,"
    " with bad placement of the"
    " whitespaces"
}
```

**Representation function (aka ‘repr()’)**

pandas uses ‘repr()’ instead of ‘%r’ and ‘!r’.

The use of ‘repr()’ will only happen when the value is not an obvious string.

For example:

**Good:**

```python
value = str
f"Unknown received value, got: {repr(value)};"
```

**Good:**

```python
value = str
f"Unknown received type, got: '{type(value).__name__}';"
```
4.2.3 Imports (aim for absolute)

In Python 3, absolute imports are recommended. Using absolute imports, doing something like `import string` will import the string module rather than `string.py` in the same directory. As much as possible, you should try to write out absolute imports that show the whole import chain from top-level pandas.

Explicit relative imports are also supported in Python 3 but it is not recommended to use them. Implicit relative imports should never be used and are removed in Python 3.

For example:

```
# preferred
import pandas.core.common as com

# not preferred
from .common import test_base

# wrong
from common import test_base
```

4.2.4 Miscellaneous

Reading from a url

Good:

```
from pandas.io.common import urlopen

with urlopen("http://www.google.com") as url:
    raw_text = url.read()
```

4.3 pandas maintenance

This guide is for pandas’ maintainers. It may also be interesting to contributors looking to understand the pandas development process and what steps are necessary to become a maintainer.

The main contributing guide is available at [Contributing to pandas](Contributing to pandas).

4.3.1 Roles

pandas uses two levels of permissions: triage and core team members.

Triage members can label and close issues and pull requests.

Core team members can label and close issues and pull request, and can merge pull requests.

GitHub publishes the full list of permissions.
4.3.2 Tasks

pandas is largely a volunteer project, so these tasks shouldn’t be read as “expectations” of triage and maintainers. Rather, they’re general descriptions of what it means to be a maintainer.

- Triage newly filed issues (see Issue triage)
- Review newly opened pull requests
- Respond to updates on existing issues and pull requests
- Drive discussion and decisions on stalled issues and pull requests
- Provide experience / wisdom on API design questions to ensure consistency and maintainability
- Project organization (run / attend developer meetings, represent pandas)

https://matthewrocklin.com/blog/2019/05/18/maintainer may be interesting background reading.

4.3.3 Issue triage

Here’s a typical workflow for triaging a newly opened issue.

1. **Thank the reporter for opening an issue**

   The issue tracker is many people’s first interaction with the pandas project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

2. **Is the necessary information provided?**

   Ideally reporters would fill out the issue template, but many don’t. If crucial information (like the version of pandas they used), is missing feel free to ask for that and label the issue with “Needs info”. The report should follow the guidelines in *Bug reports and enhancement requests*. You may want to link to that if they didn’t follow the template.

   Make sure that the title accurately reflects the issue. Edit it yourself if it’s not clear.

3. **Is this a duplicate issue?**

   We have many open issues. If a new issue is clearly a duplicate, label the new issue as “Duplicate” assign the milestone “No Action”, and close the issue with a link to the original issue. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

   If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

4. **Is the issue minimal and reproducible?**

   For bug reports, we ask that the reporter provide a minimal reproducible example. See https://matthewrocklin.com/blog/work/2018/02/28/minimal-bug-reports for a good explanation. If the example is not reproducible, or if it’s *clearly* not minimal, feel free to ask the reporter if they can provide and example or simplify the provided one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself and we’ll edit the original post to include it.

   If a reproducible example can’t be provided, add the “Needs info” label.

   If a reproducible example is provided, but you see a simplification, edit the original post with your simpler reproducible example.

5. **Is this a clearly defined feature request?**

   Generally, pandas prefers to discuss and design new features in issues, before a pull request is made. Encourage the submitter to include a proposed API for the new feature. Having them write a full docstring is a good way to pin down specifics.
We’ll need a discussion from several pandas maintainers before deciding whether the proposal is in scope for pandas.

6. **Is this a usage question?**

We prefer that usage questions are asked on StackOverflow with the pandas tag. [https://stackoverflow.com/questions/tagged/pandas](https://stackoverflow.com/questions/tagged/pandas)

If it’s easy to answer, feel free to link to the relevant documentation section, let them know that in the future this kind of question should be on StackOverflow, and close the issue.

7. **What labels and milestones should I add?**

Apply the relevant labels. This is a bit of an art, and comes with experience. Look at similar issues to get a feel for how things are labeled.

If the issue is clearly defined and the fix seems relatively straightforward, label the issue as “Good first issue”.

Typically, new issues will be assigned the “Contributions welcome” milestone, unless it’s know that this issue should be addressed in a specific release (say because it’s a large regression).

### 4.3.4 Closing issues

Be delicate here: many people interpret closing an issue as us saying that the conversation is over. It’s typically best to give the reporter some time to respond or self-close their issue if it’s determined that the behavior is not a bug, or the feature is out of scope. Sometimes reporters just go away though, and we’ll close the issue after the conversation has died.

### 4.3.5 Reviewing pull requests

Anybody can review a pull request: regular contributors, triagers, or core-team members. But only core-team members can merge pull requests when they’re ready.

Here are some things to check when reviewing a pull request.

- Tests should be in a sensible location: in the same file as closely related tests.
- New public APIs should be included somewhere in doc/source/reference/.
- New / changed API should use the [versionadded](#) or [versionchanged](#) directives in the docstring.
- User-facing changes should have a [whatsnew](#) in the appropriate file.
- Regression tests should reference the original GitHub issue number like # GH-1234.
- The pull request should be labeled and assigned the appropriate milestone (the next patch release for regression fixes and small bug fixes, the next minor milestone otherwise)
- Changes should comply with our [Version policy](#).
4.3.6 Cleaning up old issues

Every open issue in pandas has a cost. Open issues make finding duplicates harder, and can make it harder to know what needs to be done in pandas. That said, closing issues isn’t a goal on its own. Our goal is to make pandas the best it can be, and that’s best done by ensuring that the quality of our open issues is high.

Occasionally, bugs are fixed but the issue isn’t linked to in the Pull Request. In these cases, comment that “This has been fixed, but could use a test.” and label the issue as “Good First Issue” and “Needs Test”.

If an older issue doesn’t follow our issue template, edit the original post to include a minimal example, the actual output, and the expected output. Uniformity in issue reports is valuable.

If an older issue lacks a reproducible example, label it as “Needs Info” and ask them to provide one (or write one yourself if possible). If one isn’t provide reasonably soon, close it according to the policies in Closing issues.

4.3.7 Cleaning up old pull requests

Occasionally, contributors are unable to finish off a pull request. If some time has passed (two weeks, say) since the last review requesting changes, gently ask if they’re still interested in working on this. If another two weeks or so passes with no response, thank them for their work and close the pull request. Comment on the original issue that “There’s a stalled PR at #1234 that may be helpful.”, and perhaps label the issue as “Good first issue” if the PR was relatively close to being accepted.

Additionally, core-team members can push to contributors branches. This can be helpful for pushing an important PR across the line, or for fixing a small merge conflict.

4.3.8 Becoming a pandas maintainer

The full process is outlined in our governance documents. In summary, we’re happy to give triage permissions to anyone who shows interest by being helpful on the issue tracker.

The current list of core-team members is at https://github.com/pandas-dev/pandas-governance/blob/master/people.md

4.3.9 Merging pull requests

Only core team members can merge pull requests. We have a few guidelines.

1. You should typically not self-merge your own pull requests. Exceptions include things like small changes to fix CI (e.g. pinning a package version).

2. You should not merge pull requests that have an active discussion, or pull requests that has any -1 votes from a core maintainer. pandas operates by consensus.

3. For larger changes, it’s good to have a +1 from at least two core team members.

In addition to the items listed in Closing issues, you should verify that the pull request is assigned the correct milestone.

Pull requests merged with a patch-release milestone will typically be backported by our bot. Verify that the bot noticed the merge (it will leave a comment within a minute typically). If a manual backport is needed please do that, and remove the “Needs backport” label once you’ve done it manually. If you forget to assign a milestone before tagging, you can request the bot to backport it with:

@Meeseeksdev backport <branch>
4.4 Internals

This section will provide a look into some of pandas internals. It’s primarily intended for developers of pandas itself.

4.4.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- **Index**: the generic “ordered set” object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do O(1) lookups.
- **Int64Index**: a version of Index highly optimized for 64-bit integer data, such as time stamps
- **Float64Index**: a version of Index highly optimized for 64-bit float data
- **MultiIndex**: the standard hierarchical index object
- **DatetimeIndex**: An Index object with Timestamp boxed elements (impl are the int64 values)
- **TimedeltaIndex**: An Index object with Timedelta boxed elements (impl are the int64 values)
- **PeriodIndex**: An Index object with Period elements

There are functions that make the creation of a regular index easy:

- **date_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Python datetime objects
- **period_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Period objects, representing timespans

The motivation for having an Index class in the first place was to enable different implementations of indexing. This means that it's possible for you, the user, to implement a custom Index subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an Index must define are one or more of the following (depending on how incompatible the new object internals are with the Index functions):

- **get_loc**: returns an “indexer” (an integer, or in some cases a slice object) for a label
- **slice_locs**: returns the “range” to slice between two labels
- **get_indexer**: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
- **get_indexer_non_unique**: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
- **reindex**: Does any pre-conversion of the input index then calls get_indexer
- **union, intersection**: computes the union or intersection of two Index objects
- **insert**: Inserts a new label into an Index, yielding a new object
- **delete**: Delete a label, yielding a new object
- **drop**: Deletes a set of labels
- **take**: Analogous to ndarray.take
**MultiIndex**

Internally, the `MultiIndex` consists of a few things: the `levels`, the integer `codes` (until version 0.24 named `labels`), and the level `names`:

```python
In [1]: index = pd.MultiIndex.from_product(
    ...:     [range(3), ["one", "two"]], names=["first", "second"]
    ...: )

In [2]: index
Out[2]:
MultiIndex([(0, 'one'),
            (0, 'two'),
            (1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['first', 'second'])

In [3]: index.levels
Out[3]: FrozenList([0, 1, 2], ['one', 'two'])

In [4]: index.codes
Out[4]: FrozenList([0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1])

In [5]: index.names
Out[5]: FrozenList(['first', 'second'])
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It’s important to note that sortedness is determined solely from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors `from_tuples` and `from_arrays` ensure that this is true, but if you compute the levels and codes yourself, please be careful.

**Values**

*pandas* extends NumPy’s type system with custom types, like `Categorical` or datetimes with a timezone, so we have multiple notions of “values”. For 1-D containers (`Index` classes and `Series`) we have the following convention:

- `cls._values` refers is the “best possible” array. This could be an `ndarray` or `ExtensionArray`.

So, for example, `Series[category]._values` is a `Categorical`.

### 4.4.2 Subclassing pandas data structures

This section has been moved to *Subclassing pandas data structures*.
4.5 Test organization

Ideally, there should be one, and only one, obvious place for a test to reside. Until we reach that ideal, these are some rules of thumb for where a test should be located.

1. Does your test depend only on code in `pd._libs.tslibs`? This test likely belongs in one of:
   - tests.tslibs

   **Note:** No file in `tests.tslibs` should import from any pandas modules outside of `pd._libs.tslibs`

   - tests.scalar
   - tests.tseries.offsets

2. Does your test depend only on code in `pd._libs`? This test likely belongs in one of:
   - tests.libs
   - tests.groupby.test_libgroupby

3. Is your test for an arithmetic or comparison method? This test likely belongs in one of:
   - tests.arithmetic

   **Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray using the `box_with_array` fixture.

   - tests.frame.test_arithmetic
   - tests.series.test_arithmetic

4. Is your test for a reduction method (min, max, sum, prod, …)? This test likely belongs in one of:
   - tests.reductions

   **Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray.

   - tests.frame.test_reductions
   - tests.series.test_reductions
   - tests.test_nanops

5. Is your test for an indexing method? This is the most difficult case for deciding where a test belongs, because there are many of these tests, and many of them test more than one method (e.g. both `Series.__getitem__` and `Series.loc.__getitem__`)

   A) Is the test specifically testing an Index method (e.g. `Index.get_loc`, `Index.get_indexer`)? This test likely belongs in one of:
      - tests.indexes.test_indexing
      - tests.indexes.fooindex.test_indexing

Within that files there should be a method-specific test class e.g. `TestGetLoc`.

In most cases, neither `Series` nor `DataFrame` objects should be needed in these tests.
B) Is the test for a Series or DataFrame indexing method other than __getitem__ or __setitem__, e.g. xs, where, take, mask, lookup, or insert? This test likely belongs in one of:
   - tests.frame.indexing.test_methodname
   - tests.series.indexing.test_methodname

C) Is the test for any of loc, iloc, at, or iat? This test likely belongs in one of:
   - tests.indexing.test_loc
   - tests.indexing.test_iat
   - tests.indexing.test_setitem

Within the appropriate file, test classes correspond to either types of indexers (e.g. TestLocBooleanMask) or major use cases (e.g. TestLocSetitemWithExpansion).

See the note in section D) about tests that test multiple indexing methods.

D) Is the test for Series.__getitem__, Series.__setitem__, DataFrame.__getitem__, or DataFrame.__setitem__? This test likely belongs in one of:
   - tests.series.test_getitem
   - tests.series.test_setitem
   - tests.frame.test_getitem
   - tests.frame.test_setitem

If many cases such a test may test multiple similar methods, e.g.

```python
import pandas as pd
import pandas._testing as tm
def test_getitem_listlike_of_ints():
    ser = pd.Series(range(5))
    result = ser[[3, 4]]
    expected = pd.Series([2, 3])
    tm.assert_series_equal(result, expected)
    result = ser.loc[[3, 4]]
    tm.assert_series_equal(result, expected)
```

In cases like this, the test location should be based on the underlying method being tested. Or in the case of a test for a bugfix, the location of the actual bug. So in this example, we know that Series.__getitem__ calls Series.loc.__getitem__, so this is really a test for loc.__getitem__. So this test belongs in tests.indexing.test_loc.

6. Is your test for a DataFrame or Series method?

   A) Is the method a plotting method? This test likely belongs in one of:
      - tests.plotting
   
   B) Is the method an IO method? This test likely belongs in one of:
      - tests.io
   
   C) Otherwise This test likely belongs in one of:
      - tests.series.methods.test_mymethod
• tests.frame.methods.test_mymethod

Note: If a test can be shared between DataFrame/Series using the frame_or_series fixture, by convention it goes in the tests.frame file.

• tests.generic.methods.test_mymethod

Note: The generic/methods/ directory is only for methods with tests that are fully parametrized over Series/DataFrame

7. Is your test for an Index method, not depending on Series/DataFrame? This test likely belongs in one of:
   • tests.indexes

8) Is your test for one of the pandas-provided ExtensionArrays (Categorical, DatetimeArray, TimedeltaArray, PeriodArray, IntervalArray, PandasArray, FloatArray, BoolArray, StringArray)? This test likely belongs in one of:
   • tests.arrays

9) Is your test for all ExtensionArray subclasses (the “EA Interface”)? This test likely belongs in one of:
   • tests.extension

4.6 Debugging C extensions

Pandas uses select C extensions for high performance IO operations. In case you need to debug segfaults or general issues with those extensions, the following steps may be helpful.

First, be sure to compile the extensions with the appropriate flags to generate debug symbols and remove optimizations. This can be achieved as follows:

```
python setup.py build_ext --inplace -j4 --with-debugging-symbols
```

4.6.1 Using a debugger

Assuming you are on a Unix-like operating system, you can use either lldb or gdb to debug. The choice between either is largely dependent on your compilation toolchain - typically you would use lldb if using clang and gdb if using gcc. For macOS users, please note that gcc is on modern systems an alias for clang, so if using Xcode you usually opt for lldb. Regardless of which debugger you choose, please refer to your operating systems instructions on how to install.

After installing a debugger you can create a script that hits the extension module you are looking to debug. For demonstration purposes, let’s assume you have a script called debug_testing.py with the following contents:

```
import pandas as pd

pd.DataFrame([[1, 2]]).to_json()
```

Place the debug_testing.py script in the project root and launch a Python process under your debugger. If using lldb:
If using gdb:

gdb python

Before executing our script, let’s set a breakpoint in our JSON serializer in its entry function called `objToJSON`. The lldb syntax would look as follows:

```bash
breakpoint set --name objToJSON
```

Similarly for gdb:

```bash
break objToJSON
```

**Note:** You may get a warning that this breakpoint cannot be resolved in lldb. gdb may give a similar warning and prompt you to make the breakpoint on a future library load, which you should say yes to. This should only happen on the very first invocation as the module you wish to debug has not yet been loaded into memory.

Now go ahead and execute your script:

```bash
run <the_script>.py
```

Code execution will halt at the breakpoint defined or at the occurrence of any segfault. LLDB’s GDB to LLDB command map provides a listing of debugger command that you can execute using either debugger.

Another option to execute the entire test suite under lldb would be to run the following:

```bash
lldb -- python -m pytest
```

Or for gdb

```bash
gdb --args python -m pytest
```

Once the process launches, simply type `run` and the test suite will begin, stopping at any segmentation fault that may occur.

### 4.6.2 Checking memory leaks with valgrind

You can use **Valgrind** to check for and log memory leaks in extensions. For instance, to check for a memory leak in a test from the suite you can run:

```bash
PYTHONMALLOC=malloc valgrind --leak-check=yes --track-origins=yes --log-file=valgrind-˓→log.txt python -m pytest <path_to_a_test>
```

Note that code execution under valgrind will take much longer than usual. While you can run valgrind against extensions compiled with any optimization level, it is suggested to have optimizations turned off from compiled extensions to reduce the amount of false positives. The `--with-debugging-symbols` flag passed during package setup will do this for you automatically.

**Note:** For best results, you should run use a Python installation configured with Valgrind support (`--with-valgrind`)
While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. pandas offers a few options for extending pandas.

### 4.7.1 Registering custom accessors

Libraries can use the decorators `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s `__init__` method gets the object being decorated. For example:

```python
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._validate(pandas_obj)
        self._obj = pandas_obj

    @staticmethod
    def _validate(obj):
        # verify there is a column latitude and a column longitude
        if "latitude" not in obj.columns or "longitude" not in obj.columns:
            raise AttributeError("Must have 'latitude' and 'longitude'.")

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the `geo` namespace:

```python
>>> ds = pd.DataFrame(
...     {"longitude": np.linspace(0, 10), "latitude": np.linspace(0, 20)}
... )
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor’s `__init__`. In our `GeoAccessor`, we validate that the data contains the expected columns, raising an `AttributeError` when the validation fails. For a `Series` accessor, you should validate the `dtype` if the accessor applies only to certain dtypes.
4.7.2 Extension types

Warning: The pandas.api.extensions.ExtensionDtype and pandas.api.extensions.ExtensionArray APIs are new and experimental. They may change between versions without warning.

pandas defines an interface for implementing data types and arrays that extend NumPy’s type system. pandas itself uses the extension system for some types that aren’t built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like pandas.isna() will dispatch to the extension type’s implementation.

If you’re building a library that implements the interface, please publicize it on ecosystem.extensions.

The interface consists of two classes.

ExtensionDtype

A pandas.api.extensions.ExtensionDtype is similar to a numpy.dtype object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the type property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be ipaddress.IPv4Address.

See the extension dtype source for interface definition.

New in version 0.24.0.

pandas.api.extension.ExtensionDtype can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate Series and .astype() with a registered string name, for example 'category' is a registered string accessor for the CategoricalDtype.

See the extension dtype dtypes for more on how to register dtypes.

ExtensionArray

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the dtype attribute.

pandas makes no restrictions on how an extension array is created via its __new__ or __init__, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for Categorical).

They may be backed by none, one, or many NumPy arrays. For example, pandas.Categorical is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the extension array source for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.
ExtensionArray operator support

New in version 0.24.0.

By default, there are no operators defined for the class `ExtensionArray`. There are two approaches for providing operator support for your ExtensionArray:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the ExtensionArray.

**Note:** Regardless of the approach, you may want to set `__array_priority__` if you want your implementation to be called when involved in binary operations with NumPy arrays.

For the first approach, you define selected operators, e.g., `__add__`, `__le__`, etc. that you want your `ExtensionArray` subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the `ExtensionArray` have the individual operators already defined. In other words, if your `ExtensionArray` named `MyExtensionArray` is implemented so that each element is an instance of the class `MyExtensionElement`, then if the operators are defined for `MyExtensionElement`, the second approach will automatically define the operators for `MyExtensionArray`.

A mixin class, `ExtensionScalarOpsMixin` supports this second approach. If developing an `ExtensionArray` subclass, for example `MyExtensionArray`, can simply include `ExtensionScalarOpsMixin` as a parent class of `MyExtensionArray`, and then call the methods `__add_arithmetic_ops()` and/or `__add_comparison_ops()` to hook the operators into your `MyExtensionArray` class, as follows:

```python
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
    pass

MyExtensionArray.__add_arithmetic_ops()
MyExtensionArray.__add_comparison_ops()
```

**Note:** Since pandas automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the `ExtensionArray`.

For arithmetic operations, this implementation will try to reconstruct a new `ExtensionArray` with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that’s valid for the `ExtensionArray`. If an `ExtensionArray` cannot be reconstructed, an `ndarray` containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy ndarrays, we recommend *not* handling Series and Indexes in your binary ops. Instead, you should detect these cases and return `NotImplemented`. When pandas encounters an operation like `op(Series, ExtensionArray)`, pandas will

1. unbox the array from the `Series(Series.array)`
2. call `result = op(values, ExtensionArray)`
3. re-box the result in a `Series`
NumPy universal functions

*Series* implements *__array_ufunc__*. As part of the implementation, pandas unboxes the *ExtensionArray* from the *Series*, applies the ufunc, and re-boxes it if necessary.

If applicable, we highly recommend that you implement *__array_ufunc__* in your extension array to avoid coercion to an *ndarray*. See the NumPy documentation for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (*Series*, *DataFrame*, *Index*) is detected in inputs. If any of those is present, you should return *NotImplemented*. pandas will take care of unboxing the array from the container and re-calling the ufunc with the unwrapped input.

Testing extension arrays

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py.

To use a test, subclass it:

```python
from pandas.tests.extension import base
class TestConstructors(base.BaseConstructorsTests):
    pass
```

See https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py for a list of all the tests available.

Compatibility with Apache Arrow

An *ExtensionArray* can support conversion to / from *pyarrow* arrays (and thus support for example serialization to the Parquet file format) by implementing two methods: *ExtensionArray.__arrow_array__* and *ExtensionDtype.__from_arrow__*.

The *ExtensionArray.__arrow_array__* ensures that *pyarrow* knows how to convert the specific extension array into a *pyarrow.Array* (also when included as a column in a pandas *DataFrame*):

```python
class MyExtensionArray(ExtensionArray):
    ...
    def __arrow_array__(self, type=None):
        # convert the underlying array values to a pyarrow Array
        import pyarrow
        return pyarrow.array(..., type=type)
```

The *ExtensionDtype.__from_arrow__* method then controls the conversion back from *pyarrow* to a pandas *ExtensionArray*. This method receives a *pyarrow Array* or *ChunkedArray* as only argument and is expected to return the appropriate pandas *ExtensionArray* for this dtype and the passed values:

```python
class ExtensionDtype:
    ...
    def __from_arrow__(self, array: pyarrow.Array/ChunkedArray) -> ExtensionArray:
        ...
```
4.7.3 Subclassing pandas data structures

**Warning:** There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with `pipe`
2. Use `composition`. See [here](#).
3. Extending by `registering an accessor`
4. Extending by `extension type`

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

**Note:** You can find a nice example in geopandas project.

**Override constructor properties**

Each data structure has several `constructor properties` for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 constructor properties to be defined:

- `__constructor`: Used when a manipulation result has the same dimensions as the original.
- `__constructor_sliced`: Used when a manipulation result has one lower dimension(s) as the original, such as DataFrame single columns slicing.
- `__constructor_expanddim`: Used when a manipulation result has one higher dimension as the original, such as `Series.to_frame()`.

Following table shows how pandas data structures define constructor properties by default.

<table>
<thead>
<tr>
<th>Property Attributes</th>
<th>Series</th>
<th>DataFrame</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__constructor</code></td>
<td>Series</td>
<td>DataFrame</td>
</tr>
<tr>
<td><code>__constructor_sliced</code></td>
<td><code>NotImplementedError</code></td>
<td>Series</td>
</tr>
<tr>
<td><code>__constructor_expanddim</code></td>
<td>DataFrame</td>
<td><code>NotImplementedError</code></td>
</tr>
</tbody>
</table>

Below example shows how to define `SubclassedSeries` and `SubclassedDataFrame` overriding constructor properties.

```python
class SubclassedSeries(pd.Series):
    @property
def __constructor(self):
```

(continues on next page)
>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0 1  4  7
1 2  5  8
2 3  6  9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df[['A', 'B']]
>>> sliced1
   A  B
0 1  4
1 2  5
2 3  6

>>> type(sliced1)
<class '__main__.SubclassedDataFrame'>

>>> sliced2 = df['A']
>>> sliced2
0 1
1 2
2 3
Name: A, dtype: int64

>>> type(sliced2)
<class '__main__.SubclassedSeries'>
Define original properties

To let original data structures have additional properties, you should let pandas know what properties are added. pandas maps unknown properties to data names overriding \_\_getattribute\_\_. Defining original properties can be done in one of 2 ways:

1. Define \_\_internal\_names\_ and \_\_internal\_names\_set for temporary properties which WILL NOT be passed to manipulation results.
2. Define \_\_metadata\_ for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “internal_cache” as a temporary property and “added_property” as a normal property

```python
class SubclassedDataFrame2(pd.DataFrame):
    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ["internal_cache"]
    _internal_names_set = set(_internal_names)

    # normal properties
    _metadata = ["added_property"]

    @property
    def _constructor(self):
        return SubclassedDataFrame2

>>> df = SubclassedDataFrame2({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0 1  4  7
1 2  5  8
2 3  6  9

>>> df.internal_cache = "cached"
>>> df.added_property = "property"

>>> df.internal_cache
cached
>>> df.added_property
property

# properties defined in _internal_names is reset after manipulation
>>> df[["A", "B"]].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df[["A", "B"]].added_property
property
```
4.7.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```python
>>> pd.set_option("plotting.backend", "backend.module")
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair,…) to generate the plots.

Libraries implementing the plotting backend should use entry points to make their backend discoverable to pandas. The key is "pandas_plotting_backends". For example, pandas registers the default “matplotlib” backend as follows.

```python
# in setup.py
setup(
    # noqa: F821
    ...,
    entry_points={
        "pandas_plotting_backends": [
            "matplotlib = pandas:plotting._matplotlib",
        ],
    },
)
```

More information on how to implement a third-party plotting backend can be found at https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/__init__.py#L1.

4.8 Developer

This section will focus on downstream applications of pandas.

4.8.1 Storing pandas DataFrame objects in Apache Parquet format

The Apache Parquet format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```plaintext
5: optional list<KeyValue> key_value_metadata
```

where `KeyValue` is

```python
struct KeyValue {
    1: required string key
    2: optional string value
}
```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a `pandas` metadata key in the `FileMetaData` with the value stored as:
The “descriptor” values \(<\text{descr0}>\) in the 'index_columns' field are strings (referring to a column) or dictionaries with values as described below.

The \(<\text{c0}>/\text{ci0}>\) and so forth are dictionaries containing the metadata for each column, including the index columns. This has JSON form:

\[
\{
'\text{name}': \text{column_name},
'\text{field_name}': \text{parquet_column_name},
'\text{pandas_type}': \text{pandas_type},
'\text{numpy_type}': \text{numpy_type},
'\text{metadata}': \text{metadata}
\}
\]

See below for the detailed specification for these.

### Index metadata descriptors

`RangeIndex` can be stored as metadata only, not requiring serialization. The descriptor format for these as is follows:

\[
\text{index} = \text{pd.RangeIndex}(0, 10, 2)
\]

\[
\{
'\text{kind}': 'range',
'\text{name}': \text{index.name},
'\text{start}': \text{index.start},
'\text{stop}': \text{index.stop},
'\text{step}': \text{index.step},
\}
\]

Other index types must be serialized as data columns along with the other DataFrame columns. The metadata for these is a string indicating the name of the field in the data columns, for example '__index_level_0__'.

If an index has a non-None `name` attribute, and there is no other column with a name matching that value, then the `index.name` value can be used as the descriptor. Otherwise (for unnamed indexes and ones with names colliding with other column names) a disambiguating name with pattern matching '__index_level_\d+__' should be used. In cases of named indexes as data columns, `name` attribute is always stored in the column descriptors as above.

### Column metadata

`pandas_type` is the logical type of the column, and is one of:

- **Boolean**: 'bool'
- **Integers**: 'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'
- **Floats**: 'float16', 'float32', 'float64'
- **Date and Time Types**: 'datetime', 'datetimetz', 'timedelta'
- **String**: 'unicode', 'bytes'
• Categorical: 'categorical'
• Other Python objects: 'object'

The `numpy_type` is the physical storage type of the column, which is the result of `str(dtype)` for the underlying NumPy array that holds the data. So for `datetimetz` this is `datetime64[ns]` and for categorical, it may be any of the supported integer categorical types.

The `metadata` field is `None` except for:

• `datetimetz`: `{"timezone": zone, "unit": "ns"}, e.g. `{"timezone": "America/New_York", "unit": "ns"}`. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
• `categorical`: `{'num_categories': K, 'ordered': is_ordered, 'type': $TYPE}`
  - Here 'type' is optional, and can be a nested pandas type specification here (but not categorical)
• `unicode`: `{"encoding": encoding}
  - The encoding is optional, and if not present is UTF-8
• `object`: `{"encoding": encoding}`. Objects can be serialized and stored in `BYTE_ARRAY` Parquet columns. The encoding can be one of:
  - 'pickle'
  - 'bson'
  - 'json'
• `timedelta`: `{"unit": "ns"}`. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.

This metadata is optional altogether

For types other than these, the 'metadata' key can be omitted. Implementations can assume `None` if the key is not present.

As an example of fully-formed metadata:

```json
{"index_columns": ["__index_level_0__"],
 'column_indexes': [ 
  {
 'name': None,
   'field_name': 'None',
   'pandas_type': 'unicode',
   'numpy_type': 'object',
   'metadata': {"encoding": 'UTF-8'}
  },
 'columns': [ 
  {
   'name': 'c0',
   'field_name': 'c0',
   'pandas_type': 'int8',
   'numpy_type': 'int8',
   'metadata': None},
  {
   'name': 'c1',
   'field_name': 'c1',
   'pandas_type': 'bytes',
   'numpy_type': 'object',
   'metadata': None},
  {
   'name': 'c2',
   'field_name': 'c2',
   'pandas_type': 'categorical',
   'numpy_type': 'int16',
   'metadata': {"num_categories": 1000, 'ordered': False}}],
  }]
```
4.9 Policies

4.9.1 Version policy

Changed in version 1.0.0.

pandas uses a loose variant of semantic versioning (SemVer) to govern deprecations, API compatibility, and version numbering.

A pandas release number is made up of MAJOR.MINOR.PATCH.

API breaking changes should only occur in major releases. These changes will be documented, with clear guidance on what is changing, why it’s changing, and how to migrate existing code to the new behavior.

Whenever possible, a deprecation path will be provided rather than an outright breaking change.

pandas will introduce deprecations in minor releases. These deprecations will preserve the existing behavior while emitting a warning that provide guidance on:

- How to achieve similar behavior if an alternative is available
- The pandas version in which the deprecation will be enforced.

We will not introduce new deprecations in patch releases.

Deprecations will only be enforced in major releases. For example, if a behavior is deprecated in pandas 1.2.0, it will continue to work, with a warning, for all releases in the 1.x series. The behavior will change and the deprecation removed in the next major release (2.0.0).

Note: pandas will sometimes make behavior changing bug fixes, as part of minor or patch releases. Whether or not a change is a bug fix or an API-breaking change is a judgement call. We’ll do our best, and we invite you to participate in development discussion on the issue tracker or mailing list.
These policies do not apply to features marked as experimental in the documentation. pandas may change the behavior of experimental features at any time.

4.9.2 Python support

pandas will only drop support for specific Python versions (e.g. 3.6.x, 3.7.x) in pandas major or minor releases.

4.10 Roadmap

This page provides an overview of the major themes in pandas’ development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will necessarily happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item not being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our issue tracker.

See Roadmap evolution for proposing changes to this document.

4.10.1 Extensibility

pandas Extension types allow for extending NumPy types with custom data types and array storage. pandas uses extension types internally, and provides an interface for 3rd-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We’d like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We’ll do this by cleaning up pandas’ internals and adding new methods to the extension array interface.

4.10.2 String data type

Currently, pandas stores text data in an object -dtype NumPy array. The current implementation has two primary drawbacks: First, object -dtype is not specific to strings: any Python object can be stored in an object -dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn’t especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting dtype="string". The array backing this string dtype may initially be the current implementation: an object -dtype NumPy array of Python strings.

To solve the second issue (performance), we’ll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in Series.str.upper). That work may be done outside of pandas.
4.10.3 Consistent missing value handling

Currently, pandas handles missing data differently for different data types. We use different types to indicate that a value is missing (np.nan for floating-point data, np.nan or None for object-dtype data – typically strings or booleans – with missing values, and pd.NaT for datetimelike data). Integer data cannot store missing data or are cast to float. In addition, pandas 1.0 introduced a new missing value sentinel, pd.NA, which is being used for the experimental nullable integer, boolean, and string data types.

These different missing values have different behaviors in user-facing operations. Specifically, we introduced different semantics for the nullable data types for certain operations (e.g. propagating in comparison operations instead of comparing as False).

Long term, we want to introduce consistent missing data handling for all data types. This includes consistent behavior in all operations (indexing, arithmetic operations, comparisons, etc.). We want to eventually make the new semantics the default.

This has been discussed at github #28095 (and linked issues), and described in more detail in this design doc.

4.10.4 Apache Arrow interoperability

Apache Arrow is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We’d like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

4.10.5 Block manager rewrite

We’d like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

pandas internal data model is quite complex. A DataFrame is made up of one or more 2-dimensional “blocks”, with one or more blocks per dtype. This collection of 2-D arrays is managed by the BlockManager.

The primary benefit of the BlockManager is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide DataFrames. However, the BlockManager substantially increases the complexity and maintenance burden of pandas.

By replacing the BlockManager we hope to achieve

- Substantially simpler code
- Easier extensibility with new logical types
- Better user control over memory use and layout
- Improved micro-performance
- Option to provide a C / Cython API to pandas’ internals

See these design documents for more.
4.10.6 Decoupling of indexing and internals

The code for getting and setting values in pandas’ data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to DataFrame.loc) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code

4.10.7 Numba-accelerated operations

Numba is a JIT compiler for Python code. We’d like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, Series.apply(), DataFrame.apply(), DataFrame.applymap(), and in groupby and window contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

4.10.8 Performance monitoring

pandas uses airspeed velocity to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project’s workflow.

The asv-runner organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project’s benchmarks, and tools managing the benchmark runs and reporting on results.

We’d like to fund improvements and maintenance of these tools to

- Be more stable. Currently, they’re maintained on the nights and weekends when a maintainer has free time.
- Tune the system for benchmarks to improve stability, following https://pyperf.readthedocs.io/en/latest/system.html
- Build a GitHub bot to request ASV runs before a PR is merged. Currently, the benchmarks are only run nightly.

4.10.9 Roadmap evolution

pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The pandas mailing list should be notified of the proposal.

When there’s agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue.
4.10.10 Completed items

This section records now completed items from the pandas roadmap.

Documentation improvements

We improved the pandas documentation

- The pandas community worked with others to build the pydata-sphinx-theme, which is now used for https://pandas.pydata.org/docs/ (GH15556).

- Getting started contains a number of resources intended for new pandas users coming from a variety of backgrounds (GH26831).

4.11 Developer meetings

We hold regular developer meetings on the second Wednesday of each month at 18:00 UTC. These meetings and their minutes are open to the public. All are welcome to join.

4.11.1 Minutes

The minutes of past meetings are available in this Google Document.

4.11.2 Calendar

This calendar shows all the developer meetings.

You can subscribe to this calendar with the following links:

- iCal
- Google calendar

Additionally, we’ll sometimes have one-off meetings on specific topics. These will be published on the same calendar.
RELEASE NOTES

This is the list of changes to pandas between each release. For full details, see the commit logs. For install and upgrade instructions, see Installation.

5.1 Version 1.2

5.1.1 What’s new in 1.2.2 (February 09, 2021)

These are the changes in pandas 1.2.2. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `read_excel()` that caused it to raise AttributeError when checking version of older xlrd versions (GH38955)

- Fixed regression in `DataFrame` constructor reordering element when construction from datetime ndarray with dtype not "datetime64[ns]" (GH39422)

- Fixed regression in `DataFrame.astype()` and `Series.astype()` not casting to bytes dtype (GH39474)

- Fixed regression in `to_pickle()` failing to create bz2/xz compressed pickle files with protocol=5 (GH39002)

- Fixed regression in `pandas.testing.assert_series_equal()` and `pandas.testing.assert_frame_equal()` always raising AssertionError when comparing extension dtypes (GH39410)

- Fixed regression in `to_csv()` opening codecs.StreamWriter in binary mode instead of in text mode and ignoring user-provided mode (GH39247)

- Fixed regression in `Categorical.astype()` casting to incorrect dtype when np.int32 is passed to dtype argument (GH39402)

- Fixed regression in `to_excel()` creating corrupt files when appending (mode="a") to an existing file (GH39576)

- Fixed regression in `DataFrame.transform()` failing in case of an empty DataFrame or Series (GH39636)

- Fixed regression in `groupby()` or `resample()` when aggregating an all-NaN or numeric object dtype column (GH39329)

- Fixed regression in `Rolling.count()` where the `min_periods` argument would be set to 0 after the operation (GH39554)
Fixed regression in `read_excel()` that incorrectly raised when the argument `io` was a non-path and non-buffer and the `engine` argument was specified (GH39528)

**Bug fixes**

- `pandas.read_excel()` error message when a specified `sheetname` does not exist is now uniform across engines (GH39250)
- Fixed bug in `pandas.read_excel()` producing incorrect results when the engine `openpyxl` is used and the excel file is missing or has incorrect dimension information; the fix requires `openpyxl` >= 3.0.0, prior versions may still fail (GH38956, GH39001)
- Fixed bug in `pandas.read_excel()` sometimes producing a `DataFrame` with trailing rows of `np.nan` when the engine `openpyxl` is used (GH39181)

**5.1.2 What’s new in 1.2.1 (January 20, 2021)**

These are the changes in pandas 1.2.1. See *Release notes* for a full changelog including other versions of pandas.
Fixed regressions

- Fixed regression in `to_csv()` that created corrupted zip files when there were more rows than chunksize (GH38714)
- Fixed regression in `to_csv()` opening codecs.StreamReaderWriter in binary mode instead of in text mode (GH39247)
- Fixed regression in `read_csv()` and other read functions were the encoding error policy (errors) did not default to "replace" when no encoding was specified (GH38989)
- Fixed regression in `read_excel()` with non-rawbyte file handles (GH38788)
- Fixed regression in `DataFrame.to_stata()` not removing the created file when an error occurred (GH39202)
- Fixed regression in `DataFrame.__setitem__` raising ValueError when expanding `DataFrame` and new column is from type "0 - name" (GH39010)
- Fixed regression in setting with `DataFrame.loc()` raising ValueError when `DataFrame` has unsorted `MultiIndex` columns and indexer is a scalar (GH38601)
- Fixed regression in setting with `DataFrame.loc()` raising KeyError with `MultiIndex` and list-like columns indexer enlarging `DataFrame` (GH39147)
- Fixed regression in `groupby()` with `Categorical` grouping column not showing unused categories for `grouped.indices` (GH38642)
- Fixed regression in `GroupBy.sem()` where the presence of non-numeric columns would cause an error instead of being dropped (GH38774)
- Fixed regression in `DataFrameGroupBy.diff()` raising for `int8` and `int16` columns (GH39050)
- Fixed regression in `DataFrame.groupby()` when aggregating an `ExtensionDType` that could fail for non-numeric values (GH38980)
- Fixed regression in `Rolling.skew()` and `Rolling.kurt()` modifying the object inplace (GH38908)
- Fixed regression in `DataFrame.any()` and `DataFrame.all()` not returning a result for tz-aware `datetime64` columns (GH38723)
- Fixed regression in `DataFrame.apply()` with `axis=1` using `str` accessor in apply function (GH38979)
- Fixed regression in `DataFrame.replace()` raising ValueError when `DataFrame` has dtype `bytes` (GH38900)
- Fixed regression in `Series.fillna()` that raised `RecursionError` with `datetime64[ns, UTC]` dtype (GH38851)
- Fixed regression in comparisons between `NaT` and `datetime.date` objects incorrectly returning True (GH39151)
- Fixed regression in calling NumPy `accumulate()` ufuncs on DataFrames, e.g. np.maximum.accumulate(df) (GH39259)
- Fixed regression in repr of float-like strings of an object dtype having trailing 0’s truncated after the decimal (GH38708)
- Fixed regression that raised `AttributeError` with PyArrow versions [0.16.0, 1.0.0) (GH38801)
- Fixed regression in `pandas.testing.assert_frame_equal()` raising TypeError with check_like=True when `Index` or columns have mixed dtype (GH39168)
We have reverted a commit that resulted in several plotting related regressions in pandas 1.2.0 (GH38969, GH38736, GH38865, GH38947 and GH39126). As a result, bugs reported as fixed in pandas 1.2.0 related to inconsistent tick labeling in bar plots are again present (GH26186 and GH11465)

### Calling NumPy ufuncs on non-aligned DataFrames

Before pandas 1.2.0, calling a NumPy ufunc on non-aligned DataFrames (or DataFrame / Series combination) would ignore the indices, only match the inputs by shape, and use the index/columns of the first DataFrame for the result:

```python
>>> df1 = pd.DataFrame({"a": [1, 2], "b": [3, 4]}, index=[0, 1])
... df2 = pd.DataFrame({"a": [1, 2], "b": [3, 4]}, index=[1, 2])
>>> df1
   a  b
0  1  3
1  2  4
>>> df2
   a  b
1  1  3
2  2  4

>>> np.add(df1, df2)
   a  b
0  2  6
1  4  8
```

This contrasts with how other pandas operations work, which first align the inputs:

```python
>>> df1 + df2
   a  b
0  NaN NaN
1  3.0  7.0
2  NaN NaN
```

In pandas 1.2.0, we refactored how NumPy ufuncs are called on DataFrames, and this started to align the inputs first (GH39184), as happens in other pandas operations and as it happens for ufuncs called on Series objects.

For pandas 1.2.1, we restored the previous behaviour to avoid a breaking change, but the above example of `np.add(df1, df2)` with non-aligned inputs will now raise a warning, and a future pandas 2.0 release will start aligning the inputs first (GH39184). Calling a NumPy ufunc on Series objects (eg `np.add(s1, s2)`) already aligns and continues to do so.

To avoid the warning and keep the current behaviour of ignoring the indices, convert one of the arguments to a NumPy array:

```python
>>> np.add(df1, np.asarray(df2))
   a  b
0  2  6
1  4  8
```

To obtain the future behaviour and silence the warning, you can align manually before passing the arguments to the ufunc:

```python
>>> df1, df2 = df1.align(df2)
>>> np.add(df1, df2)
   a  b
0  NaN NaN
```

(continues on next page)
虫修复

- 缺失在 `read_csv()` 与 float_precision="high" 导致 segfault 或错误解析长指数字符串。这在某些情况下导致 float_precision 的默认值在 pandas 1.2.0（GH38753）中发生变化。
- 缺失在 `read_csv()` 不封闭打开的文件句柄时的 csv.Error 或 UnicodeDecodeError，而初始时（GH39024）。
- 缺失在 `pandas.testing.assert_index_equal()` 时，check_order=False 时导致 Index 变量具有混合 dtype（GH39168）。

其他

- 已废弃的属性 _AXIS_NAMES 和 _AXIS_NUMBERS 的 DataFrame 和 Series 将不会出现在 dir 或 inspect.getmembers 调用中（GH38740）。
- 将 minimum fastparquet 版本提升到 0.4.0 以避免从 numba 的 AttributeError（GH38344）。
- 将 minimum pymysql 版本提升到 0.8.1 以避免测试失败（GH38344）。
- 在 MacOS 11 上修复了 Python 3.9.1 的构建失败（GH38766）。
- 在 pandas 1.1.0 中添加了新功能 check_freq 参数的 `testing.assert_frame_equal()` 和 `testing.assert_series_equal()` 中（GH34050）。

5.1.3 What’s new in 1.2.0 (December 26, 2020)

These are the changes in pandas 1.2.0. See Release notes for a full changelog including other versions of pandas.

**Warning:** The xlwt package for writing old-style .xls excel files is no longer maintained. The xlrd package is now only for reading old-style .xls files.

Previously, the default argument engine=None to read_excel() would result in using the xlrd engine in many cases, including new Excel 2007+ (.xlsx) files. If openpyxl is installed, many of these cases will now default to using the openpyxl engine. See the read_excel() documentation for more details.

Thus, it is strongly encouraged to install openpyxl to read Excel 2007+ (.xlsx) files. **Please do not report issues when using ``xlrd`` to read ``.xlsx`` files.** This is no longer supported, switch to using openpyxl instead.

Attempting to use the xlwt engine will raise a FutureWarning unless the option io.excel.xls.writer is set to "xlwt". While this option is now deprecated and will also raise a FutureWarning, it can be globally set and the warning suppressed. Users are recommended to write .xlsx files using the openpyxl engine instead.

**Enhancements**

**Optionally disallow duplicate labels**

Series and DataFrame can now be created with allows_duplicate_labels=False flag to control whether the index or columns can contain duplicate labels (GH28394). This can be used to prevent accidental introduction of duplicate labels, which can affect downstream operations.

By default, duplicates continue to be allowed.

```
In [1]: pd.Series([1, 2], index=['a', 'a'])
Out[1]:
a    1
   a  2
Length: 2, dtype: int64

In [2]: pd.Series([1, 2], index=['a', 'a']).set_flags(allows_duplicate_labels=False)
```

```
... DuplicateLabelError: Index has duplicates.
   positions
label
a   [0, 1]
```

pandas will propagate the allows_duplicate_labels property through many operations.
In [3]: a = (  
...:     pd.Series([1, 2], index=['a', 'b'])  
...:     .set_flags(allows_duplicate_labels=False)  
...: )

In [4]: a
Out[4]:
   a  1
   b  2
Length: 2, dtype: int64

# An operation introducing duplicates
In [5]: a.reindex(['a', 'b', 'a'])
...:  
DuplicateLabelError: Index has duplicates.

Warning: This is an experimental feature. Currently, many methods fail to propagate the allows_duplicate_labels value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate allows_duplicate_labels.

See Duplicate Labels for more.

The allows_duplicate_labels flag is stored in the new DataFrame.flags attribute. This stores global attributes that apply to the pandas object. This differs from DataFrame.attrs, which stores information that applies to the dataset.

Passing arguments to fsspec backends

Many read/write functions have acquired the storage_options optional argument, to pass a dictionary of parameters to the storage backend. This allows, for example, for passing credentials to S3 and GCS storage. The details of what parameters can be passed to which backends can be found in the documentation of the individual storage backends (detailed from the fsspec docs for builtin implementations and linked to external ones). See Section Reading/writing remote files.

GH35655 added fsspec support (including storage_options) for reading excel files.

Support for binary file handles in to_csv

to_csv() supports file handles in binary mode (GH19827 and GH35058) with encoding (GH13068 and GH23854) and compression (GH22555). If pandas does not automatically detect whether the file handle is opened in binary or text mode, it is necessary to provide mode="wb".

For example:

In [1]: import io

In [2]: data = pd.DataFrame([0, 1, 2])

(continues on next page)
Support for short caption and table position in `to_latex`

`DataFrame.to_latex()` now allows one to specify a floating table position (GH35281) and a short caption (GH36267).

The keyword `position` has been added to set the position.

```python
In [5]: data = pd.DataFrame([{'a': [1, 2], 'b': [3, 4]}
In [6]: table = data.to_latex(position='ht')
In [7]: print(table)
\begin{table}
\centering
\begin{tabular}{lrr}
\toprule
{} & a & b \\
\midrule
0 & 1 & 3 \\
1 & 2 & 4 \\
\bottomrule
\end{tabular}
\end{table}
```

Usage of the keyword `caption` has been extended. Besides taking a single string as an argument, one can optionally provide a tuple `(full_caption, short_caption)` to add a short caption macro.

```python
In [8]: data = pd.DataFrame([{'a': [1, 2], 'b': [3, 4]}
In [9]: table = data.to_latex(caption=('the full long caption', 'short caption'))
In [10]: print(table)
\begin{table}
\centering
\caption[short caption]{the full long caption}
\begin{tabular}{lrr}
\toprule
{} & a & b \\
\midrule
0 & 1 & 3 \\
1 & 2 & 4 \\
\bottomrule
\end{tabular}
\end{table}
```
Change in default floating precision for `read_csv` and `read_table`

For the C parsing engine, the methods `read_csv()` and `read_table()` previously defaulted to a parser that could read floating point numbers slightly incorrectly with respect to the last bit in precision. The option `floating_precision="high"` has always been available to avoid this issue. Beginning with this version, the default is now to use the more accurate parser by making `floating_precision=None` correspond to the high precision parser, and the new option `floating_precision="legacy"` to use the legacy parser. The change to using the higher precision parser by default should have no impact on performance. (GH17154)

Experimental nullable data types for float data

We’ve added `Float32Dtype/Float64Dtype` and `FloatingArray`. These are extension data types dedicated to floating point data that can hold the `pd.NA` missing value indicator (GH32265, GH34307).

While the default float data type already supports missing values using `np.nan`, these new data types use `pd.NA` (and its corresponding behavior) as the missing value indicator, in line with the already existing nullable `integer` and `boolean` data types.

One example where the behavior of `np.nan` and `pd.NA` is different is comparison operations:

```python
# the default NumPy float64 dtype
In [11]: s1 = pd.Series([1.5, None])

In [12]: s1
Out[12]:
0  1.5
1  NaN
Length: 2, dtype: float64

In [13]: s1 > 1
Out[13]:
0  True
1  False
Length: 2, dtype: bool

# the new nullable float64 dtype
In [14]: s2 = pd.Series([1.5, None], dtype="Float64")

In [15]: s2
Out[15]:
0  1.5
1  <NA>
Length: 2, dtype: Float64

In [16]: s2 > 1
Out[16]:
0  True
1  <NA>
Length: 2, dtype: boolean
```

See the [Experimental NA scalar to denote missing values](https://pandas.pydata.org/pandas-docs/dev/user_guide/indexing.html#nullable-data-types) doc section for more details on the behavior when using the `pd.NA` missing value indicator.

As shown above, the dtype can be specified using the “Float64” or “Float32” string (capitalized to distinguish it from the default “float64” data type). Alternatively, you can also use the dtype object:

```python
# the default NumPy float64 dtype
In [11]: s1 = pd.Series([1.5, None])

In [12]: s1
Out[12]:
0  1.5
1  NaN
Length: 2, dtype: float64

In [13]: s1 > 1
Out[13]:
0  True
1  False
Length: 2, dtype: bool

# the new nullable float64 dtype
In [14]: s2 = pd.Series([1.5, None], dtype=Float64)

In [15]: s2
Out[15]:
0  1.5
1  <NA>
Length: 2, dtype: Float64

In [16]: s2 > 1
Out[16]:
0  True
1  <NA>
Length: 2, dtype: boolean
```
In [17]: pd.Series([1.5, None], dtype=pd.Float32Dtype())
Out[17]:
   0    1.5
  <NA>
Length: 2, dtype: Float32

Operations with the existing integer or boolean nullable data types that give float results will now also use the nullable floating data types (GH38178).

**Warning:** Experimental: the new floating data types are currently experimental, and their behavior or API may still change without warning. Especially the behavior regarding NaN (distinct from NA missing values) is subject to change.

### Index/column name preservation when aggregating

When aggregating using `concat()` or the `DataFrame` constructor, pandas will now attempt to preserve index and column names whenever possible (GH35847). In the case where all inputs share a common name, this name will be assigned to the result. When the input names do not all agree, the result will be unnamed. Here is an example where the index name is preserved:

```python
In [18]: idx = pd.Index(range(5), name='abc')
In [19]: ser = pd.Series(range(5, 10), index=idx)
In [20]: pd.concat({'x': ser[1:], 'y': ser[:-1]}, axis=1)
```

```
Out[20]:
   x   y
  abc
   0  NaN  5.0
   1  6.0  6.0
   2  7.0  7.0
   3  8.0  8.0
   4  9.0  NaN
[5 rows x 2 columns]
```

The same is true for `MultiIndex`, but the logic is applied separately on a level-by-level basis.

### GroupBy supports EWM operations directly

`DataFrameGroupBy` now supports exponentially weighted window operations directly (GH16037).

```python
In [21]: df = pd.DataFrame({'A': ['a', 'b', 'a', 'b'], 'B': range(4)})
In [22]: df
Out[22]:
   A   B
   0 a   0
   1 b   1
   2 a   2
   3 b   3
```

(continues on next page)
Additionally, `mean` supports execution via Numba with the `engine` and `engine_kwargs` arguments. Numba must be installed as an optional dependency to use this feature.

**Other enhancements**

- Added `day_of_week` (compatibility alias `dayofweek`) property to `Timestamp`, `DatetimeIndex`, `Period`, `PeriodIndex` (GH9605)
- Added `day_of_year` (compatibility alias `dayofyear`) property to `Timestamp`, `DatetimeIndex`, `Period`, `PeriodIndex` (GH9605)
- Added `set_flags()` for setting table-wide flags on a Series or DataFrame (GH28394)
- `DataFrame.applymap()` now supports `na_action` (GH23803)
- `Index` with object dtype supports division and multiplication (GH34160)
- `io.sql.get_schema()` now supports a `schema` keyword argument that will add a schema into the create table statement (GH28486)
- `DataFrame.explode()` and `Series.explode()` now support exploding of sets (GH35614)
- `DataFrame.hist()` now supports time series (datetime) data (GH32590)
- `Styler.set_table_styles()` now allows the direct styling of rows and columns and can be chained (GH35607)
- `Styler` now allows direct CSS class name addition to individual data cells (GH36159)
- `Rolling.mean()` and `Rolling.sum()` use Kahan summation to calculate the mean to avoid numerical problems (GH10319, GH11645, GH13254, GH32761, GH36031)
- `DatetimeIndex.searchsorted()`, `TimedeltaIndex.searchsorted()`, `PeriodIndex.searchsorted()`, and `Series.searchsorted()` with datetime-like dtypes will now try to cast string arguments (list-like and scalar) to the matching datetime-like type (GH36346)
- Added methods `IntegerArray.prod()`, `IntegerArray.min()`, and `IntegerArray.max()` (GH33790)
- Calling a NumPy ufunc on a `DataFrame` with extension types now preserves the extension types when possible (GH23743)
- Calling a binary-input NumPy ufunc on multiple `DataFrame` objects now aligns, matching the behavior of binary operations and ufuncs on `Series` (GH23743). This change has been reverted in pandas 1.2.1, and the behaviour to not align DataFrames is deprecated instead, see the the 1.2.1 release notes.
• Where possible, `RangeIndex.difference()` and `RangeIndex.symmetric_difference()` will return `RangeIndex` instead of `Int64Index` (GH36564)
• `DataFrame.to_parquet()` now supports `MultiIndex` for columns in parquet format (GH34777)
• `read_parquet()` gained a `use_nullable_dtypes=True` option to use nullable dtypes that use `pd.NA` as missing value indicator where possible for the resulting DataFrame (default is False, and only applicable for `engine="pyarrow"`) (GH31242)
• Added `Rolling.sem()` and `Expanding.sem()` to compute the standard error of the mean (GH26476)
• `Rolling.var()` and `Rolling.std()` use Kahan summation and Welford’s Method to avoid numerical issues (GH3051)
• `DataFrame.corr()` and `DataFrame.cov()` use Welford’s Method to avoid numerical issues (GH37448)
• `DataFrame.plot()` now recognizes `xlabel` and `ylabel` arguments for plots of type `scatter` and `hexbin` (GH37001)
• `DataFrame` now supports the `divmod` operation (GH37165)
• `DataFrame.to_parquet()` now returns a `bytes` object when no `path` argument is passed (GH37105)
• `Rolling` now supports the `closed` argument for fixed windows (GH34315)
• `DatetimeIndex` and `Series` with `datetime64` or `datetime64tz` dtypes now support `std` (GH37436)
• Window now supports all Scipy window types in `win_type` with flexible keyword argument support (GH34556)
• `testing.assert_index_equal()` now has a `check_order` parameter that allows indexes to be checked in an order-insensitive manner (GH37478)
• `read_csv()` supports memory-mapping for compressed files (GH37621)
• Add support for `min_count` keyword for `DataFrame.groupby()` and `DataFrame.resample()` for functions `min`, `max`, `first` and `last` (GH37821, GH37768)
• Improve error reporting for `DataFrame.merge()` when invalid merge column definitions were given (GH16228)
• Improve numerical stability for `Rolling.skew()`, `Rolling.kurt()`, `Expanding.skew()` and `Expanding.kurt()` through implementation of Kahan summation (GH6929)
• Improved error reporting for subsetting columns of a `DataFrameGroupBy` with `axis=1` (GH37725)
• Implement method `cross` for `DataFrame.merge()` and `DataFrame.join()` (GH5401)
• When `read_csv()`, `read_sas()` and `read_json()` are called with `chunksize/iterator` they can be used in a `with` statement as they return context-managers (GH38225)
• Augmented the list of named colors available for styling Excel exports, enabling all of CSS4 colors (GH38247)
Notable bug fixes

These are bug fixes that might have notable behavior changes.

Consistency of DataFrame Reductions

`DataFrame.any()` and `DataFrame.all()` with `bool_only=True` now determines whether to exclude object-dtype columns on a column-by-column basis, instead of checking if all object-dtype columns can be considered boolean.

This prevents pathological behavior where applying the reduction on a subset of columns could result in a larger Series result. See (GH37799).

```
In [24]: df = pd.DataFrame({"A": ["foo", "bar"], "B": [True, False]}, dtype=object)
In [25]: df["C"] = pd.Series([True, True])
```

**Previous behavior:**

```
In [5]: df.all(bool_only=True)
Out[5]:
   C  True
dtype: bool

In [6]: df["B", "C"].all(bool_only=True)
Out[6]:
   B  False
   C  True
dtype: bool
```

**New behavior:**

```
In [26]: In [5]: df.all(bool_only=True)
Out[26]:
   B  False
   C  True
Length: 2, dtype: bool

In [27]: In [6]: df["B", "C"].all(bool_only=True)
Out[27]:
   B  False
   C  True
Length: 2, dtype: bool
```

Other DataFrame reductions with `numeric_only=None` will also avoid this pathological behavior (GH37827):

```
in [28]: df = pd.DataFrame({"A": [0, 1, 2], "B": ["a", "b", "c"], }, dtype=object)
in [29]: df.mean()
Out[29]:
   A  1.0
```

**Previous behavior:**

```
in [3]: df.mean()
Out[3]: Series([], dtype: float64)

in [4]: df["A"].mean()
Out[4]:
   A  1.0
dtype: float64
```

5.1. Version 1.2
New behavior:

```python
In [29]: df.mean()
Out[29]:
A   1.0
Length: 1, dtype: float64

In [30]: df["A"].mean()
Out[30]:
A   1.0
Length: 1, dtype: float64
```

Moreover, DataFrame reductions with `numeric_only=None` will now be consistent with their Series counterparts. In particular, for reductions where the Series method raises `TypeError`, the DataFrame reduction will now consider that column non-numeric instead of casting to a NumPy array which may have different semantics (GH36076, GH28949, GH21020).

```python
In [31]: ser = pd.Series([0, 1], dtype="category", name="A")
In [32]: df = ser.to_frame()
```

Previous behavior:

```python
In [5]: df.any()
Out[5]:
A   True
dtype: bool
```

New behavior:

```python
In [33]: df.any()
Out[33]:
Series([], Length: 0, dtype: bool)
```

**Increased minimum version for Python**

pandas 1.2.0 supports Python 3.7.1 and higher (GH35214).

**Increased minimum supported versions for dependencies**

Some minimum supported versions of dependencies were updated (GH35214). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.16.5</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>pytz</td>
<td>2017.3</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.7.3</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.6.8</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>5.0.1</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>mypy (dev)</td>
<td>0.782</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.
### Other API changes

- Sorting in descending order is now stable for `Series.sort_values()` and `Index.sort_values()` for Datetime-like `Index` subclasses. This will affect sort order when sorting a DataFrame on multiple columns, sorting with a key function that produces duplicates, or requesting the sorting index when using `Index.sort_values()`. When using `Series.value_counts()`, the count of missing values is no longer necessarily last in the list of duplicate counts. Instead, its position corresponds to the position in the original Series. When using `Index.sort_values()` for Datetime-like `Index` subclasses, NaTs ignored the `na_position` argument and were sorted to the beginning. Now they respect `na_position`, the default being last, same as other `Index` subclasses (GH35992)

- Passing an invalid `fill_value` to `Categorical.take()`, `DatetimeArray.take()`, `TimedeltaArray.take()`, or `PeriodArray.take()` now raises a `TypeError` instead of a `ValueError` (GH37733)

- Passing an invalid `fill_value` to `Series.shift()` with a `CategoricalDtype` now raises a `TypeError` instead of a `ValueError` (GH37733)

- Passing an invalid value to `IntervalIndex.insert()` or `CategoricalIndex.insert()` now raises a `TypeError` instead of a `ValueError` (GH37733)

- Attempting to reindex a Series with a `CategoricalIndex` with an invalid `fill_value` now raises a `TypeError` instead of a `ValueError` (GH37733)

- `CategoricalIndex.append()` with an index that contains non-category values will now cast instead of raising `TypeError` (GH38098)
Deprecations

- Deprecated parameter `inplace` in `MultiIndex.set_codes()` and `MultiIndex.set_levels()` (GH35626)
- Deprecated parameter `dtype` of method `copy()` for all `Index` subclasses. Use the `astype()` method instead for changing dtype (GH35853)
- Deprecated parameters `levels` and `codes` in `MultiIndex.copy()`. Use the `set_levels()` and `set_codes()` methods instead (GH36685)
- Date parser functions `parse_date_time()`, `parse_date_fields()`, `parse_all_fields()` and `generic_parser()` from `pandas.io.date_converters` are deprecated and will be removed in a future version; use `to_datetime()` instead (GH35741)
- `DataFrame.lookup()` is deprecated and will be removed in a future version, use `DataFrame.melt()` and `DataFrame.loc()` instead (GH35224)
- The method `Index.to_native_types()` is deprecated. Use `.astype(str)` instead (GH28867)
- Deprecated indexing `DataFrame` rows with a single datetime-like string as `df[string]` (given the ambiguity whether it is indexing the rows or selecting a column), use `df.loc[string]` instead (GH36179)
- Deprecated `Index.is_all_dates()` (GH27744)
- The default value of `regex` for `Series.str.replace()` will change from `True` to `False` in a future release. In addition, single character regular expressions will not be treated as literal strings when `regex=True` is set (GH24804)
- Deprecated automatic alignment on comparison operations between `DataFrame` and `Series`, do `frame, ser = frame.align(ser, axis=1, copy=False)` before e.g. `frame == ser` (GH28759)
- `Rolling.count()` with `min_periods=None` will default to the size of the window in a future version (GH31302)
- Using “outer” ufuncs on DataFrames to return 4d ndarray is now deprecated. Convert to an ndarray first (GH23743)
- Deprecated slice-indexing on tz-aware `DatetimeIndex` with naive datetime objects, to match scalar indexing behavior (GH36148)
- `Index.ravel()` returning a np.ndarray is deprecated, in the future this will return a view on the same index (GH19956)
- Deprecated use of strings denoting units with ‘M’, ‘Y’ or ‘y’ in `to_timedelta()` (GH36666)
- `Index` methods `&`, `|`, and `^` behaving as the set operations `Index.intersection()`, `Index.union()`, and `Index.symmetric_difference()`, respectively, are deprecated and in the future will behave as pointwise boolean operations matching `Series` behavior. Use the named set methods instead (GH36758)
- `Categorical.is_dtype_equal()` and `CategoricalIndex.is_dtype_equal()` are deprecated, will be removed in a future version (GH37545)
- `Series.slice_shift()` and `DataFrame.slice_shift()` are deprecated, use `Series.shift()` or `DataFrame.shift()` instead (GH37601)
- Partial slicing on unordered `DatetimeIndex` objects with keys that are not in the index is deprecated and will be removed in a future version (GH18531)
- The `how` keyword in `PeriodIndex.astype()` is deprecated and will be removed in a future version, use `index.to_timestamp(how=how)` instead (GH37982)
- Deprecated `Index.asi8()` for `Index` subclasses other than `DatetimeIndex`, `TimedeltaIndex`, and `PeriodIndex` (GH37877)
• The inplace parameter of Categorical.remove_unused_categories() is deprecated and will be removed in a future version (GH37643)

• The null_counts parameter of DataFrame.info() is deprecated and replaced by show_counts. It will be removed in a future version (GH37999)

Calling NumPy ufuncs on non-aligned DataFrames

Calling NumPy ufuncs on non-aligned DataFrames changed behaviour in pandas 1.2.0 (to align the inputs before calling the ufunc), but this change is reverted in pandas 1.2.1. The behaviour to not align is now deprecated instead, see the the 1.2.1 release notes for more details.

Performance improvements

• Performance improvements when creating DataFrame or Series with dtype str or StringDtype from array with many string elements (GH36304, GH36317, GH36325, GH36432, GH37371)

• Performance improvement in GroupBy.agg() with the numba engine (GH35759)

• Performance improvements when creating Series.map() from a huge dictionary (GH34717)

• Performance improvement in GroupBy.transform() with the numba engine (GH36240)

• Styler uuid method altered to compress data transmission over web whilst maintaining reasonably low table collision probability (GH36345)

• Performance improvement in to_datetime() with non-ns time unit for float dtype columns (GH20445)

• Performance improvement in setting values on an IntervalArray (GH36310)

• The internal index method _shallow_copy() now makes the new index and original index share cached attributes, avoiding creating these again, if created on either. This can speed up operations that depend on creating copies of existing indexes (GH36840)

• Performance improvement in RollingGroupby.count() (GH35625)

• Small performance decrease to Rolling.min() and Rolling.max() for fixed windows (GH36567)

• Reduced peak memory usage in DataFrame.to_pickle() when using protocol=5 in python 3.8+ (GH34244)

• Faster dir calls when the object has many index labels, e.g. dir(ser) (GH37450)

• Performance improvement in ExpandingGroupby (GH37064)

• Performance improvement in Series.astype() and DataFrame.astype() for Categorical (GH8628)

• Performance improvement in DataFrame.groupby() for float dtype (GH28303), changes of the underlying hash-function can lead to changes in float based indexes sort ordering for ties (e.g. Index.value_counts())

• Performance improvement in pd.isin() for inputs with more than 1e6 elements (GH36611)

• Performance improvement for DataFrame._setitem__() with list-like indexers (GH37954)

• read_json() now avoids reading entire file into memory when chunksize is specified (GH34548)
Bug fixes

Categorical

- `Categorical.fillna()` will always return a copy, validate a passed fill value regardless of whether there are any NAs to fill, and disallow an NaT as a fill value for numeric categories (GH36530).
- Bug in `Categorical.__setitem__()` that incorrectly raised when trying to set a tuple value (GH20439).
- Bug in `CategoricalIndex.equals()` incorrectly casting non-category entries to np.nan (GH37667).
- Bug in `CategoricalIndex.where()` incorrectly setting non-category entries to np.nan instead of raising `TypeError` (GH37977).
- Bug in `Categorical.to_numpy()` and `np.array(categorical)` with tz-aware datetime64 categories incorrectly dropping the time zone information instead of casting to object dtype (GH38136).

Datetime-like

- Bug in `DataFrame.combine_first()` that would convert datetime-like column on other `DataFrame` to integer when the column is not present in original `DataFrame` (GH28481).
- Bug in `DatetimeArray.date` where a `ValueError` would be raised with a read-only backing array (GH33530).
- Bug in `NaT` comparisons failing to raise `TypeError` on invalid inequality comparisons (GH35046).
- Bug in `DateOffset` where attributes reconstructed from pickle files differ from original objects when input values exceed normal ranges (e.g. months=12) (GH34511).
- Bug in `DatetimeIndex.get_slice_bound()` where `datetime.date` objects were not accepted or naive `Timestamp` with a tz-aware `DatetimeIndex` (GH35690).
- Bug in `DatetimeIndex.slice_loc()` where `datetime.date` objects were not accepted (GH34077).
- Bug in `DatetimeIndex.searchsorted()`, `TimedeltaIndex.searchsorted()`, `PeriodIndex.searchsorted()`, and `Series.searchsorted()` with datetime64, timedelta64 or `Period` dtype placement of NaT values being inconsistent with NumPy (GH36176, GH36254).
- Inconsistency in `DatetimeArray`, `TimedeltaArray`, and `PeriodArray` method `__setitem__` casting arrays of strings to datetime-like scalars but not scalar strings (GH36261).
- Bug in `DatetimeArray.take()` incorrectly allowing `fill_value` with a mismatched time zone (GH37356).
- Bug in `DatetimeIndex.shift` incorrectly raising when shifting empty indexes (GH14811).
- `Timestamp` and `DatetimeIndex` comparisons between tz-aware and tz-naive objects now follow the standard library datetime behavior, returning `True/False` for `!=/==` and raising for inequality comparisons (GH28507).
- Bug in `DatetimelIndex.equals()` and `TimedeltaIndex.equals()` incorrectly considering int64 indexes as equal (GH36744).
- `Series.to_json()`, `DataFrame.to_json()`, and `read_json()` now implement time zone parsing when orient structure is table (GH35973).
- `astype()` now attempts to convert to `datetime64[ns, tz]` directly from `object` with inferred time zone from string (GH35973).
- Bug in `TimedeltaIndex.sum()` and `Series.sum()` with timedelta64 dtype on an empty index or series returning NaT instead of `Timedelta(0)` (GH31751)

- Bug in `DatetimeArray.shift()` incorrectly allowing `fill_value` with a mismatched time zone (GH37299)

- Bug in adding a `BusinessDay` with nonzero offset to a non-scalar other (GH37457)

- Bug in `to_datetime()` with a read-only array incorrectly raising (GH34857)

- Bug in `Series.isin()` with `datetime64[ns]` dtype and `DatetimeIndex.isin()` incorrectly casting integers to datetimes (GH36621)

- Bug in `Series.isin()` with `datetime64[ns]` dtype and `DatetimeIndex.isin()` failing to consider tz-aware and tz-naive datetimes as always different (GH35728)

- Bug in `Series.isin()` with `PeriodDtype` dtype and `PeriodIndex.isin()` failing to consider arguments with different `PeriodDtype` as always different (GH37528)

- Bug in `Period` constructor now correctly handles nanoseconds in the `value` argument (GH34621 and GH17053)

**Timedelta**

- Bug in `TimedeltaIndex`, `Series`, and `DataFrame` floor-division with timedelta64 dtypes and NaT in the denominator (GH35529)

- Bug in parsing of ISO 8601 durations in `Timedelta` and `to_datetime()` (GH29773, GH36204)

- Bug in `to_timedelta()` with a read-only array incorrectly raising (GH34857)

- Bug in `Timedelta` incorrectly truncating to sub-second portion of a string input when it has precision higher than nanoseconds (GH36738)

**Timezones**

- Bug in `date_range()` was raising `AmbiguousTimeError` for valid input with `ambiguous=False` (GH35297)

- Bug in `Timestamp.replace()` was losing fold information (GH37610)

**Numeric**

- Bug in `to_numeric()` where float precision was incorrect (GH31364)

- Bug in `DataFrame.any()` with `axis=1` and `bool_only=True` ignoring the `bool_only` keyword (GH32432)

- Bug in `Series.equals()` where a `ValueError` was raised when NumPy arrays were compared to scalars (GH35267)

- Bug in `Series` where two Series each have a `DatetimeIndex` with different time zones having those indexes incorrectly changed when performing arithmetic operations (GH33671)

- Bug in `pandas.testing` module functions when used with `check_exact=False` on complex numeric types (GH28235)

- Bug in `DataFrame.__rmatmul__()` error handling reporting transposed shapes (GH21581)
• Bug in `Series` flex arithmetic methods where the result when operating with a list, tuple or np.
  ndarray would have an incorrect name (GH36760)
• Bug in `IntegerArray` multiplication with timedelta and np.timedelta64 objects (GH36870)
• Bug in `MultiIndex` comparison with tuple incorrectly treating tuple as array-like (GH21517)
• Bug in `DataFrame.diff()` with datetime64 dtypes including NaT values failing to fill NaT results
  correctly (GH32441)
• Bug in `DataFrame` arithmetic ops incorrectly accepting keyword arguments (GH36843)
• Bug in `IntervalArray` comparisons with `Series` not returning Series (GH36908)
• Bug in `DataFrame` allowing arithmetic operations with list of array-likes with undefined results. Behavior
  changed to raising `ValueError` (GH36702)
• Bug in `DataFrame.std()` with timedelta64 dtype and skipna=False (GH37392)
• Bug in `DataFrame.min()` and `DataFrame.max()` with datetime64 dtype and skipna=False
  (GH36907)
• Bug in `DataFrame.idxmax()` and `DataFrame.idxmin()` with mixed dtypes incorrectly raising
  `TypeError` (GH38195)

**Conversion**

• Bug in `DataFrame.to_dict()` with orient='records' now returns python native datetime objects
  for datetime-like columns (GH21256)
• Bug in `Series.astype()` conversion from string to float raised in presence of pd.NA values
  (GH37626)

**Strings**

• Bug in `Series.to_string()`, `DataFrame.to_string()`, and `DataFrame.to_latex()` adding
  a leading space when index=False (GH24980)
• Bug in `to_numeric()` raising a `TypeError` when attempting to convert a string dtype Series containing
  only numeric strings and NA (GH37262)

**Interval**

• Bug in `DataFrame.replace()` and `Series.replace()` where Interval dtypes would be converted
  to object dtypes (GH34871)
• Bug in `IntervalIndex.take()` with negative indices and fill_value=None (GH37330)
• Bug in `IntervalIndex.putmask()` with datetime-like dtype incorrectly casting to object dtype
  (GH37968)
• Bug in `IntervalArray.astype()` incorrectly dropping dtype information with a `CategoricalDtype`
  object (GH37984)
Indexing

- **Bug in **`PeriodIndex.get_loc()` **incorrectly raising** `ValueError` **on non-datelike strings instead of** `KeyError`, **causing similar errors in Series.__getitem__(), Series.__contains__(), and Series.loc.__getitem__()** (GH34240)

- **Bug in **`Index.sort_values()` **where, when empty values were passed, the method would break by trying to compare missing values instead of pushing them to the end of the sort order** (GH35584)

- **Bug in **`Index.get_indexer()` **and Index.get_indexer_non_unique()` where int64 arrays are returned instead of intp** (GH36359)

- **Bug in **`DataFrame.sort_index()` **where parameter ascending passed as a list on a single level index gives wrong result** (GH32334)

- **Bug in **`DataFrame.reset_index()` **was incorrectly raising a ValueError for input with a MultiIndex with missing values in a level with Categorical dtype** (GH24206)

- **Bug in indexing with boolean masks on datetime-like values sometimes returning a view instead of a copy** (GH36210)

- **Bug in DataFrame.__getitem__() and DataFrame.loc.__getitem__() with IntervalIndex columns and a numeric indexer** (GH26490)

- **Bug in Series.__getitem__() with a non-unique MultiIndex and an empty-list indexer** (GH13691)

- **Bug in indexing on a Series or DataFrame with a MultiIndex and a level named "0"** (GH37194)

- **Bug in Series.__getitem__() when using an unsigned integer array as an indexer giving incorrect results or segfaulting instead of raising KeyError** (GH37218)

- **Bug in Index.where() incorrectly casting numeric values to strings** (GH37591)

- **Bug in DataFrame.loc() returning empty result when indexer is a slice with negative step size** (GH38071)

- **Bug in Series.loc() and DataFrame.loc() raises when the index was of object dtype and the given numeric label was in the index** (GH26491)

- **Bug in DataFrame.loc() returned requested key plus missing values when loc was applied to single level from a MultiIndex** (GH27104)

- **Bug in indexing on a Series or DataFrame with a CategoricalIndex using a list-like indexer containing NA values** (GH37722)

- **Bug in DataFrame.loc.__setitem__() expanding an empty DataFrame with mixed dtypes** (GH37932)

- **Bug in DataFrame.xs() ignored droplevel=False for columns** (GH19056)

- **Bug in DataFrame.reindex() raising IndexError wrongly for empty DataFrame with tolerance not None or method="nearest"** (GH27315)

- **Bug in indexing on a Series or DataFrame with a CategoricalIndex using list-like indexer that contains elements that are in the index’s categories but not in the index itself failing to raise Key Error** (GH37901)

- **Bug on inserting a boolean label into a DataFrame with a numeric Index columns incorrectly casting to integer** (GH36319)

- **Bug in DataFrame.iloc() and Series.iloc() aligning objects in __setitem__**(GH22046)

- **Bug in MultiIndex.drop() does not raise if labels are partially found** (GH37820)
- Bug in `DataFrame.loc()` did not raise `KeyError` when missing combination was given with `slice(None)` for remaining levels (GH19556)
- Bug in `DataFrame.loc()` raising `TypeError` when non-integer slice was given to select values from `MultiIndex` (GH25165, GH24263)
- Bug in `Series.at()` returning `Series` with one element instead of scalar when index is a `MultiIndex` with one level (GH38053)
- Bug in `DataFrame.loc()` returning and assigning elements in wrong order when indexer is differently ordered than the `MultiIndex` to filter (GH31330, GH34603)
- Bug in `DataFrame.loc()` and `DataFrame.__getitem__()` raising `KeyError` when columns were `MultiIndex` with only one level (GH29749)
- Bug in `Series.__getitem__()` and `DataFrame.__getitem__()` raising blank `KeyError` without missing keys for `IntervalIndex` (GH27365)
- Bug in setting a new label on a `DataFrame` or `Series` with a `CategoricalIndex` incorrectly raising `TypeError` when the new label is not among the index's categories (GH38098)
- Bug in `Series.loc()` and `Series.iloc()` raising `ValueError` when inserting a list-like `np.array`, `list` or `tuple` in an `object` `Series` of equal length (GH37748, GH37486)
- Bug in `Series.loc()` and `Series.iloc()` setting all the values of an `object` `Series` with those of a list-like `ExtensionArray` instead of inserting it (GH38271)

**Missing**

- Bug in `SeriesGroupBy.transform()` now correctly handles missing values for `dropna=False` (GH35014)
- Bug in `Series.nunique()` with `dropna=True` was returning incorrect results when both NA and None missing values were present (GH37566)
- Bug in `Series.interpolate()` where kwarg `limit_area` and `limit_direction` had no effect when using methods `pad` and `backfill` (GH31048)

**MultiIndex**

- Bug in `DataFrame.xs()` when used with `IndexSlice` raises `TypeError` with message "Expected label or tuple of labels" (GH35301)
- Bug in `DataFrame.reset_index()` with NaT values in index raises `ValueError` with message "cannot convert float NaN to integer" (GH36541)
- Bug in `DataFrame.combine_first()` when used with `MultiIndex` containing string and NaN values raises `TypeError` (GH36562)
- Bug in `MultiIndex.drop()` dropped NaN values when non existing key was given as input (GH18853)
- Bug in `MultiIndex.drop()` dropping more values than expected when index has duplicates and is not sorted (GH33494)
I/O

- `read_sas()` no longer leaks resources on failure (GH35566)
- Bug in `DataFrame.to_csv()` and `Series.to_csv()` caused a `ValueError` when it was called with a filename in combination with `mode` containing a b (GH35058)
- Bug in `read_csv()` with `float_precision='round_trip'` did not handle decimal and thousands parameters (GH35365)
- `to_pickle()` and `read_pickle()` were closing user-provided file objects (GH35679)
- `to_csv()` passes compression arguments for 'gzip' always to `gzip.GzipFile` (GH28103)
- `to_csv()` did not support zip compression for binary file object not having a filename (GH35058)
- `to_csv()` and `read_csv()` did not honor compression and encoding for path-like objects that are internally converted to file-like objects (GH35677, GH26124, GH32392)
- `DataFrame.to_pickle()`, `Series.to_pickle()`, and `read_pickle()` did not support compression for file-objects (GH26237, GH29054, GH29570)
- Bug in `LongTableBuilder.middle_separator()` was duplicating LaTeX longtable entries in the List of Tables of a LaTeX document (GH34360)
- Bug in `read_csv()` with `engine='python'` truncating data if multiple items present in first row and first element started with BOM (GH36343)
- Removed `private_key` and `verbose` from `read_gbq()` as they are no longer supported in pandas-gbq (GH34654, GH30200)
- Bumped minimum pytables version to 3.5.1 to avoid a `ValueError` in `read_hdf()` (GH24839)
- Bug in `read_table()` and `read_csv()` when `delim_whitespace=True` and `sep=default` (GH36583)
- Bug in `DataFrame.to_json()` and `Series.to_json()` when used with `lines=True` and `orient='records'` the last line of the record is not appended with 'new line character' (GH36888)
- Bug in `DataFrame.to_hdf()` was not dropping missing rows with `dropna=True` (GH35719)
- Bug in `read_html()` was raising a `TypeError` when supplying a `pathlib.Path` argument to the `io` parameter (GH37705)
- `DataFrame.to_excel()`, `Series.to_excel()`, `DataFrame.to_markdown()`, and `Series.to_markdown()` now support writing to fsspec URLs such as S3 and Google Cloud Storage (GH33987)
- Bug in `read_fwf()` with `skip_blank_lines=True` was not skipping blank lines (GH37758)
pandas: powerful Python data analysis toolkit, Release 1.2.2

- Parse missing values using `read_json()` with `dtype=False` to NaN instead of None (GH28501)
- `read_fwf()` was inferring compression with `compression=None` which was not consistent with the other `read_*` functions (GH37909)
- `DataFrame.to_html()` was ignoring formatters argument for `ExtensionDtype` columns (GH36525)
- Bumped minimum xarray version to 0.12.3 to avoid reference to the removed `Panel` class (GH27101, GH37983)
- `DataFrame.to_csv()` was re-opening file-like handles that also implement `os.PathLike` (GH38125)
- Bug in the conversion of a sliced `pyarrow.Table` with missing values to a DataFrame (GH38525)
- Bug in `read_sql_table()` raising a `sqlalchemy.exc.OperationalError` when column names contained a percentage sign (GH37517)

**Period**

- Bug in `DataFrame.replace()` and `Series.replace()` where `Period` dtypes would be converted to object dtypes (GH34871)

**Plotting**

- Bug in `DataFrame.plot()` was rotating xticklabels when `subplots=True`, even if the x-axis wasn’t an irregular time series (GH29460)
- Bug in `DataFrame.plot()` where a marker letter in the `style` keyword sometimes caused a `ValueError` (GH21003)
- Bug in `DataFrame.plot.bar()` and `Series.plot.bar()` where ticks positions were assigned by value order instead of using the actual value for numeric or a smart ordering for string (GH26186, GH11465). This fix has been reverted in pandas 1.2.1, see What's new in 1.2.1 (January 20, 2021)
- Twinned axes were losing their tick labels which should only happen to all but the last row or column of ‘externally’ shared axes (GH33819)
- Bug in `Series.plot()` and `DataFrame.plot()` was throwing a `ValueError` when the Series or DataFrame was indexed by a `TimedeltaIndex` with a fixed frequency and the x-axis lower limit was greater than the upper limit (GH37454)
- Bug in `DataFrameGroupBy.boxplot()` when `subplots=False` would raise a `KeyError` (GH16748)
- Bug in `DataFrame.plot()` and `Series.plot()` was overwriting matplotlib’s shared y axes behavior when no `sharey` parameter was passed (GH37942)
- Bug in `DataFrame.plot()` was raising a `TypeError` with `ExtensionDtype` columns (GH32073)
Styler

- Bug in `Styler.render()` HTML was generated incorrectly because of formatting error in `rowspan` attribute, it now matches with w3 syntax (GH38234)

Groupby/resample/rolling

- Bug in `DataFrameGroupBy.count()` and `SeriesGroupBy.sum()` returning NaN for missing categories when grouped on multiple Categoricals. Now returning 0 (GH35028)
- Bug in `DataFrameGroupBy.apply()` that would sometimes throw an erroneous `ValueError` if the grouping axis had duplicate entries (GH16646)
- Bug in `DataFrame.resample()` that would throw a `ValueError` when resampling from "D" to "24H" over a transition into daylight savings time (DST) (GH35219)
- Bug when combining methods `DataFrame.groupby()` with `DataFrame.resample()` and `DataFrame.interpolate()` raising a `TypeError` (GH35325)
- Bug in `DataFrameGroupBy.apply()` where a non-nuisance grouping column would be dropped from the output columns if another groupby method was called before `.apply` (GH34656)
- Bug when subsetting columns on a `DataFrameGroupBy` (e.g. `df.groupby('a')[[b]]`) would reset the attributes `axis`, `dropna`, `group_keys`, `level`, `mutated`, `sort`, and `squeeze` to their default values (GH9959)
- Bug in `DataFrameGroupBy.tshift()` failing to raise `ValueError` when a frequency cannot be inferred for the index of a group (GH35937)
- Bug in `DataFrame.groupby()` does not always maintain column index name for any, all, bfill, ffill, shift (GH29764)
- Bug in `DataFrameGroupBy.apply()` raising error with `np.nan` group(s) when dropna=False (GH35889)
- Bug in `Rolling.sum()` returned wrong values when dtypes where mixed between float and integer and axis=1 (GH20649, GH35596)
- Bug in `Rolling.count()` returned `np.nan` with `FixedForwardWindowIndexer` as window, min_periods=0 and only missing values in the window (GH35579)
- Bug where pandas.core.window.Rolling produces incorrect window sizes when using a `PeriodIndex` (GH34225)
- Bug in `DataFrameGroupBy.ffill()` and `DataFrameGroupBy.bfill()` where a NaN group would return filled values instead of NaN when dropna=True (GH34725)
- Bug in `RollingGroupby.count()` where a `ValueError` was raised when specifying the `closed` parameter (GH35869)
- Bug in `DataFrameGroupBy.rolling()` returning wrong values with partial centered window (GH36040)
- Bug in `DataFrameGroupBy.rolling()` returned wrong values with time aware window containing NaN. Raises `ValueError` because windows are not monotonic now (GH34617)
- Bug in `Rolling.__iter__()` where a `ValueError` was not raised when `min_periods` was larger than window (GH37156)
- Using `Rolling.var()` instead of `Rolling.std()` avoids numerical issues for `Rolling.corr()` when `Rolling.var()` is still within floating point precision while `Rolling.std()` is not (GH31286)
• Bug in DataFrameGroupBy.quantile() and Resampler.quantile() raised TypeError when values were of type Timedelta (GH29485)

• Bug in Rolling.median() and Rolling.quantile() returned wrong values for BaseIndexer subclasses with non-monotonic starting or ending points for windows (GH37153)

• Bug in DataFrame.groupby() dropped nan groups from result with dropna=False when grouping over a single column (GH35646, GH35542)

• Bug in DataFrameGroupBy.head(), DataFrameGroupBy.tail(), SeriesGroupBy.head(), and SeriesGroupBy.tail() would raise when used with axis=1 (GH9772)

• Bug in DataFrameGroupBy.transform() would raise when used with axis=1 and a transformation kernel (e.g. “shift”) (GH36308)

• Bug in DataFrameGroupBy.resample() using .agg with sum produced different result than just calling .sum (GH33548)

• Bug in DataFrameGroupBy.apply() dropped values on nan group when returning the same axes with the original frame (GH38227)

• Bug in DataFrameGroupBy.quantile() couldn’t handle with arraylike q when grouping by columns (GH33795)

• Bug in DataFrameGroupBy.rank() with datetime64tz or period dtype incorrectly casting results to those dtypes instead of returning float64 dtype (GH38187)

Reshaping

• Bug in DataFrame.crosstab() was returning incorrect results on inputs with duplicate row names, duplicate column names or duplicate names between row and column labels (GH22529)

• Bug in DataFrame.pivot_table() with aggfunc='count' or aggfunc='sum' returning NaN for missing categories when pivoted on a Categorical. Now returning 0 (GH31422)

• Bug in concat() and DataFrame constructor where input index names are not preserved in some cases (GH13475)

• Bug in func crosstab() when using multiple columns with margins=True and normalize=True (GH35144)

• Bug in DataFrame.stack() where an empty DataFrame.stack would raise an error (GH36113). Now returning an empty Series with empty MultiIndex.

• Bug in Series.unstack(). Now a Series with single level of Index trying to unstack would raise a ValueError (GH36113)

• Bug in DataFrame.agg() with func={'name':<FUNC>} incorrectly raising TypeError when DataFrame.columns==['Name'] (GH36212)

• Bug in Series.transform() would give incorrect results or raise when the argument func was a dictionary (GH35811)

• Bug in DataFrame.pivot() did not preserve MultiIndex level names for columns when rows and columns are both multiindexed (GH36360)

• Bug in DataFrame.pivot() modified index argument when columns was passed but values was not (GH37635)

• Bug in DataFrame.join() returned a non deterministic level-order for the resulting MultiIndex (GH36910)
- Bug in `DataFrame.combine_first()` caused wrong alignment with dtype `string` and one level of `MultiIndex` containing only `NA` (GH37591)
- Fixed regression in `merge()` on merging `DatetimeIndex` with empty DataFrame (GH36895)
- Bug in `DataFrame.apply()` not setting index of return value when `func` return type is `dict` (GH37544)
- Bug in `DataFrame.merge()` and `pandas.merge()` returning inconsistent ordering in result for `how=right` and `how=left` (GH35382)
- Bug in `merge_ordered()` couldn’t handle list-like `left_by` or `right_by` (GH35269)
- Bug in `merge_ordered()` returned wrong join result when length of `left_by` or `right_by` equals to the rows of `left` or `right` (GH38166)
- Bug in `merge_ordered()` didn’t raise when elements in `left_by` or `right_by` not exist in `left` columns or `right` columns (GH38167)
- Bug in `DataFrame.drop_duplicates()` not validating bool dtype for `ignore_index` keyword (GH38274)

**ExtensionArray**

- Fixed bug where `DataFrame` column set to scalar extension type via a dict instantiation was considered an object type rather than the extension type (GH35965)
- Fixed bug where `astype()` with equal dtype and `copy=False` would return a new object (GH28488)
- Fixed bug when applying a NumPy ufunc with multiple outputs to an `IntegerArray` returning `None` (GH36913)
- Fixed an inconsistency in `PeriodArray`'s `__init__` signature to those of `DatetimeArray` and `TimedeltaArray` (GH37289)
- Reductions for `BooleanArray`, `Categorical`, `DatetimeArray`, `FloatingArray`, `IntegerArray`, `PeriodArray`, `TimedeltaArray`, and `PandasArray` are now keyword-only methods (GH37541)
- Fixed bug where a `TypeError` was wrongly raised if a membership check was made on an `ExtensionArray` containing `nan-like` values (GH37867)

**Other**

- Bug in `DataFrame.replace()` and `Series.replace()` incorrectly raising an `AssertionError` instead of a `ValueError` when invalid parameter combinations are passed (GH36045)
- Bug in `DataFrame.replace()` and `Series.replace()` with numeric values and string `to_replace` (GH34789)
- Fixed metadata propagation in `Series.abs()` and ufmcns called on Series and DataFrames (GH28283)
- Bug in `DataFrame.replace()` and `Series.replace()` incorrectly casting from `PeriodDtype` to object dtype (GH34871)
- Fixed bug in metadata propagation incorrectly copying DataFrame columns as metadata when the column name overlaps with the metadata name (GH37037)
- Fixed metadata propagation in the `Series.dt`, `Series.str` accessors, `DataFrame.duplicated`, `DataFrame.stack`, `DataFrame.unstack`, `DataFrame.pivot`, `DataFrame.append`, `DataFrame.diff`, `DataFrame.applymap` and `DataFrame.update` methods (GH28283, GH37381)
• Fixed metadata propagation when selecting columns with `DataFrame.__getitem__` (GH28283)
• Bug in `Index.intersection()` with non-`Index` failing to set the correct name on the returned `Index` (GH38111)
• Bug in `RangeIndex.intersection()` failing to set the correct name on the returned `Index` in some corner cases (GH38197)
• Bug in `Index.difference()` failing to set the correct name on the returned `Index` in some corner cases (GH38268)
• Bug in `Index.union()` behaving differently depending on whether operand is an `Index` or other list-like (GH38384)
• Bug in `Index.intersection()` with non-matching numeric dtypes casting to `object` dtype instead of minimal common dtype (GH38122)
• Bug in `IntervalIndex.union()` returning an incorrectly-typed `Index` when empty (GH38282)
• Passing an array with 2 or more dimensions to the `Series` constructor now raises the more specific `ValueError` rather than a bare `Exception` (GH35744)
• Bug in `dir` where `dir(obj)` wouldn’t show attributes defined on the instance for pandas objects (GH37173)
• Bug in `Index.drop()` raising `InvalidIndexError` when index has duplicates (GH38051)
• Bug in `RangeIndex.difference()` returning `Int64Index` in some cases where it should return `RangeIndex` (GH38028)
• Fixed bug in `assert_series_equal()` when comparing a datetime-like array with an equivalent non extension dtype array (GH37609)
• Bug in `is_bool_dtype()` would raise when passed a valid string such as "boolean" (GH38386)
• Fixed regression in logical operators raising `ValueError` when columns of `DataFrame` are a `CategoricalIndex` with unused categories (GH38367)

5.2 Version 1.1

5.2.1 What’s new in 1.1.5 (December 07, 2020)

These are the changes in pandas 1.1.5. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in addition of a timedelta-like scalar to a `DatetimeIndex` raising incorrectly (GH37295)
- Fixed regression in `Series.groupby()` raising when the `Index` of the `Series` had a tuple as its name (GH37755)
- Fixed regression in `DataFrame.loc()` and `Series.loc()` for `__setitem__` when one-dimensional tuple was given to select from `MultiIndex` (GH37711)
- Fixed regression in inplace operations on `Series` with `ExtensionDtype` with NumPy dtyped operand (GH37910)
- Fixed regression in metadata propagation for `groupby` iterator (GH37343)
- Fixed regression in `MultiIndex` constructed from a `DatetimeIndex` not retaining frequency (GH35563)
- Fixed regression in `Index` constructor raising a `AttributeError` when passed a `SparseArray` with datetime64 values (GH35843)
- Fixed regression in `DataFrame.unstack()` with columns with integer dtype (GH37115)
- Fixed regression in indexing on a `Series` with `CategoricalDtype` after unpickling (GH37631)
- Fixed regression in `DataFrame.groupby()` aggregation with out-of-bounds datetime objects in an object-dtype column (GH36003)
- Fixed regression in `df.groupby(..).rolling(..)` with the resulting `MultiIndex` when grouping by a label that is in the index (GH37641)
- Fixed regression in `DataFrame.fillna()` not filling NaN after other operations such as `DataFrame.pivot()` (GH36495).
- Fixed performance regression in `df.groupby(..).rolling(..)` (GH38038)
- Fixed regression in `MultiIndex.intersection()` returning duplicates when at least one of the indexes had duplicates (GH36915)
- Fixed regression in `GroupBy.first()` and `GroupBy.last()` where `None` was considered a non-NA value (GH38286)

Bug fixes

- Bug in pytables methods in python 3.9 (GH38041)
Other

- Only set `-Werror` as a compiler flag in the CI jobs (GH33315, GH33314)

Contributors

A total of 12 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.2.2 What’s new in 1.1.4 (October 30, 2020)

These are the changes in pandas 1.1.4. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `read_csv()` raising a `ValueError` when `names` was of type `dict_keys` (GH36928)
- Fixed regression in `read_csv()` with more than 1M rows and specifying a `index_col` argument (GH37094)
- Fixed regression where attempting to mutate a `DateOffset` object would no longer raise an `AttributeError` (GH36940)
- Fixed regression where `DataFrame.agg()` would fail with `TypeError` when passed positional arguments to be passed on to the aggregation function (GH36948).
- Fixed regression in `RollingGroupby` with `sort=False` not being respected (GH36889)
- Fixed regression in `Series.astype()` converting `None` to "nan" when casting to string (GH36904)
- Fixed regression in `Series.rank()` method failing for read-only data (GH37290)
- Fixed regression in `RollingGroupby` causing a segmentation fault with Index of dtype object (GH36727)
- Fixed regression in `DataFrame.resample(...) .apply(...) ()` raised `AttributeError` when input was a `DataFrame` and only a `Series` was evaluated (GH36951)
- Fixed regression in `DataFrame.groupby(...).std()` with nullable integer dtype (GH37415)
pandas: powerful Python data analysis toolkit, Release 1.2.2

• Fixed regression in PeriodDtype comparing both equal and unequal to its string representation (GH37265)
• Fixed regression where slicing DatetimeIndex raised AssertionError on irregular time series with pd.NaT or on unsorted indices (GH36953 and GH35509)
• Fixed regression in certain offsets (pd.offsets.Day() and below) no longer being hashable (GH37267)
• Fixed regression in StataReader which required chunksize to be manually set when using an iterator to read a dataset (GH37280)
• Fixed regression in setitem with DataFrame.iloc() which raised error when trying to set a value while filtering with a boolean list (GH36741)
• Fixed regression in setitem with a Series getting aligned before setting the values (GH37427)
• Fixed regression in MultiIndex.is_monotonic_increasing returning wrong results with NaN in at least one of the levels (GH37220)
• Fixed regression in inplace arithmetic operation on a Series not updating the parent DataFrame (GH36373)

Bug fixes

• Bug causing groupby(...).sum() and similar to not preserve metadata (GH29442)
• Bug in Series.isin() and DataFrame.isin() raising a ValueError when the target was read-only (GH37174)
• Bug in GroupBy.fillna() that introduced a performance regression after 1.0.5 (GH36757)
• Bug in DataFrame.info() was raising a KeyError when the DataFrame has integer column names (GH37245)
• Bug in DataFrameGroupby.apply() would drop a CategoricalIndex when grouped on (GH35792)

Contributors

A total of 18 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

• Daniel Saxton
• Fangchen Li
• Janus +
• Joris Van den Bossche

5.2.3 What’s new in 1.1.3 (October 5, 2020)

These are the changes in pandas 1.1.3. See Release notes for a full changelog including other versions of pandas.

Enhancements

Added support for new Python version

pandas 1.1.3 now supports Python 3.9 (GH36296).

Development Changes

• The minimum version of Cython is now the most recent bug-fix version (0.29.21) (GH36296).

Fixed regressions

• Fixed regression in DataFrame.agg(), DataFrame.apply(), Series.agg(), and Series.apply() where internal suffix is exposed to the users when no relabelling is applied (GH36189)
• Fixed regression in IntegerArray unary plus and minus operations raising a TypeError (GH36063)
• Fixed regression when adding a timedelta_range() to a Timestamp raised a ValueError (GH35897)
• Fixed regression in Series.__getitem__() incorrectly raising when the input was a tuple (GH35534)
• Fixed regression in Series.__getitem__() incorrectly raising when the input was a frozenset (GH35747)
• Fixed regression in modulo of Index, Series and DataFrame using numexpr using C not Python semantics (GH36047, GH36526)
• Fixed regression in read_excel() with engine="odf" caused UnboundLocalError in some cases where cells had nested child nodes (GH36122, GH35802)
• Fixed regression in DataFrame.replace() inconsistent replace when using a float in the replace method (GH35376)
• Fixed regression in Series.loc() on a Series with a MultiIndex containing Timestamp raising InvalidIndexError (GH35858)
• Fixed regression in DataFrame and Series comparisons between numeric arrays and strings (GH35700, GH36377)
• Fixed regression in DataFrame.apply() with raw=True and user-function returning string (GH35940)
• Fixed regression when setting empty DataFrame column to a Series in preserving name of index in frame (GH36527)
• Fixed regression in Period incorrect value for ordinal over the maximum timestamp (GH36430)
pandas: powerful Python data analysis toolkit, Release 1.2.2

- Fixed regression in `read_table()` raised `ValueError` when `delim_whitespace` was set to `True` (GH35958)
- Fixed regression in `Series.dt.normalize()` when normalizing pre-epoch dates the result was shifted one day (GH36294)

**Bug fixes**

- Bug in `read_spss()` where passing a `pathlib.Path` as `path` would raise a `TypeError` (GH33666)
- Bug in `Series.str.startswith()` and `Series.str.endswith()` with `category` dtype not propagating `na` parameter (GH36241)
- Bug in `Series` constructor where integer overflow would occur for sufficiently large scalar inputs when an index was provided (GH36291)
- Bug in `DataFrame.sort_values()` raising an `AttributeError` when sorting on a key that casts column to categorical dtype (GH36383)
- Bug in `DataFrame.stack()` raising a `ValueError` when stacking `MultiIndex` columns based on position when the levels had duplicate names (GH36353)
- Bug in `Series.astype()` showing too much precision when casting from `np.float32` to string dtype (GH36451)
- Bug in `Series.isin()` and `DataFrame.isin()` when using `NaN` and a row length above 1,000,000 (GH22205)
- Bug in `cut()` raising a `ValueError` when passed a `Series` of labels with `ordered=False` (GH36603)

**Other**

- Reverted enhancement added in pandas-1.1.0 where `timedelta_range()` infers a frequency when passed `start`, `stop`, and `periods` (GH32377)

**Contributors**

A total of 16 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Asish Mahapatra
- Dan Moore +
- Daniel Saxton
- Fangchen Li
- Hans
- Irv Lustig
- Joris Van den Bossche
- Kaiqi Dong
- MeeseeksMachine
- Number42 +
- Pandas Development Team
5.2.4 What's new in 1.1.2 (September 8, 2020)

These are the changes in pandas 1.1.2. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Regression in `DatetimeIndex.intersection()` incorrectly raising `AssertionError` when intersecting against a list (GH35876)
- Fix regression in updating a column inplace (e.g. using `df['col'].fillna(.., inplace=True)`) (GH35731)
- Fix regression in `DataFrame.append()` mixing tz-aware and tz-naive datetime columns (GH35460)
- Performance regression for `RangeIndex.format()` (GH35712)
- Regression where `MultiIndex.get_loc()` would return a slice spanning the full index when passed an empty list (GH35878)
- Fix regression in invalid cache after an indexing operation; this can manifest when setting which does not update the data (GH35521)
- Regression in `DataFrame.replace()` where a `TypeError` would be raised when attempting to replace elements of type `Interval` (GH35931)
- Fix regression in pickle roundtrip of the closed attribute of `IntervalIndex` (GH35658)
- Fixed regression in DataFrameGroupBy.agg() where a `ValueError: buffer source array is read-only` would be raised when the underlying array is read-only (GH36014)
- Fixed regression in Series.groupby.rolling() number of levels of `MultiIndex` in input was compressed to one (GH36018)
- Fixed regression in DataFrameGroupBy on an empty `DataFrame` (GH36197)

Bug fixes

- Bug in `DataFrame.eval()` with object dtype column binary operations (GH35794)
- Bug in `Series` constructor raising a `TypeError` when constructing sparse datetime64 dtypes (GH35762)
- Bug in `DataFrame.apply()` with result_type="reduce" returning with incorrect index (GH35683)
- Bug in `Series.astype()` and `DataFrame.astype()` not respecting the `errors` argument when set to "ignore" for extension dtypes (GH35471)
- Bug in `DateTimeIndex.format()` and `PeriodIndex.format()` with name=True setting the first item to "None" where it should be "" (GH35712)
- Bug in `Float64Index.__contains__()` incorrectly raising `TypeError` instead of returning False (GH35788)
pandas: powerful Python data analysis toolkit, Release 1.2.2

• Bug in `Series` constructor incorrectly raising a `TypeError` when passed an ordered set (GH36044)
• Bug in `Series.dt.isocalendar()` and `DatetimeIndex.isocalendar()` that returned incorrect year for certain dates (GH36032)
• Bug in `DataFrame` indexing returning an incorrect `Series` in some cases when the series has been altered and a cache not invalidated (GH33675)
• Bug in `DataFrame.corr()` causing subsequent indexing lookups to be incorrect (GH35882)
• Bug in `import_optional_dependency()` returning incorrect package names in cases where package name is different from import name (GH35948)
• Bug when setting empty `DataFrame` column to a `Series` in preserving name of index in frame (GH31368)

Other

• `factorize()` now supports `na_sentinel=None` to include NaN in the uniques of the values and remove `dropna` keyword which was unintentionally exposed to public facing API in 1.1 version from `factorize()` (GH35667)
• `DataFrame.plot()` and `Series.plot()` raise `UserWarning` about usage of `FixedFormatter` and `FixedLocator` (GH35684 and GH35945)

5.2.5 What’s new in 1.1.1 (August 20, 2020)

These are the changes in pandas 1.1.1. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `CategoricalIndex.format()` where, when stringified scalars had different lengths, the shorter string would be right-filled with spaces, so it had the same length as the longest string (GH35439)
- Fixed regression in `Series.truncate()` when trying to truncate a single-element series (GH35544)
- Fixed regression where `DataFrame.to_numpy()` would raise a `RuntimeError` for mixed dtypes when converting to `str` (GH35455)
- Fixed regression where `read_csv()` would raise a `ValueError` when `pandas.options.mode.use_inf_as_na` was set to `True` (GH35493)
- Fixed regression where `pandas.testing.assert_series_equal()` would raise an error when non-numeric dtypes were passed with `check_exact=True` (GH35446)
- Fixed regression in `.groupby(...).rolling(...)` where column selection was ignored (GH35486)
- Fixed regression where `DataFrame.interpolate()` would raise a `TypeError` when the `DataFrame` was empty (GH35598)
- Fixed regression in `DataFrame.shift()` with `axis=1` and heterogeneous dtypes (GH35488)
- Fixed regression in `DataFrame.diff()` with read-only data (GH35559)
- Fixed regression in `.groupby(...).rolling(...)` where a segfault would occur with `center=True` and an odd number of values (GH35552)
- Fixed regression in `DataFrame.apply()` where functions that altered the input in-place only operated on a single row (GH3462)
- Fixed regression in `DataFrame.reset_index()` would raise a `ValueError` on empty `DataFrame` with a `MultiIndex` with a `datetime64` dtype level (GH35606, GH35657)
- Fixed regression where `pandas.merge_asof()` would raise a `UnboundLocalError` when `left_index`, `right_index` and `tolerance` were set (GH35558)
- Fixed regression in `.groupby(...).rolling(...)` where a custom `BaseIndexer` would be ignored (GH35557)
- Fixed regression in `DataFrame.replace()` and `Series.replace()` where compiled regular expressions would be ignored during replacement (GH35680)
- Fixed regression in `aggregate()` where a list of functions would produce the wrong results if at least one of the functions did not aggregate (GH35490)
- Fixed memory usage issue when instantiating large `pandas.arrays.StringArray` (GH35499)
Bug fixes

- Bug in `Styler` whereby `cell_ids` argument had no effect due to other recent changes (GH35588) (GH35663)
- Bug in `pandas.testing.assert_series_equal()` and `pandas.testing.assert_frame_equal()` where extension dtypes were not ignored when `check_dtypes` was set to `False` (GH35715)
- Bug in `to_timedelta()` fails when `arg` is a `Series` with `Int64` dtype containing null values (GH35574)
- Bug in `.groupby(..).rolling(..)` where passing `closed` with column selection would raise a `ValueError` (GH35549)
- Bug in `DataFrame` constructor failing to raise `ValueError` in some cases when `data` and `index` have mismatched lengths (GH33437)

5.2.6 What’s new in 1.1.0 (July 28, 2020)

These are the changes in pandas 1.1.0. See Release notes for a full changelog including other versions of pandas.

Enhancements

KeyErrors raised by loc specify missing labels

Previously, if labels were missing for a .loc call, a KeyErrors was raised stating that this was no longer supported. Now the error message also includes a list of the missing labels (max 10 items, display width 80 characters). See GH34272.

All dtypes can now be converted to StringDtype

Previously, declaring or converting to StringDtype was in general only possible if the data was already only str or nan-like (GH31204). StringDtype now works in all situations where astype(str) or dtype=str work:

For example, the below now works:

```
In [1]: ser = pd.Series([1, "abc", np.nan], dtype="string")
In [2]: ser
Out[2]:
   0    1
  1   abc
  2   <NA>
Length: 3, dtype: string
In [3]: ser[0]
Out[3]: '1'
In [4]: pd.Series([1, 2, np.nan], dtype="Int64").astype("string")
Out[4]:
   0    1
  1    2
  2   <NA>
Length: 3, dtype: string
```

Non-monotonic PeriodIndex partial string slicing

PeriodIndex now supports partial string slicing for non-monotonic indexes, mirroring DatetimeIndex behavior (GH31096)

For example:

```
In [5]: dti = pd.date_range("2014-01-01", periods=30, freq="30D")
In [6]: pi = dti.to_period("D")
In [7]: ser_monotonic = pd.Series(np.arange(30), index=pi)
In [8]: shuffler = list(range(0, 30, 2)) + list(range(1, 31, 2))
```

(continues on next page)
Comparing two DataFrame or two Series and summarizing the differences

We’ve added DataFrame.compare() and Series.compare() for comparing two DataFrame or two Series (GH30429)

```python
In [13]: df = pd.DataFrame(
   ....:     {  
   ....:         "col1": ["a", "a", "b", "b", "a"],  
   ....:         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],  
   ....:         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]  
   ....:     },  
   ....:     columns=["col1", "col2", "col3"],  
   ....: )
```
In [14]: df
Out[14]:
   col1  col2  col3
0    a    1.0  1.0
1    a    2.0  2.0
2    b    3.0  3.0
3    b   NaN  4.0
4    a    5.0  5.0

[5 rows x 3 columns]

In [15]: df2 = df.copy()
In [16]: df2.loc[0, 'col1'] = 'c'
In [17]: df2.loc[2, 'col3'] = 4.0
In [18]: df2
Out[18]:
   col1  col2  col3
0    c    1.0  1.0
1    a    2.0  2.0
2    b    3.0  4.0
3    b   NaN  4.0
4    a    5.0  5.0

[5 rows x 3 columns]

In [19]: df.compare(df2)
Out[19]:
   self other
self  other
0    a    c
2  NaN   NaN

[2 rows x 4 columns]

See User Guide for more details.

Allow NA in groupby key

With groupby, we've added a dropna keyword to DataFrame.groupby() and Series.groupby() in order to allow NA values in group keys. Users can define dropna to False if they want to include NA values in groupby keys. The default is set to True for dropna to keep backwards compatibility (GH3729)

In [20]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
In [21]: df_dropna = pd.DataFrame(df_list, columns=['a', 'b', 'c'])
In [22]: df_dropna
Out[22]:
   a  b  c
0  1  2.0  3
1  1  NaN  4
The default setting of `dropna` argument is `True` which means NA are not included in group keys.

### Sorting with keys

We've added a `key` argument to the `DataFrame` and `Series` sorting methods, including `DataFrame.sort_values()`, `DataFrame.sort_index()`, `Series.sort_values()`, and `Series.sort_index()`. The key can be any callable function which is applied column-by-column to each column used for sorting, before sorting is performed (GH27237). See `sort_values with keys` and `sort_index with keys` for more information.

```python
In [25]: s = pd.Series(['C', 'a', 'B'])
In [26]: s
Out[26]:
0   C
1   a
2   B
Length: 3, dtype: object

In [27]: s.sort_values()
Out[27]:
0   B
1   a
2   C
Length: 3, dtype: object
```

Note how this is sorted with capital letters first. If we apply the `Series.str.lower()` method, we get
When applied to a DataFrame, they key is applied per-column to all columns or a subset if by is specified, e.g.

```
In [28]: s.sort_values(key=lambda x: x.str.lower())
Out[28]:
1 a
2 B
0 C
Length: 3, dtype: object
```

For more details, see examples and documentation in `DataFrame.sort_values()`, `Series.sort_values()`, and `sort_index()`.

**Fold argument support in Timestamp constructor**

Timestamp now supports the keyword-only fold argument according to PEP 495 similar to parent `datetime.datetime` class. It supports both accepting fold as an initialization argument and inferring fold from other constructor arguments (GH25057, GH31338). Support is limited to `dateutil` timezones as `pytz` doesn’t support fold.

For example:

```
In [32]: ts = pd.Timestamp("2019-10-27 01:30:00+00:00")
In [33]: ts.fold
Out[33]: 0
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.2.2

(continued from previous page)

In [35]: ts
Out[35]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil//usr/share/zoneinfo/Europe/London')

For more on working with fold, see Fold subsection in the user guide.

Parsing timezone-aware format with different timezones in to_datetime

to_datetime() now supports parsing formats containing timezone names (%Z) and UTC offsets (%z) from different timezones then converting them to UTC by setting utc=True. This would return a DatetimeIndex with timezone at UTC as opposed to an Index with object dtype if utc=True is not set (GH32792).

For example:

In [36]: tz_strs = ['2010-01-01 12:00:00 +0100', '2010-01-01 12:00:00 -0100',
   '2010-01-01 12:00:00 +0300', '2010-01-01 12:00:00 +0400']

In [37]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z', utc=True)
Out[37]:
DatetimeIndex(['2010-01-01 11:00:00+00:00', '2010-01-01 13:00:00+00:00',
   '2010-01-01 09:00:00+00:00', '2010-01-01 08:00:00+00:00'],
   dtype='datetime64[ns, UTC]', freq=None)

In [38]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z')
Out[38]:
Index(['2010-01-01 12:00:00+01:00', '2010-01-01 12:00:00-01:00',
   '2010-01-01 12:00:00+03:00', '2010-01-01 12:00:00+04:00'],
   dtype='object')

Grouper and resample now supports the arguments origin and offset

Grouper and DataFrame.resample() now supports the arguments origin and offset. It let the user control the timestamp on which to adjust the grouping. (GH31809)

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like 30D) or that divides a day (like 90s or 1min). But it can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can now specify a fixed timestamp with the argument origin.

Two arguments are now deprecated (more information in the documentation of DataFrame.resample()):

- base should be replaced by offset.
- loffset should be replaced by directly adding an offset to the index DataFrame after being resampled.

Small example of the use of origin:

In [39]: start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
In [40]: middle = '2000-10-02 00:00:00'
In [41]: rng = pd.date_range(start, end, freq='7min')

(continues on next page)
In [42]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)

In [43]: ts
Out[43]:
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, Length: 9, dtype: int64

Resample with the default behavior 'start_day' (origin is 2000-10-01 00:00:00):

In [44]: ts.resample('17min').sum()
Out[44]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, Length: 5, dtype: int64

In [45]: ts.resample('17min', origin='start_day').sum()
Out[45]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, Length: 5, dtype: int64

Resample using a fixed origin:

In [46]: ts.resample('17min', origin='epoch').sum()
Out[46]:
2000-10-01 23:18:00    0
2000-10-01 23:35:00   18
2000-10-01 23:52:00   27
2000-10-02 00:09:00   39
2000-10-02 00:26:00   24
Freq: 17T, Length: 5, dtype: int64

In [47]: ts.resample('17min', origin='2000-01-01').sum()
Out[47]:
2000-10-01 23:24:00    3
2000-10-01 23:41:00   15
2000-10-01 23:58:00   45
2000-10-02 00:15:00   45
Freq: 17T, Length: 4, dtype: int64

If needed you can adjust the bins with the argument offset (a Timedelta) that would be added to the default origin.
For a full example, see: *Use origin or offset to adjust the start of the bins.*

**fsspec now used for filesystem handling**

For reading and writing to filesystems other than local and reading from HTTP(S), the optional dependency `fsspec` will be used to dispatch operations (GH33452). This will give unchanged functionality for S3 and GCS storage, which were already supported, but also add support for several other storage implementations such as Azure DataLake and Blob, SSH, FTP, dropbox and github. For docs and capabilities, see the `fsspec` docs.

The existing capability to interface with S3 and GCS will be unaffected by this change, as `fsspec` will still bring in the same packages as before.

**Other enhancements**

- Compatibility with matplotlib 3.3.0 (GH34850)
- `IntegerArray.astype()` now supports `datetime64` dtype (GH32538)
- `IntegerArray` now implements the `sum` operation (GH33172)
- Added `pandas.errors.InvalidIndexError` (GH34570).
- Added `DataFrame.value_counts()` (GH5377).
- Added a `pandas.api.indexers.FixedForwardWindowIndexer()` class to support forward-looking windows during rolling operations.
- Added a `pandas.api.indexers.VariableOffsetWindowIndexer()` class to support rolling operations with non-fixed offsets (GH34994)
- `describe()` now includes a `datetime_is_numeric` keyword to control how datetime columns are summarized (GH30164, GH34798)
- `Styler` may now render CSS more efficiently where multiple cells have the same styling (GH30876)
- `highlight_null()` now accepts `subset` argument (GH31345)
- When writing directly to a sqlite connection `DataFrame.to_sql()` now supports the `multi` method (GH29921)
- `pandas.errors.OptionError` is now exposed in `pandas.errors` (GH27553)
- Added `api.extensions.ExtensionArray.argmax()` and `api.extensions.ExtensionArray.argmin()` (GH24382)
- `timedelta_range()` will now infer a frequency when passed `start`, `stop`, and `periods` (GH32377)
- Positional slicing on a `IntervalIndex` now supports slices with `step > 1` (GH31658)
- `Series.str` now has a `fullmatch` method that matches a regular expression against the entire string in each row of the `Series`, similar to `re.fullmatch` (GH32806).
- `DataFrame.sample()` will now also allow array-like and BitGenerator objects to be passed to `random_state` as seeds (GH32503)
- `Index.union()` will now raise `RuntimeWarning` for `MultiIndex` objects if the object inside are unsortable. Pass `sort=False` to suppress this warning (GH33015)
- Added `Series.dt.isocalendar()` and `DatetimeIndex.isocalendar()` that returns a `DataFrame` with year, week, and day calculated according to the ISO 8601 calendar (GH33206, GH34392).
• The `DataFrame.to_feather()` method now supports additional keyword arguments (e.g. to set the compression) that are added in pyarrow 0.17 (GH33422).

• The `cut()` will now accept parameter `ordered` with default `ordered=True`. If `ordered=False` and no labels are provided, an error will be raised (GH33141).

• `DataFrame.to_csv()`, `DataFrame.to_pickle()` and `DataFrame.to_json()` now support passing a dict of compression arguments when using the gzip and bz2 protocols. This can be used to set a custom compression level, e.g., `df.to_csv(path, compression={'method': 'gzip', 'compresslevel': 1})` (GH33196).

• `melt()` has gained an `ignore_index` (default True) argument that, if set to False, prevents the method from dropping the index (GH17440).

• `Series.update()` now accepts objects that can be coerced to a `Series`, such as `dict` and `list`, mirroring the behavior of `DataFrame.update()` (GH33215).

• `transform()` and `aggregate()` have gained `engine` and `engine_kwargs` arguments that support executing functions with Numba (GH32854, GH33388).

• `DataFrameGroupBy` and `SeriesGroupBy` now implement the `sample` method for doing random sampling within groups (GH31775).

• `DataFrame.to_numpy()` now supports the `na_value` keyword to control the NA sentinel in the output array (GH33820).

• Added `api.extension.ExtensionArray.equals` to the extension array interface, similar to `Series.equals()` (GH27081).

• The minimum supported dta version has increased to 105 in `read_stata()` and `StataReader` (GH26667).

• `to_stata()` supports compression using the `compression` keyword argument. Compression can either be inferred or explicitly set using a string or a dictionary containing both the method and any additional arguments that are passed to the compression library. Compression was also added to the low-level Stata-file writers `StataWriter`, `StataWriter117`, and `StataWriterUTF8` (GH26599).

• `HDFStore.put()` now accepts a `track_times` parameter. This parameter is passed to the `create_table` method of PyTables (GH32682).

• `Series.plot()` and `DataFrame.plot()` now accepts `xlabel` and `ylabel` parameters to present labels on x and y axis (GH9093).

• Made `pandas.core.window.rolling.Rolling` and `pandas.core.window.expanding.Expanding` `iterable` (GH11704).

• Made `option_context` a `contextlib.ContextDecorator`, which allows it to be used as a decorator over an entire function (GH34253).

• `DataFrame.to_csv()` and `Series.to_csv()` now accept an `errors` argument (GH22610).

• `transform()` now allows `func` to be `pad`, `backfill` and `cumcount` (GH31269).

• `read_json()` now accepts an `nrows` parameter. (GH33916).

• `DataFrame.hist()`, `Series.hist()`, `core.groupby.DataFrameGroupBy.hist()`, and `core.groupby.SeriesGroupBy.hist()` have gained the `legend` argument. Set to True to show a legend in the histogram. (GH6279).

• `concat()` and `append()` now preserve extension dtypes, for example combining a nullable integer column with a numpy integer column will no longer result in object dtype but preserve the integer dtype (GH33607, GH34339, GH34095).
• `read_gbq()` now allows to disable progress bar (GH33360).
• `read_gbq()` now supports the `max_results` kwarg from pandas-gbq (GH34639).
• `DataFrame.cov()` and `Series.cov()` now support a new parameter `ddof` to support delta degrees of freedom as in the corresponding numpy methods (GH34611).
• `DataFrame.to_html()` and `DataFrame.to_string()`'s `col_space` parameter now accepts a list or dict to change only some specific columns' width (GH28917).
• `DataFrame.to_excel()` can now also write OpenOffice spreadsheet (.ods) files (GH27222)
• `explode()` now accepts `ignore_index` to reset the index, similar to `pd.concat()` or `DataFrame.sort_values()` (GH34932).
• `DataFrame.to_markdown()` and `Series.to_markdown()` now accept `index` argument as an alias for `tabulate`'s `showindex` (GH32667)
• `read_csv()` now accepts string values like “0”, “0.0”, “1”, “1.0” as convertible to the nullable Boolean dtype (GH34859)
• `pandas.core.window.ExponentialMovingWindow` now supports a `times` argument that allows mean to be calculated with observations spaced by the timestamps in `times` (GH34839)
• `DataFrame.agg()` and `Series.agg()` now accept named aggregation for renaming the output columns/indexes. (GH26513)
• `compute.use_numba` now exists as a configuration option that utilizes the numba engine when available (GH33966, GH35374)
• `Series.plot()` now supports asymmetric error bars. Previously, if `Series.plot()` received a “2xN” array with error values for `yerr` and/or `xerr`, the left/lower values (first row) were mirrored, while the right/upper values (second row) were ignored. Now, the first row represents the left/lower error values and the second row the right/upper error values. (GH9536)

Notable bug fixes

These are bug fixes that might have notable behavior changes.

**MultiIndex.get_indexer interprets method argument correctly**

This restores the behavior of `MultiIndex.get_indexer()` with `method='backfill'` or `method='pad'` to the behavior before pandas 0.23.0. In particular, MultiIndexes are treated as a list of tuples and padding or backfilling is done with respect to the ordering of these lists of tuples (GH29896).

As an example of this, given:

```python
In [48]: df = pd.DataFrame({
        ....:     'a': [0, 0, 0, 0],
        ....:     'b': [0, 2, 3, 4],
        ....:     'c': ['A', 'B', 'C', 'D'],
        ....: }).set_index(['a', 'b'])
        ....:

In [49]: mi_2 = pd.MultiIndex.from_product([[0], [-1, 0, 1, 3, 4, 5]])
```

The differences in reindexing `df` with `mi_2` and using `method='backfill'` can be seen here:

`pandas >= 0.23, < 1.1.0:`
In [1]: df.reindex(mi_2, method='backfill')
Out[1]:
   c
0  A
1  D
3  A
4  A
5  C

pandas <0.23, >= 1.1.0

In [50]: df.reindex(mi_2, method='backfill')
Out[50]:
   c
0  A
1  B
3  C
4  D
5  NaN

[6 rows x 1 columns]

And the differences in reindexing df with mi_2 and using method='pad' can be seen here:

pandas >= 0.23, < 1.1.0

In [1]: df.reindex(mi_2, method='pad')
Out[1]:
   c
0  NaN
0  NaN
1  D
3  NaN
4  A
5  C

pandas < 0.23, >= 1.1.0

In [51]: df.reindex(mi_2, method='pad')
Out[51]:
   c
0  NaN
0  A
1  A
3  C
4  D
5  D

[6 rows x 1 columns]
Failed label-based lookups always raise KeyError

Label lookups `series[key]`, `series.loc[key]` and `frame.loc[key]` used to raise either `KeyError` or `TypeError` depending on the type of key and type of `Index`. These now consistently raise `KeyError` (GH31867)

<table>
<thead>
<tr>
<th>In [52]:</th>
<th><code>ser1 = pd.Series(range(3), index=[0, 1, 2])</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>In [53]:</td>
<td><code>ser2 = pd.Series(range(3), index=pd.date_range(&quot;2020-02-01&quot;, periods=3))</code></td>

<td><code>ser1.loc[&quot;foo&quot;]</code></td>
</tr>
<tr>
<td>...</td>
<td>KeyError: 'foo'</td>
</tr>
<tr>
<td>In [7]:</td>
<td><code>ser2.loc[1]</code></td>
</tr>
</tbody>
</table>

(continues on next page)
... KeyError: 1

In [8]: ser2.loc[pd.Timestamp(0)]
...
KeyError: Timestamp('1970-01-01 00:00:00')

Similarly, DataFrame.at() and Series.at() will raise a TypeError instead of a ValueError if an incompatible key is passed, and KeyError if a missing key is passed, matching the behavior of .loc[] (GH31722)

Failed Integer Lookups on MultiIndex Raise KeyError

Indexing with integers with a MultiIndex that has an integer-dtype first level incorrectly failed to raise KeyError when one or more of those integer keys is not present in the first level of the index (GH33539)

In [54]: idx = pd.Index(range(4))
In [55]: dti = pd.date_range("2000-01-03", periods=3)
In [56]: mi = pd.MultiIndex.from_product([idx, dti])
In [57]: ser = pd.Series(range(len(mi)), index=mi)

Previous behavior:

In [5]: ser[[5]]
Out[5]: Series([], dtype: int64)

New behavior:

In [5]: ser[[5]]
...
KeyError: ' [5] not in index'

DataFrame.merge() preserves right frame’s row order

DataFrame.merge() now preserves the right frame’s row order when executing a right merge (GH27453)

In [58]: left_df = pd.DataFrame({'animal': ['dog', 'pig'],
                   'max_speed': [40, 11]})
   ....:
   ....:
In [59]: right_df = pd.DataFrame({'animal': ['quetzal', 'pig'],
                   'max_speed': [80, 11]})
   ....:
   ....:
In [60]: left_df
Out[60]:
   animal  max_speed
  0  dog       40
  1  pig       11
[2 rows x 2 columns]
Assignment to multiple columns of a DataFrame when some columns do not exist

Assignment to multiple columns of a DataFrame when some of the columns do not exist would previously assign the values to the last column. Now, new columns will be constructed with the right values. (GH13658)
Consistency across groupby reductions

Using `DataFrame.groupby()` with `as_index=True` and the aggregation `nunique` would include the grouping column(s) in the columns of the result. Now the grouping column(s) only appear in the index, consistent with other reductions. (GH32579)

Using `DataFrame.groupby()` with `as_index=False` and the function `idxmax`, `idxmin`, `mad`, `nunique`, `sem`, `skew`, or `std` would modify the grouping column. Now the grouping column remains unchanged, consistent with other reductions. (GH21090, GH10355)

**Previous behavior:**

```python
In [3]: df.groupby("a", as_index=True).nunique()
Out[4]:
    a  b
   a  x  1
   x  1  1
   y  1  2
```

**New behavior:**

```python
In [69]: df.groupby("a", as_index=True).nunique()
Out[69]:
   b
   a  x  1
   y  2
```

Using `DataFrame.groupby()` with `as_index=False` and the function `idxmax`, `idxmin`, `mad`, `nunique`, `sem`, `skew`, or `std` would modify the grouping column. Now the grouping column remains unchanged, consistent with other reductions. (GH21090, GH10355)

**Previous behavior:**

```python
In [3]: df.groupby("a", as_index=True).nunique()
Out[4]:
    a  b
   a  x  1
   x  1  1
   y  1  2
```
In [3]: df.groupby("a", as_index=False).unique()
Out[4]:
   a  b
0 1 1
1 1 2

New behavior:

In [70]: df.groupby("a", as_index=False).unique()
Out[70]:
   a  b
0 1 2
1 y 2
[2 rows x 2 columns]

The method `size()` would previously ignore `as_index=False`. Now the grouping columns are returned as columns, making the result a DataFrame instead of a Series. (GH32599)

Previous behavior:

In [3]: df.groupby("a", as_index=False).size()
Out[4]:
a
   x    2
   y    2
dtype: int64

New behavior:

In [71]: df.groupby("a", as_index=False).size()
Out[71]:
   a  size
0  x    2
1  y    2
[2 rows x 2 columns]

`agg()` lost results with `as_index=False` when relabeling columns

Previously `agg()` lost the result columns, when the `as_index` option was set to `False` and the result columns were relabeled. In this case the result values were replaced with the previous index (GH32240).

In [72]: df = pd.DataFrame({'key': ['x', 'y', 'z', 'x', 'y', 'z'],
                      'val': [1.0, 0.8, 2.0, 3.0, 3.6, 0.75]})

In [73]: df
Out[73]:
   key  val
0   x   1.00
1   y   0.80
2   z   2.00
3   x   3.00
4   y   3.60
5   z   0.75
Previous behavior:

```python
In [2]: grouped = df.groupby("key", as_index=False)
In [3]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))
In [4]: result
Out[4]:
    min_val
0    x
1    y
2    z
```

New behavior:

```python
In [74]: grouped = df.groupby("key", as_index=False)
In [75]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))
In [76]: result
Out[76]:
      key  min_val
0      x    1.00
1      y    0.80
2      z    0.75
```

apply and applymap on DataFrame evaluates first row/column only once

```python
In [77]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 6]})
In [78]:
def func(row):
    ....:     print(row)
    ....:     return row
    ....:

In [79]: df.apply(func, axis=1)
```

Previous behavior:

```python
In [4]: df.apply(func, axis=1)
a  1
b  3
Name: 0, dtype: int64
da  1
b  3
Name: 0, dtype: int64
```

```python
Out[4]:
a b
0 1 3
1 2 6
```
New behavior:

```python
In [79]: df.apply(func, axis=1)
a 1
b 3
Name: 0, Length: 2, dtype: int64
a 2
b 6
Name: 1, Length: 2, dtype: int64
Out[79]:
a b
0 1 3
1 2 6
[2 rows x 2 columns]
```

Backwards incompatible API changes

Added `check_freq` argument to `testing.assert_frame_equal` and `testing.assert_series_equal`

The `check_freq` argument was added to `testing.assert_frame_equal()` and `testing.assert_series_equal()` in pandas 1.1.0 and defaults to `True`. `testing.assert_frame_equal()` and `testing.assert_series_equal()` now raise `AssertionError` if the indexes do not have the same frequency. Before pandas 1.1.0, the index frequency was not checked.

Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated (GH33718, GH29766, GH29723, pytables >= 3.4.3). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.15.4</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>pytz</td>
<td>2015.4</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.7.3</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.6.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>4.0.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.
## Development changes

- The minimum version of Cython is now the most recent bug-fix version (0.29.16) (GH33334).

### Deprecations

- Lookups on a `Series` with a single-item list containing a slice (e.g. `ser[[slice(0, 4)]]`) are deprecated and will raise in a future version. Either convert the list to a tuple, or pass the slice directly instead (GH31333).
- `DataFrame.mean()` and `DataFrame.median()` with `numeric_only=None` will include `datetime64` and `datetime64tz` columns in a future version (GH29941).
- Setting values with `.loc` using a positional slice is deprecated and will raise in a future version. Use `.loc` with labels or `.iloc` with positions instead (GH31840).
- `DataFrame.to_dict()` has deprecated accepting short names for `orient` and will raise in a future version (GH32515).
- `Categorical.to_dense()` is deprecated and will be removed in a future version, use `np.asarray(cat)` instead (GH32639).
- The `fastpath` keyword in the `SingleBlockManager` constructor is deprecated and will be removed in a future version (GH33092).
- Providing suffixes as a set in `pandas.merge()` is deprecated. Provide a tuple instead (GH33740, GH34741).
- Indexing a `Series` with a multi-dimensional indexer like `[ :, None]` to return an `ndarray` now raises a `FutureWarning`. Convert to a NumPy array before indexing instead (GH27837).
- `Index.is_mixed()` is deprecated and will be removed in a future version, check `index.inferred_type` directly instead (GH32922).
• Passing any arguments but the first one to `read_html()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).

• Passing any arguments but `path_or_buf` (the first one) to `read_json()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).

• Passing any arguments but the first two to `read_excel()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).

• `pandas.api.types.is_categorical()` is deprecated and will be removed in a future version; use `pandas.api.types.is_categorical_dtype()` instead (GH33385)

• `Index.get_value()` is deprecated and will be removed in a future version (GH19728)

• `Series.dt.week()` and `Series.dt.year()` are deprecated and will be removed in a future version, use `Series.dt.isocalendar().week()` instead (GH33595)

• `DateTimeIndex.week()` and `DateTimeIndex.year()` are deprecated and will be removed in a future version, use `DateTimeIndex.isocalendar().week` instead (GH33595)

• `DateOffset.__call__()` is deprecated and will be removed in a future version, use `offset + other` instead (GH34171)

• `apply_index()` is deprecated and will be removed in a future version. Use `offset + other` instead (GH34580)

• `DataFrame.tshift()` and `Series.tshift()` are deprecated and will be removed in a future version, use `DataFrame.shift()` and `Series.shift()` instead (GH11631)

• Indexing an `Index` object with a float key is deprecated, and will raise an `IndexError` in the future. You can manually convert to an integer key instead (GH34191).

• The `squeeze` keyword in `groupby()` is deprecated and will be removed in a future version (GH32380)

• The `tz` keyword in `Period.to_timestamp()` is deprecated and will be removed in a future version; use `per.to_timestamp(...).tz_localize(tz)` instead (GH34522)

• `DateTimeIndex.to_perioddelta()` is deprecated and will be removed in a future version. Use `index - index.to_period(freq).to_timestamp()` instead (GH34853)

• `DataFrame.melt()` accepting a `value_name` that already exists is deprecated, and will be removed in a future version (GH34731)

• The `center` keyword in the `DataFrame.expanding()` function is deprecated and will be removed in a future version (GH20647)

Performance improvements

• Performance improvement in `Timedelta` constructor (GH30543)

• Performance improvement in `Timestamp` constructor (GH30543)

• Performance improvement in flex arithmetic ops between `DataFrame` and `Series` with `axis=0` (GH31296)

• Performance improvement in arithmetic ops between `DataFrame` and `Series` with `axis=1` (GH33600)

• The internal index method `_shallow_copy()` now copies cached attributes over to the new index, avoiding creating these again on the new index. This can speed up many operations that depend on creating copies of existing indexes (GH28584, GH32640, GH32669)
• Significant performance improvement when creating a *DataFrame* with sparse values from *scipy.sparse* matrices using the *DataFrame.sparse.from_spmatrix()* constructor (GH32821, GH32825, GH32826, GH32856, GH32858).

• Performance improvement for groupby methods *first()* and *last()* (GH34178)

• Performance improvement in *factorize()* for nullable (integer and Boolean) dtypes (GH33064).

• Performance improvement when constructing *Categorical* objects (GH33921)

• Fixed performance regression in *pandas.qcut()* and *pandas.cut()* (GH33921)

• Performance improvement in reductions (sum, prod, min, max) for nullable (integer and Boolean) dtypes (GH30982, GH33261, GH33442).

• Performance improvement in arithmetic operations between two *DataFrame* objects (GH32779)

• Performance improvement in *pandas.core.groupby.RollingGroupby* (GH34052)

• Performance improvement in arithmetic operations (sub, add, mul, div) for *MultiIndex* (GH34297)

• Performance improvement in *DataFrame[bool_indexer]* when *bool_indexer* is a list (GH33924)

• Significant performance improvement of *io.formats.style.Styler.render()* with styles added with various ways such as *io.formats.style.Styler.apply()* or *io.formats.style.Styler.bar()* (GH19917)

### Bug fixes

#### Categorical

• Passing an invalid *fill_value* to *Categorical.take()* raises a *ValueError* instead of *TypeError* (GH33660)

• Combining a *Categorical* with integer categories and which contains missing values with a float dtype column in operations such as *concat()* or *append()* will now result in a float column instead of an object dtype column (GH33607)

• Bug where *merge()* was unable to join on non-unique categorical indices (GH28189)

• Bug when passing categorical data to *Index* constructor along with *dtype=object* incorrectly returning a *CategoricalIndex* instead of object-dtype *Index* (GH32167)

• Bug where *Categorical* comparison operator *__ne__* would incorrectly evaluate to *False* when either element was missing (GH32276)

• *Categorical.fillna()* now accepts *Categorical* other argument (GH32420)

• Repr of *Categorical* was not distinguishing between *int* and *str* (GH33676)

#### Datetimelike

• Passing an integer dtype other than *int64* to *np.array(period_index, dtype=...)* will now raise *TypeError* instead of incorrectly using *int64* (GH32255)

• *Series.to_timestamp()* now raises a *TypeError* if the axis is not a *PeriodIndex*. Previously an *AttributeError* was raised (GH33327)

• *Series.to_period()* now raises a *TypeError* if the axis is not a *DatetimeIndex*. Previously an *AttributeError* was raised (GH33327)
- **Period** no longer accepts tuples for the freq argument (GH34658)
- Bug in **Timestamp** where constructing a Timestamp from ambiguous epoch time and calling constructor again changed the Timestamp.value() property (GH24329)
- **DatetimeArray.searchsorted()**, **TimedeltaArray.searchsorted()**, **PeriodArray.searchsorted()** not recognizing non-pandas scalars and incorrectly raising ValueError instead of TypeError (GH30950)
- Bug in **Timestamp** where constructing Timestamp with dateutil timezone less than 128 nanoseconds before daylight saving time switch from winter to summer would result in nonexistent time (GH31043)
- Bug in **Period.to_timestamp()**, **Period.start_time()** with microsecond frequency returning a timestamp one nanosecond earlier than the correct time (GH31475)
- **Timestamp** raised a confusing error message when year, month or day is missing (GH31200)
- Bug in **DatetimeIndex** constructor incorrectly accepting bool-dtype inputs (GH32668)
- Bug where **PeriodIndex()** raised when passed a Series of strings (GH26109)
- Bug in **Timestamp** arithmetic when adding or subtracting an np.ndarray with timedelta64 dtype (GH33296)
- Bug in **DatetimeIndex.to_period()** not inferring the frequency when called with no arguments (GH33358)
- Bug in **DatetimeIndex.tz_localize()** incorrectly retaining freq in some cases where the original freq is no longer valid (GH30511)
- Bug in **DatetimeIndex.intersection()** losing freq and timezone in some cases (GH33604)
- Bug in **DatetimeIndex.get_indexer()** where incorrect output would be returned for mixed datetime-like targets (GH33741)
- Bug in **DatetimeIndex** addition and subtraction with some types of DateOffset objects incorrectly retaining an invalid freq attribute (GH33779)
- Bug in **DatetimeIndex** where setting the freq attribute on an index could silently change the freq attribute on another index viewing the same data (GH33552)
- **DataFrame.min()** and **DataFrame.max()** were not returning consistent results with **Series.min()** and **Series.max()** when called on objects initialized with empty pd.to_datetime()
- Bug in **DatetimeIndex.intersection()** and **TimedeltaIndex.intersection()** with results not having the correct name attribute (GH33904)
- Bug in **DatetimeArray.__setitem__()**, **TimedeltaArray.__setitem__()**, **PeriodArray.__setitem__()** incorrectly allowing values with int64 dtype to be silently cast (GH33717)
- Bug in subtracting **TimedeltaIndex** from **Period** incorrectly raising TypeError in some cases where it should succeed and IncompatibleFrequency in some cases where it should raise TypeError (GH33883)
- Bug in constructing a Series or Index from a read-only NumPy array with non-ns resolution which converted to object dtype instead of coercing to datetime64[ns] dtype when within the timestamp bounds (GH34843).
- The freq keyword in **Period**, **date_range()**, **period_range()**, **pd.tseries.frequencies.to_offset()** no longer allows tuples, pass as string instead (GH34703)
- Bug in **DataFrame.append()** when appending a Series containing a scalar tz-aware Timestamp to an empty DataFrame resulted in an object column instead of datetime64[ns, tz] dtype (GH35038)
• OutOfBoundsDatetime issues an improved error message when timestamp is out of implementation bounds. (GH32967)
• Bug in AbstractHolidayCalendar.holidays() when no rules were defined (GH31415)
• Bug in Tick comparisons raising TypeError when comparing against timedelta-like objects (GH34088)
• Bug in Tick multiplication raising TypeError when multiplying by a float (GH34486)

**Timedelta**

• Bug in constructing a Timedelta with a high precision integer that would round the Timedelta components (GH31354)
• Bug in dividing np.nan or None by Timedelta incorrectly returning NaT (GH31869)
• Timedelta now understands μs as an identifier for microsecond (GH32899)
• Timedelta string representation now includes nanoseconds, when nanoseconds are non-zero (GH9309)
• Bug in comparing a Timedelta object against an np.ndarray with timedelta64 dtype incorrectly viewing all entries as unequal (GH33441)
• Bug in timedelta_range() that produced an extra point on a edge case (GH30353, GH33498)
• Bug in DataFrame.resample() that produced an extra point on a edge case (GH30353, GH13022, GH33498)
• Bug in DataFrame.resample() that ignored the loffset argument when dealing with timedelta (GH7687, GH33498)
• Bug in Timedelta and pandas.to_timedelta() that ignored the unit argument for string input (GH12136)

**Timezones**

• Bug in to_datetime() with infer_datetime_format=True where timezone names (e.g. UTC) would not be parsed correctly (GH33133)

**Numeric**

• Bug in DataFrame.floordiv() with axis=0 not treating division-by-zero like Series.floordiv() (GH31271)
• Bug in to_numeric() with string argument "uint64" and errors="coerce" silently fails (GH32394)
• Bug in to_numeric() with downcast="unsigned" fails for empty data (GH32493)
• Bug in DataFrame.mean() with numeric_only=False and either datetime64 dtype or PeriodDtype column incorrectly raising TypeError (GH32426)
• Bug in DataFrame.count() with level="foo" and index level "foo" containing NaNs causes segmentation fault (GH21824)
• Bug in DataFrame.diff() with axis=1 returning incorrect results with mixed dtypes (GH32995)
• Bug in DataFrame.corr() and DataFrame.cov() raising when handling nullable integer columns with pandas.NA (GH33803)
• Bug in arithmetic operations between DataFrame objects with non-overlapping columns with duplicate labels causing an infinite loop (GH35194)
• Bug in DataFrame and Series addition and subtraction between object-dtype objects and datetime64 dtype objects (GH33824)
• Bug in Index.difference() giving incorrect results when comparing a Float64Index and object Index (GH35217)
• Bug in DataFrame reductions (e.g. df.min(), df.max()) with ExtensionArray dtypes (GH34520, GH32651)
• Series.interpolate() and DataFrame.interpolate() now raise a ValueError if limit_direction is 'forward' or 'both' and method is 'backfill' or 'bfill' or limit_direction is 'backward' or 'both' and method is 'pad' or 'ffill' (GH34746)

Conversion

• Bug in Series construction from NumPy array with big-endian datetime64 dtype (GH29684)
• Bug in Timedelta construction with large nanoseconds keyword value (GH32402)
• Bug in DataFrame construction where sets would be duplicated rather than raising (GH32582)
• The DataFrame constructor no longer accepts a list of DataFrame objects. Because of changes to NumPy, DataFrame objects are now consistently treated as 2D objects, so a list of DataFrame objects is considered 3D, and no longer acceptable for the DataFrame constructor (GH32289).
• Bug in DataFrame when initiating a frame with lists and assign columns with nested list for MultiIndex (GH32173)
• Improved error message for invalid construction of list when creating a new index (GH35190)

Strings

• Bug in the astype() method when converting “string” dtype data to nullable integer dtype (GH32450).
• Fixed issue where taking min or max of a StringArray or Series with StringDtype type would raise. (GH31746)
• Bug in Series.str.cat() returning NaN output when other had Index type (GH33425)
• pandas.api.dtypes.is_string_dtype() no longer incorrectly identifies categorical series as string.

Interval

• Bug in IntervalArray incorrectly allowing the underlying data to be changed when setting values (GH32782)
Indexing

- `DataFrame.xs()` now raises a `TypeError` if a `level` keyword is supplied and the axis is not a `MultiIndex`. Previously an `AttributeError` was raised (GH33610)
- Bug in slicing on a `DatetimeIndex` with a partial-timestamp dropping high-resolution indices near the end of a year, quarter, or month (GH31064)
- Bug in `PeriodIndex.get_loc()` treating higher-resolution strings differently from `PeriodIndex.get_value()` (GH31172)
- Bug in `Series.at()` and `DataFrame.at()` not matching `.loc` behavior when looking up an integer in a `Float64Index` (GH31329)
- Bug in `PeriodIndex.is_monotonic()` incorrectly returning `True` when containing leading `NaT` entries (GH31437)
- Bug in `DatetimeIndex.get_loc()` raising `KeyError` with converted-integer key instead of the user-passed key (GH31425)
- Bug in `Series.xs()` incorrectly returning `Timestamp` instead of `datetime64` in some object-dtype cases (GH31630)
- Bug in `DataFrame.iat()` incorrectly returning `Timestamp` instead of `datetime` in some object-dtype cases (GH32809)
- Bug in `DataFrame.at()` when either columns or index is non-unique (GH33041)
- Bug in `Series.loc()` and `DataFrame.loc()` when indexing with an integer key on a object-dtype `Index` that is not all-integers (GH31905)
- Bug in `DataFrame.iloc.__setitem__()` on a `DataFrame` with duplicate columns incorrectly setting values for all matching columns (GH15686, GH22036)
- Bug in `DataFrame.loc()` and `Series.loc()` with a `DatetimeIndex`, `TimedeltaIndex`, or `PeriodIndex` incorrectly allowing lookups of non-matching datetime-like dtypes (GH32650)
- Bug in `Series.__getitem__()` indexing with non-standard scalars, e.g. `np.dtype` (GH32684)
- Bug in `Index` constructor where an unhelpful error message was raised for NumPy scalars (GH33017)
- Bug in `DataFrame.lookup()` incorrectly raising an `AttributeError` when `frame.index` or `frame.columns` is not unique; this will now raise a `ValueError` with a helpful error message (GH33041)
- Bug in `Interval` where a `Timedelta` could not be added or subtracted from a `Timestamp` interval (GH33023)
- Bug in `DataFrame.copy()` not invalidating `_item_cache` after copy caused post-copy value updates to not be reflected (GH31784)
- Fixed regression in `DataFrame.loc()` and `Series.loc()` throwing an error when a `datetime64[ns, tz]` value is provided (GH32395)
- Bug in `Series.__getitem__()` with an integer key and a `MultiIndex` with leading integer level failing to raise `KeyError` if the key is not present in the first level (GH33355)
- Bug in `DataFrame.iloc()` when slicing a single column `DataFrame` with `ExtensionDtype` (e.g. `df.iloc[:, :1]`) returning an invalid result (GH32957)
- Bug in `Datet imeIndex.insert()` and `TimedeltaIndex.insert()` causing index `freq` to be lost when setting an element into an empty `Series` (GH33573)
- Bug in `Series.__setItem__()` with an `IntervalIndex` and a list-like key of integers (GH33473)
• Bug in Series.__getitem__() allowing missing labels with np.ndarray, Index, Series indexers but not list, these now all raise KeyError (GH33646)

• Bug in DataFrame.truncate() and Series.truncate() where index was assumed to be monotone increasing (GH33756)

• Indexing with a list of strings representing datetimes failed on DatetimeIndex or PeriodIndex (GH11278)

• Bug in Series.at() when used with a MultiIndex would raise an exception on valid inputs (GH26989)

• Bug in DataFrame.loc() with dictionary of values changes columns with dtype of int to float (GH34573)

• Bug in Series.loc() when used with a MultiIndex would raise an IndexError when accessing a None value (GH34318)

• Bug in DataFrame.reset_index() and Series.reset_index() would not preserve data types on an empty DataFrame or Series with a MultiIndex (GH19602)

• Bug in Series and DataFrame indexing with a time key on a DatetimeIndex with NaT entries (GH35114)

Missing

• Callingfillna() on an empty Series now correctly returns a shallow copied object. The behaviour is now consistent with Index, DataFrame and a non-empty Series (GH32543).

• Bug in Series.replace() when argument to_replace is of type dict/list and is used on a Series containing <NA> was raising a TypeError. The method now handles this by ignoring <NA> values when doing the comparison for the replacement (GH32621)

• Bug in any() and all() incorrectly returning <NA> for all False or all True values using the nullable Boolean dtype and with skipna=False (GH33253)

• Clarified documentation on interpolate with method=akima. The der parameter must be scalar or None (GH33426)

• DataFrame.interpolate() uses the correct axis convention now. Previously interpolating along columns lead to interpolation along indices and vice versa. Furthermore interpolating with methods pad,ffill,bfill and backfill are identical to using these methods with DataFrame.fillna() (GH12918, GH29146)

• Bug in DataFrame.interpolate() when called on a DataFrame with column names of string type was throwing a ValueError. The method is now independent of the type of the column names (GH33956)

• Passing NA into a format string using format specs will now work. For example "{:.1f}".format(pd.NA) would previously raise a ValueError, but will now return the string "<NA>" (GH34740)

• Bug in Series.map() not raising on invalid na_action (GH32815)
MultiIndex

- DataFrame.swaplevels() now raises a TypeError if the axis is not a MultiIndex. Previously an AttributeError was raised (GH31126)
- Bug in DataFrame.loc() when used with a MultiIndex. The returned values were not in the same order as the given inputs (GH22797)

```python
In [80]: df = pd.DataFrame(np.arange(4),
                 index=[['a', 'a', 'b', 'b'], [1, 2, 1, 2]])
                 ....:                   
                 ....:

# Rows are now ordered as the requested keys
In [81]: df.loc[(['b', 'a'], [2, 1]), :]
Out[81]:
      0
   b 2 3
   1 2
   a 2 1
   1 0
[4 rows x 1 columns]
```

- Bug in MultiIndex.intersection() was not guaranteed to preserve order when sort=False. (GH31325)
- Bug in DataFrame.truncate() was dropping MultiIndex names. (GH34564)

```python
In [82]: left = pd.MultiIndex.from_arrays([['b', 'a'], [2, 1]])
In [83]: right = pd.MultiIndex.from_arrays([['c', 'b', 'a'], [1, 2, 3]])

# Common elements are now guaranteed to be ordered by the left side
In [84]: left.intersection(right, sort=False)
Out[84]:
MultiIndex([('b', 2), ('a', 1)],
            )
```

- Bug when joining two MultiIndex without specifying level with different columns. Return-indexers parameter was ignored. (GH34074)

IO

- Passing a set as names argument to pandas.read_csv(), pandas.read_table(), or pandas.read_fwf() will raise ValueError: Names should be an ordered collection. (GH34946)
- Bug in print-out when display.precision is zero. (GH20359)
- Bug in read_json() where integer overflow was occurring when json contains big number strings. (GH30320)
- read_csv() will now raise a ValueError when the arguments header and prefix both are not None. (GH27394)
- Bug in DataFrame.to_json() was raising NotFoundError when path_or_buf was an S3 URI (GH28375)
• Bug in DataFrame.to_parquet() overwriting pyarrow’s default for coerce_timestamps; following pyarrow’s default allows writing nanosecond timestamps with version="2.0" (GH31652).

• Bug in read_csv() was raising TypeError when sep=None was used in combination with comment keyword (GH31396)

• Bug in HDFStore that caused it to set to int64 the dtype of a datetime64 column when reading a DataFrame in Python 3 from fixed format written in Python 2 (GH31750)

• read_sas() now handles dates and datetimes larger than Timestamp.max returning them as datetime objects (GH20927)

• Bug in DataFrame.to_json() where Timedelta objects would not be serialized correctly with date_format="iso" (GH28256)

• read_csv() will raise a ValueError when the column names passed in parse_dates are missing in the Dataframe (GH31251)

• Bug in read_excel() where a UTF-8 string with a high surrogate would cause a segmentation violation (GH23809)

• Bug in read_csv() was causing a file descriptor leak on an empty file (GH31488)

• Bug in read_csv() was causing a segfault when there were blank lines between the header and data rows (GH28071)

• Bug in read_csv() was raising a misleading exception on a permissions issue (GH23784)

• Bug in read_csv() was raising an IndexError when header=None and two extra data columns

• Bug in read_sas() was raising an AttributeError when reading files from Google Cloud Storage (GH33069)

• Bug in DataFrame.to_sql() where an AttributeError was raised when saving an out of bounds date (GH26761)

• Bug in read_excel() did not correctly handle multiple embedded spaces in OpenDocument text cells. (GH32207)

• Bug in read_json() was raising TypeError when reading a list of Booleans into a Series. (GH31464)

• Bug in pandas.io.json.json_normalize() where location specified by record_path doesn’t point to an array. (GH26284)

• pandas.read_hdf() has a more explicit error message when loading an unsupported HDF file (GH9539)

• Bug in read_feather() was raising an ArrowIOError when reading an s3 or http file path (GH29055)

• Bug in to_excel() could not handle the column name render and was raising an KeyError (GH34331)

• Bug in execute() was raising a ProgrammingError for some DB-API drivers when the SQL statement contained the % character and no parameters were present (GH34211)

• Bug in StataReader() which resulted in categorical variables with different dtypes when reading data using an iterator. (GH31544)

• HDFStore.keys() has now an optional include parameter that allows the retrieval of all native HDF5 table names (GH29916)

• TypeError exceptions raised by read_csv() and read_table() were showing as parser_f when an unexpected keyword argument was passed (GH25648)

• Bug in read_excel() for ODS files removes 0.0 values (GH27222)
• Bug in ujson.encode() was raising an OverflowError with numbers larger than sys.maxsize (GH34395)
• Bug in HDFStore.append_to_multiple() was raising a ValueError when the min_itemsize parameter is set (GH11238)
• Bug in create_table() now raises an error when column argument was not specified in data_columns on input (GH28156)
• read_json() now could read line-delimited json file from a file url while lines and chunksize are set.
• Bug in DataFrame.to_sql() when reading DataFrames with -np.inf entries with MySQL now has a more explicit ValueError (GH34431)
• Bug where capitalised files extensions were not decompressed by read_* functions (GH35164)
• Bug in read_excel() that was raising a TypeError when header=None and index_col is given as a list (GH31783)
• Bug in read_excel() where datetime values are used in the header in a MultiIndex (GH34748)
• read_excel() no longer takes **kwds arguments. This means that passing in the keyword argument chunksize now raises a TypeError (previously raised a NotImplementedError), while passing in the keyword argument encoding now raises a TypeError (GH34464)
• Bug in DataFrame.to_records() was incorrectly losing timezone information in timezone-aware datetime64 columns (GH32535)

Plotting

• DataFrame.plot() for line/bar now accepts color by dictionary (GH8193).
• Bug in DataFrame.plot.hist() where weights are not working for multiple columns (GH33173)
• Bug in DataFrame.boxplot() and DataFrame.plot.boxplot() lost color attributes of medianprops, whiskerprops, capprops and boxprops (GH30346)
• Bug in DataFrame.hist() where the order of column argument was ignored (GH29235)
• Bug in DataFrame.plot.scatter() that when adding multiple plots with different cmap, colorbars always use the first cmap (GH33389)
• Bug in DataFrame.plot.scatter() was adding a colorbar to the plot even if the argument c was assigned to a column containing color names (GH34316)
• Bug in pandas.plotting.bootstrap_plot() was causing cluttered axes and overlapping labels (GH34905)
• Bug in DataFrame.plot.scatter() caused an error when plotting variable marker sizes (GH32904)

GroupBy/resample/rolling

• Using a pandas.api.indexers.BaseIndexer with count, min, max, median, skew, cov, corr will now return correct results for any monotonic pandas.api.indexers.BaseIndexer descendant (GH32865)
• DataFrameGroupby.mean() and SeriesGroupby.mean() (and similarly for median(), std() and var()) now raise a TypeError if a non-accepted keyword argument is passed into it. Previously an UnsupportedFunctionCall was raised (AssertionError if min_count passed into median()) (GH31485)
• Bug in `GroupBy.apply()` raises `ValueError` when the by axis is not sorted, has duplicates, and the applied `func` does not mutate passed in objects (GH30667)

• Bug in `DataFrameGroupBy.transform()` produces an incorrect result with transformation functions (GH30918)

• Bug in `Groupby.transform()` was returning the wrong result when grouping by multiple keys of which some were categorical and others not (GH32494)

• Bug in `GroupBy.count()` causes segmentation fault when grouped-by columns contain NaNs (GH32841)

• Bug in `DataFrame.groupby()` and `Series.groupby()` produces inconsistent type when aggregating Boolean `Series` (GH32894)

• Bug in `DataFrameGroupBy.sum()` and `SeriesGroupBy.sum()` where a large negative number would be returned when the number of non-null values was below `min_count` for nullable integer dtypes (GH32861)

• Bug in `SeriesGroupBy.quantile()` was raising on nullable integers (GH33136)

• Bug in `DataFrame.resample()` where an `AmbiguousTimeError` would be raised when the resulting timezone aware `DatetimeIndex` had a DST transition at midnight (GH25758)

• Bug in `DataFrame.groupby()` where a `ValueError` would be raised when grouping by a categorical column with read-only categories and `sort=False` (GH33410)

• Bug in `GroupBy.agg()`, `GroupBy.transform()`, and `GroupBy.resample()` where subclasses are not preserved (GH28330)

• Bug in `SeriesGroupBy.agg()` where any column name was accepted in the named aggregation of `SeriesGroupBy` previously. The behaviour now allows only `str` and callables else would raise `TypeError`. (GH34422)

• Bug in `DataFrame.groupby()` lost the name of the `Index` when one of the `agg` keys referenced an empty list (GH32580)

• Bug in `Rolling.apply()` where `center=True` was ignored when `engine='numba'` was specified (GH34784)

• Bug in `DataFrame.ewm.cov()` was throwing `AssertionError` for `MultiIndex` inputs (GH34440)

• Bug in `core.groupby.DataFrameGroupBy.quantile()` raised `TypeError` for non-numeric types rather than dropping the columns (GH27892)

• Bug in `core.groupby.DataFrameGroupBy.transform()` when `func='nunique'` and columns are of type `datetime64`, the result would also be of type `datetime64` instead of `int64` (GH35109)

• Bug in `DataFrame.groupby()` raising an `AttributeError` when selecting a column and aggregating with `as_index=False` (GH35246).

• Bug in `DataFrameGroupBy.first()` and `DataFrameGroupBy.last()` that would raise an unnecessary `ValueError` when grouping on multiple Categoricals (GH34951)
Reshaping

- Bug effecting all numeric and Boolean reduction methods not returning subclassed data type. (GH25596)
- Bug in DataFrame.pivot_table() when only MultiIndexed columns is set (GH17038)
- Bug in DataFrame.unstack() and Series.unstack() can take tuple names in MultiIndexed data (GH19966)
- Bug in DataFrame.pivot_table() when margin is True and only column is defined (GH31016)
- Fixed incorrect error message in DataFrame.pivot() when columns is set to None. (GH30924)
- Bug in crosstab() when inputs are two Series and have tuple names, the output will keep a dummy MultiIndex as columns. (GH18321)
- DataFrame.pivot() can now take lists for index and columns arguments (GH21425)
- Bug in concat() where the resulting indices are not copied when copy=True (GH29879)
- Bug in SeriesGroupBy.aggregate() was resulting in aggregations being overwritten when they shared the same name (GH30880)
- Bug where Index.astype() would lose the name attribute when converting from Float64Index to Int64Index, or when casting to an ExtensionArray dtype (GH32013)
- Series.append() will now raise a TypeError when passed a DataFrame or a sequence containing DataFrame (GH31413)
- DataFrame.replace() and Series.replace() will raise a TypeError if to_replace is not an expected type. Previously the replace would fail silently (GH18634)
- Bug on inplace operation of a Series that was adding a column to the DataFrame from where it was originally dropped from (using inplace=True) (GH30871)
- Bug in DataFrame.apply() where callback was called with Series parameter even though raw=True requested. (GH32423)
- Bug in DataFrame.pivot_table() losing timezone information when creating a MultiIndex level from a column with timezone-aware dtype (GH32558)
- Bug in concat() where when passing a non-dict mapping as objs would raise a TypeError (GH32863)
- DataFrame.agg() now provides more descriptive SpecificationError message when attempting to aggregate a non-existent column (GH32755)
- Bug in DataFrame.unstack() when MultiIndex columns and MultiIndex rows were used (GH32624, GH24729 and GH28306)
- Appending a dictionary to a DataFrame without passing ignore_index=True will raise TypeError: Can only append a dict if ignore_index=True instead of TypeError: Can only append a :class:`Series` if ignore_index=True or if the :class:`Series` has a name (GH30871)
- Bug in DataFrame.corrwith(), DataFrame.memory_usage(), DataFrame.dot(), DataFrame.idxmin(), DataFrame.idxmax(), DataFrame.duplicated(), DataFrame.isin(), DataFrame.count(), Series.explode(), Series.asof() and DataFrame.asof() not returning subclassed types. (GH31331)
- Bug in concat() was not allowing for concatenation of DataFrame and Series with duplicate keys (GH33654)
- Bug in cut() raised an error when the argument labels contains duplicates (GH33141)
- Ensure only named functions can be used in eval() (GH32460)
• Bug in `Dataframe.aggregate()` and `Series.aggregate()` was causing a recursive loop in some cases (GH34224)
• Fixed bug in `melt()` where melting `MultiIndex` columns with `col_level > 0` would raise a `KeyError` on `id_vars` (GH34129)
• Bug in `Series.where()` with an empty `Series` and empty `cond` having non-bool dtype (GH34592)
• Fixed regression where `DataFrame.apply()` would raise `ValueError` for elements with `S` dtype (GH34529)

Sparse

• Creating a `SparseArray` from timezone-aware dtype will issue a warning before dropping timezone information, instead of doing so silently (GH32501)
• Bug in `arrays.SparseArray.from_spmatrix()` wrongly read scipy sparse matrix (GH31991)
• Bug in `Series.sum()` with `SparseArray` raised a `TypeError` (GH25777)
• Bug where `DataFrame` containing an all-sparse `SparseArray` filled with NaN when indexed by a list-like (GH27781, GH29563)
• The repr of `SparseDtype` now includes the repr of its `fill_value` attribute. Previously it used `fill_value`’s string representation (GH34352)
• Bug where empty `DataFrame` could not be cast to `SparseDtype` (GH33113)
• Bug in `arrays.SparseArray()` was returning the incorrect type when indexing a sparse dataframe with an iterable (GH34526, GH34540)

ExtensionArray

• Fixed bug where `Series.value_counts()` would raise on empty input of `Int64` dtype (GH33317)
• Fixed bug in `concat()` when concatenating `DataFrame` objects with non-overlapping columns resulting in object-dtype columns rather than preserving the extension dtype (GH27692, GH33027)
• Fixed bug where `StringArray.isna()` would return `False` for NA values when `pandas.options.mode.use_inf_as_na` was set to True (GH33655)
• Fixed bug in `Series` construction with EA dtype and index but no data or scalar data fails (GH26469)
• Fixed bug that caused `Series.__repr__()` to crash for extension types whose elements are multidimensional arrays (GH33770).
• Fixed bug where `Series.update()` would raise a `ValueError` for `ExtensionArray` dtypes with missing values (GH33980)
• Fixed bug where `StringArray.memory_usage()` was not implemented (GH33963)
• Fixed bug where `DataFrameGroupBy()` would ignore the `min_count` argument for aggregations on nullable Boolean dtypes (GH34051)
• Fixed bug where the constructor of `DataFrame` with `dtype='string'` would fail (GH27953, GH33623)
• Bug where `DataFrame` column set to scalar extension type was considered an object type rather than the extension type (GH34832)
• Fixed bug in `IntegerArray.astype()` to correctly copy the mask as well (GH34931).
Other

- Set operations on an object-dtype Index now always return object-dtype results (GH31401)
- Fixed pandas.testing.assert_series_equal() to correctly raise if the left argument is a different subclass with check_series_type=True (GH32670).
- Getting a missing attribute in a DataFrame.query() or DataFrame.eval() string raises the correct AttributeError (GH32408)
- Fixed bug in pandas.testing.assert_series_equal() where dtypes were checked for Interval and ExtensionArray operands when check_dtype was False (GH32747)
- Bug in DataFrame.__dir__() caused a segfault when using unicode surrogates in a column name (GH25509)
- Bug in DataFrame.equals() and Series.equals() in allowing subclasses to be equal (GH34402).

5.3 Version 1.0

5.3.1 What’s new in 1.0.5 (June 17, 2020)

These are the changes in pandas 1.0.5. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

• Fix regression in read_parquet() when reading from file-like objects (GH34467).
• Fix regression in reading from public S3 buckets (GH34626).

Note this disables the ability to read Parquet files from directories on S3 again (GH26388, GH34632), which was added in the 1.0.4 release, but is now targeted for pandas 1.1.0.

• Fixed regression in replace() raising an AttributeError when replacing values in an extension dtype with values of a different dtype (GH34530)
Bug fixes

- Fixed building from source with Python 3.8 fetching the wrong version of NumPy (GH34666)

Contributors

A total of 8 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Joris Van den Bossche

5.3.2 What’s new in 1.0.4 (May 28, 2020)

These are the changes in pandas 1.0.4. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fix regression where Series.isna() and DataFrame.isna() would raise for categorical dtype when pandas.options.mode.use_inf_as_na was set to True (GH33594)
- Fix regression in GroupBy.first() and GroupBy.last() where None is not preserved in object dtype (GH32800)
- Fix regression in DataFrame reductions using numeric_only=True and ExtensionArrays (GH33256).
- Fix performance regression in memory_usage(deep=True) for object dtype (GH33012)
- Fix regression where Categorical.replace() would replace with NaN whenever the new value and replacement value were equal (GH33288)
- Fix regression where an ordered Categorical containing only NaN values would raise rather than returning NaN when taking the minimum or maximum (GH33450)
- Fix regression in DataFrameGroupBy.agg() with dictionary input losing ExtensionArray dtypes (GH32194)
- Fix to preserve the ability to index with the “nearest” method with xarray’s CFTimeIndex, an Index subclass (pydata/xarray#3751, GH32905).
- Fix regression in DataFrame.describe() raising TypeError: unhashable type: 'dict' (GH32409)
- Fix regression in DataFrame.replace() casts columns to object dtype if items in to_replace not in values (GH32988)
- Fix regression in Series.groupby() would raise ValueError when grouping by PeriodIndex level (GH34010)
• Fix regression in `GroupBy.rolling.apply()` ignores args and kwargs parameters (GH33433)
• Fix regression in error message with `np.min` or `np.max` on unordered `Categorical` (GH33115)
• Fix regression in `DataFrame.loc()` and `Series.loc()` throwing an error when a `datetime64[ns, tz]` value is provided (GH32395)

**Bug fixes**

• Bug in `SeriesGroupBy.first()`, `SeriesGroupBy.last()`, `SeriesGroupBy.min()`, and `SeriesGroupBy.max()` returning floats when applied to nullable Booleans (GH33071)
• Bug in `Rolling.min()` and `Rolling.max()`: Growing memory usage after multiple calls when using a fixed window (GH30726)
• Bug in `to_parquet()` was not raising `PermissionError` when writing to a private s3 bucket with invalid creds. (GH27679)
• Bug in `to_csv()` was silently failing when writing to an invalid s3 bucket. (GH32486)
• Bug in `read_parquet()` was raising a `FileNotFoundError` when passed an s3 directory path. (GH26388)
• Bug in `to_parquet()` was throwing an `AttributeError` when writing a partitioned parquet file to s3 (GH27596)
• Bug in `GroupBy.quantile()` causes the quantiles to be shifted when the `by` axis contains NaN (GH33200, GH33569)

5.3.3 What’s new in 1.0.3 (March 17, 2020)

These are the changes in pandas 1.0.3. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `resample.agg` when the underlying data is non-writeable (GH31710)
- Fixed regression in `DataFrame` exponentiation with reindexing (GH32685)

Bug fixes

Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- MeeseeksMachine
- Pandas Development Team
- Tom Augspurger
- William Ayd
- jbrockmendel

5.3.4 What’s new in 1.0.2 (March 12, 2020)

These are the changes in pandas 1.0.2. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

Groupby

- Fixed regression in `groupby(..).agg()` which was failing on frames with `MultiIndex` columns and a custom function (GH31777)
- Fixed regression in `groupby(..).rolling(..).apply()` (RollingGroupby) where the `raw` parameter was ignored (GH31754)
- Fixed regression in `rolling(..).corr()` when using a time offset (GH31789)
- Fixed regression in `groupby(..).nunique()` which was modifying the original values if NaN values were present (GH31950)
- Fixed regression in `DataFrame.groupby` raising a `ValueError` from an internal operation (GH31802)
- Fixed regression in `groupby(..).agg()` calling a user-provided function an extra time on an empty input (GH31760)

I/O
• Fixed regression in `read_csv()` in which the `encoding` option was not recognized with certain file-like objects (GH31819)

• Fixed regression in `DataFrame.to_excel()` when the `columns` keyword argument is passed (GH31677)

• Fixed regression in `ExcelFile` where the stream passed into the function was closed by the destructor. (GH31467)

• Fixed regression where `read_pickle()` raised a `UnicodeDecodeError` when reading a py27 pickle with `MultiIndex` column (GH31988).

Reindexing/alignment

• Fixed regression in `Series.align()` when `other` is a `DataFrame` and `method` is not `None` (GH31785)

• Fixed regression in `DataFrame.reindex()` and `Series.reindex()` when reindexing with (tz-aware) index and `method=nearest` (GH26683)

• Fixed regression in `DataFrame.reindex_like()` on a `DataFrame` subclass raised an `AssertionError` (GH31925)

• Fixed regression in `DataFrame` arithmetic operations with mis-matched columns (GH31623)

Other

• Fixed regression in joining on `DatetimeIndex` or `TimedeltaIndex` to preserve `freq` in simple cases (GH32166)

• Fixed regression in `Series.shift()` with `datetime64` dtype when passing an integer `fill_value` (GH32591)

• Fixed regression in the repr of an object-dtype `Index` with bools and missing values (GH32146)

Indexing with nullable boolean arrays

Previously indexing with a nullable Boolean array containing NA would raise a `ValueError`, however this is now permitted with NA being treated as `False`. (GH31503)

```
In [1]: s = pd.Series([1, 2, 3, 4])

In [2]: mask = pd.array([True, True, False, None], dtype="boolean")

In [3]: s
Out[3]:
   0   1
  --- ---
   1   2
   2   3
   3   4
Length: 4, dtype: int64

In [4]: mask
Out[4]:
<BooleanArray>
[True, True, False, <NA>]  
Length: 4, dtype: boolean
```

```
pandas 1.0.0-1.0.1
```

```
>>> s[mask]
Traceback (most recent call last):
```
(continues on next page)
...  
**ValueError**: cannot mask with array containing NA / NaN values

**pandas 1.0.2**

```python
In [5]: s[mask]  
Out[5]:  
0   1  
1   2  
Length: 2, dtype: int64
```

**Bug fixes**

**Datetimelike**

- Bug in `Series.astype()` not copying for tz-naive and tz-aware `datetime64` dtype (GH32490)
- Bug where `to_datetime()` would raise when passed `pd.NA` (GH32213)
- Improved error message when subtracting two `Timestamp` that result in an out-of-bounds `Timedelta` (GH31774)

**Categorical**

- Fixed bug where `Categorical.from_codes()` improperly raised a `ValueError` when passed nullable integer codes. (GH31779)
- Fixed bug where `Categorical()` constructor would raise a `TypeError` when given a numpy array containing `pd.NA`. (GH31927)
- Bug in `Categorical` that would ignore or crash when calling `Series.replace()` with a list-like `to_replace` (GH31720)

**I/O**

- Using `pd.NA` with `DataFrame.to_json()` now correctly outputs a null value instead of an empty object (GH31615)
- Bug in `pandas.json_normalize()` when value in meta path is not iterable (GH31507)
- Fixed pickling of `pandas.NA`. Previously a new object was returned, which broke computations relying on `NA` being a singleton (GH31847)
- Fixed bug in parquet roundtrip with nullable unsigned integer dtypes (GH31896).

**Experimental dtypes**

- Fixed bug in `DataFrame.convert_dtypes()` for columns that were already using the "string" dtype (GH31731).
- Fixed bug in `DataFrame.convert_dtypes()` for series with mix of integers and strings (GH32117)
- Fixed bug in `DataFrame.convert_dtypes()` where `BooleanDtype` columns were converted to `Int64` (GH32287)
- Fixed bug in setting values using a slice indexer with string dtype (GH31772)
- Fixed bug where `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` would raise a `TypeError` when groups contained `pd.NA` in a column of object dtype (GH32123)
• Fixed bug where `DataFrameGroupBy.mean()`, `DataFrameGroupBy.median()`, `DataFrameGroupBy.var()`, and `DataFrameGroupBy.std()` would raise a `TypeError` on `Int64` dtype columns (GH32219)

**Strings**

• Using `pd.NA` with `Series.str.repeat()` now correctly outputs a null value instead of raising error for vector inputs (GH31632)

**Rolling**

• Fixed rolling operations with variable window (defined by time duration) on decreasing time index (GH32385).

**Contributors**

A total of 25 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.3.5 What’s new in 1.0.1 (February 5, 2020)

These are the changes in pandas 1.0.1. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in DataFrame setting values with a slice (e.g. df[-4:] = 1) indexing by label instead of position (GH31469)
- Fixed regression when indexing a Series or DataFrame indexed by DatetimeIndex with a slice containing a datetime.date (GH31501)
- Fixed regression in DataFrame.__setitem__ raising an AttributeError with a MultiIndex and a non-monotonic indexer (GH31449)
- Fixed regression in Series multiplication when multiplying a numeric Series with >10000 elements with a timedelta-like scalar (GH31457)
- Fixed regression in .groupby().agg() raising an AssertionError for some reductions like min on object-dtype columns (GH31522)
- Fixed regression in .groupby() aggregations with categorical dtype using Cythonized reduction functions (e.g. first)(GH31450)
- Fixed regression in GroupBy.apply() if called with a function which returned a non-pandas non-scalar object (e.g. a list or numpy array) (GH31441)
- Fixed regression in DataFrame.groupby() whereby taking the minimum or maximum of a column with period dtype would raise a TypeError. (GH31471)
- Fixed regression in DataFrame.groupby() with an empty DataFrame grouping by a level of a MultiIndex (GH31670).
- Fixed regression in DataFrame.apply() with object dtype and non-reducing function (GH31505)
- Fixed regression in to_datetime() when parsing non-nanosecond resolution datetimes (GH31491)
- Fixed regression in to_csv() where specifying an na_rep might truncate the values written (GH31491)
- Fixed regression in Categorical construction with numpy.str_.categories (GH31499)
- Fixed regression in DataFrame.loc() and DataFrame.iloc() when selecting a row containing a single datetime64 or timedelta64 column (GH31649)
- Fixed regression where setting pd.options.display.max_colwidth was not accepting negative integer. In addition, this behavior has been deprecated in favor of using None (GH31532)
- Fixed regression in objTOJSON.c fix return-type warning (GH31463)
- Fixed regression in qcut() when passed a nullable integer. (GH31389)
- Fixed regression in assigning to a Series using a nullable integer dtype (GH31446)
- Fixed performance regression when indexing a DataFrame or Series with a MultiIndex for the index using a list of labels (GH31648)
- Fixed regression in read_csv() used in file like object RawIOBase is not recognize encoding option (GH31575)
Deprecations

• Support for negative integer for `pd.options.display.max_colwidth` is deprecated in favor of using `None` (GH31532)

Bug fixes

Datetimelike

• Fixed bug in `to_datetime()` raising when `cache=True` and out-of-bound values are present (GH31491)

Numeric

• Bug in dtypes being lost in `DataFrame.__invert__` (~ operator) with mixed dtypes (GH31183) and for extension-array backed `Series` and `DataFrame` (GH23087)

Plotting

• Plotting tz-aware timeseries no longer gives `UserWarning` (GH31205)

Interval

• Bug in `Series.shift()` with `interval` dtype raising a `TypeError` when shifting an interval array of integers or datetimes (GH34195)

5.3.6 What’s new in 1.0.0 (January 29, 2020)

These are the changes in pandas 1.0.0. See Release notes for a full changelog including other versions of pandas.

Note: The pandas 1.0 release removed a lot of functionality that was deprecated in previous releases (see below for an overview). It is recommended to first upgrade to pandas 0.25 and to ensure your code is working without warnings, before upgrading to pandas 1.0.

New deprecation policy

Starting with pandas 1.0.0, pandas will adopt a variant of SemVer to version releases. Briefly,
- Deprecations will be introduced in minor releases (e.g. 1.1.0, 1.2.0, 2.1.0, …)
- Deprecations will be enforced in major releases (e.g. 1.0.0, 2.0.0, 3.0.0, …)
- API-breaking changes will be made only in major releases (except for experimental features)

See Version policy for more.

Enhancements

Using Numba in `rolling.apply` and `expanding.apply`

We’ve added an engine keyword to `apply()` and `apply()` that allows the user to execute the routine using Numba instead of Cython. Using the Numba engine can yield significant performance gains if the apply function can operate on numpy arrays and the data set is larger (1 million rows or greater). For more details, see rolling apply documentation (GH28987, GH30936)

Defining custom windows for rolling operations

We’ve added a `pandas.api.indexers.BaseIndexer()` class that allows users to define how window bounds are created during rolling operations. Users can define their own `get_window_bounds` method on a pandas.api.indexers.BaseIndexer() subclass that will generate the start and end indices used for each window during the rolling aggregation. For more details and example usage, see the custom window rolling documentation

Converting to markdown

We’ve added `to_markdown()` for creating a markdown table (GH11052)

```
In [1]: df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 2, 3]}, index=['a', 'a', 'b'])

In [2]: print(df.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>a</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>b</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
```
Experimental new features

Experimental NA scalar to denote missing values

A new `pd.NA` value (singleton) is introduced to represent scalar missing values. Up to now, pandas used several values to represent missing data: `np.nan` is used for this for float data, `np.nan` or `None` for object-dtype data and `pd.NaT` for datetime-like data. The goal of `pd.NA` is to provide a “missing” indicator that can be used consistently across data types. `pd.NA` is currently used by the nullable integer and boolean data types and the new string data type (GH28095).

**Warning:** Experimental: the behaviour of `pd.NA` can still change without warning.

For example, creating a Series using the nullable integer dtype:

```
In [3]: s = pd.Series([1, 2, None], dtype="Int64")

In [4]: s
Out[4]:
0  1
1  2
2  <NA>
Length: 3, dtype: Int64

In [5]: s[2]
Out[5]: <NA>
```

Compared to `np.nan`, `pd.NA` behaves differently in certain operations. In addition to arithmetic operations, `pd.NA` also propagates as “missing” or “unknown” in comparison operations:

```
In [6]: np.nan > 1
Out[6]: False

In [7]: pd.NA > 1
Out[7]: <NA>
```

For logical operations, `pd.NA` follows the rules of the three-valued logic (or Kleene logic). For example:

```
In [8]: pd.NA | True
Out[8]: True
```

For more, see **NA section** in the user guide on missing data.

Dedicated string data type

We’ve added `StringDtype`, an extension type dedicated to string data. Previously, strings were typically stored in object-dtype NumPy arrays. (GH29975)

**Warning:** `StringDtype` is currently considered experimental. The implementation and parts of the API may change without warning.

The 'string' extension type solves several issues with object-dtype NumPy arrays:
1. You can accidentally store a *mixture* of strings and non-strings in an `object` dtype array. A `StringArray` can only store strings.

2. `object` dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn’t a clear way to select *just* text while excluding non-text, but still object-dtype columns.

3. When reading code, the contents of an `object` dtype array is less clear than `string`.

```python
In [9]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype())
Out[9]:
0     abc
1    <NA>
2      def
Length: 3, dtype: string
```

You can use the alias "string" as well.

```python
In [10]: s = pd.Series(['abc', None, 'def'], dtype="string")
In [11]: s
Out[11]:
0     abc
1    <NA>
2      def
Length: 3, dtype: string
```

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have string dtype.

```python
In [12]: s.str.upper()
Out[12]:
0    ABC
1   <NA>
2     DEF
Length: 3, dtype: string
```

```python
In [13]: s.str.split('b', expand=True).dtypes
Out[13]:
0    string
1    string
Length: 2, dtype: object
```

String accessor methods returning integers will return a value with `Int64Dtype`

```python
In [14]: s.str.count("a")
Out[14]:
0    1
1   <NA>
2    0
Length: 3, dtype: Int64
```

We recommend explicitly using the `string` data type when working with strings. See *Text data types* for more.
Boolean data type with missing values support

We’ve added `BooleanDtype/BooleanArray`, an extension type dedicated to boolean data that can hold missing values. The default bool data type based on a bool-dtype NumPy array, the column can only hold `True` or `False`, and not missing values. This new `BooleanArray` can store missing values as well by keeping track of this in a separate mask. (GH29555, GH30095, GH31131)

```python
In [15]: pd.Series([True, False, None], dtype=pd.BooleanDtype())
Out[15]:
0   True
1   False
2     <NA>
Length: 3, dtype: boolean
```

You can use the alias "boolean" as well.

```python
In [16]: s = pd.Series([True, False, None], dtype="boolean")
In [17]: s
Out[17]:
0   True
1   False
2     <NA>
Length: 3, dtype: boolean
```

Method `convert_dtypes` to ease use of supported extension dtypes

In order to encourage use of the extension dtypes `StringDtype`, `BooleanDtype`, `Int64Dtype`, `Int32Dtype`, etc., that support `pd.NA`, the methods `DataFrame.convert_dtypes()` and `Series.convert_dtypes()` have been introduced. (GH29752) (GH30929)

Example:

```python
In [18]: df = pd.DataFrame({
    'x': ['abc', None, 'def'],
    ....:     'y': [1, 2, np.nan],
    ....:     'z': [True, False, True])

In [19]: df
Out[19]:
   x      y     z
0  abc    1.0  True
1  None   2.0  False
2  def   NaN   True

[3 rows x 3 columns]
```

```python
In [20]: df.dtypes
Out[20]:
x    object
y  float64
z     bool
Length: 3, dtype: object
```
In [21]: converted = df.convert_dtypes()

In [22]: converted
Out[22]:
   x      y   z
0  abc    1  True
1  <NA>    2  False
2  def  <NA>  True

[3 rows x 3 columns]

In [23]: converted.dtypes
Out[23]:
   x    string
   y    Int64
   z   boolean
Length: 3, dtype: object

This is especially useful after reading in data using readers such as `read_csv()` and `read_excel()`. See here for a description.

Other enhancements

- `DataFrame.to_string()` added the `max_colwidth` parameter to control when wide columns are truncated (GH9784)
- Added the `na_value` argument to `Series.to_numpy()`, `Index.to_numpy()` and `DataFrame.to_numpy()` to control the value used for missing data (GH30322)
- `MultiIndex.from_product()` infers level names from inputs if not explicitly provided (GH27292)
- `DataFrame.to_latex()` now accepts `caption` and `label` arguments (GH25436)
- DataFrames with `nullable integer`, the `new string dtype` and period data type can now be converted to `pyarrow` (>=0.15.0), which means that it is supported in writing to the Parquet file format when using the `pyarrow` engine (GH28368). Full roundtrip to parquet (writing and reading back in with `to_parquet()` / `read_parquet()`) is supported starting with pyarrow >= 0.16 (GH20612).
- `to_parquet()` now appropriately handles the `schema` argument for user defined schemas in the `pyarrow` engine. (GH30270)
- `DataFrame.to_json()` now accepts an `indent` integer argument to enable pretty printing of JSON output (GH12004)
- `read_stata()` can read Stata 119 dta files. (GH28250)
- Implemented pandas.core.window.Window.var() and pandas.core.window.Window.std() functions (GH26597)
- Added encoding argument to `DataFrame.to_string()` for non-ascii text (GH28766)
- Added encoding argument to `DataFrame.to_html()` for non-ascii text (GH28663)
- Styler.background_gradient() now accepts vmin and vmax arguments (GH12145)
- Styler.format() added the `na_rep` parameter to help format the missing values (GH21527, GH28358)
- `read_excel()` now can read binary Excel (.xlsb) files by passing `engine='pyxlsb'`. For more details and example usage, see the Binary Excel files documentation. Closes GH8540.
- The `partition_cols` argument in `DataFrame.to_parquet()` now accepts a string (GH27117)
• `pandas.read_json()` now parses NaN, Infinity and -Infinity (GH12213)

• DataFrame constructor preserve ExtensionArray dtype with ExtensionArray (GH11363)

• DataFrame.sort_values() and Series.sort_values() have gained ignore_index keyword to be able to reset index after sorting (GH30114)

• DataFrame.sort_index() and Series.sort_index() have gained ignore_index keyword to reset index (GH30114)

• DataFrame.drop_duplicates() has gained ignore_index keyword to reset index (GH30114)

• Added new writer for exporting Stata dta files in versions 118 and 119, StataWriterUTF8. These files formats support exporting strings containing Unicode characters. Format 119 supports data sets with more than 32,767 variables (GH23573, GH30959)

• Series.map() now accepts collections.abc.Mapping subclasses as a mapper (GH29733)

• Added an experimental attrs for storing global metadata about a dataset (GH29062)

• Timestamp.fromisocalendar() is now compatible with python 3.8 and above (GH28115)

• DataFrame.to_pickle() and read_pickle() now accept URL (GH30163)

Backwards incompatible API changes

Avoid using names from MultiIndex.levels

As part of a larger refactor to MultiIndex the level names are now stored separately from the levels (GH27242). We recommend using MultiIndex.names to access the names, and Index.set_names() to update the names.

For backwards compatibility, you can still access the names via the levels.

```python
In [24]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])
In [25]: mi.levels[0].name
Out[25]: 'x'
```

However, it is no longer possible to update the names of the MultiIndex via the level.

```python
In [26]: mi.levels[0].name = "new name"
```

```
RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names' instead.
```

```python
In [27]: mi.names
Out[27]: FrozenList(['x', 'y'])
```
To update, use `MultiIndex.set_names`, which returns a new `MultiIndex`.

```python
In [28]: mi2 = mi.set_names("new name", level=0)
In [29]: mi2.names
Out[29]: FrozenList(['new name', 'y'])
```

### New repr for `IntervalArray`

`pandas.arrays.IntervalArray` adopts a new `__repr__` in accordance with other array classes (GH25022).

**pandas 0.25.x**

```python
In [1]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[2]:
IntervalArray([(0, 1), (2, 3)],
              closed='right',
              dtype='interval[int64]')
```

**pandas 1.0.0**

```python
In [30]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[30]:
<IntervalArray>
[(0, 1), (2, 3)]
Length: 2, closed: right, dtype: interval[int64]
```

### DataFrame.rename now only accepts one positional argument

`DataFrame.rename()` would previously accept positional arguments that would lead to ambiguous or undefined behavior. From pandas 1.0, only the very first argument, which maps labels to their new names along the default axis, is allowed to be passed by position (GH29136).

**pandas 0.25.x**

```python
>>> df = pd.DataFrame([[1]])
>>> df.rename({0: 1}, {0: 2})
FutureWarning: ...Use named arguments to resolve ambiguity...
  2
  1 1
```

**pandas 1.0.0**

```python
>>> df.rename({0: 1}, {0: 2})
Traceback (most recent call last):
...
TypeError: rename() takes from 1 to 2 positional arguments but 3 were given
```

Note that errors will now be raised when conflicting or potentially ambiguous arguments are provided.

**pandas 0.25.x**

```python
>>> df.rename({0: 1}, index={0: 2})
  0
  1 1
```

(continues on next page)
pandas 1.0.0

You can still change the axis along which the first positional argument is applied by supplying the `axis` keyword argument.

```python
In [31]: df.rename({0: 1})
Out[31]:
   0  1
0  1  1
[1 rows x 1 columns]
In [32]: df.rename({0: 1}, axis=1)
Out[32]:
    1
0  1  1
[1 rows x 1 columns]
```

If you would like to update both the index and column labels, be sure to use the respective keywords.

```python
In [33]: df.rename(index={0: 1}, columns={0: 2})
Out[33]:
    2
  1  1
[1 rows x 1 columns]
```

**Extended verbose info output for DataFrame**

`DataFrame.info()` now shows line numbers for the columns summary (GH17304)

```python
pandas 0.25.x

>>> df = pd.DataFrame({"int_col": [1, 2, 3],
...                      "text_col": ["a", "b", "c"],
...                      "float_col": [0.0, 0.1, 0.2]})
>>> df.info(verbos...
### pandas 1.0.0

#### pandas.array() inference changes

`pandas.array()` now infers pandas’ new extension types in several cases (GH29791):

1. String data (including missing values) now returns a `arrays.StringArray`.
2. Integer data (including missing values) now returns a `arrays.IntegerArray`.
3. Boolean data (including missing values) now returns the new `arrays.BooleanArray`.

```python
In [36]: pd.array(['a', None])
<StringArray>
['a', <NA>]  
Length: 2, dtype: string
```

#### pandas 0.25.x

```python
>>> pd.array(['a', None])
<PandasArray>
['a', None]  
Length: 2, dtype: object
```

#### pandas 1.0.0

```python
In [36]: pd.array(['a', None])
Out[36]:
<StringArray>
['a', <NA>]  
Length: 2, dtype: string
```

(continues on next page)
As a reminder, you can specify the `dtype` to disable all inference.

**arrays.IntegerArray now uses pandas.NA**

`arrays.IntegerArray` now uses `pandas.NA` rather than `numpy.nan` as its missing value marker (GH29964).

**pandas 0.25.x**

```python
>>> a = pd.array([1, 2, None], dtype="Int64")
>>> a
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

**pandas 1.0.0**

```python
In [38]: a = pd.array([1, 2, None], dtype="Int64")

In [39]: a
Out[39]: <IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

In [40]: a[2]
Out[40]: <NA>
```

This has a few API-breaking consequences.

**Converting to a NumPy ndarray**

When converting to a NumPy array missing values will be `pd.NA`, which cannot be converted to a float. So calling `np.asarray(integer_array, dtype="float")` will now raise.

**pandas 0.25.x**

```python
>>> np.asarray(a, dtype="float")
array([ 1., 2., nan])
```

**pandas 1.0.0**

```
ValueError Traceback (most recent call last)
<ipython-input-41-4578f04da2b3> in <module>
----> 1 np.asarray(a, dtype="float")

ValueError: can't convert float NaN to integer
```
Use arrays.IntegerArray.to_numpy() with an explicit na_value instead.

```
In [42]: a.to_numpy(dtype="float", na_value=np.nan)
Out[42]: array([ 1., 2., nan])
```

**Reductions can return `pd.NA`**

When performing a reduction such as a sum with `skipna=False`, the result will now be `pd.NA` instead of `np.nan` in presence of missing values (GH30958).

**pandas 0.25.x**

```
>>> pd.Series(a).sum(skipna=False)
nan
```

**pandas 1.0.0**

```
In [43]: pd.Series(a).sum(skipna=False)
Out[43]: <NA>
```

**value_counts returns a nullable integer dtype**

`Series.value_counts()` with a nullable integer dtype now returns a nullable integer dtype for the values.

**pandas 0.25.x**

```
>>> pd.Series([2, 1, None], dtype="Int64").value_counts().dtype
dtype('int64')
```

**pandas 1.0.0**

```
In [44]: pd.Series([2, 1, None], dtype="Int64").value_counts().dtype
Out[44]: Int64Dtype()
```
See *Experimental NA scalar to denote missing values* for more on the differences between `pandas.NA` and `numpy.nan`.

**`arrays.IntegerArray` comparisons return `arrays.BooleanArray`**

Comparison operations on a `arrays.IntegerArray` now return a `arrays.BooleanArray` rather than a NumPy array (GH29964).

```python
>>> a = pd.array([1, 2, None], dtype="Int64"
>>> a  
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

>>> a > 1
array([False, True, False])
```

```python
pandas 1.0.0

In [45]: a = pd.array([1, 2, None], dtype="Int64"

In [46]: a > 1
Out[46]:
<BooleanArray>
[False, True, <NA>]
Length: 3, dtype: boolean
```

Note that missing values now propagate, rather than always comparing unequal like `numpy.nan`. See *Experimental NA scalar to denote missing values* for more.

**By default `Categorical.min()` now returns the minimum instead of `np.nan`**

When `Categorical` contains `np.nan`, `Categorical.min()` no longer return `np.nan` by default (skipna=True) (GH25303)

```python
pandas 0.25.x

In [1]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[1]: nan

pandas 1.0.0

In [47]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[47]: 1
```
Default dtype of empty pandas.Series

Initialising an empty pandas.Series without specifying a dtype will raise a DeprecationWarning now (GH17261). The default dtype will change from float64 to object in future releases so that it is consistent with the behaviour of DataFrame and Index.

```
pandas 1.0.0

In [1]: pd.Series()
Out[2]:
DeprecationWarning: The default dtype for empty Series will be 'object' instead of 'float64' in a future version. Specify a dtype explicitly to silence this warning.
Series([], dtype: float64)
```

Result dtype inference changes for resample operations

The rules for the result dtype in DataFrame.resample() aggregations have changed for extension types (GH31359). Previously, pandas would attempt to convert the result back to the original dtype, falling back to the usual inference rules if that was not possible. Now, pandas will only return a result of the original dtype if the scalar values in the result are instances of the extension dtype’s scalar type.

```
pandas 0.25.x

>>> df.resample("2D").agg(lambda x: 'a').A.dtype
CategoricalDtype(categories=['a', 'b'], ordered=False)

pandas 1.0.0

In [50]: df.resample("2D").agg(lambda x: 'a').A.dtype
Out[50]: dtype('O')
```

This fixes an inconsistency between resample and groupby. This also fixes a potential bug, where the values of the result might change depending on how the results are cast back to the original dtype.

```
pandas 0.25.x

>>> df.resample("2D").agg(lambda x: 'c')
     A
2000-01-01  NaN
2000-01-02  NaN
```

```
pandas 1.0.0

2000-01-01  NaN
2000-01-02  NaN
```
In [51]: df.resample("2D").agg(lambda x: 'c')
Out[51]:
   A
2000-01-01  c
[1 rows x 1 columns]

**Increased minimum version for Python**

pandas 1.0.0 supports Python 3.6.1 and higher (GH29212).

**Increased minimum versions for dependencies**

Some minimum supported versions of dependencies were updated (GH29766, GH29723). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.13.3</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>pytz</td>
<td>2015.4</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.6.1</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.6.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>4.0.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>beautifulsoup4</td>
<td>4.6.0</td>
<td></td>
</tr>
<tr>
<td>fastparquet</td>
<td>0.3.2</td>
<td>X</td>
</tr>
<tr>
<td>gcsfs</td>
<td>0.2.2</td>
<td></td>
</tr>
<tr>
<td>lxml</td>
<td>3.8.0</td>
<td></td>
</tr>
<tr>
<td>matplotlib</td>
<td>2.2.2</td>
<td></td>
</tr>
<tr>
<td>numba</td>
<td>0.46.0</td>
<td>X</td>
</tr>
<tr>
<td>openpyxl</td>
<td>2.5.7</td>

</tr>
<tr>
<td>xlwt</td>
<td>1.2.0</td>
<td></td>
</tr>
</tbody>
</table>

See [Dependencies](#) and [Optional dependencies](#) for more.
pandas: powerful Python data analysis toolkit, Release 1.2.2

Build changes

pandas has added a `pyproject.toml` file and will no longer include cythonized files in the source distribution uploaded to PyPI (GH28341, GH20775). If you’re installing a built distribution (wheel) or via conda, this shouldn’t have any effect on you. If you’re building pandas from source, you should no longer need to install Cython into your build environment before calling `pip install pandas`.

Other API changes

- `core.groupby.GroupBy.transform` now raises on invalid operation names (GH27489)
- `pandas.api.types.infer_dtype()` will now return “integer-na” for integer and `np.nan` mix (GH27283)
- `MultiIndex.from_arrays()` will no longer infer names from arrays if `names=None` is explicitly provided (GH27292)
- In order to improve tab-completion, pandas does not include most deprecated attributes when introspecting a pandas object using `dir` (e.g. `dir(df)`). To see which attributes are excluded, see an object’s `_deprecations` attribute, for example `pd.DataFrame._deprecations` (GH28805).
- The returned dtype of `unique()` now matches the input dtype. (GH27874)
- Changed the default configuration value for `options.matplotlib.register_converters` from `True` to "auto" (GH18720). Now, pandas custom formatters will only be applied to plots created by pandas, through `plot()`. Previously, pandas’ formatters would be applied to all plots created after a `plot()`. See units registration for more.
- `Series.dropna()` has dropped its `**kwargs` argument in favor of a single `how` parameter. Supplying anything else than `how` to `**kwargs` raised a `TypeError` previously (GH29388)
- When testing pandas, the new minimum required version of pytest is 5.0.1 (GH29664)
- `Series.str.__iter__()` was deprecated and will be removed in future releases (GH28277).
- Added `<NA>` to the list of default NA values for `read_csv()` (GH30821)

Documentation improvements

- Added new section on Scaling to large datasets (GH28315).
- Added sub-section on Query MultiIndex for HDF5 datasets (GH28791).

Deprecations

- `Series.item()` and `Index.item()` have been _undeprecated_ (GH29250)
- `Index.set_value` has been deprecated. For a given index `idx`, array `arr`, value in `idx` of `idx_val` and a new value of `val`, `idx.set_value(arr, idx_val, val)` is equivalent to `arr[idx.get_loc(idx_val)] = val`, which should be used instead (GH28621).
- `is_extension_type()` is deprecated, `is_extension_array_dtype()` should be used instead (GH29457)
- `eval()` keyword argument “truediv” is deprecated and will be removed in a future version (GH29812)
• `DateOffset.isAnchored()` and `DateOffset.onOffset()` are deprecated and will be removed in a future version, use `DateOffset.is_anchored()` and `DateOffset.is_on_offset()` instead (GH30340)

• `pandas.tseries.frequencies.get_offset` is deprecated and will be removed in a future version, use `pandas.tseries.frequencies.to_offset` instead (GH4205)

• `Categorical.take_nd()` and `CategoricalIndex.take_nd()` are deprecated, use `Categorical.take()` and `CategoricalIndex.take()` instead (GH27745)

• The parameter `numeric_only` of `Categorical.min()` and `Categorical.max()` is deprecated and replaced with `skipna` (GH25303)

• The parameter `label` in `lreshape()` has been deprecated and will be removed in a future version (GH29742)

• `pandas.core.index` has been deprecated and will be removed in a future version, the public classes are available in the top-level namespace (GH19711)

• `pandas.json_normalize()` is now exposed in the top-level namespace. Usage of `json_normalize` as `pandas.io.json.json_normalize` is now deprecated and it is recommended to use `json_normalize` as `pandas.json_normalize()` instead (GH27586).

• The numpy argument of `pandas.read_json()` is deprecated (GH28512).

• `DataFrame.to_stata()`, `DataFrame.to_feather()`, and `DataFrame.to_parquet()` argument “fname” is deprecated, use “path” instead (GH23574)

• The deprecated internal attributes `_start`, `_stop` and `_step` of `RangeIndex` now raise a `FutureWarning` instead of a `DeprecationWarning` (GH26581)

• The `pandas.util.testing` module has been deprecated. Use the public API in `pandas.testing` documented at `Testing functions` (GH16232).

• `pandas.SparseArray` has been deprecated. Use `pandas.arrays.SparseArray` instead. (GH30642)

• The parameter `is_copy` of `Series.take()` and `DataFrame.take()` has been deprecated and will be removed in a future version. (GH27357)

• Support for multi-dimensional indexing (e.g. `index[:, None]`) on a `Index` is deprecated and will be removed in a future version, convert to a numpy array before indexing instead (GH30588)

• The `pandas.np` submodule is now deprecated. Import numpy directly instead (GH30296)

• The `pandas.datetime` class is now deprecated. Import from `datetime` instead (GH30610)

• `diff` will raise a `TypeError` rather than implicitly losing the dtype of extension types in the future. Convert to the correct dtype before calling `diff` instead (GH31025)

Selecting Columns from a Grouped DataFrame

When selecting columns from a `DataFrameGroupBy` object, passing individual keys (or a tuple of keys) inside single brackets is deprecated, a list of items should be used instead. (GH23566) For example:

```python
df = pd.DataFrame(
    {
        "A": ["foo", "bar", "foo", "bar", "foo", "foo"],
        "B": np.random.randn(8),
        "C": np.random.randn(8),
    })
g = df.groupby('A')

# single key, returns SeriesGroupBy
```

(continues on next page)
Removal of prior version deprecations/changes

Removed SparseSeries and SparseDataFrame

SparseSeries, SparseDataFrame and the DataFrame.to_sparse method have been removed (GH28425). We recommend using a Series or DataFrame with sparse values instead. See Migrating for help with migrating existing code.

Matplotlib unit registration

Previously, pandas would register converters with matplotlib as a side effect of importing pandas (GH18720). This changed the output of plots made via matplotlib plots after pandas was imported, even if you were using matplotlib directly rather than plot().

To use pandas formatters with a matplotlib plot, specify

```python
import pandas as pd
pd.options.plotting.matplotlib.register_converters = True
```

Note that plots created by DataFrame.plot() and Series.plot() do register the converters automatically. The only behavior change is when plotting a date-like object via matplotlib.pyplot.plot or matplotlib.Axes.plot. See Custom formatters for timeseries plots for more.

Other removals

- Removed the previously deprecated keyword “index” from read_stata(), StataReader, and StataReader.read(), use “index_col” instead (GH17328)
- Removed StataReader.data method, use StataReader.read() instead (GH9493)
- Removed pandas.plotting._matplotlib.tsplot, use Series.plot() instead (GH19980)
- pandas.tseries.converter.register has been moved to pandas.plotting.register_matplotlib_converters() (GH18307)
- Series.plot() no longer accepts positional arguments, pass keyword arguments instead (GH30003)
- DataFrame.hist() and Series.hist() no longer allows figsize="default", specify figure size by passing a tuple instead (GH30003)
- Floordiv of integer-dtyped array by Timedelta now raises TypeError (GH21036)
- TimedeltaIndex and DatetimeIndex no longer accept non-nanosecond dtype strings like “timedelta64” or “datetime64”, use “timedelta64[ns]” and “datetime64[ns]” instead (GH24806)
• Changed the default “skipna” argument in pandas.api.types.infer_dtype() from False to True (GH24050)
• Removed Series.ix and DataFrame.ix (GH26438)
• Removed Index.summary (GH18217)
• Removed the previously deprecated keyword “fastpath” from the Index constructor (GH23110)
• Removed Series.get_value, Series.set_value, DataFrame.get_value, DataFrame.set_value (GH17739)
• Removed Series.compound and DataFrame.compound (GH26405)
• Changed the default “inplace” argument in DataFrame.set_index() and Series.set_axis() from None to False (GH27600)
• Removed Series.cat.categorical, Series.cat.index, Series.cat.name (GH24751)
• Removed the previously deprecated keyword “box” from to_datetime() and to_timedelta(); in addition these now always return DatetimeIndex, TimedeltaIndex, Index, Series, or DataFrame (GH24486)
• to_timedelta(), Timedelta, and TimedeltaIndex no longer allow “M”, “y”, or “Y” for the “unit” argument (GH23264)
• Removed the previously deprecated keyword “time_rule” from (non-public) offsets.generate_range, which has been moved to core.arrays._ranges.generate_range() (GH24157)
• DataFrame.loc() or Series.loc() with listlike indexers and missing labels will no longer reindex (GH17295)
• DataFrame.to_excel() and Series.to_excel() with non-existent columns will no longer reindex (GH17295)
• Removed the previously deprecated keyword “join_axes” from concat(); use reindex_like on the result instead (GH22318)
• Removed the previously deprecated keyword “by” from DataFrame.sort_index(), use DataFrame.sort_values() instead (GH10726)
• Removed support for nested renaming in DataFrame.aggregate(), Series.aggregate(), core.groupby.DataFrameGroupBy.aggregate(), core.groupby.SeriesGroupBy.aggregate(), core.window.rolling.Rolling.aggregate() (GH18529)
• Passing datetime64 data to TimedeltaIndex or timedelta64 data to DatetimeIndex now raises TypeError (GH23539, GH23937)
• Passing int64 values to DatetimeIndex and a timezone now interprets the values as nanosecond timesteps in UTC, not wall times in the given timezone (GH24559)
• A tuple passed to DataFrame.groupby() is now exclusively treated as a single key (GH18314)
• Removed Index.contains, use key in index instead (GH30103)
• Addition and subtraction of int or integer-arrays is no longer allowed in Timestamp, DatetimeIndex, TimedeltaIndex, use obj + n * obj.freq instead of obj + n (GH22535)
• Removed Series.ptp (GH21614)
• Removed Series.from_array (GH18258)
• Removed DataFrame.from_items (GH18458)
• Removed DataFrame.as_matrix, Series.as_matrix (GH18458)
pandas: powerful Python data analysis toolkit, Release 1.2.2

- Removed `Series.asobject` (GH18477)
- Removed `DataFrame.as_blocks`, `Series.as_blocks`, `DataFrame.blocks`, `Series.blocks` (GH17656)
- `pandas.Series.str.cat()` now defaults to aligning others, using `join='left'` (GH27611)
- `pandas.Series.str.cat()` does not accept list-likes within list-likes anymore (GH27611)
- `Series.where()` with Categorical dtype (or `DataFrame.where()` with Categorical column) no longer allows setting new categories (GH24114)
- Removed the previously deprecated keywords “start”, “end”, and “periods” from the `DatetimeIndex`, `TimedeltaIndex`, and `PeriodIndex` constructors; use `date_range()`, `timedelta_range()`, and `period_range()` instead (GH23919)
- Removed the previously deprecated keyword “verify_integrity” from the `DatetimeIndex` and `TimedeltaIndex` constructors (GH23919)
- Removed the previously deprecated keyword “fastpath” from `pandas.core.internals.blocks.make_block` (GH19265)
- Removed the previously deprecated keyword “dtype” from `Block.make_block_same_class()` (GH19434)
- Removed `ExtensionArray._formatting_values`. Use `ExtensionArray._formatter` instead. (GH23601)
- Removed `MultiIndex.to_hierarchical` (GH21613)
- Removed `MultiIndex.labels`, use `MultiIndex.codes` instead (GH23752)
- Removed the previously deprecated keyword “labels” from the `MultiIndex` constructor, use “codes” instead (GH23752)
- Removed `MultiIndex.set_labels`, use `MultiIndex.set_codes()` instead (GH23752)
- Removed the previously deprecated keyword “labels” from `MultiIndex.set_codes()`, `MultiIndex.copy()`, `MultiIndex.drop()`; use “codes” instead (GH23752)
- Removed support for legacy HDF5 formats (GH29787)
- Passing a dtype alias (e.g. ‘datetime64[ns, UTC]’) to `DatetimeTZDtype` is no longer allowed, use `DatetimeTZDtype.construct_from_string()` instead (GH23990)
- Removed the previously deprecated keyword “skip_footer” from `read_excel()`; use “skipfooter” instead (GH18836)
- `read_excel()` no longer allows an integer value for the parameter `usecols`, instead pass a list of integers from 0 to `usecols` inclusive (GH23635)
- Removed the previously deprecated keyword “convert_datetime64” from `DataFrame.to_records()` (GH18902)
- Removed `IntervalIndex.from_intervals` in favor of the `IntervalIndex` constructor (GH19263)
- Changed the default “keep_tz” argument in `DatetimeIndex.to_series()` from None to True (GH23739)
- Removed `api.types.is_period` and `api.types.is_datetimetz` (GH23917)
- Ability to read pickles containing `Categorical` instances created with pre-0.16 version of pandas has been removed (GH27538)
- Removed `pandas.tseries.plotting.tsplot` (GH18627)
• Removed the previously deprecated keywords “reduce” and “broadcast” from DataFrame.apply() (GH18577)
• Removed the previously deprecated assert_raises_regex function in pandas._testing (GH29174)
• Removed the previously deprecated FrozenNDArray class in pandas.core.indexes.frozen (GH29335)
• Removed the previously deprecated keyword “nthreads” from read_feather(), use “use_threads” instead (GH23053)
• Removed Index.is_lexsorted_for_tuple (GH29305)
• Removed support for nested renaming in DataFrame.aggregate(), Series.aggregate(), core.groupby.DataFrameGroupBy.aggregate(), core.groupby.SeriesGroupBy.aggregate(), core.window.rolling.Rolling.aggregate() (GH29608)
• Removed Series.valid; use Series.dropna() instead (GH18800)
• Removed DataFrame.is_copy, Series.is_copy (GH18812)
• Removed DataFrame.get_ftype_counts, Series.get_ftype_counts (GH18243)
• Removed DataFrame.ftypes, Series.ftypes, Series.dtype (GH26744)
• Removed Index.get_duplicates, use idx[idx.duplicated()].unique() instead (GH20239)
• Removed Series.clip_upper, Series.clip_lower, DataFrame.clip_upper, DataFrame.clip_lower (GH24203)
• Removed the ability to alter DatetimeIndex.freq, TimedeltaIndex.freq, or PeriodIndex.freq (GH20772)
• Removed DatetimeIndex.offset (GH20730)
• Removed DatetimeIndex.asobject, TimedeltaIndex.asobject, PeriodIndex.asobject, use asarray(object) instead (GH29801)
• Removed the previously deprecated keyword “order” from factorize() (GH19751)
• Removed the previously deprecated keyword “encoding” from read_stata() and DataFrame.to_stata() (GH21400)
• Changed the default “sort” argument in concat() from None to False (GH20613)
• Removed the previously deprecated keyword “raise_conflict” from DataFrame.update(), use “errors” instead (GH23585)
• Removed the previously deprecated keyword “n” from DatetimeIndex.shift(), TimedeltaIndex.shift(), PeriodIndex.shift(), use “periods” instead (GH22458)
• Removed the previously deprecated keywords “how”, “fill_method”, and “limit” from DataFrame.resample() (GH30139)
• Passing an integer to Series.fillna() or DataFrame.fillna() with timedelta64[ns] dtype now raises TypeError (GH24694)
• Passing multiple axes to DataFrame.dropna() is no longer supported (GH20995)
• Removed Series.nonzero, use to_numpy().nonzero() instead (GH24048)
• Passing floating dtype codes to Categorical.from_codes() is no longer supported, pass codes.astype(np.int64) instead (GH21775)
• Removed the previously deprecated keyword “pat” from Series.str.partition() and Series.str.rpartition(), use “sep” instead (GH23767)
• Removed `Series.put` (GH27106)
• Removed `Series.real, Series.imag` (GH27106)
• Removed `Series.to_dense, DataFrame.to_dense` (GH26684)
• Removed `Index.dtype_str, use str(index.dtype)` instead (GH27106)
  Categorical.ravel() returns a Categorical instead of an array (GH27199)
• The ‘outer’ method on Numpy ufuncs, e.g. np.subtract.outer operating on Series objects is no longer supported, and will raise NotImplementedError (GH27198)
• Removed `Series.get_dtype_counts` and `DataFrame.get_dtype_counts` (GH27145)
• Changed the default “fill_value” argument in Categorical.take() from True to False (GH20841)
• Changed the default value for the raw argument in Series.rolling().apply(), DataFrame.rolling().apply(), Series.expanding().apply(), and DataFrame.expanding().apply() from None to False (GH20584)
• Changed the default “ordered” argument in CategoricalDtype from None to False (GH26336)
• Series.set_axis() and DataFrame.set_axis() now require “labels” as the first argument and “axis” as an optional named parameter (GH30089)
• Removed Series.base, Index.base, Categorical.base, Series.flags, Index.flags, PeriodArray.flags, Series.strides, Index.strides, Series.itemsize, Index.itemsize, Series.data, Index.data (GH20721)
• Changed Timedelta.resolution() to match the behavior of the standard library datetime.timedelta.resolution, for the old behavior, use Timedelta.resolution_string() (GH26839)
• Removed Timestamp.weekday_name, DatetimeIndex.weekday_name, and Series.dt.weekday_name (GH18164)
• Changed the default “ordered” argument in CategoricalDtype from None to False (GH26336)
• Removed Series.get_dtype_counts and DataFrame.get_dtype_counts (GH27145)
• Changed the default “fill_value” argument in Categorical.take() from True to False (GH20841)
• Changed the default value for the raw argument in Series.rolling().apply(), DataFrame.rolling().apply(), Series.expanding().apply(), and DataFrame.expanding().apply() from None to False (GH20584)
• Removed deprecated behavior of `Series.argmin()` and `Series.argmax()`, use `Series.idxmin()` and `Series.idxmax()` for the old behavior (GH16955)
• Passing a tz-aware datetime.datetime or Timestamp into the Timestamp constructor with the tz argument now raises a ValueError (GH23621)
• Removed Series.base, Index.base, Categorical.base, Series.flags, Index.flags, PeriodArray.flags, Series.strides, Index.strides, Series.itemsize, Index.itemsize, Series.data, Index.data (GH20721)
• Changed Timedelta.resolution() to match the behavior of the standard library datetime.timedelta.resolution, for the old behavior, use Timedelta.resolution_string() (GH26839)
• Removed Timestamp.weekday_name, DatetimeIndex.weekday_name, and Series.dt.weekday_name (GH18164)
• Removed the previously deprecated keyword “errors” in Timestamp.tz_localize(), DatetimeIndex.tz_localize(), and Series.tz_localize() (GH22644)
• Removed the previously deprecated keyword “fill_value” from Categorical.fillna(), use “value” instead (GH19269)
• Removed the previously deprecated keyword “data” from andrews_curves(), use “frame” instead (GH6956)
• Removed the previously deprecated keyword “data” from parallel_coordinates(), use “frame” instead (GH6956)
• Removed the previously deprecated keyword “colors” from parallel_coordinates(), use “color” instead (GH6956)
• Removed the previously deprecated keywords “verbose” and “private_key” from read_gbq() (GH30200)
• Calling np.array and np.asarray on tz-aware Series and DatetimeIndex will now return an object array of tz-aware Timestamp (GH24596)
Performance improvements

- Performance improvement in DataFrame arithmetic and comparison operations with scalars (GH24990, GH29853)
- Performance improvement in indexing with a non-unique IntervalIndex (GH27489)
- Performance improvement in MultiIndex.is_monotonic (GH27495)
- Performance improvement in cut() when bins is an IntervalIndex (GH27668)
- Performance improvement when initializing a DataFrame using a range (GH30171)
- Performance improvement in DataFrame.corr() when method is "spearman" (GH28139)
- Performance improvement in DataFrame.replace() when provided a list of values to replace (GH28099)
- Performance improvement in DataFrame.select_dtypes() by using vectorization instead of iterating over a loop (GH28317)
- Performance improvement in Categorical.searchsorted() and CategoricalIndex.searchsorted() (GH28795)
- Performance improvement when comparing a Categorical with a scalar and the scalar is not found in the categories (GH29750)
- Performance improvement when checking if values in a Categorical are equal, equal or larger or larger than a given scalar. The improvement is not present if checking if the Categorical is less than or less than or equal than the scalar (GH29820)
- Performance improvement in Index.equals() and MultiIndex.equals() (GH29134)
- Performance improvement in infer_dtype() when skipna is True (GH28814)

Bug fixes

Categorical

- Added test to assert the fillna() raises the correct ValueError message when the value isn’t a value from categories (GH13628)
- Bug in Categorical.astype() where NaN values were handled incorrectly when casting to int (GH28406)
- DataFrame.reindex() with a CategoricalIndex would fail when the targets contained duplicates, and wouldn’t fail if the source contained duplicates (GH28107)
- Bug in Categorical.astype() not allowing for casting to extension dtypes (GH28668)
- Bug where merge() was unable to join on categorical and extension dtype columns (GH28668)
- Categorical.searchsorted() and CategoricalIndex.searchsorted() now work on unordered categories also (GH21667)
- Added test to assert roundtripping to parquet with DataFrame.to_parquet() or read_parquet() will preserve Categorical dtypes for string types (GH27955)
- Changed the error message in Categorical.remove_categories() to always show the invalid removals as a set (GH28669)
• Using date accessors on a categorical typed `Series` of datetimes was not returning an object of the same type as if one used the `str()` / `dt()` on a `Series` of that type. E.g. when accessing `Series.dt.tz_localize()` on a `Categorical` with duplicate entries, the accessor was skipping duplicates (GH27952)

• Bug in `DataFrame.replace()` and `Series.replace()` that would give incorrect results on categorical data (GH26988)

• Bug where calling `Categorical.min()` or `Categorical.max()` on an empty Categorical would raise a numpy exception (GH30227)

• The following methods now also correctly output values for unobserved categories when called through `groupby(..., observed=False)` (GH17605) * `core.groupby.SeriesGroupBy.count()` * `core.groupby.SeriesGroupBy.size()` * `core.groupby.SeriesGroupBy.nunique()` * `core.groupby.SeriesGroupBy.nth()`

**Datetimelike**

• Bug in `Series.__setitem__()` incorrectly casting `np.timedelta64("NaT")` to `np.datetime64("NaT")` when inserting into a `Series` with datetime64 dtype (GH27311)

• Bug in `Series.dt()` property lookups when the underlying data is read-only (GH27529)

• Bug in `HDFStore._getitem__()` incorrectly reading tz attribute created in Python 2 (GH26443)

• Bug in `to_datetime()` where passing arrays of malformed str with errors="coerce" could incorrectly lead to raising `ValueError` (GH28299)

• Bug in `core.groupby.SeriesGroupBy.nunique()` where NaT values were interfering with the count of unique values (GH27951)

• Bug in `Timestamp` subtraction when subtracting a `Timestamp` from a `np.datetime64` object incorrectly raising `TypeError` (GH28286)

• Addition and subtraction of integer or integer-dtype arrays with `Timestamp` will now raise `NullFrequencyError` instead of `ValueError` (GH28268)

• Bug in `Series` and `DataFrame` with integer dtype failing to raise `TypeError` when adding or subtracting a `np.datetime64` object (GH28080)

• Bug in `Series.astype()`, `Index.astype()`, and `DataFrame.astype()` failing to handle `NaT` when casting to an integer dtype (GH28492)

• Bug in `Week` with `weekday` incorrectly raising `AttributeError` instead of `TypeError` when adding or subtracting an invalid type (GH28530)

• Bug in `DataFrame` arithmetic operations when operating with a `Series` with dtype 'timedelta64[ns]' (GH28049)

• Bug in `core.groupby.generic.SeriesGroupBy.apply()` raising `ValueError` when a column in the original DataFrame is a datetime and the column labels are not standard integers (GH28247)

• Bug in `pandas._config.localization.get_locales()` where the locales -a encodes the locales list as windows-1252 (GH23638, GH24760, GH27368)

• Bug in `Series.var()` failing to raise `TypeError` when called with `timedelta64[ns]` dtype (GH28289)

• Bug in `DatetimeIndex.strftime()` and `Series.dt.strftime()` where `NaT` was converted to the string 'NaT' instead of np.nan (GH29578)
• Bug in masking datetime-like arrays with a boolean mask of an incorrect length not raising an `IndexError` (GH30308)

• Bug in `Timestamp.resolution` being a property instead of a class attribute (GH29910)

• Bug in `pandas.to_datetime()` when called with `None` raising `TypeError` instead of returning `NaT` (GH30011)

• Bug in `pandas.to_datetime()` failing for `deques` when using `cache=True` (the default) (GH29403)

• Bug in `Series.item()` with `datetime64` or `timedelta64` dtype, `DatetimeIndex.item()`, and `TimedeltaIndex.item()` returning an integer instead of a `Timestamp` or `Timedelta` (GH30175)

• Bug in `DatetimeIndex.addition` when adding a non-optimized `DateOffset` incorrectly dropping timezone information (GH30336)

• Bug in `DataFrame.drop()` where attempting to drop non-existent values from a `DatetimelIndex` would yield a confusing error message (GH30399)

• Bug in `DataFrame.append()` would remove the timezone-awareness of new data (GH30238)

• Bug in `Series.cummin()` and `Series.cummax()` with timezone-aware dtype incorrectly dropping its timezone (GH15553)

• Bug in `DatetimelArray`, `TimedeltaArray`, and `PeriodArray` where inplace addition and subtraction did not actually operate inplace (GH24115)

• Bug in `pandas.to_datetime()` when called with `Series` storing `IntegerArray` raising `TypeError` instead of returning `Series` (GH30050)

• Bug in `date_range()` with custom business hours as `freq` and given number of `periods` (GH30593)

• Bug in `PeriodIndex` comparisons with incorrectly casting integers to `Period` objects, inconsistent with the `Period` comparison behavior (GH30722)

• Bug in `DatetimeIndex.insert()` raising a `ValueError` instead of a `TypeError` when trying to insert a timezone-aware `Timestamp` into a timezone-naive `DatetimeIndex`, or vice-versa (GH30806)

**Timedelta**

• Bug in subtracting a `TimedeltaIndex` or `TimedeltaArray` from a `np.datetime64` object (GH29558)

**Timezones**

• Bug in `DataFrame.quantile()` with zero-column `DataFrame` incorrectly raising (GH23925)

• `DataFrame` flex inequality comparisons methods (`DataFrame.lt()`, `DataFrame.le()`, `DataFrame.gt()`, `DataFrame.ge()`) with object-dtype and complex entries failing to raise `TypeError` like their `Series` counterparts (GH28079)

• Bug in `DataFrame` logical operations (`&`, `|`, `^`) not matching `Series` behavior by filling NA values (GH28741)
- Bug in `DataFrame.interpolate()` where specifying axis by name references variable before it is assigned (GH29142)

- Bug in `Series.var()` not computing the right value with a nullable integer dtype series not passing through ddof argument (GH29128)

- Improved error message when using `frac > 1` and `replace = False` (GH27451)

- Bug in numeric indexes resulted in it being possible to instantiate an `Int64Index`, `UInt64Index`, or `Float64Index` with an invalid dtype (e.g. datetime-like) (GH29539)

- Bug in `UInt64Index` precision loss while constructing from a list with values in the `np.uint64` range (GH29526)

- Bug in `NumericIndex` construction that caused indexing to fail when integers in the `np.uint64` range were used (GH28023)

- Bug in `NumericIndex` construction that caused `UInt64Index` to be casted to `Float64Index` when integers in the `np.uint64` range were used to index a `DataFrame` (GH28279)

- Bug in `Series.interpolate()` when using `method=`index` with an unsorted index, would previously return incorrect results. (GH21037)

- Bug in `DataFrame.round()` where a `DataFrame` with a `CategoricalIndex` of `IntervalIndex` columns would incorrectly raise a `TypeError` (GH30063)

- Bug in `Series.pct_change()` and `DataFrame.pct_change()` when there are duplicated indices (GH30463)

- Bug in `DataFrame` cumulative operations (e.g. `cumsum`, `cummax`) incorrect casting to object-dtype (GH19296)

- Bug in `diff` losing the dtype for extension types (GH30889)

- Bug in `DataFrame.diff` raising an `IndexError` when one of the columns was a nullable integer dtype (GH30967)

**Conversion**

- ...

**Strings**

- Calling `Series.str.isalnum()` (and other “ismethods”) on an empty `Series` would return an object dtype instead of `bool` (GH29624)

- ...

**Interval**

- Bug in `IntervalIndex.get_indexer()` where a `Categorical` or `CategoricalIndex` target would incorrectly raise a `TypeError` (GH30063)

- Bug in `pandas.core.dtypes.cast.infer_dtype_from_scalar` where passing `pandas_dtype=True` did not infer `IntervalDtype` (GH30337)

- Bug in `Series` constructor where constructing a `Series` from a list of `Interval` objects resulted in object dtype instead of `IntervalDtype` (GH23563)
• Bug in `IntervalDtype` where the `kind` attribute was incorrectly set as `None` instead of "O" (GH30568)
• Bug in `IntervalIndex`, `IntervalArray`, and `Series` with interval data where equality comparisons were incorrect (GH24112)

**Indexing**

• Bug in assignment using a reverse slicer (GH26939)
• Bug in `DataFrame.explode()` would duplicate frame in the presence of duplicates in the index (GH28010)
• Bug in reindexing a `PeriodIndex()` with another type of index that contained a `Period` (GH28323) (GH28337)
• Fix assignment of column via `.loc` with numpy non-ns datetime type (GH27395)
• Bug in `Float64Index.astype()` where `np.inf` was not handled properly when casting to an integer dtype (GH28475)
• `Index.union()` could fail when the left contained duplicates (GH28257)
• Bug when indexing with `.loc` where the index was a `CategoricalIndex` with non-string categories didn’t work (GH17569, GH30225)
• `Index.get_indexer_non_unique()` could fail with `TypeError` in some cases, such as when searching for ints in a string index (GH28257)
• Bug in `Float64Index.get_loc()` incorrectly raising `TypeError` instead of `KeyError` (GH29189)
• Bug in `DataFrame.loc()` with incorrect dtype when setting Categorical value in 1-row DataFrame (GH25495)
• `MultiIndex.get_loc()` can’t find missing values when input includes missing values (GH19132)
• Bug in `Series.__setitem__()` incorrectly assigning values with boolean indexer when the length of new data matches the number of `True` values and new data is not a `Series` or an `np.array` (GH30567)
• Bug in indexing with a `PeriodIndex` incorrectly accepting integers representing years, use e.g. `ser.loc["2007"]` instead of `ser.loc[2007]` (GH30763)

**Missing**

•

**MultiIndex**

• Constructor for `MultiIndex` verifies that the given `sortorder` is compatible with the actual `lexsort_depth` if `verify_integrity` parameter is True (the default) (GH28735)
• `Series` and `MultiIndex`.drop with `MultiIndex` raise exception if labels not in given in level (GH8594)
IO

- `read_csv()` now accepts binary mode file buffers when using the Python csv engine (GH23779)
- Bug in `DataFrame.to_json()` where using a Tuple as a column or index value and using `orient="columns"` or `orient="index"` would produce invalid JSON (GH20500)
- Improve infinity parsing. `read_csv()` now interprets `Infinity`, `+Infinity`, `-Infinity` as floating point values (GH10065)
- Bug in `DataFrame.to_csv()` where values were truncated when the length of `na_rep` was shorter than the text input data. (GH25099)
- Bug in `DataFrame.to_string()` where values were truncated using display options instead of outputting the full content (GH9784)
- Bug in `DataFrame.to_json()` where a datetime column label would not be written out in ISO format with `orient="table"` (GH28130)
- Bug in `DataFrame.to_parquet()` where writing to GCS would fail with `engine='fastparquet'` if the file did not already exist (GH28326)
- Bug in `read_hdf()` closing stores that it didn’t open when Exceptions are raised (GH28699)
- Bug in `DataFrame.read_json()` where using `orient="index"` would not maintain the order (GH28557)
- Bug in `DataFrame.to_html()` where the length of the `formatters` argument was not verified (GH28469)
- Bug in `DataFrame.read_excel()` with `engine='ods'` when `sheet_name` argument references a non-existent sheet (GH27676)
- Bug in `pandas.io.formats.style.Styler()` formatting for floating values not displaying decimals correctly (GH13257)
- Bug in `DataFrame.to_html()` when using `formatters=<list>` and `max_cols` together. (GH25955)
- Bug in `Styler.background_gradient()` not able to work with `dtype` `Int64` (GH28869)
- Bug in `DataFrame.to_clipboard()` which did not work reliably in ipython (GH22707)
- Bug in `read_json()` where default encoding was not set to `utf-8` (GH29565)
- Bug in `PythonParser` where `str` and `bytes` were being mixed when dealing with the decimal field (GH29650)
- `read_gbq()` now accepts `progress_bar_type` to display progress bar while the data downloads. (GH29857)
- Bug in `pandas.io.json.json_normalize()` where a missing value in the location specified by `record_path` would raise a `TypeError` (GH30148)
- `read_excel()` now accepts binary data (GH15914)
- Bug in `read_csv()` in which encoding handling was limited to just the string `utf-16` for the C engine (GH24130)
Plotting

- Bug in `Series.plot()` not able to plot boolean values (GH23719)
- Bug in `DataFrame.plot()` not able to plot when no rows (GH27758)
- Bug in `DataFrame.plot()` producing incorrect legend markers when plotting multiple series on the same axis (GH18222)
- Bug in `DataFrame.plot()` when `kind='box'` and data contains datetime or timedelta data. These types are now automatically dropped (GH22799)
- Bug in `DataFrame.plot.line()` and `DataFrame.plot.area()` produce wrong xlim in x-axis (GH27686, GH25160, GH24784)
- Bug where `DataFrame.boxplot()` would not accept a color parameter like `DataFrame.plot.box()` (GH26214)
- Bug in the `xticks` argument being ignored for `DataFrame.plot.bar()` (GH14119)
- `set_option()` now validates that the plot backend provided to 'plotting.backend' implements the backend when the option is set, rather than when a plot is created (GH28163)
- `DataFrame.plot()` now allow a `backend` keyword argument to allow changing between backends in one session (GH28619).
- Bug in color validation incorrectly raising for non-color styles (GH29122).
- Allow `DataFrame.plot.scatter()` to plot objects and datetime type data (GH18755, GH30391)
- Bug in `DataFrame.hist()`, `xrot=0` does not work with `by` and subplots (GH30288).

GroupBy/resample/rolling

- Bug in `core.groupby.DataFrameGroupBy.apply()` only showing output from a single group when function returns an `Index` (GH28652)
- Bug in `DataFrame.groupby()` with multiple groups where an `IndexError` would be raised if any group contained all NA values (GH20519)
- Bug in `pandas.core.resample.Resampler.size()` and `pandas.core.resample.Resampler.count()` returning wrong dtype when used with an empty `Series` or `DataFrame` (GH28427)
- Bug in `DataFrame.rolling()` not allowing for rolling over datetimes when `axis=1` (GH28192)
- Bug in `DataFrame.rolling()` not allowing rolling over multi-index levels (GH15584).
- Bug in `DataFrame.rolling()` not allowing rolling on monotonic decreasing time indexes (GH19248).
- Bug in `DataFrame.groupby()` not offering selection by column name when `axis=1` (GH27614)
- Bug in `core.groupby.DataFrameGroupby.agg()` not able to use lambda function with named aggregation (GH27519)
- Bug in `DataFrame.groupby()` losing column name information when grouping by a categorical column (GH28787)
- Remove error raised due to duplicated input functions in named aggregation in `DataFrame.groupby()` and `Series.groupby()`. Previously error will be raised if the same function is applied on the same column and now it is allowed if new assigned names are different. (GH28426)
• core.groupby.SeriesGroupBy.value_counts() will be able to handle the case even when the Grouper makes empty groups (GH28479)
• Bug in core.window.rolling.Rolling.quantile() ignoring interpolation keyword argument when used within a groupby (GH28779)
• Bug in DataFrame.groupby() where any, all, nunique and transform functions would incorrectly handle duplicate column labels (GH21668)
• Bug in core.groupby.DataFrameGroupBy.agg() with timezone-aware datetime64 column incorrectly casting results to the original dtype (GH29641)
• Bug in DataFrame.groupby() when using axis=1 and having a single level columns index (GH30208)
• Bug in DataFrame.groupby() when using nunique on axis=1 (GH30253)
• Bug in GroupBy.quantile() with multiple list-like q value and integer column names (GH30289)
• Bug in GroupBy.pct_change() and core.groupby.SeriesGroupBy.pct_change() causes TypeError when fill_method is None (GH30463)
• Bug in Rolling.count() and Expanding.count() argument where min_periods was ignored (GH26996)

Reshaping

• Bug in DataFrame.apply() that caused incorrect output with empty DataFrame (GH28202, GH21959)
• Bug in DataFrame.stack() not handling non-unique indexes correctly when creating MultiIndex (GH28301)
• Bug in pivot_table() not returning correct type float when margins=True and aggfunc='mean' (GH24893)
• Bug merge_asof() could not use datetime.timedelta for tolerance kwarg (GH28098)
• Bug in merge(), did not append suffixes correctly with MultiIndex (GH28518)
• qcut() and cut() now handle boolean input (GH20303)
• Fix to ensure all int dtypes can be used in merge_asof() when using a tolerance value. Previously every non-int64 type would raise an erroneous MergeError (GH28870).
• Better error message in get_dummies() when columns isn’t a list-like value (GH28383)
• Bug in Index.join() that caused infinite recursion error for mismatched MultiIndex name orders. (GH25760, GH28956)
• Bug Series.pct_change() where supplying an anchored frequency would throw a ValueError (GH28664)
• Bug where DataFrame.equals() returned True incorrectly in some cases when two DataFrames had the same columns in different orders (GH28839)
• Bug in DataFrame.replace() that caused non-numeric replacer’s dtype not respected (GH26632)
• Bug in melt() where supplying mixed strings and numeric values for id_vars or value_vars would incorrectly raise a ValueError (GH29718)
• Dtypes are now preserved when transposing a DataFrame where each column is the same extension dtype (GH30091)
• Bug in merge_asof() merging on a tz-aware left_index and right_on a tz-aware column (GH29864)
pandas: powerful Python data analysis toolkit, Release 1.2.2

- Improved error message and docstring in `cut()` and `qcut()` when `labels=True` (GH13318)
- Bug in missing `fill_na` parameter to `DataFrame.unstack()` with list of levels (GH30740)

**Sparse**

- Bug in `SparseDataFrame` arithmetic operations incorrectly casting inputs to float (GH28107)
- Bug in `DataFrame.sparse` returning a `Series` when there was a column named `sparse` rather than the accessor (GH30758)
- Fixed `operator.xor()` with a boolean-dtype `SparseArray`. Now returns a sparse result, rather than object dtype (GH31025)

**ExtensionArray**

- Bug in `arrays.PandasArray` when setting a scalar string (GH28118, GH28150).
- Bug where nullable integers could not be compared to strings (GH28930)
- Bug where `DataFrame` constructor raised `ValueError` with list-like data and `dtype` specified (GH30280)

**Other**

- Trying to set the `display.precision`, `display.max_rows` or `display.max_columns` using `set_option()` to anything but a None or a positive int will raise a `ValueError` (GH23348)
- Using `DataFrame.replace()` with overlapping keys in a nested dictionary will no longer raise, now matching the behavior of a flat dictionary (GH27660)
- `DataFrame.to_csv()` and `Series.to_csv()` now support dicts as `compression` argument with key 'method' being the compression method and others as additional compression options when the compression method is 'zip'. (GH26023)
- Bug in `Series.diff()` where a boolean series would incorrectly raise a `TypeError` (GH17294)
- `Series.append()` will no longer raise a `TypeError` when passed a tuple of `Series` (GH28410)
- Fix corrupted error message when calling `pandas.libs._json.encode()` on a 0d array (GH18878)
- Backtick quoting in `DataFrame.query()` and `DataFrame.eval()` can now also be used to use invalid identifiers like names that start with a digit, are python keywords, or are using single character operators. (GH27017)
- Bug in `pd.core.util.hashing.hash_pandas_object` where arrays containing tuples were incorrectly treated as non-hashable (GH28969)
- Bug in `DataFrame.append()` that raised `IndexError` when appending with empty list (GH28769)
- Fix `AbstractHolidayCalendar` to return correct results for years after 2030 (now goes up to 2200) (GH27790)
- Fixed `IntegerArray` returning `inf` rather than `NaN` for operations dividing by 0 (GH27398)
- Fixed `pow` operations for `IntegerArray` when the other value is 0 or 1 (GH29997)
- Bug in `Series.count()` raises if `use_inf_as_na` is enabled (GH29478)
- Bug in `Index` where a non-hashable name could be set without raising `TypeError` (GH29069)
pandas: powerful Python data analysis toolkit, Release 1.2.2

• Bug in DataFrame constructor when passing a 2D ndarray and an extension dtype (GH12513)
• Bug in DataFrame.to_csv() when supplied a series with a dtype="string" and a na_rep, the na_rep was being truncated to 2 characters. (GH29975)
• Bug where DataFrame.itertuples() would incorrectly determine whether or not namedtuples could be used for dataframes of 255 columns (GH28282)
• Handle nested NumPy object arrays in testing.assert_series_equal() for ExtensionArray implementations (GH30841)
• Bug in Index constructor incorrectly allowing 2-dimensional input arrays (GH13601, GH27125)

5.4 Version 0.25

5.4.1 What’s new in 0.25.3 (October 31, 2019)

These are the changes in pandas 0.25.3. See Release notes for a full changelog including other versions of pandas.

Bug fixes

GroupBy/resample/rolling

- Bug in DataFrameGroupBy.quantile() where NA values in the grouping could cause segfaults or incorrect results (GH28882)

Contributors

A total of 2 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Will Ayd
- William Ayd

5.4.2 What’s new in 0.25.2 (October 15, 2019)

These are the changes in pandas 0.25.2. See Release notes for a full changelog including other versions of pandas.

Note: pandas 0.25.2 adds compatibility for Python 3.8 (GH28147).

Bug fixes

Indexing

- Fix regression in DataFrame.reindex() not following the limit argument (GH28631).
- Fix regression in RangeIndex.get_indexer() for decreasing RangeIndex where target values may be improperly identified as missing/present (GH28678)

IO

- Fix regression in notebook display where <th> tags were missing for DataFrame.index values (GH28204).
- Regression in to_csv() where writing a Series or DataFrame indexed by an IntervalIndex would incorrectly raise a TypeError (GH28210)
- Fix to_csv() with ExtensionArray with list-like values (GH28840).
GroupBy/resample/rolling

- Bug incorrectly raising an IndexError when passing a list of quantiles to pandas.core.groupby.DataFrameGroupBy.quantile() (GH28113).
- Bug in pandas.core.groupby.GroupBy.shift(), pandas.core.groupby.GroupBy.bfill() and pandas.core.groupby.GroupBy.ffill() where timezone information would be dropped (GH19995, GH27992)

Other

- Compatibility with Python 3.8 in DataFrame.query() (GH27261)
- Fix to ensure that tab-completion in an IPython console does not raise warnings for deprecated attributes (GH27900).

Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.4.3 What’s new in 0.25.1 (August 21, 2019)

These are the changes in pandas 0.25.1. See Release notes for a full changelog including other versions of pandas.

IO and LZMA

Some users may unknowingly have an incomplete Python installation lacking the lzma module from the standard library. In this case, import pandas failed due to an ImportError (GH27575). pandas will now warn, rather than raising an ImportError if the lzma module is not present. Any subsequent attempt to use lzma methods will raise a RuntimeError. A possible fix for the lack of the lzma module is to ensure you have the necessary libraries and then re-install Python. For example, on MacOS installing Python with pyenv may lead to an incomplete Python installation due to unmet system dependencies at compilation time (like xz). Compilation will succeed, but Python might fail at run time. The issue can be solved by installing the necessary dependencies and then re-installing Python.
Bug fixes

Categorical

- Bug in `Categorical.fillna()` that would replace all values, not just those that are NaN (GH26215)

Datetimelike

- Bug in `to_datetime()` where passing a timezone-naive `DatetimeArray` or `DateTimeIndex` and `utc=True` would incorrectly return a timezone-naive result (GH27733)
- Bug in `Period.to_timestamp()` where a `Period` outside the `Timestamp` implementation bounds (roughly 1677-09-21 to 2262-04-11) would return an incorrect `Timestamp` instead of raising `OutOfBoundsDatetime` (GH19643)
- Bug in iterating over `DatetimeIndex` when the underlying data is read-only (GH28055)

Timezones

- Bug in `Index` where a numpy object array with a timezone aware `Timestamp` and `np.nan` would not return a `DatetimeIndex` (GH27011)

Numeric

- Bug in `Series.interpolate()` when using a timezone aware `DatetimeIndex` (GH27548)
- Bug when printing negative floating point complex numbers would raise an `IndexError` (GH27484)
- Bug where `DataFrame` arithmetic operators such as `DataFrame.mul()` with a `Series` with `axis=1` would raise an `AttributeError` on `DataFrame` larger than the minimum threshold to invoke `numexpr` (GH27636)
- Bug in `DataFrame` arithmetic where missing values in results were incorrectly masked with `NaN` instead of `Inf` (GH27464)

Conversion

- Improved the warnings for the deprecated methods `Series.real()` and `Series.imag()` (GH27610)

Interval

- Bug in `IntervalIndex` where `dir(obj)` would raise `ValueError` (GH27571)
Indexing

- Bug in partial-string indexing returning a NumPy array rather than a Series when indexing with a scalar like `.loc['2015']` (GH27516)
- Break reference cycle involving Index and other index classes to allow garbage collection of index objects without running the GC. (GH27585, GH27840)
- Fix regression in assigning values to a single column of a DataFrame with a MultiIndex columns (GH27841).
- Fix regression in `.ix` fallback with an IntervalIndex (GH27865).

Missing

- Bug in `pandas.isnull()` or `pandas.isna()` when the input is a type e.g. `type(pandas.Series())` (GH27482)

IO

- Avoid calling `S3File.s3` when reading parquet, as this was removed in s3fs version 0.3.0 (GH27756)
- Better error message when a negative header is passed in `pandas.read_csv()` (GH27779)
- Follow the `min_rows` display option (introduced in v0.25.0) correctly in the HTML repr in the notebook (GH27991).

Plotting

- Added a `pandas_plotting_backends` entrypoint group for registering plot backends. See Plotting backends for more (GH26747).
- Fixed the re-instatement of Matplotlib datetime converters after calling `pandas.plotting.deregister_matplotlib_converters()` (GH27481).
- Fix compatibility issue with matplotlib when passing a pandas Index to a plot call (GH27775).

GroupBy/resample/rolling

- Fixed regression in `pandas.core.groupby.DataFrameGroupBy.quantile()` raising when multiple quantiles are given (GH27526)
- Bug in `pandas.core.groupby.DataFrameGroupBy.transform()` where applying a timezone conversion lambda function would drop timezone information (GH27496)
- Bug in `pandas.core.groupby.GroupBy.nth()` where `observed=False` was being ignored for Categorical groupers (GH26385)
- Bug in windowing over read-only arrays (GH27766)
- Fixed segfault in `pandas.core.groupby.DataFrameGroupBy.quantile` when an invalid quantile was passed (GH27470)
Reshaping

- A `KeyError` is now raised if `.unstack()` is called on a `Series` or `DataFrame` with a flat `Index` passing a name which is not the correct one (GH18303)
- Bug in `merge_asof()` could not merge `Timedelta` objects when passing `tolerance kwarg` (GH27642)
- Bug in `DataFrame.crosstab()` when margins set to `True` and normalize is not `False`, an error is raised. (GH27500)
- `DataFrame.join()` now suppresses the `FutureWarning` when the `sort` parameter is specified (GH21952)
- Bug in `DataFrame.join()` raising with readonly arrays (GH27943)

Sparse

- Bug in reductions for `Series` with Sparse dtypes (GH27080)

Other

- Bug in `Series.replace()` and `DataFrame.replace()` when replacing timezone-aware timestamps using a dict-like replacer (GH27720)
- Bug in `Series.rename()` when using a custom type indexer. Now any value that isn’t callable or dict-like is treated as a scalar. (GH27814)

Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Jeff Reback
- Joris Van den Bossche

- jbrockmendel

5.4.4 What’s new in 0.25.0 (July 18, 2019)

**Warning:** Starting with the 0.25.x series of releases, pandas only supports Python 3.5.3 and higher. See Dropping Python 2.7 for more details.

**Warning:** The minimum supported Python version will be bumped to 3.6 in a future release.

**Warning:** Panel has been fully removed. For N-D labeled data structures, please use `xarray`
Warning: read_pickle() and read_msgpack() are only guaranteed backwards compatible back to pandas version 0.20.3 (GH27082)

These are the changes in pandas 0.25.0. See Release notes for a full changelog including other versions of pandas.

Enhancements

GroupBy aggregation with relabeling

pandas has added special groupby behavior, known as “named aggregation”, for naming the output columns when applying multiple aggregation functions to specific columns (GH18366, GH26512).

```
In [1]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
                           ...
                           'height': [9.1, 6.0, 9.5, 34.0],
                           ...
                           'weight': [7.9, 7.5, 9.9, 198.0]})

In [2]: animals
Out[2]:
    kind  height  weight
   0   cat     9.1      7.9
   1  dog      6.0      7.5
   2   cat     9.5      9.9
   3  dog    34.0    198.0
[4 rows x 3 columns]

In [3]: animals.groupby("kind").agg(
   ...:    min_height=pd.NamedAgg(column='height', aggfunc='min'),
   ...:    max_height=pd.NamedAgg(column='height', aggfunc='max'),
   ...:    average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
   ...:)
   ...
Out[3]:
    min_height  max_height  average_weight
    kind
   cat      9.1      9.5       8.90
   dog      6.0    34.0    102.75
[2 rows x 3 columns]
```

Pass the desired columns names as the **kwargs to .agg. The values of **kwargs should be tuples where the first element is the column selection, and the second element is the aggregation function to apply. pandas provides the pandas.NamedAgg namedtuple to make it clearer what the arguments to the function are, but plain tuples are accepted as well.

```
In [4]: animals.groupby("kind").agg(
   ...:    min_height=('height', 'min'),
   ...:    max_height=('height', 'max'),
   ...:    average_weight=('weight', np.mean),
   ...:)
   ...
Out[4]:
    min_height  max_height  average_weight
    kind
   cat      9.1      9.5       8.90
   dog      6.0    34.0    102.75
```

(continues on next page)
Named aggregation is the recommended replacement for the deprecated “dict-of-dicts” approach to naming the output of column-specific aggregations (Deprecate groupby.agg() with a dictionary when renaming).

A similar approach is now available for Series groupby objects as well. Because there’s no need for column selection, the values can just be the functions to apply

```python
In [5]: animals.groupby("kind").height.agg(
   ...:     min_height="min",
   ...:     max_height="max",
   ...: )
   ...
Out[5]:
   min_height  max_height
kind
   cat    9.1     9.5
   dog    6.0    34.0
[2 rows x 2 columns]
```

This type of aggregation is the recommended alternative to the deprecated behavior when passing a dict to a Series groupby aggregation (Deprecate groupby.agg() with a dictionary when renaming).

See Named aggregation for more.

**GroupBy aggregation with multiple lambdas**

You can now provide multiple lambda functions to a list-like aggregation in pandas.core.groupby.GroupBy.agg (GH26430).

```python
In [6]: animals.groupby('kind').height.agg(
   ...:     lambda x: x.iloc[0], lambda x: x.iloc[-1]
   ...: )
   ...
Out[6]:
   <lambda_0>  <lambda_1>
kind
   cat    9.1     9.5
   dog    6.0    34.0
[2 rows x 2 columns]
```

```python
In [7]: animals.groupby('kind').agg(
   ...:     lambda x: x.iloc[0] - x.iloc[1],
   ...:     lambda x: x.iloc[0] + x.iloc[1]
   ...: )
   ...
Out[7]:
   height  weight
   <lambda_0>  <lambda_1>  <lambda_0>  <lambda_1>
```

(continues on next page)
Previously, these raised a `SpecificationError`.

Better repr for `MultiIndex`

Printing of `MultiIndex` instances now shows tuples of each row and ensures that the tuple items are vertically aligned, so it’s now easier to understand the structure of the `MultiIndex`. (GH13480):

The repr now looks like this:

```python
In [8]: pd.MultiIndex.from_product([['a', 'abc'], range(500)])
Out[8]:
MultiIndex([( 'a', 0),
             ( 'a', 1),
             ( 'a', 2),
             ( 'a', 3),
             ( 'a', 4),
             ( 'a', 5),
             ( 'a', 6),
             ( 'a', 7),
             ( 'a', 8),
             ( 'a', 9),
             ...
             ('abc', 490),
             ('abc', 491),
             ('abc', 492),
             ('abc', 493),
             ('abc', 494),
             ('abc', 495),
             ('abc', 496),
             ('abc', 497),
             ('abc', 498),
             ('abc', 499)],
           length=1000)
```

Previously, outputting a `MultiIndex` printed all the levels and codes of the `MultiIndex`, which was visually unappealing and made the output more difficult to navigate. For example (limiting the range to 5):

```python
In [1]: pd.MultiIndex.from_product([['a', 'abc'], range(5)])
Out[1]: MultiIndex(levels=[['a', 'abc'], [0, 1, 2, 3]],
                   codes=[[0, 0, 0, 0, 1, 1, 1, 1], [0, 1, 2, 3, 0, 1, 2, 3]])
```

In the new repr, all values will be shown, if the number of rows is smaller than `options.display.max_seq_items` (default: 100 items). Horizontally, the output will truncate, if it’s wider than `options.display.width` (default: 80 characters).
Shorter truncated repr for Series and DataFrame

Currently, the default display options of pandas ensure that when a Series or DataFrame has more than 60 rows, its repr gets truncated to this maximum of 60 rows (the display.max_rows option). However, this still gives a repr that takes up a large part of the vertical screen estate. Therefore, a new option display.min_rows is introduced with a default of 10 which determines the number of rows showed in the truncated repr:

- For small Series or DataFrames, up to max_rows number of rows is shown (default: 60).
- For larger Series of DataFrame with a length above max_rows, only min_rows number of rows is shown (default: 10, i.e. the first and last 5 rows).

This dual option allows to still see the full content of relatively small objects (e.g. df.head(20) shows all 20 rows), while giving a brief repr for large objects.

To restore the previous behaviour of a single threshold, set pd.options.display.min_rows = None.

JSON normalize with max_level param support

json_normalize() normalizes the provided input dict to all nested levels. The new max_level parameter provides more control over which level to end normalization (GH23843):

The repr now looks like this:

```python
from pandas.io.json import json_normalize
data = [{
    'CreatedBy': {'Name': 'User001'},
    'Lookup': {'TextField': 'Some text',
               'UserField': {'Id': 'ID001', 'Name': 'Name001'}},
    'Image': {'a': 'b'}
}]
json_normalize(data, max_level=1)
```

Series.explode to split list-like values to rows

Series and DataFrame have gained the DataFrame.explode() methods to transform list-likes to individual rows. See section on Exploding list-like column in docs for more information (GH16538, GH10511)

Here is a typical usecase. You have comma separated string in a column.

```python
In [9]: df = pd.DataFrame([{'var1': 'a,b,c', 'var2': 1},
                        {'var1': 'd,e,f', 'var2': 2}])
```

Creating a long form DataFrame is now straightforward using chained operations
In [11]: df.assign(var1=df.var1.str.split(','),).explode('var1')
Out[11]:
   var1  var2
0    a    1
0    b    1
0    c    1
1    d    2
1    e    2
1    f    2
[6 rows x 2 columns]

Other enhancements

- `DataFrame.plot()` keywords logy, logx and loglog can now accept the value 'sym' for symlog scaling. (GH24867)
- Added support for ISO week year format (‘%G-%V-%u’) when parsing datetimes using `to_datetime()` (GH16607)
- Indexing of DataFrame and Series now accepts zerodim np.ndarray (GH24919)
- `Timestamp.replace()` now supports the fold argument to disambiguate DST transition times (GH25017)
- `DataFrame.at_time()` and `Series.at_time()` now support `datetime.time` objects with timezones (GH24043)
- `DataFrame.pivot_table()` now accepts an observed parameter which is passed to underlying calls to `DataFrame.groupby()` to speed up grouping categorical data. (GH24923)
- `Series.str` has gained `Series.str.casefold()` method to removes all case distinctions present in a string (GH25405)
- `DataFrame.set_index()` now works for instances of abc.Iterator, provided their output is of the same length as the calling frame (GH22484, GH24984)
- `DatetimeIndex.union()` now supports the sort argument. The behavior of the sort parameter matches that of `Index.union()` (GH24994)
- `RangeIndex.union()` now supports the sort argument. If sort=False an unsorted Int64Index is always returned. sort=None is the default and returns a monotonically increasing RangeIndex if possible or a sorted Int64Index if not (GH24471)
- `TimedeltaIndex.intersection()` now also supports the sort keyword (GH24471)
- `DataFrame.rename()` now supports the errors argument to raise errors when attempting to rename nonexistent keys (GH13473)
- Added Sparse accessor for working with a DataFrame whose values are sparse (GH25681)
- `RangeIndex` has gained start, stop, and step attributes (GH25710)
- `datetime.timezone` objects are now supported as arguments to timezone methods and constructors (GH25065)
- `DataFrame.query()` and `DataFrame.eval()` now supports quoting column names with backticks to refer to names with spaces (GH6508)
- `merge_asof()` now gives a more clear error message when merge keys are categoricals that are not equal (GH26136)
• pandas.core.window.Rolling() supports exponential (or Poisson) window type (GH21303)
• Error message for missing required imports now includes the original import error’s text (GH23868)
• DatetimeIndex and TimedeltaIndex now have a mean method (GH24757)
• DataFrame.describe() now formats integer percentiles without decimal point (GH26660)
• Added support for reading SPSS .sav files using read_spss() (GH26537)
• Added new option plotting.backend to be able to select a plotting backend different than the existing matplotlib one. Use pandas.set_option('plotting.backend', '<backend-module>') where <backend-module> is a library implementing the pandas plotting API (GH14130)
• pandas.offsets.BusinessHour supports multiple opening hours intervals (GH15481)
• read_excel() can now use openpyxl to read Excel files via the engine='openpyxl' argument. This will become the default in a future release (GH11499)
• pandas.io.excel.read_excel() supports reading OpenDocument tables. Specify engine='odf' to enable. Consult the IO User Guide for more details (GH9070)
• Interval, IntervalIndex, and IntervalArray have gained an is_empty attribute denoting if the given interval(s) are empty (GH27219)

Backwards incompatible API changes

Indexing with date strings with UTC offsets

Indexing a DataFrame or Series with a DatetimeIndex with a date string with a UTC offset would previously ignore the UTC offset. Now, the UTC offset is respected in indexing. (GH24076, GH16785)

```
In [12]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific'))

In [13]: df
Out[13]:
      0
2019-01-01 00:00:00-08:00  0
[1 rows x 1 columns]

Previous behavior:

```
In [3]: df['2019-01-01 00:00:00+04:00':'2019-01-01 01:00:00+04:00']
Out[3]:
      0
2019-01-01 00:00:00-08:00  0
```

New behavior:

```
In [14]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out[14]:
      0
2019-01-01 00:00:00-08:00  0
[1 rows x 1 columns]
```
MultiIndex constructed from levels and codes

Constructing a MultiIndex with NaN levels or codes value < -1 was allowed previously. Now, construction with codes value < -1 is not allowed and NaN levels’ corresponding codes would be reassigned as -1. (GH19387)

Previous behavior:

```python
In [1]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
   codes=[[0, -1, 1, 2, 3, 4]])
...:
Out[1]: MultiIndex(levels=[[nan, None, NaT, 128, 2]],
   codes=[[0, -1, 1, 2, 3, 4]])

In [2]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
Out[2]: MultiIndex(levels=[[1, 2]],
   codes=[[0, -2]])
```

New behavior:

```python
In [15]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
   codes=[[0, -1, 1, 2, 3, 4]])
   ....:
Out[15]: MultiIndex((nan,),
   (nan,),
   (nan,),
   (nan,),
   (128,),
   ( 2,)),
   )

In [16]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
